Abstract

This specification introduces features to HTML and the DOM that ease the authoring of Web-based applications. Additions include the context menus, a direct-mode graphics canvas, inline popup windows, server-sent events, and more.

Status of this document

This is a work in progress! This document is changing on a daily if not hourly basis in response to comments and as a general part of its development process. Comments are very welcome, please send them to whatwg@whatwg.org. Thank you.

Implementors should be aware that this specification is not stable. **Implementors who are not taking part in the discussions are likely to find the specification changing out from under them in incompatible ways.** Vendors interested in implementing this specification before it eventually reaches the call for implementations should join the [WHATWG mailing list](#) and take part in the discussions.

This draft may contain namespaces that use the `uuid:` URI scheme. These are temporary and will be changed before those parts of the specification are ready to be implemented in shipping products.

To find the latest version of this working draft, please follow the "Latest version" link above.

Sections marked [SCS] are sections intended to be self-contained (Self Contained Section). Such sections are considered logical units that it would make sense to implement independent of most of the rest of the specification, provided that enough of the infrastructure is already implemented.

1. Introduction

The World Wide Web's markup language has always been HTML. HTML was primarily designed as a language for semantically describing scientific documents, although its general design and adaptations over the years has enabled it to be used to describe a number of other types of documents.

The main area that has not been adequately addressed by HTML is a vague subject referred to as Web Applications. This specification attempts to rectify this, while at the same time updating the HTML specifications to address issues raised in the past few years.

1.1. Scope

This specification is limited to providing a semantic-level markup language and associated semantic-

The screenshot shows a search bar at the top left, a 'Go' button, and navigation arrows for months (DEC, JAN, FEB) and years (2004, 2006, 2007). A date '02' is highlighted in yellow. On the right, there are icons for user profile, help, and sharing, along with a link 'About this capture'.

5 Jun 2004 - 22 Aug 2020

DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

The scope of this specification does not include documenting every HTML or DOM feature supported by Web browsers. Browsers support many features that are considered to be very bad for accessibility or that are otherwise inappropriate. For example, the `blink` element is clearly presentational and authors wishing to cause text to blink should instead use CSS.

The scope of this specification is not to describe an entire operating system. In particular, office productivity applications, image manipulation, and other applications that users would be expected to use with high-end workstations on a daily basis are out of scope. In terms of applications, this specification is targeted specifically at applications that would be expected to be used by users on an occasional basis, or regularly but from disparate locations. For instance online purchasing systems, searching systems, games (especially multiplayer online games), public telephone books or address books, communications software (e-mail clients, instant messaging clients, discussion software), etc.

For sophisticated cross-platform applications, there already exist several proprietary solutions (such as Mozilla's XUL and Macromedia's Flash). These solutions are evolving faster than any standards process could follow, and the requirements are evolving even faster. These systems are also significantly more complicated to specify, and are orders of magnitude more difficult to achieve interoperability with, than the solutions described in this document. Platform-specific solutions for such sophisticated applications (for example the MacOS X Core APIs) are even further ahead.

1.2. Structure of this specification [\[TBW\]](#)

This spec is probably big enough to need a guide as to where to look for various things. Hence once the structure is stable we should probably fill out this section.

1.3. Requirements and ideas

This section will probably be dropped in due course.

HTML, CSS, DOM, and JavaScript provide enough power that Web developers have managed to base entire businesses on them. What is required are extensions to these technologies to provide much-needed features such as:

- Native pop-up menus and context menus.
- Inline markup for pop-up windows, for example for dialog boxes or tool palettes, so that dialogs need not be defined in separate files.
- Command updating: applications that have several access points for the same feature, for instance a menu item and a tool-bar button, would benefit from having to disable such commands only once, instead of having to keep each access point synchronized with the feature's availability at all times. Similarly menu items or tool-bar buttons that represent a toggle state could automatically stay synchronized whenever toggled.
- Server-sent events: triggering DOM3 Events from the server-side, for example for tickers or status updates.

3,445 captures
5 Jun 2004 - 22 Aug 2020

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

- More device-independent DOM events: The DOM event set needs device-independent events, such as events that fire when a button or link is activated, whether via the mouse or the keyboard. DOMActivate is a start, but it lacks equivalent HTML attributes, and additional events may be needed.
- Sortable and multicolumn tree views and list views with rich formatting.
- Rich text editing: an underlying architecture upon which domain-specific editors can be created, including things like control over the caret position.
- A predefined HTML editor based on the rich text editing architecture.
- Drag and drop APIs.
- Text selection manipulation APIs.
- Clipboard APIs (if the security and privacy concerns can be addressed).

Some less important features would be good to have as well:

- Window-based state management (so that new windows don't interfere with existing sessions), for example implemented as a per-domain, per-window "file system". This would allow multiple instances of the same application (from the same site) to run without the instances overwriting each other's cookies.
- Elements for semantics commonly found in applications, such as `<byline>`, `<footer>`, `<section>`, `<nav>`, etc.
- Markup to denote [mutually exclusive sections](#) (as in the commonly seen wizard interfaces).
- Better defined user authentication state handling. (Being able to "log out" of sites reliably, for instance, or being able to integrate the HTTP authentication model into the Web page.)

Several of the features in these two lists have been supported in non-standard ways by some user agents for some time.

1.4. Relationship to HTML 4.01, XHTML 1.1, DOM2 HTML

This specification represents a new version of HTML4 and XHTML1, along with a new version of the associated DOM2 HTML API. Migration from HTML4 or XHTML1 to the format and APIs described in this specification should in most cases be straightforward, as care has been taken to ensure that backwards-compatibility is retained.

1.5. Relationship to XHTML2

XHTML2 [\[XHTML2\]](#) defines a new HTML vocabulary with better features for hyperlinks, multimedia content, annotating document edits, rich metadata, declarative interactive forms, and describing the semantics of human literary works such as poems and scientific papers.

However, it lacks elements to express the semantics of many of the non-document types of content

3,445 captures
5 Jun 2004 - 22 Aug 2020

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

XHTML2 and this specification use different namespaces and therefore can both be implemented in the same XML processor.

1.6. Relationship to Web Forms 2.0

This specification is designed to complement Web Forms 2.0. [WF2] Where Web Forms concentrates on input controls, data validation, and form submission, this specification concentrates on client-side user interface features needed to create modern applications.

Eventually WF2 will simply be folded into this spec.

1.7. Relationship to XUL, Avalon/XAML, and other proprietary UI languages

This specification is independent of the various proprietary UI languages that various vendors provide.

1.8. Conformance requirements

As well as sections marked as non-normative, all diagrams, examples, and notes in this specification are non-normative. Everything else in this specification is normative.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in the normative parts of this document are to be interpreted as described in [RFC2119]. For readability, these words do not appear in all uppercase letters in this specification.

This specification describes the conformance criteria for user agents (implementations and their implementors) and documents (and their authors).

Conformance requirements phrased as requirements on elements, attributes, methods or objects are conformance requirements on user agents.

User agents fall into several (overlapping) categories with different conformance requirements.

Web browsers and other interactive user agents

Web browsers that support [XHTML](#) must process elements and attributes from the XHTML namespace found in XML documents as described in this specification, so that users can interact with them, unless the semantics of those elements have been overridden by other specifications.

A conforming XHTML processor would, upon finding an XHTML `script` element in an XML document, execute the script contained in that element. However, if the element is found within an XSLT transformation sheet (assuming the UA also supports XSLT), then the processor would instead treat the `script` element as an opaque element that forms part of the transform.

Web browsers that support [HTML](#) must process documents labelled as `text/html` as

versions of them must comply to the same conformance criteria as Web browsers, except that they are exempt from requirements regarding user interaction.

Note: Typical examples of non-interactive presentation user agents are printers (static UAs) and overhead displays (dynamic UAs). It is expected that most static non-interactive presentation user agents will also opt to lack scripting support.

A non-interactive but dynamic presentation UA would still execute scripts, allowing forms to be dynamically submitted, and so forth. However, since the concept of "focus" is irrelevant when the user cannot interact with the document, the UA would not need to support any of the focus-related DOM APIs.

User agents with no scripting support

Implementations that do not support scripting (or which have their scripting features disabled) are exempt from supporting the events and DOM interfaces mentioned in this specification. For the parts of this specification that are defined in terms of an events model or in terms of the DOM, such user agents must still act as if events and the DOM were supported.

Note: Scripting can form an integral part of an application. Web browsers that do not support scripting, or that have scripting disabled, might be unable to fully convey the author's intent.

Conformance checkers

Conformance checkers must verify that a document conforms to the applicable conformance criteria described in this specification. Conformance checkers are exempt from detecting errors that require interpretation of the author's intent (for example, while a document is non-conforming if the content of a blockquote element is not a quote, conformance checkers do not have to check that blockquote elements only contain quoted material).

The term "validation" specifically refers to a subset of conformance checking that only verifies that a document complies with the requirements given by an SGML or XML DTD. Conformance checkers that only perform validation are non-conforming, as there are many conformance requirements described in this specification that cannot be checked by SGML or XML DTDs.

To put it another way, there are three types of conformance criteria:

- 1. Criteria that can be expressed in a DTD.**
- 2. Criteria that cannot be expressed by a DTD, but can still be checked by a machine.**
- 3. Criteria that can only be checked by a human.**

A conformance checker must check for the first two. A simple DTD-based validator only checks for the first class of errors and is therefore not a conforming conformance checker according to this specification.

semantics of the documents that they process.

A tool that generates document outlines but increases the nesting level for each paragraph and does not increase the nesting level for each section would not be conforming.

Authoring tools and markup generators

Authoring tools and markup generators must generate conforming documents. Conformance criteria that apply to authors also apply to authoring tools, where appropriate.

Conformance requirements phrased as algorithms or specific steps may be implemented in any manner, so long as the end result is equivalent. (In particular, the algorithms defined in this specification are intended to be easy to follow, and not intended to be performant.)

Note: *There is no implied relationship between document conformance requirements and implementation conformance requirements. User agents are not free to handle non-conformant documents as they please; the processing model described in this specification applies to implementations regardless of the conformity of the input documents.*

For compatibility with existing content and prior specifications, this specification describes two authoring formats: one based on XML (referred to as **XHTML**), and one using a [custom format](#) inspired by SGML (referred to as **HTML**). Implementations may support only one of these two formats, although supporting both is encouraged.

XML documents using elements from the XHTML namespace that use the new features described in this specification and that are served over the wire (e.g. by HTTP) must be sent using an XML MIME type such as `application/xml` or `application/xhtml+xml` and must not be served as `text/html`. [\[RFC3023\]](#)

These XML documents may contain a `DOCTYPE` if desired, but this is not required to conform to this specification.

HTML documents that use the new features described in this specification and that are served over the wire (e.g. by HTTP) must be sent as `text/html` and must start with the following `DOCTYPE`:

```
<!DOCTYPE html>
```

1.9. Terminology

This specification refers to both HTML and XML attributes and DOM attributes, often in the same context. When it is not clear which is being referred to, they are referred to as **content attributes** for HTML and XML attributes, and **DOM attributes** for those from the DOM. Similarly, the term "properties" is used for both ECMAScript object properties and CSS properties. When these are ambiguous they are qualified as object properties and CSS properties respectively.

To ease migration from HTML to XHTML, UAs conforming to this specification will place elements in HTML in the `http://www.w3.org/1999/xhtml` namespace, at least for the purposes of the DOM and CSS. The term "**elements in the HTML namespace**", when used in this specification, thus refers to both HTML and XHTML elements.

About this capture

Generally, when the specification states that a feature applies to HTML or XHTML, it also includes the other. When a feature specifically only applies to one of the two languages, it is called out by explicitly stating that it does not apply to the other format, as in "for HTML, ... (this does not apply to XHTML)".

The readability, the term URI is used to refer to both ASCII URIs and Unicode IRIs, as those terms are defined by [\[RFC3986\]](#) and [\[RFC3987\]](#) respectively. On the rare occasions where IRIs are not allowed but ASCII URIs are, this is called out explicitly.

The term **root element**, when not qualified to explicitly refer to the document's root element, means the furthest ancestor element node of whatever node is being discussed, or the node itself if there is none. When the node is a part of the document, then that is indeed the document's root element. However, if the node is not currently part of the document tree, the root element will be an orphaned node.

When it is stated that some element or attribute is ignored, or treated as some other value, or handled as if it was something else, this refers only to the processing of the node after it is in the DOM. A user agent must not mutate the DOM in such situations.

When an XML name, such as an attribute or element name, is referred to in the form `prefix:localName`, as in `xml:id` or `svg:rect`, it refers to a name with the local name `localName` and the namespace given by the prefix, as defined by the following table:

xml

`http://www.w3.org/XML/1998/namespace`

html

`http://www.w3.org/1999/xhtml`

For simplicity, terms such as *shown*, *displayed*, and *visible* might sometimes be used when referring to the way a document is rendered to the user. These terms are not meant to imply a visual medium; they must be considered to apply to other media in equivalent ways.

This specification uses the term *HTML documents* to generally refer to any use of HTML, ranging from short static documents to long essays or reports with rich multimedia, as well as to fully-fledged interactive applications.

Various DOM interfaces are defined in this specification using pseudo-IDL. This looks like OMG IDL but isn't. For instance, method overloading is used, and types from the W3C DOM specifications are used without qualification. Language-specific bindings for these abstract interface definitions must be derived in the way consistent with W3C DOM specifications. Some interface-specific binding information for ECMAScript is included in this specification.

The construction "a `Foo` object", where `Foo` is actually an interface, is sometimes used instead of the more accurate "an object implementing the interface `Foo`".

The terms *fire* and *dispatch* are used interchangeably in the context of events, as in the DOM Events specifications. [\[DOM3EVENTS\]](#)

About this capture

When a UA needs to convert a string to a number, algorithms equivalent to those specified in ECMA262 sections 9.3.1 ("ToNumber Applied to the String Type") and 8.5 ("The Number type") should be used (possibly after suitably altering the algorithms to handle numbers of the range that the UA can support). [\[ECMA262\]](#)

The `alt` attribute on images must not be shown in a tooltip in visual browsers.

DOM mutation events must not fire for changes caused by the UA parsing the document. (Conceptually, the parser is not mutating the DOM, it is constructing it.) This includes the parsing of any content inserted using `document.write()` and `document.writeln()` calls. Other changes, including fragment insertions involving `innerHTML` and similar attributes, must fire mutation events. [\[DOM3EVENTS\]](#)

The default value of `Content-Style-Type` and the default value of the `type` attribute of the `style` element is `text/css`.

The default value of `Content-Script-Type` and the default value of the `type` attribute of the `script` element is the ECMAScript MIME type.

User agents must follow the rules given by XML Base to resolve relative URIs in HTML and XHTML fragments. [\[XMLBASE\]](#)

Note: *It is possible for `xml:base` attributes to be present even in HTML fragments, as such attributes can be added dynamically using `script`.*

2. Semantics and structure of HTML elements

2.1. Introduction [\[TBW\]](#)

This section is non-normative.

An introduction to marking up a document.

2.2. The DOM

The Document Object Model (DOM) is a representation — a model — of the document and its content. [\[DOM3CORE\]](#) The DOM is not just an API; operations on the in-memory document are defined, in this specification, in terms of the DOM.

2.2.1. DOM feature strings

DOM3 Core defines mechanisms for checking for interface support, and for obtaining implementations of interfaces, using `feature strings`. [\[DOM3CORE\]](#)

A DOM application can use the `hasFeature(feature, version)` method of the `DOMImplementation` interface with parameter values "HTML" and "5.0" (respectively) to

The screenshot shows a top navigation bar with a search input field, a 'Go' button, and month abbreviations (DEC, JAN, FEB) with arrows for navigation. Below this is a section titled '3,445 captures' with a date range from '5 Jun 2004 - 22 Aug 2020'. To the right are icons for user profile, help, and sharing (Facebook, Twitter). A large blue '02' is prominently displayed, likely indicating the day of the capture. Below the date range are two sets of dates: '2004 2006 2007'.

returning true might not be perfectly compliant, and that UAs returning false might well have support for features in this specification; in general, therefore, use of this method is discouraged.

The values "HTML" and "XHTML" (both with version "5.0") should also be supported in the context of the `getFeature()` and `isSupported()` methods, as defined by DOM3 Core.

Note: *The interfaces defined in this specification are not always supersets of the interfaces defined in DOM2 HTML; some features that were formerly deprecated, poorly supported, rarely used or considered unnecessary have been removed. Therefore it is not guaranteed that an implementation that supports "HTML" "5.0" also supports "HTML" "2.0".*

2.2.2. Reflecting content attributes in DOM attributes

Some DOM attributes are defined to **reflect** a particular content attribute. This means that on getting, the DOM attribute returns the current value of the content attribute, and on setting, the DOM attribute changes the value of the content attribute to the given value.

If a reflecting DOM attribute is a `DOMString` attribute defined to contain a URI, then on getting, the DOM attribute returns the value of the content attribute, resolved to an absolute URI, and on setting, sets the content attribute to the specified literal value. If the content attribute is absent, the DOM attribute must return the default value, if the content attribute has one, or else the empty string.

If a reflecting DOM attribute is a `DOMString` attribute that is not defined to contain a URI, then the getting and setting is done in a transparent, case-sensitive manner, except if the content attribute is defined to only allow a specific set of values. In this latter case, the attribute's value is first converted to lowercase before being returned. If the content attribute is absent, the DOM attribute must return the default value, if the content attribute has one, or else the empty string.

If a reflecting DOM attribute is a boolean attribute, then the DOM attribute returns true if the attribute is set, and false if it is absent. On setting, the content attribute is removed if the DOM attribute is set to false, and is set to have the same value as its name if the DOM attribute is set to true.

If a reflecting DOM attribute is a numeric type (`long`) then the content attribute must be [converted to a numeric type](#) first (truncating any fractional part). If that fails, or if the attribute is absent, the default value should be returned instead, or 0 if there is no default value. On setting, the given value is converted to a string representing the number in base ten and then that string should be used as the new content attribute value.

2.2.3. Event listeners

In the ECMAScript DOM binding, the ECMAScript native `Function` type must implement the `EventListener` interface such that invoking the `handleEvent()` method of that interface on the object from another language binding invokes the function itself, with the `event` argument as its only argument. In the ECMAScript binding itself, however, the `handleEvent()` method of the interface is not directly accessible on `Function` objects. Such functions must be called in the global scope. If the function returns false, the `event's preventDefault()` method must then be invoked. Exception: for historical reasons, for the HTML `mouseover` event, the `preventDefault()` method must be called when the function returns true instead.

3,445 captures
5 Jun 2004 - 22 Aug 2020

actually defined to exist by specifications implemented by the UA (e.g. HTML, Web Forms 2, Web Apps) are actually registered, however; for example if an author created an `onfoo` attribute, it would not be fired for `foo` events.

The scope chain for ECMAScript executed in HTML event handler attributes must link from the activation object for the handler, to its `this` parameter (the event target), to the element's `form` element if it is a form control, to the document, to the default view (the `Window` object).

Note: This definition is compatible with how most browsers implemented DOM Level 0, but does not exactly describe IE's behaviour. See also ECMA262 Edition 3, sections 10.1.6 and 10.2.3, for more details on activation objects. [[ECMA262](#)]

2.2.4. Event firing

Certain operations and methods are defined as firing events on elements. For example, the `click()` method on the [HTMLCommandElement](#) is defined as firing a `click` event on the element. [[DOM3EVENTS](#)]

Firing a click event means that a [click](#) event in the <http://www.w3.org/2001/xml-events> namespace, which bubbles and is cancelable, and which uses the `MouseEvent` interface, must be dispatched at the given element. The event object must have its `screenX`, `screenY`, `clientX`, `clientY`, and `button` attributes set to 0, its `ctrlKey`, `shiftKey`, `altKey`, and `metaKey` attributes set according to the current state of the key input device, if any (false for any keys that are not available), its `detail` attribute set to 1, and its `relatedTarget` attribute set to null. The `getModifierState()` method on the object must return values appropriately describing the state of the key input device at the time the event is created.

Firing a change event means that a [change](#) event in the <http://www.w3.org/2001/xml-events> namespace, which bubbles but is not cancelable, and which uses the `Event` interface, must be dispatched at the given element. The event object must have its `detail` attribute set to 0.

Firing a contextmenu event means that a [contextmenu](#) event in the <http://www.w3.org/2001/xml-events> namespace, which bubbles and is cancelable, and which uses the `Event` interface, must be dispatched at the given element. The event object must have its `detail` attribute set to 0.

Firing a show event means that a [show](#) event in the <http://www.w3.org/2001/xml-events> namespace, which does not bubble but is cancelable, and which uses the `Event` interface, must be dispatched at the given element. The event object must have its `detail` attribute set to 0.

The default action of these event is to do nothing unless otherwise stated.

If you dispatch a custom "click" event at an element that would normally have default actions, they should get triggered. We need to go through the entire spec and make sure that any default actions are defined in terms of any event of the right type on that element, not those that are dispatched in expected ways.

2.2.5. The `textContent` attribute

Go DEC JAN FEB

3,445 captures 02 2004 2006 2007 About this capture

Should `textContent` be defined differently for `<div>` and `<dd>`? Should we come up with an alternative to `textContent` that handles those and other things, like `alt=""`?

2.2.6. Common DOM interfaces [TBW]

Still need to define `HTMLCollection`.

```
interface DOMTokenString {
    bool has(in DOMString token);
    void add(in DOMString token);
    void remove(in DOMString token);
};
```

Need to define those members.

2.2.7. The document [TBW]

Every XML and HTML document in an HTML UA must be represented by a `Document` object. [\[DOM3CORE\]](#)

All `Document` objects (in user agents implementing this specification) must also implement the `HTMLDocument` interface, available using binding-specific methods.

`Document` objects must also implement the document-level interface of any other namespaces found in the document that the UA supports. For example, if an HTML implementation also supports SVG, then the `Document` object must implement `HTMLDocument` and `SVGDocument`.

```
interface HTMLDocument : Document {
    attribute DOMString title;
    readonly attribute DOMString referrer;
    readonly attribute DOMString domain;
    readonly attribute DOMString URL;
    attribute HTMLElement body;
    readonly attribute HTMLCollection images;
    readonly attribute HTMLCollection applets;
    readonly attribute HTMLCollection links;
    readonly attribute HTMLCollection forms;
    readonly attribute HTMLCollection anchors;
    attribute DOMString cookie;

    void open();
    void close();
    void write(in DOMString text);
    void writeln(in DOMString text);
    NodeList getElementsByTagName(in DOMString elementName);
    NodeList getElementsByClassName(in DOMString className [, in DOMString
};
```

◀ 02 ▶
2004 2006 2007
About this capture

3,445 captures
5 Jun 2004 - 22 Aug 2020

Need to define those members; the `body` attribute will be used to define the `body` element.

The `getElementsByClassName()` method takes one or more strings representing classes and must return all the elements in that document that are of all those classes. HTML, XHTML, SVG and MathML elements define which classes they are in by having an attribute in the per-element partition with the name `class` containing a space-separated list of classes to which the element belongs. Other specifications may also allow elements in their namespaces to be labelled as being in specific classes. UAs must not assume that all attributes of the name `class` for elements in any namespace work in this way, however, and must not assume that such attributes, when used as global attributes, label other elements as being in specific classes.

There is an open issue on whether we should use multiple arguments or just one argument that needs to be split on spaces.

The space character (U+0020) is not special in the method's arguments. In HTML, XHTML, SVG and MathML it is impossible for an element to belong to a class whose name contains a space character, however, and so typically the method would return no nodes if one of its arguments contained a space.

Similarly, if the method is passed an argument consisting of the empty string, it will typically not return any nodes since in HTML, XHTML, SVG and MathML it is impossible to assign an element to the "" class.

Given the following XHTML fragment:

```
<div id="example">
  <p id="p1" class="aaa bbb"/>
  <p id="p2" class="aaa ccc"/>
  <p id="p3" class="bbb ccc"/>
</div>
```

A call to `document.getElementById('example').getElementsByClassName('aaa')` would return a `NodeList` with the two paragraphs `p1` and `p2` in it. A call to `getElementsByClassName('ccc', 'bbb')` would only return one node, however, namely `p3`.

A call to `getElementsByClassName('aaa bbb')` would return no nodes; none of the elements above are in the "aaa bbb" class.

2.2.8. The elements [TBW]

The nodes representing HTML elements in the DOM must implement, and expose to scripts, the interfaces listed for them in the relevant sections of this specification. This includes XHTML elements in XML documents, even when those documents are in another context (e.g. inside an XSLT transform).

The basic interface, from which all the HTML elements' interfaces inherit, and which is used by elements that have no additional requirements, is the `HTMLElement` interface.

3,445 captures

◀ 02 ▶
2004 2006 2007

About this capture

names in uppercase, regardless of the case with which they were created. This does not apply to XML documents; in XML documents, the DOM APIs must always return tag names and attribute names in the original case used to create those nodes.

2.3. HTML documents and document fragments

2.3.1. Semantics

Elements, attributes, and attribute values in HTML are defined (by this specification) to have certain meanings (semantics). For example, the `ol` element represents an ordered list, and the `lang` attribute represents the language of the content.

Authors must only use elements, attributes, and attribute values for their appropriate semantic purposes.

For example, the following document is non-conforming, despite being syntactically correct:

```
<!DOCTYPE html>
<html lang="en-GB">
  <head> <title> Demonstration </title> </head>
  <body>
    <table>
      <tr> <td> My favourite animal is the cat. </td> </tr>
      <tr>
        <td>
          <a href="http://example.org/~ernest/"><cite>Ernest</cite></a>,
          in an essay from 1992
        </td>
      </tr>
    </table>
  </body>
</html>
```

...because the data placed in the cells is clearly not tabular data. A corrected version of this document might be:

```
<!DOCTYPE html>
<html lang="en-GB">
  <head> <title> Demonstration </title> </head>
  <body>
    <blockquote>
      <p> My favourite animal is the cat. </p>
    </blockquote>
    <p>
      <a href="http://example.org/~ernest/"><cite>Ernest</cite></a>,
      in an essay from 1992
    </p>
  </body>
</html>
```

The screenshot shows a search interface with a search bar, a 'Go' button, and a date range selector. The date range is set from '2004' to '2007' with '02' highlighted. Below the date range are social sharing icons for user, help, and X. At the bottom, there's a link to 'About this capture'.

```
<body>
<h1>ABC Company</h1>
<h2>Leading the way in widget design since 1432</h2>
...

```

The `header` element should be used in these kinds of situations:

```
<body>
<header>
<h1>ABC Company</h1>
<h2>Leading the way in widget design since 1432</h2>
</header>
...

```

2.3.2. Structure

All the elements in this specification have a defined content model, which describes what nodes are allowed inside the elements, and thus what the structure of an HTML document or fragment must look like. Authors must only put elements inside an element if that element allows them to be there according to its content model.

For the purposes of determining if an element matches its content model or not, CDATA nodes in the DOM must be treated as text nodes, and character entity reference nodes must be treated as if they were expanded in place.

The whitespace characters U+0020 SPACE, U+000A LINE FEED, and U+000D CARRIAGE RETURN are always allowed between elements. User agents must always represent these characters between elements in the source markup as text nodes in the DOM. Empty text nodes and text nodes consisting of just sequences of those characters are considered **inter-element whitespace** and must be ignored when establishing whether an element matches its content model or not.

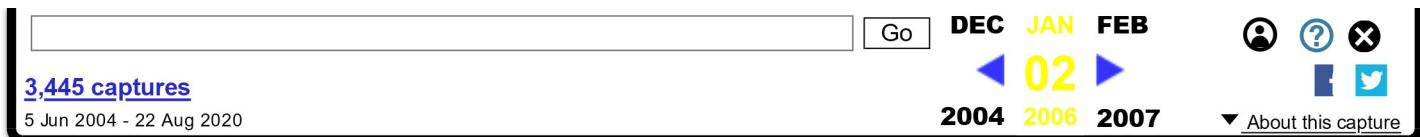

Authors must only use elements from the HTML namespace in the contexts where they are allowed, as defined for each element. For XML compound documents, these contexts could be inside elements from other namespaces, if those elements are defined as providing the relevant contexts.

The SVG specification defines the SVG `foreignObject` element as allowing foreign namespaces to be included, thus allowing compound documents to be created by inserting subdocument content under that element. This specification defines the XHTML `html` element as being allowed where subdocument fragments are allowed in a compound document. Together, these two definitions mean that placing an XHTML `html` element as a child of an SVG `foreignObject` element is conforming.

2.3.3. Kinds of elements

Each element in HTML falls into zero or more categories that group elements with similar characteristics together. This specification uses the following categories:

- [Metadata elements](#)
- [Sectioning elements](#)

- [Structured inline-level elements](#)
- [Interactive elements](#)
- Form control elements

Some elements have unique requirements and do not fit into any particular category.

2.3.3.1. *Block-level elements*

Block-level elements are used for structural grouping of page content.

There are several kinds of block-level elements:

- Some can only contain other block-level elements: [blockquote](#), [section](#), [article](#), [header](#).
- Some can only contain [inline-level content](#): [p](#), [h1-h6](#), [address](#).
- Some can contain either block-level elements or [inline-level content](#) (but not both): [nav](#), [aside](#), [footer](#), [div](#).
- Finally, some have very specific content models: [ul](#), [ol](#), [dl](#), [table](#), [script](#).

There are also elements that seem to be block-level but aren't, such as [body](#), [li](#), [dt](#), [dd](#), and [td](#). These elements are allowed only in specific places, not simply anywhere that block-level elements are allowed.

Some block-level elements play multiple roles. For instance, the [script](#) element is allowed inside [head](#) elements and can also be used as [inline-level content](#). Similarly, the [ul](#), [ol](#), [dl](#), [table](#), and [blockquote](#) elements play dual roles as both block-level and inline-level elements.

2.3.3.2. *Inline-level content*

Inline-level content consists of text and various elements to annotate the text, as well as some [embedded content](#) (such as images or sound clips).

Inline-level content comes in various types:

Strictly inline-level content

Text, embedded content, and elements that annotate the text without introducing structural grouping. For example: [a](#), [i](#), [noscript](#). Elements used in contexts allowing only strictly inline-level content must not contain anything other than strictly inline-level content.

Structured inline-level elements

Block-level elements that can also be used as inline-level content. For example: [ol](#), [blockquote](#), [table](#).

Unless an element's content model explicitly states that it must contain [significant inline content](#), simply having no text nodes and no elements satisfies an element whose content model is some kind of inline content.

Some elements are defined to have as a content model **significant inline content**. This means that

The screenshot shows a search interface with a text input field, a 'Go' button, and a date range selector. The date range is set to 'DEC 02 2004 2006 FEB 2007'. Below the date range are social sharing icons for user, help, and X, and links for 'About this capture' and 'Twitter'.

About this capture

[UNICODE]

The following three paragraphs are non-conforming because their content model is not satisfied (they all count as empty).

```
<p></p>
<p><em>Ā</em></p>
<p>
<ol>
<li></li>
</ol>
</p>
```

2.3.3.3. Determining if a particular element contains block-level elements or inline-level content

Some elements are defined to have content models that allow either [block-level elements](#) or [inline-level content](#), but not both. For example, the `aside` and `li` elements.

To establish whether such an element is being used as a block-level container or as an inline-level container, for example in order to determine if a document conforms to these requirements, user agents must look at the element's child nodes. If any of the child nodes are not allowed in block-level contexts, then the element is being used for [inline-level content](#). If all the child nodes are allowed in a block-level context, then the element is being used for [block-level elements](#).

For instance, in the following (non-conforming) fragment, the `li` element is being used as an inline-level element container, because the `style` element is not allowed in a block-level context. (It doesn't matter, for the purposes of determining whether it is an inline-level or block-level context, that the `style` element is not allowed in inline-level contexts either.)

```
<ol>
<li>
<p> Hello World </p>
<style>
/* This example is illegal. */
</style>
</li>
</ol>
```

In the following fragment, the `aside` element is being used as a block-level container, because even though all the elements it contains could be considered inline-level elements, there are no nodes that can only be considered inline-level.

```
<aside>
<ol>
<li> ... </li>
</ol>
<ul>
<li> ... </li>
</ul>
</aside>
```

```

2.3.3.4. Interactive elements

Certain elements in HTML can be activated, for instance `a` elements, button elements, or `input` elements when their `type` attribute is set to `radio`. Activation of those elements can happen in various (UA-defined) ways, for instance via the mouse or keyboard.

When activation is performed via some method other than clicking the pointing device, the default action of the event that triggers the activation must, instead of being activating the element directly, be to [fire a click event](#) on the same element.

The default action of this `click` event, or of the real `click` event if the element was activated by clicking a pointing device, must be to dispatch yet another event, namely [DOMActivate](#). It is the default action of *that* event that then performs the actual action.

For certain form controls, this process is complicated further by [changes that must happen around the click event](#). [WF2]

Note: Most interactive elements have content models that disallowed nesting interactive elements.

Need to define how default actions actually work. For instance, if you click an event inside a link, the event is triggered on that element, but then we'd like a click is sent on the link itself. So how does that happen? Does the link have a bubbling listener that triggers that second click event? what if there are multiple nested links, which one should we send that event to?

2.3.4. Global attributes [\[WIP\]](#)

User agents must support the following common attributes on all elements in the HTML namespace (including elements that are not defined to exist by this specification).

`id`

The element's unique identifier. The value must be unique in the document and must contain at least one character.

If the value is not the empty string, user agents must associate the element with the given value (exactly) for the purposes of ID matching (e.g. for selectors in CSS or for the `getElementById()` method in the DOM).

Identifiers are opaque strings. Particular meanings should not be derived from the value of the `id` attribute.

When an element has an ID set through multiple methods (for example, if it has both `id` and `xml:id` attributes simultaneously [\[XMLID\]](#)), then the element has multiple identifiers. User

About this capture

Advisory information for the element, such as would be appropriate for a tooltip. On a link, this could be the title or a description of the target resource; on an image, it could be the caption or a description of the image; on a paragraph, it could be a footnote or commentary on the text; on a citation, it could be further information about the source; and so forth. The value is text.

If this attribute is omitted from an element, then it implies that the `title` attribute of the nearest ancestor with a `title` attribute set is also relevant to this element. Setting the attribute overrides this, explicitly stating that the advisory information of any ancestors is not relevant to this element. Setting the attribute to the empty string indicates that the element has no advisory information.

Note: Some elements, such as `link` and `dfn`, define their own `title` attributes instead of using the global `title` attribute.

`lang` (HTML only) and `xml:lang` (XML only)

The primary language for the element's contents and for any of the element's attributes that contain text. The value must be a valid RFC 3066 language code, or the empty string.

[RFC3066](#)

If this attribute is omitted from an element, then it implies that the language of this element is the same as the language of the parent element. Setting the attribute to the empty string indicates that the primary language is unknown.

The `lang` attribute only applies to HTML documents. Authors must not use the `lang` attribute in XML documents. Authors must instead use the `xml:lang` attribute, defined in XML. [\[XML\]](#)

To determine the language of a node, user agents must look at the nearest ancestor element (including the element itself if the node is an element) that has a `lang` or `xml:lang` attribute set. That specifies the language of the node.

If both the `xml:lang` attribute and the `lang` attribute are set, user agents must use the `xml:lang` attribute, and the `lang` attribute must be ignored for the purposes of determining the element's language.

If no explicit language is given for the [root element](#), then language information from a higher-level protocol (such as HTTP), if any, must be used as the final fallback language. In the absence of any language information, the default value is unknown (the empty string).

User agents may use the element's language to determine proper processing or rendering (e.g. in the selection of appropriate fonts or pronunciations, or for dictionary selection).

`dir`

The element's text directionality. The attribute, if specified, must have either the literal value `ltr` or the literal value `rtl`.

If the attribute has the literal value `ltr`, the element's directionality is left-to-right. If the attribute has the literal value `rtl`, the element's directionality is right-to-left. If the attribute is omitted or has another value, then the directionality is unchanged.

About this capture

class

The element's classes. The value must be a list of zero or more words (consisting of one or more non-space characters) separated by one or more spaces.

User agents must assign all the given classes to the element, for the purposes of class matching (e.g. for selectors in CSS or for the `getElementsByClassName()` method in the DOM).

Unless defined by one of the URLs given in the `profile` attribute, classes are opaque strings. Particular meanings must not be derived from undefined values in the `class` attribute.

Authors should bear in mind that using the `class` attribute does not convey any additional meaning to the element (unless using classes defined by a `profile`). There is no semantic difference between an element *with* a class attribute and one *without*. Authors that use classes that are not defined in a `profile` should make sure, therefore, that their documents make as much sense once all `class` attributes have been removed as they do with the attributes present.

contextmenu

The element's `context menu`. The value must be the ID of a `menu` element in the DOM. If the node that would be obtained by the invoking the `getElementById()` method using the attribute's value as the only argument is null or not a `menu` element, then the element has no assigned context menu. Otherwise, the element's assigned context menu is the element so identified.

Event handler attributes aren't handled yet.

The following DOM interface, common to elements in the HTML namespace, provides scripts with convenient access to the content attributes listed above:

```
interface HTMLElement : Element {
    attribute DOMString id;
    attribute DOMString title;
    attribute DOMString lang;
    attribute DOMString dir;
    attribute DOMString className;

    NodeList getElementsByTagName(in DOMString className1 [, in DOMString
};
```

The `id` attribute must [reflect](#) the content `id` attribute.

The `title` attribute must [reflect](#) the content `title` attribute.

The `lang` attribute must [reflect](#) the content `lang` attribute.

The `dir` attribute must [reflect](#) the content `dir` attribute.

02 2004 2006 2007

About this capture

The `getElementsByClassName()` method must return the nodes that the `HTMLDocument` `getElementsByClassName()` method would return, excluding any elements that are not descendants of the `HTMLElement` on which the method was invoked.

2.3.5. The `html` element

Contexts in which this element may be used:

As the root element of a document.

Wherever a subdocument fragment is allowed in a compound document.

Content model:

A `head` element followed by a `body` element.

Element-specific attributes:

None.

DOM interface:

No difference from `HTMLElement`.

The `html` element represents the root of an HTML document.

2.4. Document metadata

Document metadata is represented by **metadata elements** in the document's `head` element.

2.4.1. The `head` element

Contexts in which this element may be used:

As the first element in an `html` element.

Content model:

In any order, exactly one `title` element, optionally one `base` element (HTML only), and zero or more other **metadata elements** (in particular, `link`, `meta`, `style`, and `script`).

Element-specific attributes:

`profile` (optional)

DOM interface:

```
interface HTMLHeadElement : HTMLElement {  
    attribute DOMString profile;  
};
```

The `head` element collects the document's metadata.

The `profile` attribute must, if specified, contain a list of zero or more URIs (or IRIs) representing definitions of classes, metadata names, and link relations. These URIs are opaque strings, like namespaces; user agents are not expected to determine any useful information from the resources

About this capture

known (to the UA) to define that name. The class, metadata, or link relationship shall then be interpreted using the semantics given by the first URI that is known to define the name. If the name is not defined by this specification and none of the specified URIs defines the name either, then the class, metadata, or link relationship is meaningless and the UA must not assign special meaning to that name.

If two profiles define the same name, then the semantic is given by the first URI specified in the profile attribute. There is no way to use the names from both profiles in one document.

User agents must ignore all the URIs given in the profile attribute that follow a URI that the UA does not recognise. (Otherwise, if a name is defined in two profiles, UAs would assign meanings to the document differently based on which profiles they supported.)

Note: If a profile's definition introduces new definitions over time, documents that use multiple profiles can change defined meaning over time. So as to avoid this problem, authors are encouraged to avoid using multiple profiles.

The profile DOM attribute must reflect the profile content attribute on getting and setting.

2.4.2. The title element

Metadata element.

Contexts in which this element may be used:

In a head element containing no other title elements.

Content model:

Text (for details, see prose).

Element-specific attributes:

None.

DOM interface:

No difference from HTMLElement.

The title element represents the document's title or name. Authors should use titles that identify their documents even when they are used out of context, for example in a user's history or bookmarks, or in search results. The document's title is often different from its first header, since the first header does not have to stand alone when taken out of context.

Here are some examples of appropriate titles, contrasted with the top-level headers that might be used on those same pages.

```
<title>Introduction to The Mating Rituals of Bees</title>
...
<h1>Introduction</h1>
<p>This companion guide to the highly successful
<cite>Introduction to Medieval Bee-Keeping</cite> book is...
```

The next page might be a part of the same site. Note how the title describes the subject matter unambiguously, while the first header assumes the reader knows what the context is and

◀ 02 ▶
2004 2006 2007

About this capture

|| <h1>The Dances</h1>

In HTML (as opposed to XHTML), the `title` element must not contain content other than text and entities; user agents parse the element so that entities are recognised and processed, but all other markup is interpreted as literal text.

In XHTML, the `title` element must not contain any elements.

User agents must concatenate the contents of all the text nodes and CDATA nodes that are direct children of the `title` element (ignoring any other nodes such as comments or elements), in tree order, to get the string to use as the document's title. User agents should use the document's title when referring to the document in their user interface.

2.4.3. The `base` element

Metadata element

Contexts in which this element may be used:

In a `head` element, before any elements that use relative URLs, and only if there are no other `base` elements anywhere in the document. Only in HTML documents (never in XML documents).

Content model:

Empty.

Element-specific attributes:

`href` (optional)

DOM interface:

```
interface HTMLBaseElement : HTMLElement {  
    attribute DOMString href;  
};
```

The `base` element allows authors to specify the document's base URI for the purposes of resolving relative URIs.

The `href` content attribute, if specified, must contain a URI (or IRI).

User agents must use the value of the `href` attribute on the first `base` element in the document as the document entity's base URI for the purposes of section 5.1.1 of RFC 2396 ("Establishing a Base URI": "Base URI within Document Content"). [\[RFC2396\]](#) Note that this base URI from RFC 2396 is referred to by the algorithm given in XML Base, which [is a normative part of this specification](#).

If the base URI given by this attribute is a relative URI, it must be resolved relative to the higher-level base URIs (i.e. the base URI from the encapsulating entity or the URI used to retrieve the entity) to obtain an absolute base URI.

The `href` content attribute must be reflected by the DOM `href` attribute.

Authors must not use the `base` element in XML documents. Authors should instead use the

Go DEC JAN FEB
02
 2004 2006 2007 ▶ About this capture

3,445 captures
 5 Jun 2004 - 22 Aug 2020

Metadata element.

Contexts in which this element may be used:

In a head element.

Content model:

Empty.

Element-specific attributes:

- href (optional)
- rel (optional)
- media (optional)
- hreflang (optional)
- type (optional)
- title (optional)

DOM interface:

```
interface HTMLLinkElement : HTMLElement {
    attribute boolean disabled;
    attribute DOMString href;
    attribute DOMString rel;
    attribute DOMString media;
    attribute DOMString hreflang;
    attribute DOMString type;
};
```

The LinkStyle interface defined in DOM2 Style must also be implemented by this element. [\[DOM2STYLE\]](#)

The link element allows authors to indicate explicit relationships between their document and other resources.

The destination of the link is given by the href attribute, which must be a URI (or IRI). If the href attribute is absent, then the element does not define a link.

The type of link indicated (the relationship) is given by the value of the rel attribute. The [allowed values and their meanings](#) are defined in a later section. If the rel attribute is absent, or if the value used is not allowed according to the definitions in this specification, then the element does not define a link.

Two categories of links can be created using the link element. **Links to external resources** are links to resources that are to be used to augment the current document, and **hyperlinks** are links to other documents. The [link types section](#) defines whether a particular link type is an external resource or a hyperlink. One element can create multiple links (of which some might be external resource links and some might be hyperlinks). User agents should process the links on a per-link basis, not a per-element basis.

The exact behaviour for links to external resources depends on the exact relationship, as defined for the relevant link type. Some of the attributes control whether or not the external resource is to be

3,445 captures

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

Interactive user agents should provide users with a means to follow the hyperlinks created using the `link` element, somewhere within their user interface. The exact interface is not defined by this specification, but it should include the following information (obtained from the element's attributes, again as defined below), in some form or another (possibly simplified), for each hyperlink created with each `link` element in the document:

- The relationship between this document and the resource (given by the `rel` attribute)
- The title of the resource (given by the `title` attribute).
- The URI of the resource (given by the `href` attribute).
- The language of the resource (given by the `hreflang` attribute).
- The optimum media for the resource (given by the `media` attribute).

User agents may also include other information, such as the type of the resource (as given by the `type` attribute).

The `media` attribute says which media the resource applies to. The value must be a valid media query. [\[MQ\]](#)

If the link is a [hyperlink](#) then the `media` attribute is purely advisory, and describes for which media the document in question was designed.

However, if the link is an [external resource link](#), then the `media` attribute is prescriptive. The user agent must only apply the external resource to [views](#) while their state match the listed media.

The default, if the `media` attribute is omitted, is `all`, meaning that by default links apply to all media.

The `hreflang` attribute gives the language of the linked resource. It is purely advisory. The value must be a valid RFC 3066 language code. [RFC3066](#) User agents must not consider this attribute authoritative — upon fetching the resource, user agents must only use language information associated with the resource to determine its language, not metadata included in the link to the resource.

The `type` attribute gives the MIME type of the linked resource. It is purely advisory. The value must be a valid MIME type, optionally with parameters. [\[RFC2046\]](#)

For [external resource links](#), user agents may use the type given in this attribute to decide whether or not to consider using the resource at all. If the UA does not support the given MIME type for the given link relationship, then the UA may opt not to download and apply the resource.

User agents must not consider the `type` attribute authoritative — upon fetching the resource, user agents must only use the Content-Type information associated with the resource to determine its type, not metadata included in the link to the resource.

If the attribute is omitted, then the UA must fetch the resource to determine its type and thus determine if it supports (and can apply) that external resource.

If a document contains three style sheet links labelled as follows:

[Go](#) DEC JAN FEB

3,445 captures
 5 Jun 2004 - 22 Aug 2020 **02** 2004 2006 2007 ▾ About this capture

...then a compliant UA that supported only CSS style sheets would fetch the A and C files, and skip the B file (since `text/plain` is not the MIME type for CSS style sheets). For these two files, it would then check the actual types returned by the UA. For those that are sent as `text/css`, it would apply the styles, but for those labelled as `text/plain`, or any other type, it would not.

The `title` attribute gives the title of the link. With one exception, it is purely advisory. The value is text. The exception is for style sheet links, where the `title` attribute defines [alternate style sheet sets](#).

Note: The `title` attribute on `link` elements differs from the global `title` attribute of most other elements in that a link without a title does not inherit the title of the parent element: it merely has no title.

Some versions of HTTP defined a `Link`: header, to be processed like a series of `link` elements. When processing links, those must be taken into consideration as well. For the purposes of ordering, links defined by HTTP headers must be assumed to come before any links in the document, in the order that they were given in the HTTP entity header. Relative URIs in these headers must be resolved according to the rules given in HTTP, not relative to base URIs set by the document (e.g. using a `base` element or `xml:base` attributes). [\[RFC2616\]](#) [\[RFC2068\]](#)

The DOM attributes `href`, `rel`, `media`, `hreflang`, and `type` each [reflect](#) the respective content attributes of the same name.

The DOM attribute `disabled` only applies to style sheet links. When the `link` element defines a style sheet link, then the `disabled` attribute behaves as defined [for the alternate style sheets DOM](#). For all other `link` elements it must always return false and must do nothing on setting.

2.4.5. The `meta` element

[Metadata element](#)

Contexts in which this element may be used:

In a `head` element.

Content model:

Empty.

Element-specific attributes:

- `name` (optional)
- `http-equiv` (HTML only, optional)
- `content` (optional)

DOM interface:

```
interface HTMLMetaElement : HTMLElement {
    attribute DOMString content;
    attribute DOMString name;
};
```

[Go](#) DEC JAN FEB

02
 2004 2006 2007 ▾ [About this capture](#)

3,445 captures
 5 Jun 2004 - 22 Aug 2020

attribute on the same element gives the value.

To set metadata with `meta` elements, authors must first specify a profile that defines metadata names, using the `profile` attribute. The value of the `name` attribute must be defined by one of the profiles, and the value of the `content` attribute must conform to the syntax given by the profile.

How user agents handle metadata set in this way depends on the definitions of the profiles involved.

If a `meta` element has no `name` attribute, it does not set document metadata. If a `meta` element has no `content` attribute, then the value part of the metadata name/value pair is the empty string.

The DOM attributes `name` and `content` reflect the respective content attributes of the same name.

2.4.5.1. Specifying and establishing the document's character encoding

The `meta` element may also be used, in HTML only (not in XHTML) to provide UAs with character encoding information for the file. To do this, the `meta` element must be the first element in the `head` element, it must have the `http-equiv` attribute set to the literal value `Content-Type`, and must have the `content` attribute set to the literal value `text/html; charset=` immediately followed by the character encoding, which must be a valid character encoding name. [IANACHARSET] When the `meta` element is used in this way, there must be no other attributes set on the element, and the `http-equiv` attribute must be listed first in the source. Other than for giving the document's character encoding in this way, the `http-equiv` attribute must not be used.

In XHTML, the XML declaration should be used for inline character encoding information, if necessary.

Authors should avoid including inline character encoding information. Character encoding information should instead be included at the transport level (e.g. using the HTTP `Content-Type` header).

2.4.6. The `style` element

[Metadata element](#).

Contexts in which this element may be used:

In a `head` element.

Content model:

Depends on the value of the `type` attribute.

Element-specific attributes:

`type` (optional)

`media` (optional)

`title` (optional)

DOM interface:

```
interface HTMLStyleElement : HTMLElement {
    attribute boolean disabled;
    attribute DOMString media;
```

The `style` interface defined in DOM2 Style must also be implemented by this element. [\[DOM2STYLE\]](#)

The `style` element allows authors to embed style information in their documents.

If the `type` attribute is given, it must contain a MIME type, optionally with parameters, that designates a styling language. [\[RFC2046\]](#) If the attribute is absent, the type defaults to `text/css`. [\[RFC2138\]](#)

If the UA supports the given styling language, then the UA must use the given styles as appropriate for that language.

When examining types to determine if they support the language, user agents must not ignore unknown MIME parameters — types with unknown parameters must be assumed to be unsupported.

The `media` attribute says which media the styles apply to. The value must be a valid media query. [\[MQ\]](#) User agents must only apply the styles to `views` while their state match the listed media.

The default, if the `media` attribute is omitted, is `all`, meaning that by default styles apply to all media.

The `title` attribute on `style` elements [defines alternate style sheet sets](#). If the `style` element has no `title` attribute, then it has no title; the `title` attribute of ancestors does not apply to the `style` element.

Note: The `title` attribute on `style` elements, like the `title` attribute on `link` elements, differs from the global `title` attribute in that a `style` block without a title does not inherit the title of the parent element: it merely has no title.

All descendant elements must be processed, according to their semantics, before the `style` element itself is evaluated. For styling languages that consist of pure text, user agents must evaluate `style` elements by passing the concatenation of the contents of all the text nodes and CDATA nodes that are direct children of the `style` element (not any other nodes such as comments or elements), in tree order, to the style system. For XML-based styling languages, user agents must pass all the children nodes of the `style` element to the style system.

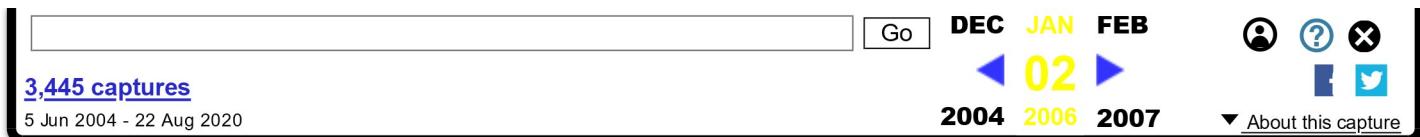

Note: This specification does not specify a style system, but CSS is expected to be supported by most Web browsers. [\[CSS21\]](#)

The DOM attributes `media` and `type` each [reflect](#) the respective content attributes of the same name.

The DOM `disabled` attribute behaves as defined [for the alternate style sheets DOM](#).

2.5. Sections

Sectioning elements are elements that divide the page into, for lack of a better word, sections. This section describes HTML's sectioning elements and elements that support them.

2.5.1. The `body` element

[Sectioning element](#).

Contexts in which this element may be used:

As the second element in an [html](#) element.

Content model:

Zero or more [block-level elements](#).

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

The `body` element represents the main content of the document.

The `body` element potentially has a heading. See the section on [headings and sections](#) for further details.

Note: Some DOM operations (for example, parts of the drag and drop model) are defined in terms of "[the body element](#)". See the definition of the `document.body` DOM attribute for details.

2.5.2. The `section` element

[Sectioning block-level element](#).

Contexts in which this element may be used:

Where [block-level elements](#) are expected.

Content model:

Zero or more [block-level elements](#).

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

The `section` element represents a generic document or application section. A section, in this context, is a thematic grouping of content, typically with a header, possibly with a footer.

Examples of sections would be chapters, the various tabbed pages in a tabbed dialog box, or the numbered sections of a thesis. A Web site's home page could be split into sections for an introduction, news items, contact information.

Each `section` element potentially has a heading. See the section on [headings and sections](#) for further details.

3,445 captures
5 Jun 2004 - 22 Aug 2020

Content model:

Where [block-level elements](#) are expected.

Content model:

Zero or more [block-level elements](#), or [inline-level content](#) (but not both).

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

The `nav` element represents a section of a page that links to other pages or to parts within the page: a section with navigation links.

When [used as an inline-level content](#) container, the element represents a [paragraph](#).

Each `nav` element potentially has a heading. See the section on [headings and sections](#) for further details.

2.5.4. The `article` element

[Sectioning block-level element](#).

Contexts in which this element may be used:

Where [block-level elements](#) are expected.

Content model:

Zero or more [block-level elements](#).

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

The `article` element represents a section of a page that consists of a composition that forms an independent part of a document, page, or site. This could be a forum post, a magazine or newspaper article, a Web log entry, a user-submitted comment, or any other independent item of content.

Note: An `article` element is "independent" in that its contents could stand alone, for example in syndication. However, the element is still associated with its ancestors; for instance, contact information that applies to a parent `body` element still covers the `article` as well.

When `article` elements are nested, the inner `article` elements represent articles that are in principle related to the contents of the outer article. For instance, a Web log entry on a site that accepts user-submitted comments could represent the comments as `article` elements nested within the `article` element for the Web log entry.

Author information associated with an `article` element (q.v. the `address` element) does not apply

3,445 captures

About this capture

2.5.5. The `blockquote` element

[Sectioning block-level element](#), and [structured inline-level element](#).

Contexts in which this element may be used:

Where [block-level elements](#) are expected.

Where [structured inline-level elements](#) are allowed.

Content model:

Zero or more [block-level elements](#).

Element-specific attributes:

`cite` (optional)

DOM interface:

```
interface HTMLQuoteElement : HTMLElement {  
    attribute DOMString cite;  
};
```

Note: The [HTMLQuoteElement](#) interface is also used by the `q` element.

The `blockquote` element represents a section that is quoted from another source.

Content inside a `blockquote` must be quoted from another source, whose URI, if it has one, should be cited in the `cite` attribute.

If the `cite` attribute is present, it must be a URI (or IRI). User agents should allow users to follow such citation links.

Each `blockquote` element potentially has a heading. See the section on [headings and sections](#) for further details.

The `cite` DOM attribute reflects the element's `cite` content attribute.

The `blockquote` element can be used with the `ol` and `cite` elements to mark up dialogue. This example demonstrates this using an extract from Abbot and Costello's famous sketch, *Who's on first*:

```
<ol>  
  <li> <cite>Costello</cite>  
    <blockquote> <p> Look, you gotta first baseman? </p> </blockquote>  
  <li> <cite>Abbott</cite>  
    <blockquote> <p> Certainly. </p> </blockquote>  
  <li> <cite>Costello</cite>  
    <blockquote> <p> Who's playing first? </p> </blockquote>  
  <li> <cite>Abbott</cite>  
    <blockquote> <p> That's right. </p> </blockquote>  
  <li> <cite>Costello</cite>
```

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

2.5.6. The `aside` element

[Sectioning block-level element.](#)

Contexts in which this element may be used:

Where [block-level elements](#) are expected.

Content model:

Zero or more [block-level elements](#), or [inline-level content](#) (but not both).

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

The `aside` element represents a section of a page that consists of content that is tangentially related to the content around the `aside` element, and which could be considered separate from that content. Such sections are often represented as sidebars in printed typography.

When [used as an inline-level content](#) container, the element represents a [paragraph](#).

Each `aside` element potentially has a heading. See the section on [headings and sections](#) for further details.

2.5.7. The `h1`, `h2`, `h3`, `h4`, `h5`, and `h6` elements

[Block-level elements.](#)

Contexts in which these elements may be used:

Where [block-level elements](#) are expected.

Content model:

[Significant strictly inline-level content.](#)

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

These elements define headers for their sections.

The semantics and meaning of these elements are defined in the section on [headings and sections](#).

These elements have a **rank** given by the number in their name. The `h1` element is said to have the highest rank, the `h6` element has the lowest rank, and two elements with the same name have equal rank.

These elements must not be [empty](#).

▼ About this capture

Contexts in which this element may be used:

Where [block-level elements](#) are expected and there are no [header](#) ancestors.

Content model:

Zero or more [block-level elements](#), including at least one descendant [h1](#), [h2](#), [h3](#), [h4](#), [h5](#), or [h6](#) element, but no sectioning element descendants, no [header](#) element descendants, and no [footer](#) element descendants.

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

The [header](#) element represents the header of a section. Headers may contain more than just the section's heading — for example it would be reasonable for the header to include version history information.

[header](#) elements must not contain any [header](#) elements, [footer](#) elements, or any sectioning elements (such as [section](#)) as descendants.

[header](#) elements must have at least one [h1](#), [h2](#), [h3](#), [h4](#), [h5](#), or [h6](#) element as a descendant.

For the purposes of document summaries, outlines, and the like, [header](#) elements are equivalent to the highest ranked [h1-h6](#) element descendant (the first such element if there are multiple elements with that [rank](#)).

Other heading elements indicate subheadings or subtitles.

Here are some examples of valid headers. In each case, the emphasised text represents the text that would be used as the header in an application extracting header data and ignoring subheadings.

```
<header>
  <h1>The reality dysfunction</h1>
  <h2>Space is not the only void</h2>
</header>

<header>
  <p>Welcome to...</p>
  <h1>Voidwars!</h1>
</header>

The section on [headings and sections](#) defines how [header](#) elements are assigned to individual sections.

The [rank](#) of a [header](#) element is the same as for an [h1](#) element (the highest rank).

2.5.9. The footer element

[Block-level element](#).

Contexts in which this element may be used:

Where [block-level elements](#) are expected.

Content model:

Either zero or more [block-level elements](#), but with no [h1](#), [h2](#), [h3](#), [h4](#), [h5](#), [h6](#), [header](#), or [footer](#) elements as descendants, and with no [sectioning elements](#) as descendants; or, [inline-level content](#) (but not both).

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

The [footer](#) element represents the footer for the section it [applies](#) to. A footer typically contains information about its section such as who wrote it, links to related documents, copyright data, and the like.

[footer](#) elements must not contain any [footer](#), [header](#), [h1](#), [h2](#), [h3](#), [h4](#), [h5](#), or [h6](#) elements, or any of the sectioning elements (such as [section](#)), as descendants.

When [used as an inline-level content](#) container, the element represents a [paragraph](#).

Contact information for the section given in a [footer](#) should be marked up using the [address](#) element.

2.5.10. The address element

[Block-level element](#).

Contexts in which this element may be used:

Where [block-level elements](#) are expected.

Content model:

[Inline-level content](#).

Go DEC JAN FEB

 2004 2006 2007 ▾ About this capture

3,445 captures
 5 Jun 2004 - 22 Aug 2020

No difference from HTMLElement.

The address element represents a paragraph of contact information for the section it applies to.

For example, a page at the W3C Web site related to HTML might include the following contact information:

```
<ADDRESS>
<A href="../People/Raggett/">Dave Raggett</A>,
<A href="../People/Arnaud/">Arnaud Le Hors</A>,
contact persons for the <A href="Activity">W3C HTML Activity</A>
</ADDRESS>
```

The address element must not be used to represent arbitrary addresses (e.g. postal addresses), unless those addresses are contact information for the section. (The p element is the appropriate element for marking up such addresses.)

The address element must not contain information other than contact information.

For example, the following is non-conforming use of the address element:

```
<ADDRESS>Last Modified: 1999/12/24 23:37:50</ADDRESS>
```

Typically, the address element would be included with other information in a footer element.

To determine the contact information for a sectioning element (such as the body element, which would give the contact information for the page), UAs must collect all the address elements that apply to that sectioning element and its ancestor sectioning elements. The contact information is the collection of all the information given by those elements.

Note: Contact information for one sectioning element, e.g. a aside element, does not apply to its ancestor elements, e.g. the page's body.

2.5.11. Headings and sections

The h1-h6 elements and the header element are headings.

The first heading in a sectioning element gives the header for that section. Subsequent headers of equal or higher rank start new (implied) sections, headers of lower rank start subsections that are part of the previous one.

Sectioning elements other than blockquote are always considered subsections of their nearest ancestor sectioning element, regardless of what implied sections other headings may have created. However, blockquote elements are associated with implied sections. Effectively, blockquote elements act like sections on the inside, and act opaquely on the outside.

For the following fragment:

```
<body>
<h1>Foo</h1>
<h2>Bar</h2>
```

Go DEC JAN FEB
02 2004 2006 2007

3,445 captures
 5 Jun 2004 - 22 Aug 2020

About this capture

```
<h2>Quux</h2>
<section>
  <h3>Thud</h3>
</section>
<p>Grunt</p>
</body>
```

...the structure would be:

1. Foo (heading of explicit body section)
 1. Bar (heading starting implied section)
 1. Bla (heading of explicit blockquote section)
 Baz (paragraph)
 2. Quux (heading starting implied section)
 3. Thud (heading of explicit section section)
 - Grunt (paragraph)

Notice how the blockquote nests inside an implicit section while the section does not (and in fact, ends the earlier implicit section so that a later paragraph is back at the top level).

Sections may contain headers of any rank, but authors are strongly encouraged to either use only h1 elements, or to use elements of the appropriate rank for the section's nesting level.

Authors are also encouraged to explicitly wrap sections in sectioning elements, instead of relying on the implicit sections generated by having multiple heading in one sectioning element.

For example, the following is correct:

```
<body>
  <h4>Apples</h4>
  <p>Apples are fruit.</p>
  <section>
    <h2>Taste</h2>
    <p>They taste lovely.</p>
    <h6>Sweet</h6>
    <p>Red apples are sweeter than green ones.</p>
    <h1>Colour</h1>
    <p>Apples come in various colours.</p>
  </section>
</body>
```

However, the same document would be more clearly expressed as:

```
<body>
  <h1>Apples</h1>
  <p>Apples are fruit.</p>
  <section>
    <h2>Taste</h2>
    <p>They taste lovely.</p>
    <section>
      <h3>Sweet</h3>
```

Go DEC JAN FEB

 2004 2006 2007 ▶ About this capture

3,445 captures
 5 Jun 2004 - 22 Aug 2020

```
<h2>Colour</h2>
<p>Apples come in various colours.</p>
</section>
</body>
```

Both of the documents above are semantically identical and would produce the same outline in compliant user agents.

2.5.11.1. Creating an outline

HTML documents can be viewed as a tree of sections, which defines how each element in the tree is semantically related to the others, in terms of the overall section structure. This tree is related to the document tree, but there is not a one-to-one relationship between elements in the DOM and the document's sections.

The tree of sections should be used when generating document outlines, for example when generating tables of contents.

To derive the tree of sections from the document tree, a hypothetical tree is used, consisting of a view of the document tree containing only the `h1-h6` and `header` elements, and the sectioning elements other than `blockquote`. Descendants of `h1-h6`, `header`, and `blockquote` elements must be removed from this view.

The hypothetical tree must be rooted at the `root element` or at a sectioning element. In particular, while the sections inside `blockquotes` do not contribute to the document's tree of sections, `blockquotes` can have outlines of their own.

UAs must take this hypothetical tree (which will become the outline) and mutate it by walking it depth first in tree order and, for each `h1-h6` or `header` element that is not the first element of its parent sectioning element, inserting a new sectioning element, as follows:

- ↳ If the element is a `header` element, or if it is an `h1-h6` node of `rank` equal to or higher than the first element in the parent sectioning element (assuming that is also an `h1-h6` node), or if the first element of the parent sectioning element is a sectioning element:

Insert the new sectioning element as the immediately following sibling of the parent sectioning element, and move all the elements from the current heading element up to the end of the parent sectioning element into the new sectioning element.

- ↳ Otherwise:

Move the current heading element, and all subsequent siblings up to but excluding the next sectioning element, `header` element, or `h1-h6` of equal or higher `rank`, whichever comes first, into the new sectioning element, then insert the new sectioning element where the current header was.

The outline is then the resulting hypothetical tree. The `ranks` of the headers become irrelevant at this point: each sectioning element in the hypothetical tree contains either no or one heading element child. If there is one, then it gives the section's heading, of there isn't, the section has no heading.

Sections are nested as in the hypothetical tree. If a sectioning element is a child of another, that means it is a subsection of that other section.

3,445 captures 02 2004 2006 2007

5 Jun 2004 - 22 Aug 2020

About this capture

Selecting the first section of the document therefore always takes the user to the top of the document, regardless of where the first header in the `body` is to be found.

The hypothetical tree (before mutations) could be generated by creating a TreeWalker with the following `NodeFilter` (described here as an anonymous ECMAScript function). [DOMTR] [ECMA262]

```
function (n) {
    // This implementation only knows about HTML elements.
    // An implementation that supports other languages might be
    // different.

    // Reject anything that isn't an element.
    if (n.nodeType != Node.ELEMENT_NODE)
        return NodeFilter.FILTER_REJECT;

    // Skip any descendants of headings.
    if (n.parentNode && n.parentNode.namespaceURI == 'http://www.w3.org'
        (n.parentNode.localName == 'h1' || n.parentNode.localName == 'h2'
         n.parentNode.localName == 'h3' || n.parentNode.localName == 'h4'
         n.parentNode.localName == 'h5' || n.parentNode.localName == 'h6'
         n.parentNode.localName == 'header')
        return NodeFilter.FILTER_REJECT;

    // Skip any blockquotes.
    if (n.namespaceURI == 'http://www.w3.org/1999/xhtml' &&
        (n.localName == 'blockquote'))
        return NodeFilter.FILTER_REJECT;

    // Accept HTML elements in the list given in the prose above.
    if ((n.namespaceURI == 'http://www.w3.org/1999/xhtml') &&
        (n.localName == 'body' || /*n.localName == 'blockquote' ||*/
         n.localName == 'section' || n.localName == 'nav' ||
         n.localName == 'article' || n.localName == 'aside' ||
         n.localName == 'h1' || n.localName == 'h2' ||
         n.localName == 'h3' || n.localName == 'h4' ||
         n.localName == 'h5' || n.localName == 'h6' ||
         n.localName == 'header'))
        return NodeFilter.FILTER_ACCEPT;

    // Skip the rest.
    return NodeFilter.FILTER_SKIP;
}
```

2.5.11.2. Determining which heading and section applies to a particular node

Given a particular node, user agents must use the following algorithm, *in the given order*, to determine which heading and section the node is most closely associated with. The processing of

3,445 captures
5 Jun 2004 - 22 Aug 2020

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

most distant such ancestor. The associated section is that header's associated section (i.e. repeat this algorithm for that header).

2. If the node has an ancestor that is an h1-h6 element, then the associated heading is the most distant such ancestor. The associated section is that heading's section (i.e. repeat this algorithm for that heading element).
3. If the node is an h1-h6 element or a header element, then the associated heading is the element itself. The UA must then generate the hypothetical section tree described in the previous section, rooted at the nearest section ancestor (or the root element if there is no such ancestor). If the parent of the heading in that hypothetical tree is an element in the real document tree, then that element is the associated section. Otherwise, there is no associated section element.
4. If the node is a sectioning element, then the associated section is itself. The UA must then generate the hypothetical section tree described in the previous section, rooted at the section itself. If the section element, in that hypothetical tree, has a child element that is an h1-h6 element or a header element, then that element is the associated heading. Otherwise, there is no associated heading element.
5. If the node is a footer or address element, then the associated section is the nearest ancestor sectioning element, if there is one. The node's associated heading is the same as that sectioning element's associated heading (i.e. repeat this algorithm for that sectioning element). If there is no ancestor sectioning element, the element has no associated section nor an associated heading.
6. Otherwise, the node is just a normal node, and the document has to be examined more closely to determine its section and heading. Create a view rooted at the nearest ancestor sectioning element (or the root element if there is none) that has just h1-h6 elements, header elements, the node itself, and sectioning elements other than blockquote elements. (Descendants of any of the nodes in this view can be ignored, as can any node later in the tree than the node in question, as the algorithm below merely walks backwards up this view.)
7. Let n be an iterator for this view, initialised at the node in question.
8. Let c be the current best candidate heading, initially null, and initially not used. It is used when top-level heading candidates are to be searched for (see below).
9. Repeat these steps (which effectively goes backwards through the node's previous siblings) until an answer is found:
 1. If n points to a node with no previous sibling, and c is null, then return the node's parent node as the answer. If the node has no parent node, return null as the answer.
 2. Otherwise, if n points to a node with no previous sibling, return c as the answer.
 3. Adjust n so that it points to the previous sibling of the current position.
 4. If n is pointing at an h1 or header element, then return that element as the answer.
 5. If n is pointing at an h2-h6 element, and heading candidates are not being searched for, then return that element as the answer.
 6. Otherwise, if n is pointing at an h2-h6 element, and either c is still null, or c is a heading of lower rank than this one, then set c to be this element, and continue going

Go DEC JAN FEB
02
 2004 2006 2007 ▾ About this capture

3,445 captures
 5 Jun 2004 - 22 Aug 2020

siblings.

10. If the answer from the previous step (the loop) is null, which can only happen if the node has no preceding headings and is not contained in a sectioning element, then there is no associated heading and no associated section.
11. Otherwise, if the answer from the earlier loop step is a sectioning element, then the associated section is that element and the associated heading is that sectioning element's associated heading (i.e. repeat this algorithm for that section).
12. Otherwise, if the answer from that same earlier step is an `h1-h6` element or a `header` element, then the associated heading is that element and the associated section is that heading element's associated section (i.e. repeat this algorithm for that heading).

Note: Not all nodes have an associated header or section. For example, if a section is implied, as when multiple headers are found in one sectioning element, then a node in that section has an anonymous associated section (its section is not represented by a real element), and the algorithm above does not associate that node with any particular sectioning element.

For the following fragment:

```
<body>
  <h1>x</h1>
  <h2>x</h2>
  <blockquote>
    <h3>x</h3>
  </blockquote>
  <p id="a">x</p>
  <h4>Text Node A</h4>
  <section>
    <h5>x</h5>
  </section>
  <p>Text Node B</p>
</body>
```

The associations are as follows (not all associations are shown):

Node	Associated heading	Associated section
<body>	<h1>	<body>
<h1>	<h1>	<body>
<h2>	<h2>	None.
<blockquote>	<h2>	None.
<h3>	<h3>	<blockquote>
<p id="a">	<h2>	None.
Text Node A	<h4>	None.
Text Node B	<h1>	<body>

The screenshot shows the Wayback Machine interface. At the top, there's a search bar with a 'Go' button, followed by month abbreviations 'DEC JAN FEB'. Below the search bar, it says '3,445 captures' and the date range '5 Jun 2004 - 22 Aug 2020'. In the center, a large date '02' is displayed above the year '2004' with arrows pointing left and right. To the right, there are icons for user profile, help, and sharing, along with a link 'About this capture'.

also a paragraph, as is a part of a form, a byline, or a stanza in a poem.

Paragraphs can be represented by several elements. The `address` element always represents a paragraph of contact information for its section, the `aside`, `nav`, `footer`, `li`, and `dd` elements represent paragraphs with various specific semantics when they are used as inline-level content containers, and the `p` element represents all the other kinds of paragraphs, for which there are no dedicated elements.

2.6.1. The `p` element

[Block-level element](#).

Contexts in which this element may be used:

Where [block-level elements](#) are expected.

Content model:

[Significant inline-level content](#).

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

The `p` element represents a [paragraph](#).

`p` elements can contain a mixture of [strictly inline-level content](#), such as text, images, hyperlinks, etc, and [structured inline-level elements](#), such as lists, tables, and block quotes. `p` elements must not be [empty](#).

The following examples are conforming HTML fragments:

```
<p>The little kitten gently seated himself on a piece of carpet. Later in his life, this would be referred to as the time the cat sat on the mat.</p>

<fieldset>
  <legend>Personal information</legend>
  <p>
    <label>Name: <input name="n"></label>
    <label><input name="anon" type="checkbox"> Hide from other users</label>
  </p>
  <p><label>Address: <textarea name="a"></textarea></label></p>
</fieldset>

<p>There was once an example from Femley,<br>
Whose markup was of dubious quality.<br>
The validator complained,<br>
So the author was pained,<br>
To move the error from the markup to the rhyming.</p>
```

The `p` element should not be used when a more specific element is more appropriate.

[Go](#) DEC JAN FEB

 2004 2006 2007 ▾ [About this capture](#)

<p>Last modified: 2001-04-23</p>
<p>Author: fred@example.com</p>
</section>

However, it would be better marked-up as:

```
<section>
<!-- ... -->
<footer>Last modified: 2001-04-23</footer>
<address>Author: fred@example.com</address>
</section>
```

Or:

```
<section>
<!-- ... -->
<footer>
<p>Last modified: 2001-04-23</p>
<address>Author: fred@example.com</address>
</footer>
</section>
```

2.6.2. The `hr` element [TBW]

thematic separator. break. transition. hinge realignment. reconstruction, refinement, remodeling, reversal, revision, revolution. Maybe an 'html respite' or a 'hypertext rest'? .

2.7. Preformatted text

2.7.1. The `pre` element

[Block-level element](#), and [structured inline-level element](#).

Contexts in which this element may be used:

Where [block-level elements](#) are expected.

Where [structured inline-level elements](#) are allowed.

Content model:

[Strictly inline-level content](#).

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

The `pre` element represents a block of preformatted text, in which structure is represented by typographic conventions rather than by elements.

Some examples of cases where the `pre` element could be used:

of that language.

- Displaying ASCII art.

If, ignoring text nodes consisting only of white space, the only child of a `pre` is a `code` element, then the `pre` element represents a block of computer code.

If, ignoring text nodes consisting only of white space, the only child of a `pre` is a `samp` element, then the `pre` element represents a block of computer output.

2.8. Lists

2.8.1. The `ol` element

[Block-level element](#), and [structured inline-level element](#).

Contexts in which this element may be used:

Where [block-level elements](#) are expected.

Where [structured inline-level elements](#) are allowed.

Content model:

Zero or more `li` elements.

Element-specific attributes:

`start` (optional)

DOM interface:

```
interface HTMLListElement : HTMLElement {
    attribute long start;
};
```

The `ol` element represents an ordered list of items (which are represented by `li` elements).

The `start` attribute, if present, must have a value that consists of an optional U+002D HYPHEN-MINUS followed by one or more digits (U+0030 to U+0039) expressing a base ten integer giving the ordinal value of the first list item.

If the `start` attribute is present, user agents must [convert the value to a numeric type](#), truncating any fractional part, in order to determine the attribute's value. The default value, used if the attribute is missing or if the value cannot be converted to a number according to the referenced algorithm, is 1.

The items of the list are the `li` element child nodes of the `ol` element, in tree order.

The first item in the list has the ordinal value given by the `ol` element's `start` attribute (unless it is further overridden by that `li` element's `value` attribute).

Each subsequent item in the list has the ordinal value given by its `value` attribute, if it has one, or, if it doesn't, the ordinal value of the previous item, plus one.

[Block-level element](#), and [structured inline-level element](#).

Contexts in which this element may be used:

Where [block-level elements](#) are expected.

Where [structured inline-level elements](#) are allowed.

Content model:

Zero or more [li](#) elements.

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

The [ul](#) element represents an unordered list of items (which are represented by [li](#) elements).

The items of the list are the [li](#) element child nodes of the [ul](#) element.

2.8.3. The [li](#) element

Contexts in which this element may be used:

Inside [ol](#) elements.

Inside [ul](#) elements.

Inside [menu](#) elements.

Content model:

When the element is a child of an [ol](#) or [ul](#) element and the grandchild of an element that is [being used as an inline-level content container](#), or, when the element is a child of a [menu](#) element: [inline-level content](#).

Otherwise: zero or more [block-level elements](#), or [inline-level content](#) (but not both).

Element-specific attributes:

If the element is a child of an [ol](#) element: [value](#) (optional)

If the element is not the child of an [ol](#) element: None.

DOM interface:

```
interface HTMLLIElement : HTMLElement {
    attribute long value;
};
```

The [li](#) element represents a list item.

When the list item is the child of an [ol](#) or [ul](#) element, the content model of the item depends on the way that parent element was used. If it was used as structured inline content (i.e. if *that* element's parent was [used as an inline-level content](#) container), then the [li](#) element must only contain [inline-level content](#). Otherwise, the element may be used either for [inline content](#) or [block-level elements](#).

When the list item is the child of a [menu](#) element, the [li](#) element must contain only [inline-level](#)

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

When [used as an inline-level content](#) container, the list item represents a single [paragraph](#).

The **value** attribute, if present, must have a value that consists of an optional U+002D HYPHEN-MINUS followed by one or more digits (U+0030 to U+0039) expressing a base ten integer giving the ordinal value of the first list item.

If the **value** attribute is present, user agents must [convert the value to a numeric type](#), truncating any fractional part, in order to determine the attribute's value. If the attribute's value cannot be converted to a number, it is treated as if the attribute was absent. The attribute has no default value.

The **value** attribute is processed by the parent [ol](#) element, if there is one. If there is not, the attribute has no effect.

The **value** DOM attribute must [reflect](#) the value of the **value** content attribute.

2.8.4. The **dl** element

[Block-level element](#), and [structured inline-level element](#).

Contexts in which this element may be used:

Where [block-level elements](#) are expected.

Where [structured inline-level elements](#) are allowed.

Content model:

Zero or more groups each consisting of one or more [dt](#) elements followed by one or more [dd](#) elements.

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

The **dl** element introduces an unordered association list consisting of zero or more name-value groups. Each group must consist of one or more names ([dt](#) elements) followed by one or more values ([dd](#) elements).

Name-value groups may be terms and definitions, metadata topics and values, or any other groups of name-value data.

The following are all conforming HTML fragments.

In the following example, one entry ("Authors") is linked to two values ("John" and "Luke").

```
<dl>
  <dt> Authors
  <dd> John
  <dd> Luke
  <dt> Editor
  <dd> Frank
</dl>
```

3,445 captures
5 Jun 2004 - 22 Aug 2020

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

```
<dt lang="en-GB"> <dfn>colour</dfn> </dt>
<dd> A sensation which (in humans) derives from the ability of
the fine structure of the eye to distinguish three differently
filtered analyses of a view. </dd>
</dl>
```

The following example illustrates the use of the `dl` element to mark up metadata of sorts. At the end of the example, one group has two metadata labels ("Authors" and "Editors") and two values ("Robert Rothman" and "Daniel Jackson").

```
<dl>
<dt> Last modified time </dt>
<dd> 2004-12-23T23:33Z </dd>
<dt> Recommended update interval </dt>
<dd> 60s </dd>
<dt> Authors </dt>
<dt> Editors </dt>
<dd> Robert Rothman </dd>
<dd> Daniel Jackson </dd>
</dl>
```

If a `dl` element is empty, it contains no groups.

If a `dl` element contains non-whitespace text nodes, or elements other than `dt` and `dd`, then those elements or text nodes do not form part of any groups in that `dl`, and the document is non-conforming.

If a `dl` element contains only `dt` elements, then it consists of one group with names but no values, and the document is non-conforming.

If a `dl` element contains only `dd` elements, then it consists of one group with values but no names, and the document is non-conforming.

Note: The `dl` element is inappropriate for marking up dialogue, since dialogue is ordered (each speaker/line pair comes after the next). For an example of how to mark up dialogue, see the [blockquote](#) element.

2.8.5. The `dt` element

Contexts in which this element may be used:

Before `dd` elements inside `dl` elements.

Content model:

[Strictly inline-level content.](#)

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

3,445 captures
5 Jun 2004 - 22 Aug 2020

defined, but this can be indicated using the dd element.

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

2.8.6. The dd element

Contexts in which this element may be used:

After dt elements inside dl elements.

Content model:

When the element is a child of a dl element and the grandchild of an element that is being used as an inline-level content container: inline-level content.

Otherwise: zero or more block-level elements, or inline-level content (but not both).

Element-specific attributes:

None.

DOM interface:

No difference from HTMLElement.

The dd element represents the definition, or value, part of a name-value group in a dl element.

The content model of a dd element depends on the way its parent element is being used. If the parent element is a dl element that is being used as structured inline content (i.e. if the dl element's parent element is being used as an inline-level content container), then the dd element must only contain inline-level content.

Otherwise, the element may be used either for inline content or block-level elements.

2.9. Phrase elements

2.9.1. The a element

Interactive, strictly inline-level content.

Contexts in which this element may be used:

Where strictly inline-level content is allowed, if there are no ancestor interactive elements.

Content model:

When used in an element whose content model is only strictly inline-level content: only significant strictly inline-level content, but there must be no interactive descendants.

Otherwise: any significant inline-level content, but there must be no interactive descendants.

Element-specific attributes:

href (optional)

rel (optional)

media (optional)

hreflang (optional)

type (optional)

ping (optional)

DOM interface:

3,445 captures
5 Jun 2004 - 22 Aug 2020

attribute DOMString media;
attribute DOMString hreflang;
attribute DOMString type;
attribute DOMString ping;
};

The Command interface must also be implemented by this element.

If the a element has an href attribute, then it represents a hyperlink.

If the a element has no href attribute, then the element is a placeholder for where a link might otherwise have been placed, if it had been relevant.

If a site uses a consistent navigation toolbar on every page, then the link that would normally link to the page itself could be marked up using an a element:

```
<nav>
  <ul>
    <li> <a href="/">Home</a> </li>
    <li> <a href="/news">News</a> </li>
    <li> <a>Examples</a> </li>
    <li> <a href="/legal">Legal</a> </li>
  </ul>
</nav>
```

The href attribute, if present, must have a value that is a URI (or IRI).

The relationship between the document containing the hyperlink and the destination resource indicated by the hyperlink is given by the value of the rel attribute. The allowed values and their meanings are defined in a later section. The rel attribute has no default value. If the attribute is omitted or if none of the values in the attribute are recognised by the UA, then the document has no particular relationship with the destination resource other than there being a hyperlink between the two.

Interactive user agents should allow users to follow hyperlinks created using the a element. The rel, media, hreflang, and type attributes may be used to indicate to the user the likely nature of the target resource.

The media attribute describes for which media the target document was designed. It is purely advisory. The value must be a valid media query. [MQ] The default, if the media attribute is omitted or has an invalid value, is all.

The hreflang attribute, if present, gives the language of the linked resource. It is purely advisory. The value must be a valid RFC 3066 language code. RFC3066 User agents must not consider this attribute authoritative — upon fetching the resource, user agents must only use language information associated with the resource to determine its language, not metadata included in the link to the resource.

The type attribute, if present, gives the MIME type of the linked resource. It is purely advisory. The value must be a valid MIME type, optionally with parameters. [RFC2046] User agents must not

About this capture

The `ping` attribute, if present, gives the URIs of the resources that are interested in being notified if the user follows the hyperlink. The value must be a space separated list of one or more URIs.

If the element has an `href` attribute and a `ping` attribute and the user follows the hyperlink, the user agent should take the `ping` attribute's value, strip leading and trailing spaces (U+0020), split the value on sequences of spaces, treat each resulting part as a URI (resolving relative URIs according to element's base URI) and then send a request to each of the resulting URIs. This may be done in parallel with the primary request, and is independent of the result of that request.

User agents should allow the user to adjust this behaviour, for example in conjunction with a setting that disables the sending of HTTP Referrer headers. Based on the user's preferences, UAs may either ignore the `ping` attribute altogether, or selectively ignore URIs in the list (e.g. ignoring any third-party URIs).

For URIs that are HTTP URIs, the requests must be performed using the POST method (with an empty entity body in the request). User agents must ignore any entity bodies returned in the responses, but must honour the HTTP headers — in particular, HTTP cookie headers. [RFC2965]

Note: To save bandwidth, implementors might wish to consider omitting optional headers such as `Accept` from these requests.

When the `ping` attribute is present, user agents should clearly indicate to the user that following the hyperlink will also cause secondary requests to be sent in the background, possibly including listing the actual target URIs.

Note: The `ping` attribute allows Web pages to track which off-site links are most popular, as well as allowing advertisers to track click-through rates without obscuring the final target URI. It is possible to track users without this feature, but authors are encouraged to use the `ping` attribute so that the user agent can improve the user experience.

The `a` element must not be [empty](#).

The DOM attributes `href`, `rel`, `media`, `hreflang`, `type`, and `ping` each [reflect](#) the respective content attributes of the same name.

2.9.2. The `em` element

[Strictly inline-level content](#).

Contexts in which this element may be used:

Where [strictly inline-level content](#) is allowed.

Content model:

When used in an element whose content model is only [strictly inline-level content](#): only [strictly inline-level content](#).

Otherwise: any [inline-level content](#).

Element-specific attributes:

None.

The screenshot shows a web page with a header indicating it's a capture from June 2004 to August 2007. The URL is https://web.archive.org/web/20060102124129/http://www.whatwg.org/s.... The page content discusses the `em` element and its use for emphasis.

The level of emphasis that a particular piece of content has is given by its number of ancestor `em` elements.

The placement of emphasis changes the meaning of the sentence. The element thus forms an integral part of the content. The precise way in which emphasis is used in this way depends on the language.

These examples show how changing the emphasis changes the meaning. First, a general statement of fact, with no emphasis:

```
<p>Cats are cute animals.</p>
```

By emphasising the first word, the statement implies that the kind of animal under discussion is in question (maybe someone is asserting that dogs are cute):

```
<p><em>Cats</em> are cute animals.</p>
```

Moving the emphasis to the verb, one highlights that the truth of the entire sentence is in question (maybe someone is saying cats are not cute):

```
<p>Cats <em>are</em> cute animals.</p>
```

By moving it to the adjective, the exact nature of the the cats is reasserted (maybe someone suggested cats were *mean* animals):

```
<p>Cats are <em>cute</em> animals.</p>
```

Similarly, if someone asserted that cats were vegetables, someone correcting this might emphasise the last word:

```
<p>Cats are cute <em>animals</em>.</p>
```

By emphasising the entire sentence, it becomes clear that the speaker is fighting hard to get the point across. This kind of emphasis also typically affects the punctuation, hence the exclamation mark here.

```
<p><em>Cats are cute animals!</em></p>
```

Anger mixed with emphasising the cuteness could lead to markup such as:

```
<p><em>Cats are <em>cute</em> animals!</em></p>
```

2.9.3. The `strong` element

[Strictly inline-level content](#).

Contexts in which this element may be used:

Where [strictly inline-level content](#) is allowed.

Content model:

When used in an element whose content model is only [strictly inline-level content](#): only [strictly inline-level content](#).

3,445 captures
5 Jun 2004 - 22 Aug 2020

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

DOM interface:

No difference from [HTMLElement](#).

The `strong` element represents strong importance for its contents.

The relative level of importance of a piece of content is given by its number of ancestor `strong` elements; each `strong` element increases the importance of its contents.

Changing the importance of a piece of text with the `strong` element does not change the meaning of the sentence.

Here is an example of a warning notice in a game, with the various parts marked up according to how important they are:

```
<p><strong>Warning.</strong> This dungeon is dangerous.  
<strong>Avoid the ducks.</strong> Take any gold you find.  
<strong><strong>Do not take any of the diamonds</strong>,  
they are explosive and <strong>will destroy anything within  
ten meters.</strong></strong> You have been warned.</p>
```

2.9.4. The `small` element

[Strictly inline-level content](#).

Contexts in which this element may be used:

Where [strictly inline-level content](#) is allowed.

Content model:

When used in an element whose content model is only [strictly inline-level content](#): only [strictly inline-level content](#).

Otherwise: any [inline-level content](#).

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

The `small` element represents small print (part of a document often describing legal restrictions, such as copyrights or other disadvantages), or other side comments.

Note: The `small` element does not "de-emphasise" or lower the importance of text emphasised by the `em` element or marked as important with the `strong` element.

In this example the footer contains contact information and a copyright.

```
<footer>  
<address>  
For more details, contact  
<a href="mailto:js@example.com">John Smith</a>.
```

3,445 captures

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

In this second example, the small element is used for a side comment.

```
<p>Example Corp today announced record profits for the  
second quarter <small>(Full Disclosure: Foo News is a subsidiary of  
Example Corp)</small>, leading to speculation about a third quarter  
merger with Demo Group.</p>
```

In this last example, the small element is marked as being *important* small print.

```
<p><strong><small>Continued use of this service will result in a kiss
```

2.9.5. The m element

[Strictly inline-level content](#).

Contexts in which this element may be used:

Where [strictly inline-level content](#) is allowed.

Content model:

When used in an element whose content model is only [strictly inline-level content](#): only [strictly inline-level content](#).

Otherwise: any [inline-level content](#).

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

The m element represents a run of text marked or highlighted.

Should we just repurpose u or b for this semantic instead? What would they stand for?

In the following snippet, a paragraph of text refers to a specific part of a code fragment.

```
<p>The highlighted part below is where the error lies:</p>  
<pre><code>var i: Integer;  
begin  
    i := <m>1.1</m>;  
end.</code></pre>
```

Another example of the m element is highlighting parts of a document that are matching some search string. If someone looked at a document, and the server knew that the user was searching for the word "kitten", then the server might return the document with one paragraph modified as follows:

```
<p>I also have some <m>kitten</m>s who are visiting me  
these days. They're really cute. I think they like my garden!</p>
```

2.9.6. The abbr element

Go DEC JAN FEB
02
 2004 2006 2007 ▶ About this capture

3,445 captures
 5 Jun 2004 - 22 Aug 2020

Content model:Strictly inline-level content.**Element-specific attributes:**title (optional)**DOM interface:**No difference from HTMLElement.

The abbr element represents an abbreviation or acronym. The title attribute should be used to provide an expansion of the abbreviation. If present, the attribute must only contain an expansion of the abbreviation.

The paragraph below contains an abbreviation marked up with the abbr element.

```
<p>The <abbr title="Web Hypertext Application Technology Working Group">WHATWG</abbr> is a loose unofficial collaboration of Web browser manufacturers and interested parties who wish to develop new technologies designed to allow authors to write and deploy Applications over the World Wide Web.</p>
```

The title attribute may be omitted if there is a dfn element in the document whose defining term is the abbreviation (the textContent of the abbr element).

In the example below, the word "Zat" is used as an abbreviation in the second paragraph. The abbreviation is defined in the first, so the explanatory title attribute has been omitted.

Because of the way dfn elements are defined, the second abbr element in this example would be connected (in some UA-specific way) to the first.

```
<p>The <dfn><abbr>Zat</abbr></dfn>, short for Zat'ni'catel, is a weap
<p>Jack used a <abbr>Zat</abbr> to make the boxes of evidence disappe
```

2.9.7. The dfn elementStrictly inline-level content.**Contexts in which this element may be used:**Where strictly inline-level content is allowed, if there are no ancestor dfn elements.**Content model:**Strictly inline-level content, but there must be no descendant dfn elements.**Element-specific attributes:**title (optional)**DOM interface:**No difference from HTMLElement.

The dfn element represents the defining instance of a term. The paragraph, definition list group, or section that contains the dfn element contains the definition for the term given by the contents of the dfn element.

Go DEC JAN FEB

 2004 2006 2007 ▾ About this capture

3,445 captures
 5 Jun 2004 - 22 Aug 2020

and that child element is an `abbr` element with a `title` attribute, then the exact value of *that* attribute is the term being defined. Otherwise, it is the exact `textContent` of the `dfn` element that gives the term being defined.

If the `title` attribute of the `dfn` element is present, then it must only contain the term being defined.

There must only be one `dfn` element per document for each term defined (i.e. there must not be any duplicate [terms](#)).

Note: The `title` attribute of ancestor elements does not affect `dfn` elements.

The `dfn` element enables automatic cross-references. Specifically, any `span`, `abbr`, `code`, `var`, `samp`, or `i` element that has a non-empty `title` attribute whose value exactly equals the `term` of a `dfn` element in the same document, or which has no `title` attribute but whose `textContent` exactly equals the `term` of a `dfn` element in the document, and that has no `interactive elements` or `dfn` elements either as ancestors or descendants, and has no other elements as ancestors that are themselves matching these conditions, should be presented in such a way that the user can jump from the element to the first `dfn` element giving the defining instance of that term.

In the following fragment, the term "DHD" is first defined in the first paragraph, then used in the second. A compliant UA could provide a link from the `abbr` element in the second paragraph to the `dfn` element in the first.

```
<p>The <dfn><abbr title="Dial Home Device">DHD</abbr></dfn>
is a device that allows off-world teams to open the iris.</p>
<!-- ... later in the document: -->
<p>Teal'c activated his <abbr title="Dial Home Device">DHD</abbr>
and so Hammond ordered the iris to be opened.</p>
```

2.9.8. The `i` element

[Strictly inline-level content](#).

Contexts in which this element may be used:

Where [strictly inline-level content](#) is allowed.

Content model:

[Strictly inline-level content](#).

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

The `i` element represents an instance of the use of a term, such as a taxonomic designation, technical term, an idiomatic phrase from another language, or similar.

Terms in languages different from the main text should be annotated with `lang` attributes

3,445 captures
 5 Jun 2004 - 22 Aug 2020

The `<var>` element represents a variable. This could be an actual variable in a mathematical expression or programming context, or it could just be a term used as a placeholder in prose.

In the paragraph below, the letter "n" is being used as a variable in prose:

```
<p>If there are <var>n</var> pipes leading to the ice cream factory then I expect at least <em>least</em> <var>n</var> flavours of ice cream to be available for purchase!</p>
```

2.9.11. The `samp` element

[Strictly inline-level content.](#)

Contexts in which this element may be used:

Where [strictly inline-level content](#) is allowed.

Content model:

When used in an element whose content model is only [strictly inline-level content](#): only [strictly inline-level content](#).

Otherwise: any [inline-level content](#).

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

The `samp` element represents (sample) output from a program or computing system.

Note: See the `pre` and `kbd` elements for more details.

This example shows the `samp` element being used inline:

```
<p>The computer said <samp>Too much cheese in tray two</samp> but I didn't know what that meant.</p>
```

This second example shows a block of sample output. Nested `samp` and `kbd` elements allow for the styling of specific elements of the sample output using a style sheet.

```
<pre><samp><samp class="prompt">jdoe@mowmow:~$</samp> <kbd>ssh demo.e
Last login: Tue Apr 12 09:10:17 2005 from mowmow.example.com on pts/1
Linux demo 2.6.10-grsec+gg3+e+rhs6b+nfs+gr0501+++p3+c4a+gr2b-reslog-v

<samp class="prompt">jdoe@demo:~$</samp> <samp class="cursor">_</samp>
```

2.9.12. The `kbd` element

[Strictly inline-level content.](#)

Contexts in which this element may be used:

Where [strictly inline-level content](#) is allowed.

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

DOM interface:

No difference from [HTMLElement](#).

The `kbd` element represents user input (typically keyboard input, although it may also be used to represent other input, such as voice commands).

When the `kbd` element is nested inside a `samp` element, it represents the input as it was echoed by the system.

When the `kbd` element contains a `samp` element, it represents input based on system output, for example invoking a menu item.

When the `kbd` element is nested inside another `kbd` element, it represents an actual key or other single unit of input as appropriate for the input mechanism.

Here the `kbd` element is used to indicate keys to press:

```
<p>To make George eat an apple, press <kbd><kbd>Shift</kbd>+<kbd>F3</kbd>
```

In this second example, the user is told to pick a particular menu item. The outer `kbd` element marks up a block of input, with the inner `kbd` elements representing each individual step of the input, and the `samp` elements inside them indicating that the steps are input based on something being displayed by the system, in this case menu labels:

```
<p>To make George eat an apple, select  
    <kbd><kbd><samp>File</samp></kbd> | <kbd><samp>Eat Apple...</samp></kbd></p>
```

2.9.13. The `sup` and `sub` elements

[Strictly inline-level content](#).

Contexts in which these elements may be used:

Where [strictly inline-level content](#) is allowed.

Content model:

[Strictly inline-level content](#).

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

The `sup` element represents a superscript and the `sub` element represents a subscript.

These elements must only be used to mark up typographical conventions with specific meanings, not for typographical presentation for presentation's sake. For example, it would be inappropriate for the `sup` and `sub` elements to be used in the name of the LaTeX document preparation system. In general, authors should not use these elements if the absence of those elements would not change the meaning of the content.

Go DEC JAN FEB

2004 2006 2007

About this capture

No difference from [HTMLElement](#).

The `cite` element represents a citation: the source, or reference, for a quote or statement made in the document.

Note: A citation is not a quote (for which the `q` element is appropriate).

This is incorrect usage:

```
<p><cite>This is wrong!</cite>, said Ian.</p>
```

This is the correct way to do it:

```
<p><q>This is correct!</q>, said <cite>Ian</cite>.</p>
```

This is also wrong, because the title and the name are not references or citations:

```
<p>My favourite book is <cite>The Reality Dysfunction</cite>  
by <cite>Peter F. Hamilton</cite>.</p>
```

2.9.16. The `span` element

[Strictly inline-level content](#).

Contexts in which this element may be used:

Where [strictly inline-level content](#) is allowed.

Content model:

When used in an element whose content model is only [strictly inline-level content](#): only [strictly inline-level content](#).

Otherwise: any [inline-level content](#).

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

The `span` element doesn't mean anything on its own, but can be useful when used together with other attributes, e.g. `lang` or `dir`.

2.9.17. The `bdo` element

[Strictly inline-level content](#).

Contexts in which this element may be used:

Where [strictly inline-level content](#) is allowed.

Content model:

[Strictly inline-level content](#).

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

The `bdo` element allows authors to override the Unicode bidi algorithm by explicitly specifying a direction override. [\[BIDI\]](#)

Authors must specify the `dir` attribute on this element, with the value `ltr` to specify a left-to-right override and with the value `rtl` to specify a right-to-left override.

If the element has the `dir` attribute set to the exact value `ltr`, then for the purposes of the bidi algorithm, the user agent must act as if there was a U+202D LEFT-TO-RIGHT OVERRIDE character at the start of the element, and a U+202C POP DIRECTIONAL FORMATTING at the end of the element.

If the element has the `dir` attribute set to the exact value `rtl`, then for the purposes of the bidi algorithm, the user agent must act as if there was a U+202E RIGHT-TO-LEFT OVERRIDE character at the start of the element, and a U+202C POP DIRECTIONAL FORMATTING at the end of the element.

The requirements on handling the `bdo` element for the bidi algorithm may be implemented indirectly through the style layer. For example, an HTML+CSS user agent should implement these requirements by implementing the CSS `unicode-bidi` property. [\[CSS21\]](#)

2.9.18. The `br` element

[Strictly inline-level content](#).

Contexts in which this element may be used:

Where [strictly inline-level content](#) is allowed.

Content model:

Empty.

Element-specific attributes:

None.

DOM interface:

No difference from [HTMLElement](#).

The `br` element represents a line break.

`br` elements must be empty. Any content inside `br` elements must not be considered part of the surrounding text.

`br` elements must only be used for line breaks that are actually part of the content, as in poems or addresses.

The following example is correct usage of the `br` element:

```
<p>P. Sherman<br>
42 Wallaby Way<br>
Sydney</p>
```

`br` elements must not be used for separating thematic groups in a paragraph.

```

2.10. Edits

The ins and del elements represent edits to the document.

2.10.1. The ins element

Block-level element, and strictly inline-level content.

Contexts in which this element may be used:

Where block-level elements is expected.

Where strictly inline-level content is allowed.

Content model:

When the element is a child of an element with only one content model (i.e. an element that only allows strictly inline-level content, or only allows inline-level content, or only allows block-level elements): same content model as the parent element.

Otherwise, when the element is a child of an element that only contains inter-element whitespace, ins elements, and del elements: same content model as the parent element, with the additional restriction that if the parent element allows a choice in content models (e.g. block or inline) then if all the children of all the sibling ins elements were placed directly in the parent element, the document would still be conforming.

Otherwise, when the element is a child of an element that is being used as an inline-level content container: inline-level content.

Otherwise, when the element is a child of an element that is being used as a block-level element container: block-level elements.

Otherwise: zero or more block-level elements, or inline-level content (but not both).

Element-specific attributes:

cite (optional)

datetime (optional)

DOM interface:

Uses the HTMLModElement interface.

The ins element represents an addition to the document.

The ins element must be used only where block-level elements or strictly inline-level content can be used.

About this capture

```
<aside>
<ins>
<p>...</p>
</ins>
</aside>
```

As would this:

```
<aside>
<ins>
<em>...</em>
</ins>
</aside>
```

However, this last example would be illegal, as em and p cannot both be used inside an aside element at the same time:

```
<aside>
<ins>
<p>...</p>
</ins>
<ins>
<em>...</em>
</ins>
</aside>
```

2.10.2. The `del` element

Block-level element, and strictly inline-level content.

Contexts in which this element may be used:

Where block-level elements is expected.

Where strictly inline-level content is allowed.

Content model:

When the element has a parent: same content model as the parent element.

Otherwise: zero or more block-level elements, or inline-level content (but not both).

Element-specific attributes:

cite (optional)

datetime (optional)

DOM interface:

Uses the HTMLModElement interface.

The del element represents a removal from the document.

The del element must only contain content that would be allowed inside the parent element (regardless of what the parent element actually contains).

|| The following would be syntactically legal:

About this capture

```
<ins>
<em>...</em>
</ins>
</aside>
```

...even though the `p` and `em` elements would never be allowed side by side in the `aside` element. This is allowed because the `del` element represents content that was removed, and it is quite possible that an edit could cause an element to go from being an inline-level container to a block-level container, or vice-versa.

2.10.3. Attributes common to `ins` and `del` elements

The `cite` attribute may be used to specify a URI that explains the change. When that document is long, for instance the minutes of a meeting, authors are encouraged to include a fragment identifier pointing to the specific part of that document that discusses the change.

If the `cite` attribute is present, it must be a URI (or IRI) that explains the change. User agents should allow users to follow such citation links.

The `datetime` attribute may be used to specify the time and date of the change.

If the `datetime` attribute is present, it must have a value consisting of four digits representing the year, a literal hyphen, two digits representing the month, a literal hyphen, two digits representing the day, a literal T, two digits for the hour, a colon, two digits for the minutes, another colon, two digits for the seconds, optionally a decimal point followed by one or more digits for the fraction of a second, and finally either a literal Z, or, a plus sign or a minus sign followed by two digits for the hour offset, a colon, and two digits for the minute offset.

In other words: `YYYY-MM-DDThh:mm:ss.sTZ`

Digits must be in the range 0-9 (U+0030 to U+0039), interpreted in base ten. The hyphen must be U+002D, the T must be U+0054, the colon must be U+003A, the Z must be U+005A, the plus must be U+002B, and the minus U+002D (same as the hyphen).

To interpret this value, user agents must first check to see if the value matches the pattern described here. If it does, then the values must be extracted and interpreted as a date and time with a timezone offset, as per ISO 8601. [\[ISO8601\]](#)

If the attribute value does not match the format, or, if the date or time given is not a valid date and time (e.g. because the month is out of range) then the user agent must ignore the attribute (the modification has no associated timestamp).

The `ins` and `del` elements must implement the `HTMLModElement` interface:

```
interface HTMLModElement : HTMLElement {
    attribute DOMString cite;
    attribute DOMString datetime;
};
```

The `cite` and `datetime` DOM attributes should reflect the elements' content attributes of the same name.

About this capture

[Strictly inline-level content.](#)

Contexts in which this element may be used:

Where [strictly inline-level content](#) is allowed.

Content model:

Empty.

Element-specific attributes:

- src (required)
- alt (required)
- height (optional)
- width (optional)
- usemap (optional)
- ismap (optional)

DOM interface:

```
interface HTMLImageElement : HTMLElement {  
    attribute DOMString src;  
    attribute DOMString alt;  
    attribute long height;  
    attribute long width;  
    attribute boolean isMap;  
    attribute DOMString useMap;  
};
```

The `img` element represents a piece of text with an alternate graphical representation. The text is given by the `alt` attribute, and the URI to the graphical representation of that text is given by the `src` attribute.

This section is (obviously) incomplete.

2.12. Tabular data [\[TBW\]](#)

This section will contain definitions of the `table` element and so forth.

2.13. Forms [\[TBW\]](#)

This section will contain definitions of the `form` element and so forth.

2.14. Scripting

About this capture

CONTEXTS in which this element may be used.

- In a `head` element.
- Where [block-level elements](#) are expected.
- Where [inline-level content](#) is expected.

Content model:

- If there is no `src` attribute, depends on the value of the `type` attribute.
- If there *is* a `src` attribute, the element must be empty.

Element-specific attributes:

- `src` (optional)
- `type` (optional)

DOM interface:

```
interface HTMLScriptElement : HTMLElement {  
    attribute DOMString text;  
    attribute DOMString src;  
    attribute DOMString type;  
};
```

The `script` element allows authors to include dynamic script in their documents.

When the `src` attribute is set, the `script` element refers to an external file, which must (if it uses a supported scripting language) be downloaded and executed. The user agent must delay the execution of other scripts associated with the page that are invoked during the download (e.g. event handlers) until after the external script has been downloaded and executed.

The language of the script is given by the `type` attribute. The value must be a valid MIME type, optionally with parameters. [\[RFC2046\]](#)

For `script` elements that have the `src` attribute set, user agents may use the type given in this attribute to decide whether or not to consider using the resource at all. If the UA does not support the given MIME type as a scripting language, then the UA may opt not to download the script.

User agents must not consider the `type` attribute authoritative, however — upon fetching the script, user agents must only use the Content-Type information associated with it to determine whether or not to execute it; user agents must not use the `type` attribute in the document to determine the actual type of the script.

If the `type` attribute is omitted but the `src` attribute is set, then the UA must fetch the resource to determine its type and thus determine if it supports (and can execute) that external script.

If the `src` attribute is not set, then the script is given by the contents of the element. The language is given by the `type` attribute. If it is omitted, then the default is the ECMAScript MIME type.

When examining types to determine if they support the language, user agents must not ignore unknown MIME parameters — types with unknown parameters must be assumed to be unsupported.

DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

the new element must not have the flag set.

For scripting languages that consist of pure text, user agents must use the value of the DOM `text` attribute (defined below) as the script to execute. For XML-based scripting languages, user agents must use all the children nodes of the `script` element as the script.

The DOM attributes `src` and `type` each [reflect](#) the respective content attributes of the same name.

The DOM attribute `text` must return a concatenation of the contents of all the text nodes and CDATA nodes that are direct children of the `script` element (ignoring any other nodes such as comments or elements), in tree order. On setting, it must act the same way as the `textContent` DOM attribute.

2.14.1.1. Script languages

The following lists some MIME types and the languages to which they refer:

`text/javascript`

ECMAScript. [\[ECMA262\]](#)

`text/javascript;e4x=1`

ECMAScript with ECMAScript for XML. [\[ECMA357\]](#)

2.14.2. The `noscript` element [\[TBW\]](#)

The `noscript` element needs to be defined too.

2.15. Other new elements [\[TBW\]](#)

all the new things in WA1: menu, calendar, card, canvas, switch, gauge, progress,datagrid, datatree, switch, etc

2.16. Notes (draft sections to be moved elsewhere) [\[TBW\]](#)

2.16.1. Classes

This section may somehow introduce some predefined classes with actual semantic meanings; possibly by defining a `profile`.

2.16.2. Link types

This section might at some future point list a small set of link relationship types and more exactly define their semantics than HTML4. This section (or indeed this specification in general) is unlikely to specify anything related to the `profile` attribute and how to extend the link types in HTML. Work in this area is currently being done by [GMPG](#) and [others](#).

The screenshot shows a navigation bar with a search input field, a 'Go' button, and month abbreviations (DEC, JAN, FEB) with arrows for navigation. Below the search is a link to '3,445 captures' and a date range from '5 Jun 2004 - 22 Aug 2020'. In the center is a large date '02' with '2004' to its left and '2006 2007' to its right. To the right are icons for user profile, help, and sharing (Facebook, Twitter). A 'About this capture' link is at the bottom right.

In CSS-aware user agents, the default presentation of this element should be achieved by including the following rules, or their equivalent, in the UA's user agent style sheet:

```
@namespace xh url(http://www.w3.org/1999/xhtml);  
xh|section { display: block; margin: 1em 0; }
```

2.16.4. Section headers

For h1 elements, CSS-aware visual user agents should derive the size of the header from the level of section nesting. This effect should be achieved by including the following rules, or their equivalent, in the UA's user agent style sheet:

```
@namespace xh url(http://www.w3.org/1999/xhtml);  
xh|section xh|h1 { /* same styles as h2 */ }  
xh|section xh|section xh|h1 { /* same styles as h4 */ }  
xh|section xh|section xh|section xh|h1 { /* same styles as h4 */ }  
xh|section xh|section xh|section xh|section xh|h1 { /* same styles as h5 */ }  
xh|section xh|section xh|section xh|section xh|h1 { /* same styles as h5 */ }
```

Authors should use h1 elements to denote headers in sections. Authors may instead use h2 ... h6 elements, for backwards compatibility with user agents that do not support section elements.

2.16.5. Section groups (tabs)

A group of related, order-neutral sections may be denoted using the tabbox element. The default presentation in a visual media (as described below) is to render each section as a separate tab in a tab box, allowing the user to switch between them. Sections can also be represented by links to other documents, instead of them being included literally in the markup.

The tabbox element is a block-level element that should only contain section, fieldset, and a elements.

Authors should only use a elements that cause the user agent to change the active page to a page with a similar structure. Other behaviours are likely to be highly confusing to users.

Each section, fieldset, and a child can have a title. If the element is a section element, then the title is taken from the title attribute of the element, if specified, or, if absent, from the textContent DOM attribute of the first element child of the section element, if that is an h1 ... h6 element. (If it is taken from a header child, then that child is hidden from the rendering.) If the element is a fieldset element, then the title is taken from the the textContent DOM attribute of the first element child of the fieldset element, if that is an legend element. If the element is an a element, then the title is taken from the textContent DOM attribute of the element. (Titles may be the empty string.)

The titles obtained in this way, and the section, fieldset, and a elements from which they were derived, represent the list of sections in the tabbox. This list is *live*, in that dynamic changes to the DOM immediately affect the representation of the tabbox element.

All the other child nodes of the tabbox shall be ignored for the purposes of rendering the tabbox. Authors may use this in order to obtain acceptable renderings even in UAs that do not support

Go DEC JAN FEB
 02 2004 2006 2007

[About this capture](#)

[3,445 captures](#)

5 Jun 2004 - 22 Aug 2020

```
@namespace xh url(http://www.w3.org/1999/xhtml);
xh|tabbox { display: block; }
xh|tabbox > xh|section:not([title]) > xh|h1:first-child,
xh|tabbox > xh|section:not([title]) > xh|h2:first-child,
xh|tabbox > xh|section:not([title]) > xh|h3:first-child,
xh|tabbox > xh|section:not([title]) > xh|h4:first-child,
xh|tabbox > xh|section:not([title]) > xh|h5:first-child,
xh|tabbox > xh|section:not([title]) > xh|h6:first-child,
xh|tabbox > xh|fieldset > xh|legend:first-child { display: none; }
```

These rules do not come even close to fully describing the full behaviour of a tabbox element, however.

The behaviour of the tabbox should be to provide quick access to any of the children of the tabbox that have a title (as described above). UAs may keep track of which section is the selected section, and report this information to the user.

When the user specifies a section to access, the relevant element must have [a click event dispatched to it](#), whose default action is to further dispatch a DOMActivate event to the element.

For section and fieldset elements, the default action of DOMActivate events is to display, or jump to, the relevant section. For a elements, the default action is the normal default action for a elements (activating the link, command, or whatever). In addition to these default actions, when a child of a tabbox is accessed, it becomes the selected section.

If the DOMActivate event is canceled (or if the click event is canceled, causing the DOMActivate event to never be fired in the first place), then the selected section does not change.

If an a element has a command attribute, it can be disabled. In such cases, the UA should not allow the user to select that section.

The initially selected section shall be the first element from the tabbox element's child list that is:

1. an a element whose href attribute matches the URI of the current document, if there is one,
2. otherwise, the first a element whose href attribute matches the URI given by the href attribute of the first link element in the document that has a rel attribute whose value contains the keyword up (treating that attribute as a space-separated list), if there is one,
3. otherwise, the first section or fieldset element that has a title, if there is one.

If no elements match, then initially no section shall be selected.

In the above algorithm, URI comparisons should be done after canonicalisation, and should ignore fragment identifiers unless the a element in question has one.

In non-interactive or non-spatial media (such as in print, on braille systems, or with speech synthesis) the UA may automatically switch the selected section to the next section once the selected section has been rendered.

Which section is selected if the element representing the currently selected section is dynamically

Go DEC JAN FEB

in the tab panel area. When the selected section is an a element, the tab panel area should be empty.

This specification does not describe how CSS properties apply to tabbox elements when the UA uses this rendering, but the children rendered in the tab panel area must be styled using CSS, as if the tab panel area defined a new containing block and new block formatting context.

User agents must support all of the common attributes and event handlers on the tabbox element.

Here is an example of a tabbox used to allow the user to read three different parts of the document:

```
<tabbox>
  <section>
    <h2>About</h2>
    <p></p>
    <p>The Application.</p>
    <p>© copyright 2004 by The First Team.</p>
  </section>
  <section>
    <h2>Credits</h2>
    <ul>
      <li>Jack O'Neill</li>
      <li>Samantha Carter</li>
      <li>Daniel Jackson</li>
      <li>Teal 'c</li>
      <li>Jonas Quinn</li>
    </ul>
  </section>
</tabbox>
```

Next, an example of a form that has been split into little groups of controls:

```
<tabbox>
  <fieldset>
    <legend>Identity</legend>
    <p><label>First name: <input name="fn"></label></p>
    <p><label>Last name: <input name="ln"></label></p>
    <p><label>Date of Birth: <input name="dob" type="date"></label></p>
  </fieldset>
  <fieldset>
    <legend>Food</legend>
    <p><label>Favourite appetizer: <input name="fa"></label></p>
    <p><label>Favourite meal: <input name="fm"></label></p>
    <p><label>Favourite desert: <input name="fd"></label></p>
  </fieldset>
</tabbox>
```

Finally, an example of a page using a tabbox to point to sections outside the document. Note the use of fallback content (elements and text in the tabbox element that are not fieldset,

Go DEC JAN FEB

```
<strong>Navigation:</strong>
<a href="/"><span>Home</span></a>,
<a href="/news/"><span>News</span></a>,
<a href="/games/"><span>Games</span></a>,
<a href="/help/"><span>Help</span></a>,
<a href="/contact/"><span>Contact</span></a>.
</tabbox>
</div>
```

This would be semantically equivalent to the following:

```
<tabbox>
<section><h2>Home</h2> ...content... </section>
<section><h2>News</h2> ...content... </section>
<section><h2>Games</h2> ...content... </section>
<section><h2>Help</h2> ...content... </section>
<section><h2>Contact</h2> ...content... </section>
</tabbox>
```

2.16.6. Mutually exclusive sections

The `switch` element represents a block of mutually exclusive sections.

For example, in an application for an online multiplayer game, there could be four mutually exclusive sections: one for the login page, one for the network status page displayed while the user is logging in, one for a "lobby" where players get together to organise a game, and one for the actual game. The different sections are the various states that the application can reach.

The `switch` element must contain only [block-level elements](#). User agents must support all of the common attributes and event handlers on the `switch` element.

All child elements of a `switch` element shall be hidden except those that have `active` attributes (or, for non-XHTML elements, `active` attributes in the XHTML namespace).

In CSS-aware user agents, the default presentation of this element should be achieved by including the following rules, or their equivalent, in the UA's user agent style sheet:

```
@namespace xh url(http://www.w3.org/1999/xhtml);
xh|switch { display: block; }
xh|switch xh|*:not([active]) { display: none; }
xh|switch *:not([xh|active]) { display: none; }
```

2.16.7. Using `switch` and `section`

```
interface HTMLSwitchElement : HTMLElement {
  readonly attribute Element activeElement;
  void setActive(in Element element);
};

interface HTMLSectionElement : HTMLElement {
```

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

When an element is added to a `switch` element as a child (whether during parsing, or later), the element is examined. If the element has an `active` attribute (or, if it is a non-XHTML element, if it has an `active` attribute in the XHTML namespace), or, if the `switch` element's `activeElement` DOM attribute is null, then the `switch` element's `setActive` method is called with that element as the argument. This causes the element to be made the active element for the switch, and causes any other elements to be deactivated if needed.

A side-effect of this definition is that the first element in a `switch` element is the default element if none have been explicitly marked as active.

2.17. [SCS] Calendars: event data [TBW]

The `calendar` element may be used for indicating hCalendar fragments that should be processed and rendered, e.g. as inline calendars.

The `calendar` element is a block-level element whose content model is any [block-level elements](#). User agents must support all the common attributes and event handlers on `calendar` elements.

Web browsers should render the `calendar` element by replacing the element by a representation of the calendar data contained within it.

2.17.1. Interpreting calendar data

UAs must process the contents of `calendar` data as described in the hCalendar specification.
[\[HCALENDAR\]](#)

2.17.2. Rendering examples

The following fragment:

```
<calendar>
  <div class="vcalendar">
    <span class="prodid">-//hCalendar//EN</span>
    <span class="version">2.0</span>
    <p class="vevent">
      <a href="http://www.web2con.com/">
        <span class="dtstart">20041005</span>-
        <span class="dtend">20041007</span>
        <span class="summary">Web 2.0 Conference</span>
      </a>
    </p>
  </div>
</calendar>
```

...might render as the following:

3,445 captures
5 Jun 2004 - 22 Aug 2020

10	11	12	13	14 Web 2.0 Conference	15	16
17	18	19	20	21	22	23
24	25	26	27	28	29	30
31						

2.18. [SCS] Business cards: personal data [TBW]

The `card` element may be used for indicating hCard fragments that should be processed and rendered, e.g. as inline business cards.

The `card` element is a block-level element whose content model is any [block-level elements](#). User agents must support all the common attributes and event handlers on `card` elements.

Web browsers should render the `card` element by replacing the element by a representation of the personal data contained within it.

2.18.1. Interpreting card data

UAs must process the contents of `card` data as described in the hCard specification. [\[HCARD\]](#)

2.18.2. Rendering examples

The following fragment:

```
<card>
  <p class="vcard">
    <a class="fn n" href="http://tantek.com/">
      <span class="Given-Name">Tantek</span>
      <span class="Family-Name">Çelik</span>
    </a>
  </p>
</card>
```

...might render as the following:

2.19. Inline data [TBW]

This section is a place-holder for where elements such as `<date>` or `<time>` might be defined. But it will probably be moved up to the earlier section. This might also just be merged with the "Semantics and structure of HTML elements" section above, or dropped, based on demand.

About this capture

2.21. Gauges [TBW]

The gauge element is an inline element that represents a fractional value, such as the relative relevance of a search result, the fraction of a user's quota that is used, or the fraction of a voting population to have selected a particular candidate.

User agents must support all of the common attributes and event handlers on the gauge element, plus the following attributes:

...

The value should come from parsing the .textContent attribute and taking the first string of digits (possibly with a single dot) as the numerator and the second string of digits (possibly with another single dot) as the denominator, defaulting the denominator to 100 if it is absent, treating zero denominators as 100, and using the resulting fraction as the value, in the range 0 to 1, for the gauge. If the numerator is absent, default to 0.

Do we want something to say that "above 0.75 is bad"? "below 0.2 is bad"?

2.22. Progress meters [TBW]

Similar to gauge, but renders as a progress bar. If the numerator is absent, default to an indeterminate progress bar (barber pole, bouncing blue box, etc).

2.23. Interactive elements

2.23.1. [SCS] The datagrid element

It has been suggested that instead of this flattened-row API, we should have all the "row" arguments in the API below be arrays of integers, and instead of getParentRow(), we would have getCount() get the number of children that a row had. A future version of this specification will make this change, along with adding a way to detect when a row/selection has been deleted, activated, etc.

This element is defined as interactive, which means it can't contain other interactive elements, despite the fact that we expect it to work with other interactive elements e.g. checkboxes and input fields. It should be called something like a Leaf Interactive Element or something, which counts for ancestors looking in and not descendants looking out.

[Interactive, block-level element.](#)

Contexts in which this element may be used:

The screenshot shows a search bar at the top left, followed by a 'Go' button and navigation links for 'DEC', 'JAN', and 'FEB'. Below these are date markers for '2004', '2006', and '2007'. To the right are icons for user profile, help, and sharing (Facebook, Twitter). At the bottom right is a link 'About this capture'.

5 Jun 2004 - 22 Aug 2020

DEC JAN FEB
2004 2006 2007

About this capture

Element-specific attributes:

multiple (optional)
disabled (optional)

DOM interface:

```
interface HTMLDataGridElement : HTMLElement {  
    attribute DataGridDataProvider data;  
    attribute SelectedRowRanges selection;  
    attribute boolean multiple;  
    attribute boolean disabled;  
    void updateEverything();  
    void updateRowsChanged(in long row, in long count);  
    void updateRowsInserted(in long row, in long count);  
    void updateRowsRemoved(in long row, in long count);  
    void updateRowChanged(in long row);  
    void updateColumnChanged(in long column);  
    void updateCellChanged(in long row, in long column);  
};
```

The datagrid element represents an interactive representation of tree, list, or tabular data.

The data being presented can come either from the content, as elements given as children of the datagrid element, or from a scripted data provider given by the data DOM attribute.

The multiple attribute, if present, must be either empty or have the literal value `multiple`. Similarly, the disabled attribute, if present, must be either empty or have the literal value `disabled`. (The actual values do not have any effect on how these attributes are processed, only the presence or absence of the attributes is important.)

The multiple and disabled DOM attributes reflect the multiple and disabled content attributes respectively.

2.23.1.1. The datagrid data model

This section is non-normative.

In the datagrid data model, data is structured as a set of rows representing a tree, each row being split into a number of columns. The columns are always present in the data model, although individual columns may be hidden in the presentation.

Each row can have a parent row. If a row r has a parent row p , then all the rows between it and its parent will also have a parent row, and for each row i between p and r the parent row of i will be either p or another row between p and i .

Rows that have other rows claiming them as their parent row are open. Rows can be closed, hiding all the data that would form child rows, but when a row is closed its child data does not appear in the data model.

Go DEC JAN FEB

[About this capture](#)

[3,445 captures](#)

5 Jun 2004 - 22 Aug 2020

multiple rows can be selected at once, otherwise the user can only select one row at a time.

The `datagrid` element can be disabled entirely by setting the `disabled` attribute.

Columns, rows, and cells can each have specific flags, known as classes, applied to them by the data provider. These classes [affect the functionality](#) of the `datagrid` element, and are also [passed to the style system](#). They are similar in concept to the `class` attribute, except that they are not specified on elements but are given by scripted data providers.

2.23.1.2. The data provider interface

The conformance criteria in this section apply to any implementation of the `DataGridDataProvider`, including (and most commonly) the content author's implementation(s).

```
// To be implemented by Web authors as a JS object
interface DataGridDataProvider {
    void initialize(in HTMLDataGridElement datagrid);
    long getRowCount();
    long getColumnCount();
    DOMString getCaptionText(in long column);
    void getCaptionClasses(in long column, in DOMTokenString classes);
    long getRowParent(in long row);
    DOMString getRowImage(in long row);
    HTMLMenuElement getRowMenu(in long row);
    void getRowClasses(in long row, in DOMTokenString classes);
    DOMString getCellData(in long row, in long column);
    void getCellClasses(in long row, in long column, in DOMTokenString classes);
    void toggleRowOpenState(in long row);
    void toggleColumnSortState(in long column);
    void setCellCheckedState(in long row, in long column, in int state);
    void cycleCell(in long row, in long column);
    void editCell(in long row, in long column, in DOMString data);
};
```

The `DataGridDataProvider` interface represents the interface that objects must implement to be used as custom data views for `datagrid` elements.

Not all the methods are required. The minimum number of methods that must be implemented in a useful view is two: the `getRowCount()` and `getCellData()` methods.

Once the object is written, it must be hooked up to the `datagrid` using the `data` DOM attribute.

The following methods may be usefully implemented:

`initialize(datagrid)`

Called by the `datagrid` element (the one given by the `datagrid` argument) after it has first populated itself. This would typically be used to set the initial selection of the `datagrid` element when it is first loaded. The data provider could also use this method call to register a `select` event handler on the `datagrid` in order to monitor selection changes.

3,445 captures
5 Jun 2004 - 22 Aug 2020

datagrid must be called first. Otherwise, this method must always return the same number.

DEC JAN FEB
2004 2006 2007

About this capture

getRowCount()

Must return the number of rows currently in the data model (including rows that might be hidden). May be omitted if there is only one row. If the value that this method would return changes, the [datagrid's updateEverything\(\)](#) method must be called.

getCaptionText(column)

Must return the caption, or label, for column *column*. May be omitted if the columns have no captions. If the value that this method would return changes, the [datagrid's updateColumnChanged\(\)](#) method must be called with the appropriate column index.

getCaptionClasses(column, classes)

Must add the classes that apply to column *column* to the *classes* object. May be omitted if the columns have no special classes. If the classes that this method would add changes, the [datagrid's updateColumnChanged\(\)](#) method must be called with the appropriate column index. Some classes have [predefined meanings](#).

getRowParent(row)

Must return the index to the row that is the parent of row *row*, or a negative number if this is a top-level row. If, for a row *r*, this method returns the index of parent row *p*, then for each row *i* between *p* and *r* the method must return either *p* or another row between *p* and *i*. May be omitted if the [datagrid](#) is a list and not a tree. If the value that this method would return changes, the [datagrid](#)'s update methods must be called to update all the rows in the range that covers the old parent, the new parent, and the row in question.

getRowImage(row)

Must return a URI to an image that represents row *row*, or the empty string if there is no applicable image. May be omitted if no rows have associated images. If the value that this method would return changes, the [datagrid](#)'s update methods must be called to update the row in question.

getRowMenu(row)

Must return an `HTMLMenuElement` object that is to be used as a context menu for row *row*, or null if there is no particular context menu. May be omitted if none of the rows have a special context menu. As this method is called immediately before showing the menu in question, no precautions need to be taken if the return value of this method changes.

getRowClasses(row, classes)

Must add the classes that apply to row *row* to the *classes* object. May be omitted if the rows have no special classes. If the classes that this method would add changes, the [datagrid](#)'s update methods must be called to update the row in question. Some classes have [predefined meanings](#).

getCellData(row, column)

Must return the value of the cell on row *row* in column *column*. For text cells, this must be the text to show for that cell. For [progress bar cells](#), this must be either a floating point number in the range 0.0 to 1.0 (converted to a string representation), indicating the fraction of the progress bar to show as full (1.0 meaning complete), or the empty string, indicating an indeterminate progress bar. If the value that this method would return changes, the [datagrid](#)'s update methods must be called to update the rows that changed. If only one cell

3,445 captures
5 Jun 2004 - 22 Aug 2020

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

May be omitted if the cells have no special classes. If the classes that this method would add changes, the `datagrid`'s update methods must be called to update the rows or cells in question. Some classes have [predefined meanings](#).

`toggleRowOpenState (row)`

Called by the `datagrid` when the user tries to open or close a row. When it is called on a closed row, the data provider must update its state so that the rows now include the child rows, and must call the `updateRowsInserted()` method appropriately. Similarly, when it is called on an open row, the data provider must update its state so that the rows that were shown under the row in question are now removed from the data model, and must then call the `updateRowsRemoved()` method appropriately. There is no need to tell the `datagrid` that the row itself has changed (as it should; in particular its classes should change to reflect the new open/closed state), as the `datagrid` automatically assumes that the row will need updating.

`toggleColumnSortState (column)`

Called by the `datagrid` when the user tries to sort the data using a particular column `column`. The data provider must update its state so that the rows are in the new order, and update the classes of the columns to represent the new sort status. There is no need to tell the `datagrid` that it the data has changed, as the `datagrid` automatically assumes that the entire data model will need updating.

It is the data provider's responsibility to ensure that the user's selection persists through a sort. Typically this will involve taking a note of which rows were selected before the sort (using the `getRangeStart()` and `getRangeLength()` methods of the `selection` DOM attribute, for instance), and then [clearing](#) the selection and reselecting all the rows in their new positions (e.g. using the `addRange()` method).

`setCellCheckedState (row, column, state)`

Called by the `datagrid` when the user changes the state of a checkbox cell on row `row`, column `column`. The checkbox should be toggled to the state given by `state`, which is a positive integer (1) if the checkbox is to be checked, zero (0) if it is to be unchecked, and a negative number (-1) if it is to be set to the indeterminate state. There is no need to tell the `datagrid` that the cell has changed, as the `datagrid` automatically assumes that the given cell will need updating.

`cycleCell (row, column)`

Called by the `datagrid` when the user changes the state of a cyclable cell on row `row`, column `column`. The data provider should change the state of the cell to the new state, as appropriate. There is no need to tell the `datagrid` that the cell has changed, as the `datagrid` automatically assumes that the given cell will need updating.

`editCell (row, column, data)`

Called by the `datagrid` when the user edits the cell on row `row`, column `column`. The new value of the cell is given by `data`. The data provider should update the cell accordingly. There is no need to tell the `datagrid` that the cell has changed, as the `datagrid` automatically assumes that the given cell will need updating.

The following classes (for rows, columns, and cells) may be usefully used in conjunction with this

>About this capture

3,445 captures	5 Jun 2004 - 22 Aug 2020	
checked	Cells	The cell has a checkbox and it is checked. (The <u>cyclable</u> and <u>progress</u> classes override this, though.)
closed	Rows	The row can be opened and closed, and, unless the <u>open</u> class is also present, the row is currently closed.
cyclable	Cells	The cell can be cycled through multiple values. (The <u>progress</u> class overrides this, though.)
editable	Cells	The cell can be edited. (The <u>cyclable</u> , <u>progress</u> , <u>checked</u> , <u>unchecked</u> and <u>indeterminate</u> classes override this, though.)
header	Rows	The row is a heading, not a data row.
indeterminate	Cells	The cell has a checkbox, and it can be set to an indeterminate state. If neither the <u>checked</u> nor <u>unchecked</u> classes are present, then the checkbox is in that state, too. (The <u>cyclable</u> and <u>progress</u> classes override this, though.)
initially-hidden	Columns	The column will not be shown when the <u>datagrid</u> is initially rendered.
open	Rows	The row can be opened and closed, and is currently open.
progress	Cells	The cell is a progress bar.
reversed	Columns	If the cell is sorted, the sort direction is descending, instead of ascending.
selectable-separator	Rows	The row is a normal, selectable, data row, except that instead of having data, it only has a separator. (The <u>header</u> and <u>separator</u> classes override this, though.)
separator	Rows	The row is a separator row, not a data row. (The <u>header</u> class overrides this, though.)
sortable	Columns	The data can be sorted by this column.
sorted	Columns	The data is sorted by this column. Unless the <u>reversed</u> class is also present, the sort direction is ascending.
unchecked	Cells	The cell has a checkbox and, unless the <u>checked</u> class is present as well, it is unchecked. (The <u>cyclable</u> and <u>progress</u> classes override this, though.)

2.23.1.3. The default data provider

The user agent must supply a default data provider for the case where the datagrid's data attribute is null. It must act as described in this section.

The behaviour of the default data provider depends on the nature of the first element child of the datagrid.

↳ While the first element child is a table

getRowCount(): The number of rows returned by the default data provider must be the number of tr elements that are children of tbody elements that are children of the table, if there are any such child tbody elements. If there are no such tbody elements

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

Note: Rows in `thead` elements do not contribute to the number of rows returned, although they do affect the columns and column captions. Rows in `tfoot` elements are ignored completely by this algorithm.

getColumnCount(): The number of columns returned must be the number of `td` element children in the first `tr` element child of the first `tbody` element child of the table, if there are any such `tbody` elements. If there are no such `tbody` elements, then it must be the number of `td` element children in the first `tr` element child of the table, if any, or otherwise 1. If the number that would be returned by these rules is 0, then 1 must be returned instead.

getCaptionText(i): If the table has no `thead` element child, or if its first `thead` element child has no `tr` element child, the default data provider must return the empty string for all captions. Otherwise, the value of the `textContent` attribute of the *i*th `th` element child of the first `tr` element child of the first `thead` element child of the table element must be returned. If there is no such `th` element, the empty string must be returned.

getCaptionClasses(i, classes): If the table has no `thead` element child, or if its first `thead` element child has no `tr` element child, the default data provider must not add any classes for any of the captions. Otherwise, each class in the `class` attribute of the *i*th `th` element child of the first `tr` element child of the first `thead` element child of the table element must be added to the `classes`. If there is no such `th` element, no classes must be added. The user agent must then:

1. Remove the `sorted` and `reversed` classes.
2. If the table element has a `class` attribute that includes the `sortable` class, add the `sortable` class.
3. If the column is the one currently being used to sort the data, add the `sorted` class.
4. If the column is the one currently being used to sort the data, and it is sorted in descending order, add the `reversed` class as well.

The various row- and cell- related methods operate relative to a particular element, the element of the row or cell specified by their arguments.

For rows: Since the view of the data can be sorted, the positions of the rows in the data model might not be the same as the positions of the real rows in the DOM. When the data is sorted, the row given by the method's argument has to be mapped to the real row. Initially, the mapping is the identity transform, but [the mapping can be changed](#) if the user sorts the rows.

Once the method's argument has been translated into an index for the real row, the row's element is found as follows. If the table has `tbody` element children, the element for the *i*th real row is the *i*th `tr` element that is a child of a `tbody` element that is a child of the table element. If the table does not have `tbody` element children, then the element for the *i*th real row is the *i*th `tr` element that is a child of the table element.

The screenshot shows a navigation interface for a web application. At the top, there is a search bar with a 'Go' button. To the right of the search bar are buttons for 'DEC', 'JAN', and 'FEB'. Below these are icons for user profile, help, and close. A date range is displayed as '2004 02 2006 2007'. A note at the bottom states: 'Note: The colspan and rowspan attributes are ignored by this algorithm.'

getRowParent (i): The default data provider must always return -1 as the parent row of any row.

Note: The table-based default data provider cannot represent a tree.

getRowImage (i): If the row's first cell's element has an img element child, then the URI of the row's image is the URI of the first img element child of the row's first cell's element. Otherwise, the URI of the row's image is the empty string.

getRowMenu (i): If the row's first cell's element has a menu element child, then the row's menu is the first menu element child of the row's first cell's element. Otherwise, the row has no menu.

getRowClasses (i, classes): The default data provider must never add a class to the row's classes.

toggleColumnSortState (i): If the data is already being sorted on the given column, then the user agent must change the current sort mapping to be the inverse of the current sort mapping; if the sort order was ascending before, it is now descending, otherwise it is now ascending. Otherwise, if the current sort column is another column, or the data model is currently not sorted, the user agent must create a new mapping, which maps rows in the data model to rows in the DOM so that the rows in the data model are sorted by the specified column, in ascending order. (Which sort comparison operator to use is left up to the UA to decide.)

**getCellData (i, j), getCellClasses (i, j, classes),
getCellCheckedState (i, j, state), cycleCell (i, j), and editCell (i, j, data)**:

See [the common definitions below](#).

The data provider must call the datagrid's update methods appropriately whenever the descendants of the datagrid mutate. For example, if a tr is removed, then the updateRowsRemoved () methods would probably need to be invoked, and any change to a cell or its descendants must cause the cell to be updated. If the table element stops being the first child of the datagrid, then the data provider must call the updateEverything () method on the datagrid. Any change to a cell that is in the column that the data provider is currently using as its sort column must also cause the sort to be reperformed, with a call to updateEverything () if the change did affect the sort order.

↳ While the first element child is a select

The default data provider must return 1 for the column count, the empty string for the column's caption, and must not add any classes to the column's classes.

For the rows, assume the existence of a linear node iterator view of the children of the first select element child of the datagrid element, that skips all nodes other than optgroup and option elements, as well as any descendants of any option elements, and descendants of optgroup elements with the closed token in their class attribute.

3,445 captures
5 Jun 2004 - 22 Aug 2020

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

getRowCount() must return the number of elements in this view.

getRowParent(i) must return the index in the view of the nearest ancestor `optgroup` element of the row's element, -1 if there is no such ancestor.

getRowImage(i) must return the empty string, getRowMenu(i) must return null.

getRowClasses(i, classes) must add the classes from the following list to `classes` when their condition is met:

- If the row's element contains other elements that are also in the view, and the element's `class` attribute contains the `closed` class: closed
- If the row's element contains other elements that are also in the view, and the element's `class` attribute doesn't contain the `closed` class: open

The toggleRowOpenState(i) method must add a `closed` class to that row's element's `class` attribute and remove any `open` class, unless it already has a `closed` class and has no `open` class, in which case it must instead remove the `closed` class and add an `open` class. It must then invoke the appropriate update methods to inform the `datagrid` of the newly added or removed rows.

The getCellData(i, j) method must return the value of the `label` attribute if the row's element is an `optgroup` element, otherwise, if the row's element is an `optionElement`, its `label` attribute if it has one, otherwise the value of its `textContent` DOM attribute.

The getCellClasses(i, j, classes) method must add no classes.

The data provider must call the `datagrid`'s update methods appropriately whenever the descendants of the `datagrid` mutate.

↳ While the first element child is another element

The default data provider must return 1 for the column count, the empty string for the column's caption, and must not add any classes to the column's classes.

For the rows, assume the existence of a linear node iterator view of the children of the `datagrid` that skips all nodes other than `li`, `h1-h6`, and `hr` elements, and skips all elements that are descendants of elements with the `closed` token in their `class` attribute, and any descendants of `menu` elements.

Given this view, each element in the view represents a row in the data model: the *i*th element in the view is the *i*th row's element. The row of a particular method call is the row given by its arguments.

getRowCount() must return the number of elements in this view.

getRowParent(i) must return the index in the view of the nearest ancestor (in the real DOM) of the row's element that is also in the view, -1 if there is no such ancestor.

In the following example, the row numbered 2 returns 1 as its parent, and the other rows return -1:

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

```
<ol>
  <li> row 2 </li>
</ol>
</li>
<li> row 3 </li>
</ol>
</datagrid>
```

`getRowImage(i)` must return the URI of the image given by the first `img` element descendant (in the real DOM) of the row's element, that is not also a descendant of another element that has a later position in the view.

In the following example, the row numbered 2 returns "http://example.com/a" as its image URI, and the other rows (including row 1) return the empty string:

```
<datagrid>
<ol>
  <li> row 0 </li>
  <li> row 1
    <ol>
      <li> row 2  </li>
    </ol>
  </li>
  <li> row 3 </li>
</ol>
</datagrid>
```

`getRowMenu(i)` must return the first `menu` element descendant (in the real DOM) of the row's element, that is not also a descendant of another element that has a later position in the view. (This is analogous to the image case above.)

`getRowClasses(i, classes)` must add the classes from the following list to `classes` when their condition is met:

- If the row's element contains other elements that are also in the view, and the element's `class` attribute contains the `closed class`: `closed`
- If the row's element contains other elements that are also in the view, and the element's `class` attribute doesn't contain the `closed class`: `open`
- If the row's element is an `h1-h6` element: `header`
- If the row's element is an `hr` element: `separator`

The `toggleRowOpenState(i)` method must add a `closed class` to that row's element's `class` attribute and remove any `open class`, unless it already has a `closed class` and has no `open class`, in which case it must instead remove the `closed class` and add an `open class`. It must then invoke the appropriate update methods to inform the `datagrid` of the newly added or removed rows.

The `getCellData(i, j)`, `getCellClasses(i, j, classes)`,

◀ 02 ▶
2004 2006 2007

About this capture

The data provider must call the datagrid's update methods appropriately whenever the descendants of the datagrid mutate.

↳ Otherwise, while there is no element child

The data provider must return 0 for the number of rows, 1 for the number of columns, the empty string for the first column's caption, and must add no classes when asked for that column's classes. If the datagrid's child list changes such that the first element child is one of the above, then the data provider must call the updateEverything() method on the datagrid.

2.23.1.3.1. COMMON DEFAULT DATA PROVIDER METHOD DEFINITIONS FOR CELLS

These definitions are used for the cell-specific methods of the default data providers (other than in the `select` case). How they behave is based on the contents of an element that represents the cell given by their first two arguments (which are the row and column indices respectively). Which element that is is defined in the previous section.

Cyclable cells

If the first element child of a cell's element is a `select` element that has a `multiple` attribute and has at least one `option` element descendent, then the cell acts as a cyclable cell.

The "current" `option` element is the selected `option` element, or the first `option` element if none is selected.

The getCellData() method must return the textContent of the current `option` element (the `label` attribute is ignored in this context as the `optgroup`s are not displayed).

The getCellClasses() method must add the cyclable class and then all the classes of the current `option` element.

The cycleCell() method must change the selection of the `select` element such that the next `option` element after the current `option` element is the only one that is selected (in tree order). If the current `option` element is the last `option` element descendent of the `select`, then the first `option` element descendent must be selected instead.

The setCellCheckedState() and editCell() methods must do nothing.

Progress bar cells

If the first element child of a cell's element is a `progress` element, then the cell acts as a progress bar cell.

The getCellData() method must return the value returned by the `progress` element's `position` DOM attribute.

The getCellClasses() method must add the progress class.

The setCellCheckedState(), cycleCell(), and editCell() methods must do nothing.

Checkbox cells

The screenshot shows a navigation bar with a search input field, a 'Go' button, and month/year buttons for December 2004, January 2006, and February 2007. A date '02' is highlighted in yellow. Below the month buttons are the years '2004', '2006', and '2007'. To the right are icons for user profile, help, and sharing (Facebook, Twitter). A link 'About this capture' is also present.

3,445 captures
5 Jun 2004 - 22 Aug 2020

DEC JAN FEB
02
2004 2006 2007

About this capture

The `getCellClasses()` method must add the `checked` class if the `input` element is checked, and the `unchecked` class otherwise.

The `setCellCheckedState()` method must set the `input` element's checkbox state to checked if the method's third argument is 1, and to unchecked otherwise.

The `cycleCell()` and `editCell()` methods must do nothing.

Editable cells

If the first element child of a cell's element is an `input` element that has a `type` attribute with the value `text` or that has no `type` attribute at all, then the cell acts as an editable cell.

The `getCellData()` method must return the value of the `input` element.

The `getCellClasses()` method must add the `editable` class.

The `editCell()` method must set the `input` element's `value` DOM attribute to the value of the third argument to the method.

The `setCellCheckedState()` and `cycleCell()` methods must do nothing.

2.23.1.4. Populating the `datagrid` element

A `datagrid` must be disabled until its end tag has been parsed (in the case of a `datagrid` element in the original document markup) or until it has been inserted into the document (in the case of a dynamically created element). After that point, the element must fire a single `load` event at itself, which doesn't bubble and cannot be canceled.

The `datagrid` must then populate itself using the data provided by the data provider assigned to the `data` DOM attribute. After the view is populated (using the methods described below), the `datagrid` must invoke the `initialize()` method on the data provider specified by the `data` attribute, passing itself (the `HTMLDataGridElement` object) as the only argument.

When the `data` attribute is null, the `datagrid` must use the default data provider described in the previous section.

To obtain data from the data provider, the element must invoke methods on the data provider object in the following ways:

To determine the total number of rows

Invoke the `getRowCount()` method with no arguments. The return value is the number of rows. If the return value is negative, not an integer, or simply not a numeric type, or if the method is not defined, then zero must be used instead.

To determine the total number of columns

Invoke the `getColumnCount()` method with no arguments. The return value is the number of columns. If the return value is zero or negative, not an integer, or simply not a numeric type, or if the method is not defined, then 1 must be used instead.

To get the captions to use for the columns

3,445 captures

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

captions.

To establish what classes apply to a column

Invoke the `getCaptionClasses()` method with the index of the column in question, and an object implementing the `DOMTokenString` interface, initialised to empty. The index i must be in the range $0 \leq i < N$, where N is the total number of columns. The values contained in the `DOMTokenString` object when the method returns represent the classes that apply to the given column. If the method is not defined, no classes apply to the column.

To establish whether a column should be initially included in the visible columns

Check whether the `initially-hidden` class applies to the column. If it does, then the column should not be initially included; if it does not, then the column should be initially included.

To establish whether the data can be sorted relative to a particular column

Check whether the `sortable` class applies to the column. If it does, then the user should be able to ask the UA to display the data sorted by that column; if it does not, then the user agent must not allow the user to ask for the data to be sorted by that column.

To establish if a column is a sorted column

If the user agent can handle multiple columns being marked as sorted simultaneously: Check whether the `sorted` class applies to the column. If it does, then that column is the sorted column, otherwise it is not.

If the user agent can only handle one column being marked as sorted at a time: Check each column in turn, starting with the first one, to see whether the `sorted` class applies to that column. The first column that has that class, if any, is the sorted column. If none of the columns have that class, there is no sorted column.

To establish the sort direction of a sorted column

Check whether the `reversed` class applies to the column. If it does, then the sort direction is descending (down; first rows have the highest values), otherwise it is ascending (up; first rows have the lowest values).

To establish a row's parent row

Invoke the `getRowParent()` method with the index of the row in question. The index i must be in the range $0 \leq i < N$, where N is the total number of rows. The return value p is the index of the parent row. If the method returns a number outside the range $0 \leq p < i$, or if the returned value is non-numeric, or if the method is not defined, then the row has no parent row (it is an unparented top-level row).

If a row r has a parent row p , but not all the rows between it and its parent also have a parent row, or if there is a row i between p and r the parent of which is neither p nor another row between p and i , then the user agent may present the tree structure in an inconsistent way instead of attempting to render the actual described tree structure.

To obtain a URI to an image representing a row

Invoke the `getRowImage()` method with the index of the row in question. The index i must be in the range $0 \leq i < N$, where N is the total number of rows. The return value is a string representing a URI or IRI to an image. Relative URIs must be interpreted relative to the `datagrid`'s base URI. If the method returns the empty string, null, or if the method is not

◀ 02 ▶
2004 2006 2007

About this capture

in the range $0 \leq i < N$, where N is the total number of rows. The return value is a reference to an object implementing the `HTMLMenuElement` interface, i.e. a `menu` element DOM node. (This element must then be interpreted as described in the section on context menus to obtain the actual context menu to use.) If the method returns something that is not an `HTMLMenuElement`, or if the method is not defined, then the row has no associated context menu. User agents may provide their own default context menu, and may add items to the author-provided context menu. For example, such a menu could allow the user to change the presentation of the `datagrid` element.

To establish what classes apply to a row

Invoke the `getRowClasses()` method with the index of the row in question, and an object implementing the `DOMTokenString` interface, initialised to empty. The index i must be in the range $0 \leq i < N$, where N is the total number of rows. The values contained in the `DOMTokenString` object when the method returns represent the classes that apply to the row in question. If the method is not defined, no classes apply to the row.

To establish whether a row is a data row or a special row

Examine the classes that apply to the row. If the `header` class applies to the row, then it is not a data row, it is a subheading. The data from the first cell of the row is the text of the subheading, the rest of the cells must be ignored. Otherwise, if the `separator` class applies to the row, then in the place of the row, a separator should be shown. Otherwise, if the `selectable-separator` class applies to the row, then the row should be a data row, but represented as a separator. (The difference between a `separator` and a `selectable-separator` is that the former is not an item that can be actually selected, whereas the second can be selected and thus has a context menu that applies to it, and so forth.) For both kinds of separator rows, the data of the rows' cells must all be ignored. If none of those three classes apply then the row is a simple data row.

To establish whether a row is openable

Check whether one of the `open` or `closed` classes applies to the row. If one (or both) of these are present, then the row can be opened and closed, otherwise neither are present and the row cannot be opened or closed. (It might still have rows that consider this row a parent, however.)

To establish whether an openable row is open or closed

Check whether the `open` class applies to the row. If it does, the row is open. Otherwise, the row is closed. The `closed` class is not examined to make this determination (although either it or the `open` class must be present to make the row openable in the first place). If a closed row has rows that consider it a parent, those rows must still be included in the rendering.

To establish the value of a particular cell

Invoke the `getCellData()` method with the first argument being the index of the cell's row and the second argument being the index of its column. The two arguments must be zero or positive integers less than the total number of rows and columns respectively. The return value is the value of the cell. If the return value is null or the empty string, or if the method is not defined, then the cell has no data. (For progress bar cells, the cell's value must be further interpreted, as described below.)

To establish what classes apply to a cell

Invoke the `getCellClasses()` method with the first argument being the index of the cell's

The screenshot shows a search bar at the top left, followed by a 'Go' button and month abbreviations (DEC, JAN, FEB) with arrows for navigation. 5 Jun 2004 - 22 Aug 2020

DEC JAN FEB
2004 2006 2007

About this capture

classes that apply to that cell. If the method is not defined, no classes apply to the cell.

To establish how the type of a cell

Examine the classes that apply to the cell. If the progress class applies to the cell, it is a progress bar. Otherwise, if the cyclable class applies to the cell, it is a cycling cell whose value can be cycled between multiple states. Otherwise, none of these classes apply, and the cell is a simple text cell.

To establish the value of a progress bar cell

If the value x of the cell is a string that can be converted to a floating point number in the range $0.0 \leq x \leq 1.0$, then the progress bar has that value (0.0 means no progress, 1.0 means complete). Otherwise, the progress bar is an indeterminate progress bar.

To establish how a simple text cell should be presented

Check whether one of the checked, unchecked, or indeterminate classes applies to the cell. If any of these are present, then the cell has a checkbox, otherwise none are present and the cell does not have a checkbox. If the cell has no checkbox, check whether the editable class applies to the cell. If it does, then the cell value is editable, otherwise the cell value is static.

To establish the state of a cell's checkbox, if it has one

Check whether the checked class applies to the cell. If it does, the cell is checked. Otherwise, check whether the unchecked class applies to the cell. If it does, the cell is unchecked. Otherwise, the indeterminate class applies to the cell and the cell's checkbox is in an indeterminate state. When the indeterminate class applies to the cell, the checkbox is a tristate checkbox, and the user can set it to the indeterminate state. Otherwise, only the checked and/or unchecked classes apply to the cell, and the cell can only be toggled between those two states.

If the data provider ever raises an exception while the datagrid is invoking one of its methods, the datagrid must act, for the purposes of that particular method call, as if the relevant method had not been defined.

The data model is considered stable: user agents may assume that subsequent calls to the data provider methods will return the same data, until one of the update methods is called on the datagrid element. If a user agent is returned inconsistent data, for example if the number of rows returned by getRowCount() varies in ways that do not match the calls made to the update methods, the user agent may disable the datagrid. User agents that do not disable the datagrid in inconsistent cases must honour the most recently returned values.

User agents may cache returned values so that the data provider is never asked for data that could contradict earlier data. User agents must not cache the return value of the getRowMenu method.

The exact algorithm used to populate the data grid is not defined here, since it will differ based on the presentation used. However, the behaviour of user agents must be consistent with the descriptions above. For example, it would be non-conformant for a user agent to make cells have both a checkbox and be editable, as the descriptions above state that cells that have a checkbox cannot be edited.

2.23.1.5. Updating the datagrid

3,445 captures
5 Jun 2004 - 22 Aug 2020

DEC JAN FEB
2004 2006 2007

About this capture

There are a number of update methods that can be invoked on the `datagrid` element to cause it to refresh itself in slightly less drastic ways:

When the `updateEverything()` method is called, the user agent must repopulate the entire `datagrid`. If the number of rows decreased, the selection must be updated appropriately. If the number of rows increased, the new rows should be left unselected.

When the `updateRowsChanged(row, count)` method is called, the user agent must refresh the rendering of the rows in the range from row `row` to row `row+count-1`.

When the `updateRowsInserted(row, count)` method is called, the user agent must assume that `count` new rows have been inserted between what used to be row `row-1` and row `row`. The user agent must update its rendering and the selection accordingly. The new rows should not be selected.

When the `updateRowsRemoved(row, count)` method is called, the user agent must assume that `count` rows have been removed starting from row `row`. The user agent must update its rendering and the selection accordingly.

The `updateRowChanged(row)` method must be exactly equivalent to calling `updateRowsChanged(row, 1)`.

When the `updateColumnChanged(column)` method is called, the user agent must refresh the rendering of the specified column `column`, for all rows.

When the `updateCellChanged(row, column)` method is called, the user agent must refresh the rendering of the cell on row `row`, in column `column`.

Any effects the update methods have on the `datagrid`'s selection is not considered a change to the selection, and must therefore not fire the `select` event.

These update methods should only be called by the data provider, or code acting on behalf of the data provider. In particular, calling the `updateRowsInserted()` and `updateRowsRemoved()` methods without actually inserting or removing rows from the data provider is likely to result in inconsistent renderings.

2.23.1.6. Requirements for interactive user agents

This section only applies to interactive user agents.

If the `datagrid` element has a `disabled` attribute, then the user agent must disable the `datagrid`, preventing the user from interacting with it. The `datagrid` element should still continue to update itself when the data provider signals changes to the data, though. Obviously, conformance requirements stating that `datagrid` elements must react to users in particular ways do not apply when one is disabled.

If a row is openable, then the user must be able to toggle its open/closed state. When the user does so, then the `datagrid` must invoke the data provider's `toggleRowOpenState()` method, with the row's index as the only argument. The `datagrid` must then act as if the `datagrid`'s `updateRowChanged()` method had been invoked with that row's index immediately before the provider's method was invoked.

◀ 02 ▶
2004 2006 2007

About this capture

datagrid's updateCellChanged() method had been invoked with those same arguments immediately before the provider's method was invoked.

When a cell has a checkbox, the user must be able to set the checkbox's state. When the user changes the state of a checkbox in such a cell, the datagrid must invoke the data provider's setCellCheckedState() method, with the cell's row index as the first argument, its column index as the second, and the checkbox's new state as the third. The state should be represented by the number 1 if the new state is checked, 0 if the new state is unchecked, and -1 if the new state is indeterminate (which must only be possible if the cell has the indeterminate class set). The datagrid must then act as if the datagrid's updateCellChanged() method had been invoked, specifying the same cell, immediately before the provider's method was invoked.

If a cell is editable, the user must be able to edit the data for that cell, and doing so must cause the user agent to invoke the editCell() method of the data provider with three arguments: the row number and column number of the cell, and the new text entered by the user. The user agent must then act as if the updateCellChanged() method had been invoked, with the same row and column specified.

2.23.1.7. The selection

This section only applies to interactive user agents. For other user agents, the selection attribute must return null.

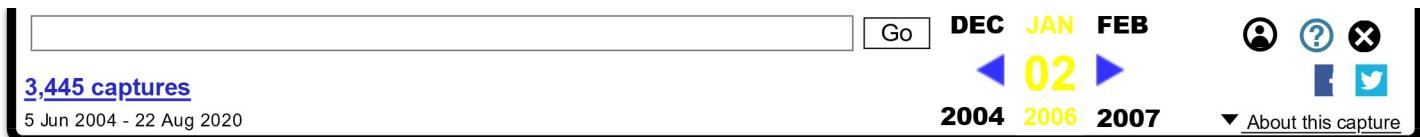

```
interface SelectedRowRanges {
    readonly attribute long count;
    long getRangeStart(in long index);
    long getRangeLength(in long index);
    void addRange(in long start, in long count);
    void removeRange(in long index);
    void setSelected(in long row, in bool selected);
    bool isSelected(in long row);
    void selectAll();
    void invert();
    void clear();
};
```

Each datagrid element must keep track of which rows are currently selected. Initially no rows are selected, but this can be changed via the methods described in this section.

The selection of a datagrid is represented by its selection DOM attribute, which must be a SelectedRowRanges object.

The SelectedRowRanges object represents the selection using ranges. Each range has a starting index and a length. The starting index is relative to the first row (index 0) of the datagrid. The length states how many of the rows are selected, starting from the starting index. A range of length one implies that only the row indicated by its starting index is selected.

The ranges in a selection must not overlap. Ranges may be adjacent (e.g. one range starting at index zero with length two, and a second range starting at index two) but user agents should

greater than the number of rows.

The `count` attribute must return the number of ranges currently present in the selection. The `getRangeStart()` and `getRangeLength()` methods must return the starting index and length (respectively) of the range specified by their argument. If the argument is out of range (less than zero or greater than the number of ranges minus one), then they must raise an `INDEX_SIZE_ERR` exception. [\[DOM3CORE\]](#)

The ranges must be returned in ascending numerical order. That is, the value returned by the `getRangeStart()` method for an index x must always be greater than the value it returns for any index less than x .

The `addRange()` method takes two arguments, an index and a length, specifying a range of rows to select. If the specified range is invalid or would contain rows outside the `datagrid` (e.g. the starting index is negative, or the length would take the selection beyond the end of the `datagrid`), then the method must raise an `INDEX_SIZE_ERR` exception. Otherwise, the specified range must be added to the selection. If the range overlaps, grows, or joins existing selections, the user agent must adjust the ranges so that no two ranges overlap, and should adjust them so that no two ranges are adjacent. Thus, calling `addRange()` may actually reduce the total number of ranges in the selection.

The `removeRange()` method takes two arguments, an index and a length, specifying a range of rows to unselect. If the specified range is invalid or would contain rows outside the `datagrid` (e.g. the starting index is negative, or the length would take the selection beyond the end of the `datagrid`), then the method must raise an `INDEX_SIZE_ERR` exception. Otherwise, the specified rows must be removed from the selection. Calling `removeRange()` may actually increase the total number of ranges in the selection, e.g. if a range had to be split in order to unselect a row in the middle.

The `setSelected()` method takes two arguments, `row` and `selected`. When invoked, it must set the selection state of row `row` to selected if `selected` is true, and unselected if it is false, by adjusting the selection's ranges accordingly. If `row` is less than zero or greater than the index of the last row then the method must raise an `INDEX_SIZE_ERR` exception.

The `isSelected()` method must return the selected state of the row specified by its argument. If the specified row exists and is in one of the ranges of the selection, it must return true, otherwise it must return false.

The `selectAll()` method must replace all the current ranges in the selection with a single selection range having index zero and a length equal to the number of rows in the `datagrid`. If there are no rows in the `datagrid` then this method must instead only remove all the current ranges. (In a compliant UA, there would not be any ranges to remove.)

The `invert()` method must adjust the selections such that the selection is inverted. That is, the ranges must be adjusted such that only the rows that were previously not a part of the selection must be made a part of the new selection.

The `clear()` method must remove all the ranges in the selection.

If the `datagrid` element has a `multiple` attribute, then the user must be able to select any

3,445 captures
5 Jun 2004 - 22 Aug 2020

DEC JAN FEB
2004 2006 2007

About this capture

multiple attribute is absent.

Whenever the selection of a `datagrid` changes, whether due to the user interacting with the element, or as a result of calls to methods of the `selection` object, a `select` event that bubbles but is not cancelable must be fired on the `datagrid` element. If multiple changes are made to the selection via calls to the object's methods during a single execution of a script, then the `select` events should be coalesced into one (which later fires once the script execution has completed).

Note: The `SelectedRowRanges` interface has no relation to the `Selection` and `Range` interfaces.

2.23.1.8. Columns and captions

This section only applies to interactive user agents.

Each `datagrid` element must keep track of which columns are currently being rendered. User agents should initially show all the columns except those with the `initially-hidden` class, but may allow users to hide or show columns. User agents should initially display the columns in the order given by the data provider, but may allow this order to be changed by the user.

If columns are not being used, as might be the case if the data grid is being presented in an icon view, or if an overview of data is being read in an aural context, then the text of the first column of each row should be used to represent the row.

If none of the columns have any captions (i.e. if the data provider does not provide a `getCaptionText()` method), then user agents may avoid showing the column headers at all. This may prevent the user from performing actions on the columns (such as reordering them, changing the sort column, and so on).

Note: Whatever the order used for rendering, and irrespective of what columns are being shown or hidden, the "first column" as referred to in this specification is always the column with index zero, and the "last column" is always the column with the index one less than the value returned by the `getColumnCount()` method of the data provider.

If a column is sortable, then the user must be able to invoke it to sort the data. When the user does so, then the `datagrid` must invoke the data provider's `toggleColumnSortState()` method, with the column's index as the only argument. The `datagrid` must then act as if the `datagrid`'s `updateEverything()` method had been invoked.

2.23.2. The command element

[Metadata element](#), and [strictly inline-level content](#).

Contexts in which this element may be used:

In a `head` element.

Where [strictly inline-level content](#) is allowed.

About this capture

label (optional)
title (optional)
icon (optional)
hidden (optional)
disabled (optional)
checked (optional)
radiogroup (optional)
default (optional)

DOM interface:

```
interface HTMLCommandElement : HTMLElement {  
    attribute DOMString type;  
    attribute DOMString label;  
    attribute DOMString icon;  
    attribute boolean hidden;  
    attribute boolean disabled;  
    attribute boolean checked;  
    attribute DOMString radiogroup;  
    attribute boolean default;  
    void click();  
};
```

The Command interface must also be implemented by this element.

The command element represents a command that the user can invoke.

The **type** attribute indicates the kind of command: either a normal command with an associated action, or a state or option that can be toggled, or a selection of one item from a list of items.

The attribute's value must be either "command", "checkbox", or "radio", denoting each of these three types of commands respectively. The attribute may also be omitted if the element is to represent the first of these types, a simple command.

The **label** attribute gives the name of the command, as shown to the user.

The **title** attribute gives a hint describing the command, which might be shown to the user to help him.

The **icon** attribute gives a picture that represents the command. If the attribute is specified, the attribute's value must contain a URI.

The **hidden** attribute indicates, if present, that the command is not relevant and is to be hidden. If present, the attribute must have the exact value `hidden`.

The **disabled** attribute indicates, if present, that the command is not available in the current state. If present, the attribute must have the exact value `disabled`.

Note: The distinction between Disabled State and Hidden State is subtle. A command

3,445 captures
5 Jun 2004 - 22 Aug 2020

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

but the command "eat" would be marked Hidden since the faucet could never be eaten.

The `checked` attribute indicates, if present, that the command is selected. If present, the attribute must have the exact value `checked`.

The `radiogroup` attribute gives the name of the group of commands that will be toggled when the command itself is toggled, for commands whose `type` attribute has the value "radio". The scope of the name is the child list of the parent element.

If the `command` element is used when generating a context menu, then the `default` attribute indicates, if present, that the command is the one that would have been invoked if the user had directly activated the menu's subject instead of using its context menu.

Need an example that shows an element that, if double-clicked, invokes an action, but that also has a context menu, showing the various `command` attributes off, and that has a default command.

The `type`, `label`, `icon`, `hidden`, `disabled`, `checked`, `radiogroup`, and `default` DOM attributes must `reflect` their respective namesake content attributes.

The `click()` method's behaviour depends on the value of the `type` attribute of the element, as follows:

↪ If the `type` attribute has the value `checkbox`

If the element has a `checked` attribute, the UA must remove that attribute. Otherwise, the UA must add a `checked` attribute, with the literal value `checked`. The UA must then `fire a click event` at the element.

↪ If the `type` attribute has the value `radio`

If the element has a parent, then the UA must walk the list of child nodes of that parent element, and for each node that is a `command` element, if that element has a `radiogroup` attribute whose value exactly matches the current element's (treating missing `radiogroup` attributes as if they were the empty string), and has a `checked` attribute, must remove that attribute and `fire a click event` at the element.

Then, the element's `checked` attribute must be set to the literal value `checked` and a `click` event must be fired at the element.

↪ Otherwise

The UA must `fire a click event` at the element.

Note: Firing a synthetic `click` event at the element does not cause any of the actions described above to happen.

Need to define the `command=""` attribute

About this capture

[Block-level element](#), and [structured inline-level element](#).

Contexts in which this element may be used:

Where [block-level elements](#) are expected.

Where [structured inline-level elements](#) are allowed.

Content model:

Zero or more [li](#) elements, or [inline-level content](#) (but not both).

Element-specific attributes:

[type](#) (optional)

[label](#) (optional)

[autosubmit](#) (optional)

DOM interface:

```
interface HTMLCommandElement : HTMLElement {  
    attribute DOMString type;  
    attribute DOMString label;  
    attribute boolean autosubmit;  
};
```

The [menu](#) element represents a list of commands.

The [type](#) attribute indicates the kind of menu. It must have either the value `popup` (to declare a context menu) or the value `toolbar` (to define a tool bar). The attribute may also be omitted, to indicate that the element is merely a list of commands that is neither declaring a context menu nor defining a tool bar.

If a [menu](#) element has a [type](#) attribute with the value `popup`, then it represents the commands of a context menu, and the user can only interact with the commands if that context menu is activated.

If a [menu](#) element has a [type](#) attribute with the value `toolbar`, then it represents a list of active commands that the user can immediately interact with.

Otherwise, if a [menu](#) element has no [type](#) attribute, or if has a [type](#) attribute with a value other than `popup` or `toolbar`, then it either represents an unordered list of items (each represented by an [li](#) element), each of which represents a command that the user may perform or activate, or, if the element has no [li](#) element children, a [paragraph](#) describing available commands.

The [label](#) attribute gives the label of the menu. It is used by user agents to display nested menus in the UI. For example, a context menu containing another menu would use the nested menu's [label](#) attribute for the submenu's menu label.

The [autosubmit](#) attribute indicates whether selections made to form controls in this menu should result in the control's form being immediately submitted. If the attribute is present, its value must be `autosubmit`.

If a `change` event bubbles through a [menu](#) element, then, in addition to any other default action that

DOM attribute, then the UA must invoke the `submit()` method of the `form` element indicated by that DOM attribute.

The [processing model](#) for menus is described in the next section.

3. Processing models

3.1. Commands

A **command** is the abstraction behind menu items, buttons, and links. Once a command is defined, other parts of the interface can refer to the same command, allowing many access points to a single feature to share aspects such as the disabled state.

Commands are defined to have the following *facets*:

Type

The kind of command: "command", meaning it is a normal command; "radio", meaning that triggering the command will, amongst other things, set the [Checked State](#) to true (and probably uncheck some other commands); or "checkbox", meaning that triggering the command will, amongst other things, toggle the value of the [Checked State](#).

ID

The name of the command, for referring to the command from the markup or from script. If a command has no ID, it is an **anonymous command**.

Label

The name of the command as seen by the user.

Hint

A helpful or descriptive string that can be shown to the user.

Icon

A graphical image that represents the action.

Hidden State

Whether the command is hidden or not (basically, whether it should be shown in menus).

Disabled State

Whether the command can be triggered or not. If the [Hidden State](#) is true (hidden) then the [Disabled State](#) will be true (disabled) regardless.

Checked State

Whether the command is checked or not.

Action

The actual effect that triggering the command will have. This could be a scripted event handler, a URI to which to navigate, or a form submission.

Triggers

The screenshot shows a top navigation bar with a search input field, a 'Go' button, and month abbreviations (DEC, JAN, FEB) with arrows for navigation. Below this is a section for '3,445 captures' from '5 Jun 2004 - 22 Aug 2020'. To the right are icons for user profile, help, and sharing, along with a link to 'About this capture'.

Commands are represented by elements in the DOM. Any element that can define a command also implements the [Command](#) interface:

```
interface Command {
    readonly attribute DOMString commandType;
    readonly attribute DOMString id;
    readonly attribute DOMString label;
    readonly attribute DOMString title;
    readonly attribute DOMString icon;
    readonly attribute boolean hidden;
    readonly attribute boolean disabled;
    readonly attribute boolean checked;
    void click();
    readonly attribute HTMLCollection triggers;
    readonly attribute Command command;
};
```

The [Command](#) interface is implemented by any element capable of defining a command. (If an element can define a command, its definition will list this interface explicitly.) All the attributes of the [Command](#) interface are read-only. Elements implementing this interface may implement other interfaces that have attributes with identical names but that are mutable; in bindings that simply flatten all supported interfaces on the object, the mutable attributes must shadow the read-only attributes defined in the [Command](#) interface.

The **commandType** attribute must return a string whose value is either "command", "radio", or "checked", depending on whether the [Type](#) of the command defined by the element is "command", "radio", or "checked" respectively. If the element does not define a command, it must return null.

The **id** attribute must return the command's [ID](#), or null if the element does not define a command or defines an [anonymous command](#). This attribute will be shadowed by the [id](#) DOM attribute on the [HTMLElement](#) interface.

The **label** attribute must return the command's [Label](#), or null if the element does not define a command or does not specify a [Label](#). This attribute will be shadowed by the [label](#) DOM attribute on [option](#) and [command](#) elements.

The **title** attribute must return the command's [Hint](#), or null if the element does not define a command or does not specify a [Hint](#). This attribute will be shadowed by the [title](#) DOM attribute on the [HTMLElement](#) interface.

The **icon** attribute must return an absolute URI to the command's [Icon](#). If the element does not specify an icon, or if the element does not define a command, then the attribute must return null. This attribute will be shadowed by the [icon](#) DOM attribute on [command](#) elements.

The **hidden** attribute must return true if the command's [Hidden State](#) is that the command is hidden, and false if it is that the command is not hidden. If the element does not define a command, the attribute must return false. This attribute will be shadowed by the [hidden](#) DOM attribute on [command](#) elements.

◀ 02 ▶
2004 2006 2007

About this capture

elements.

The `checked` attribute must return true if the command's [Checked State](#) is that the command is checked, and false if it is that the command is not checked. If the element does not define a command, the attribute must return false. This attribute will be shadowed by the `checked` attribute on `input` and `command` elements.

The `click()` method must trigger the [Action](#) for the command. If the element does not define a command, this method must do nothing. This method will be shadowed by the `click()` method on `button`, `input`, and `command` elements.

The `triggers` attribute must return a list containing the elements that can trigger the command (the command's [Triggers](#)). The list must be live. While the element does not define a command, the list must be empty.

All the commands that have IDs must be in the list returned by the `commands` attribute of the document's [DocumentWindow](#) interface. The collection represented by this attribute is live; as commands are defined in or removed from the document, the attribute is updated.

The following elements may define commands: `a`, `button`, `input`, `option`, `command`.

3.1.1. Using the `a` element to define a command

An `a` element with an `href` attribute [defines a command](#).

The [Type](#) of the command is "command".

The [ID](#) of the command is the value of the `id` attribute of the element, if the attribute is present and not empty. Otherwise the command is an [anonymous command](#).

The [Label](#) of the command is the string given by the element's `textContent` DOM attribute.

The [Hint](#) of the command is the value of the `title` attribute of the `a` element. If the attribute is not present, the [Hint](#) is the empty string.

The [Icon](#) of the command is the absolute URI of the first image in the element. Specifically, in a depth-first search of the children of the element, the first element that is `img` element with a `src` attribute is the one that is used as the image. The URI must be taken from the element's `src` attribute. Relative URIs must be resolved relative to the base URI of the image element. If no image is found, then the Icon facet is left blank.

The [Hidden State](#) and [Disabled State](#) facets of the command are always false. (The command is always enabled.)

The [Checked State](#) of the command is always false. (The command is never checked.)

The [Action](#) of the command is to [fire a click event](#) at the element.

3.1.2. Using the `button` element to define a command

A `button` element always [defines a command](#).

3,445 captures
5 Jun 2004 - 22 Aug 2020

DEC JAN FEB
2004 2006 2007

About this capture

by the element's `disabled` attribute, but certain button types become disabled at other times too (for example, the `move-up` button type is disabled when it would have no effect).

3.1.3. Using the `input` element to define a command

An `input` element whose `type` attribute is one of `submit`, `reset`, `button`, `radio`, `checkbox`, `move-up`, `move-down`, `add`, and `remove` [defines a command](#).

The [Type](#) of the command is "radio" if the `type` attribute has the value `radio`, "checkbox" if the `type` attribute has the value `checkbox`, and "command" otherwise.

The [ID](#) of the command is the value of the `id` attribute of the element, if the attribute is present and not empty. Otherwise the command is an [anonymous command](#).

The [Label](#) of the command depends on the Type of the command:

If the [Type](#) is "command", then it is the string given by the `value` attribute, if any, and a UA-dependent value that the UA uses to label the button itself if the attribute is absent.

Otherwise, the [Type](#) is "radio" or "checkbox". If the element has a `label` element associated with it, the `textContent` of the first such element is the [Label](#) (in DOM terms, this the string given by `element.labels[0].textContent`). Otherwise, the value of the `value` attribute, if present, is the [Label](#). Otherwise, the [Label](#) is the empty string.

The [Hint](#) of the command is the value of the `title` attribute of the `input` element. If the attribute is not present, the [Hint](#) is the empty string.

There is no [Icon](#) for the command.

The [Hidden State](#) of the command is always false. (The command is never hidden.)

The [Disabled State](#) of the command mirrors the disabled state of the control. Typically this is given by the element's `disabled` attribute, but certain input types become disabled at other times too (for example, the `move-up` input type is disabled when it would have no effect).

The [Checked State](#) of the command is true if the command is of [Type](#) "radio" or "checkbox" and the element has a `checked` attribute, and false otherwise.

The [Action](#) of the command is to [fire a click event](#) at the element.

3.1.4. Using the `option` element to define a command

An `option` element with an ancestor `select` element and either no `value` attribute or a `value` attribute that is not the empty string [defines a command](#).

The [Type](#) of the command is "radio" if the `option`'s nearest ancestor `select` element has no `multiple` attribute, and "checkbox" if it does.

The [ID](#) of the command is the value of the `id` attribute of the element, if the attribute is present and not empty. Otherwise the command is an [anonymous command](#).

The [Label](#) of the command is the value of the `option` element's `label` attribute, if there is one, or

The screenshot shows a top navigation bar with a search input field, a 'Go' button, and month abbreviations (DEC, JAN, FEB) with arrows for navigation. Below this is a date range selector showing '2004 2006 2007' with '02' highlighted. To the right are icons for user profile, help, and sharing (Facebook, Twitter).

There is no [Icon](#) for the command.

The [Hidden State](#) of the command is always false. (The command is never hidden.)

The [Disabled State](#) of the command is true (disabled) if the element has a `disabled` attribute, and false otherwise.

The [Checked State](#) of the command is true (checked) if the element's `selected` DOM attribute is true, and false otherwise.

The [Action](#) of the command depends on its [Type](#). If the command is of [Type](#) "radio" then this must set the `selected` DOM attribute of the option element to true, otherwise it must toggle the state of the `selected` DOM attribute (set it to true if it is false and vice versa). Then [a change event must be fired](#) on the option element's nearest ancestor `select` element (if there is one), as if the selection had been changed directly.

3.1.5. Using the `command` element to define a command

A [command](#) element [defines a command](#).

The [Type](#) of the command is "radio" if the [command's type](#) attribute is "radio", "checkbox" if the attribute's value is "checkbox", and "command" otherwise.

The [ID](#) of the command is the value of the `id` attribute of the element, if the attribute is present and not empty. Otherwise the command is an [anonymous command](#).

The [Label](#) of the command is the value of the element's `label` attribute, if there is one, or the empty string if it doesn't.

The [Hint](#) of the command is the string given by the element's `title` attribute, if any, and the empty string if the attribute is absent.

The [Icon](#) for the command is the absolute URI resulting from resolving the value of the element's `icon` attribute as a URI relative to the element's base URI. If the element has no `icon` attribute then the command has no [Icon](#).

The [Hidden State](#) of the command is true (hidden) if the element has a `hidden` attribute, and false otherwise.

The [Disabled State](#) of the command is true (disabled) if the element has either a `disabled` attribute or a `hidden` attribute (or both), and false otherwise.

The [Checked State](#) of the command is true (checked) if the element has a `checked` attribute, and false otherwise.

The [Action](#) of the command is to invoke the behaviour described in the definition of the `click()` method of the [HTMLCommandElement](#) interface.

3.3. Menus

3.3.1. Introduction [\[TBW\]](#)

...

3.3.2. Building menus

A menu consists of a list of zero or more of the following components:

- [Commands](#), which can be marked as default commands
- Separators
- Other menus (which allows the list to be nested)

The list corresponding to a particular element is built by iterating over its child nodes.

For each child node in document order, the required behaviour depends on what the node is, as follows:

↳ An element that [defines a command](#)

Append the command to the menu. If the element is a `command` element with a `default` attribute, mark the command as being a default command.

↳ An `hr` element

↳ An `option` element that has a `value` attribute set to the empty string, and has a `disabled` attribute, and whose `textContent` consists of a string of one or more hyphens (`U+002D HYPHEN-MINUS`)

Append a separator to the menu.

↳ An `li` element

Iterate over the children of the `li` element.

↳ A `menu` element with no `label` attribute

↳ A `select` element

Append a separator to the menu, then iterate over the children of the `menu` or `select` element, then append another separator.

↳ A `menu` element with a `label` attribute

↳ An `optgroup` element

Append a submenu to the menu, using the value of the element's `label` attribute as the label of the menu. The submenu must be constructed by taking the element and creating a new menu for it using the complete process described in this section.

2004 2006 2007

About this capture

the menu as follows:

1. Any menu item with no label, or whose label is the empty string, must be removed.
2. Any sequence of two or more separators in a row must be collapsed to a single separator.
3. Any separator at the start or end of the menu must be removed.

3.3.3. Context menus

The `contextmenu` attribute associates an element with a `menu` element.

When an element's context menu is requested (e.g. by the user right-clicking the element, or pressing a context menu key), the UA must [fire a `contextmenu` event](#) on the element for which the menu was requested.

Note: Typically, therefore, the firing of the `contextmenu` event will be the default action of a `mouseup` or `keyup` event. The exact sequence of events is UA-dependent, as it will vary based on platform conventions.

The default action of the `contextmenu` event depends on whether the element has a context menu assigned (using the `contextmenu` attribute) or not. If it does not, the default action must be for the user agent to show its default context menu, if it has one.

If the element *does* have a context menu assigned, then the user agent must [fire a `show` event](#) on the relevant `menu` element.

The default action of *this* event is that the user agent must show a context menu [built](#) from the `menu` element.

The user agent may also provide access to its default context menu, if any, with the context menu shown. For example, it could merge the menu items from the two menus together, or provide the page's context menu as a submenu of the default menu.

If the user dismisses the menu without making a selection, nothing in particular happens.

If the user selects a menu item that represents a command, then the UA must invoke that command's [Action](#), as defined above.

Context menus must not, while being shown, reflect changes in the DOM; they are constructed as the default action of the `show` event and must remain like that until dismissed.

User agents may provide means for bypassing the context menu processing model, ensuring that the user can always access the UA's default context menus. For example, the user agent could handle right-clicks that have the Shift key depressed in such a way that it does not fire the `contextmenu` event and instead always shows the default context menu.

3.3.4. Toolbars

Toolbars are a kind of menu that is always visible.

When a `menu` element has a `type` attribute with the value `toolbar`, then the user agent must [build](#)

3.4. Repetition templates [\[TBW\]](#)

See [WF2](#) for now

4. Browsing contexts

Web browsers and other user agents that display HTML documents to the user in the context of a browsing environment may display one or more views of the document to the user.

Each set of one or more views is considered a **browsing context**.

A [browsing context](#) may have further browsing contexts nested within it; the `iframe` element, for instance, instantiates a [browsing context](#) within the context of a parent document. The lifetime of a nested browsing context is bounded by the lifetime of the document in which it lives, or by the UA if the [browsing context](#) does not have a parent document.

A [browsing context](#) that does not have a parent document or browsing context is the **top-level browsing context** for any browsing contexts nested within it (and their documents).

Each [browsing context](#) must have a single unique [session history](#), consisting of one or more documents, each represented by an object implementing the [DocumentWindow](#) interface.

Note: *A document can have more than one entry in the session history of a particular browsing context. All the entries related to a particular DocumentWindow object are contiguous.*

Each view of each document in a [browsing context](#) must be represented by an object implementing the [Window](#) interface. In each set of such objects there is a **default view**, represented by one of the [Window](#) objects, which is the primary output mode of the document (and, for interactive user agents, nominally the user's primary way of interacting with the document).

When a UI event is fired, the `view` attribute of the `UIEvent` object must point to the [Window](#) object representing the view in which the user triggered the event.

Note: *Typically Web browsers only have one view per document, but a Web browser that rendered document to a screen while simultaneously providing a speech synthesis version would be one example where two views were present.*

4.1. The [DocumentWindow](#) interface

The [DocumentWindow](#) interface extends the [DocumentView](#) interface defined in DOM2 Views. [\[DOM2VIEWS\]](#)

Every `Document` object that is being rendered in a [browsing context](#) must implement the

3,445 captures
5 Jun 2004 - 22 Aug 2020

Dec 02 Jan Feb 2004 2006 2007 ▾ About this capture

```
readonly attribute Window window;
```

```
// helper objects
    attribute Location location; /* performs magic on setting */
Selection getSelection();
readonly attribute HTMLCollection commands;

// editing
    attribute boolean designMode;
boolean execCommand(in DOMString commandID);
boolean execCommand(in DOMString commandID, in boolean doShowUI);
boolean execCommand(in DOMString commandID, in boolean doShowUI, in DC
};
```

The `window` attribute of the `DocumentWindow` interface must return the document's [default view](#). It must return the same object as the `defaultView` attribute inherited from the `DocumentView` interface. [\[DOM2VIEWS\]](#)

The **domain of a DocumentWindow object** is the domain given by the `hostname` attribute of the `Location` object returned by the `DocumentWindow` object's `location` attribute, *if that hostname attribute is not the empty string.* If it is, the domain of the document is UA-defined. For now.

The **domain of a script** is the [domain of the DocumentWindow object](#) that is returned by the `document` attribute of the script's primary `Window` object (in UAs that implement ECMAScript, [that is the global scope object](#)).

The **the string representing the script's domain in IDNA format** is obtained as follows: take the [script's domain](#) and apply the IDNA ToASCII algorithm and then the IDNA ToUnicode algorithm to each component of the domain name (with both the AllowUnassigned and UseSTD3ASCIIRules flags set both times). [\[RFC3490\]](#) If ToASCII fails to convert one of the components of the string, e.g. because it is too long or because it contains invalid characters, then the string representing the script's domain in IDNA format cannot be obtained. (ToUnicode is defined to never fail.)

4.2. The Window interface

The `Window` interface extends the `AbstractView` interface defined in DOM2 Views. [\[DOM2VIEWS\]](#)

```
interface Window : AbstractView {

    // self-reference
    readonly attribute Window window;

    // timers
    long setTimeout(in TimeoutHandler handler, in long timeout);
    long setTimeout(in TimeoutHandler handler, in long timeout, arguments);
    long setTimeout(in DOMString code, in long timeout);
```

long setInterval(in DOMString code, in long timeout, in DOMString lang);
void clearInterval(in long handle);

// convenient event handlers
attribute ErrorHandler onerror;

// helper objects
readonly attribute History history;
attribute Location location; /* performs magic on setting */
attribute Storage sessionStorage;
readonly attribute StorageList globalStorage;
readonly attribute ClientInformation navigator;
readonly attribute UndoManager undoManager;
Selection getSelection();

};

interface TimeoutHandler {
void handleEvent(arguments...);
};

interface ErrorHandler {
void handleEvent(in DOMString errorMessage, in DOMString fileName, in
};

```

Objects implementing the Window interface must also implement the EventTarget interface.

In UAs that expose the DOM to ECMAScript [ECMA262] scripts, the global scope object must implement the Window interface described above.

The window attribute of an object implementing the Window interface must always point to the object itself. In other words, the following equality must also always hold:

`x.window == x`

...where x is an object implementing the Window interface.

Thus, in ECMAScript, the ECMAScript global object must have a property window pointing at the global object itself.

The document attribute inherited from the AbstractView interface must return the document associated with this view.

4.3. Events

We need a section to define how events all work, default actions, etc. For example, how does clicking on a span in a link that is in another link actually cause a link to be followed? which one?

▼ About this capture

4.4. FOCUS [WIC]

This entire section will be merged with earlier sections in due course.

When an element is focused, key events are targetted at that element instead of at the document's root element.

4.4.1. The `tabindex` Attribute

The `tabindex` attribute defined in HTML4 is extended to apply to all HTML elements by defining it as a common attribute.

The `tabindex` attribute specifies the relative order of elements for the purposes of sequential focus navigation. The name "tab index" comes from the common use of the "tab" key to navigate through the focusable elements. The term "tabbing" refers to moving forward through the focusable elements.

The `tabindex` attribute can take any integer (an optional U+002D HYPHEN-MINUS representing negativity followed by one or more digits in the range 0-9, U+0030 to U+0039, interpreted as base ten).

A positive integer (including zero) specifies the index of the element in the current scope's tab order. Elements with the same index are sorted in document order for the purposes of tabbing.

A negative integer specifies that the element should be removed from the tab order. If the element does normally take focus, it may still be focused using other means (e.g. it could be focussed by a click).

Other values are ignored, as if the attribute was absent. Certain elements may default absent `tabindex` attributes to zero, at the user agent's discretion. (In other words, some elements are focusable by default, and they are assumed to have tab index 0. Text fields will typically be in the tab order by default, for instance.)

When an element that does not normally take focus has the `tabindex` attribute specified with a positive value, then it is added to the tab order and is made focusable. When focused, the element matches the CSS `:focus` pseudo-class and key events are dispatched on that element when appropriate, just like focusing a link.

Since all HTML elements can thus be focused and unfocused, the `onfocus` and `onblur` attributes shall also apply to all HTML elements.

4.4.2. The `ElementFocus` interface

The `ElementFocus` interface contains methods for moving focus to and from an element. It can be obtained from objects that implement the `Element` interface using binding-specific casting methods.

```
interface ElementFocus {
    attribute long tabIndex;
    void focus();
    void blur();
```

The screenshot shows a navigation bar with a search input field, a 'Go' button, and month/year buttons for 'DEC', 'JAN', and 'FEB'. Below this is a date range selector from '2004' to '2007'. To the right are icons for user profile, help, and sharing. A status bar at the bottom indicates '3,445 captures' and the date '5 Jun 2004 - 22 Aug 2020'.

If the `tabindex` attribute is present (or has an invalid value), then the DOM attribute should return the SAX's default value for that element, typically either 0 (for elements in the tab order) or -1 (for elements not in the tab order).

The `focus()` and `blur()` methods focus and unfocus the element respectively, if the element is focusable.

4.4.3. The DocumentFocus interface

The `DocumentFocus` interface contains methods for moving focus around the document. It can be obtained from objects that implement the `Document` interface using binding-specific casting methods.

```
interface DocumentFocus {
    readonly attribute Element currentFocus;
    void moveFocusForward();
    void moveFocusBackward();
    void moveFocusUp();
    void moveFocusRight();
    void moveFocusDown();
    void moveFocusLeft();
};
```

The `currentFocus` attribute returns the element to which key events will be sent when the document receives key events.

The `moveFocusForward` method uses the '`nav-index`' property and the `tabindex` attribute to find the next focusable element and focuses it.

The `moveFocusBackward` method uses the '`nav-index`' property and the `tabindex` attribute to find the previous focusable element and focuses it.

The `moveFocusUp` method uses the '`nav-up`' property and the `tabindex` attribute to find an appropriate focusable element and focuses it.

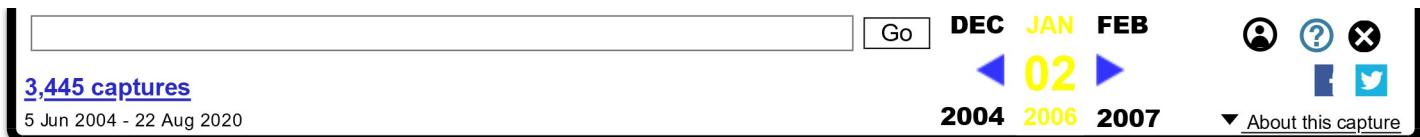

In a similar manner, the `moveFocusRight`, `moveFocusDown`, and `moveFocusLeft` methods use the '`nav-right`', '`nav-down`', and '`nav-left`' properties (respectively), and the `tabindex` attribute, to find an appropriate focusable element and focus it.

The '`nav-index`', '`nav-up`', '`nav-right`', '`nav-down`', and '`nav-left`' properties are defined in [\[CSS3UI\]](#).

4.5. [SCS] Runtime script errors

The `onerror` attribute takes a reference to an object implementing the `ErrorHandler` interface. In ECMAScript, such an interface is implemented by any function that takes three arguments and returns a boolean value, as well as by the `null` value and the `undefined` value.

The function to which the `onerror` attributes points must be invoked whenever a runtime script error occurs in the context of the `window` object, before the error is reported to the user. If the function is `null` or if the function returns true then the error should not be reported to the user. If the

the UA is considering reporting, the second gives the URI to the resource in which the error occurred, and the third gives the line number in the resource on which the error occurred.

The initial value of `onerror` must be `undefined`.

4.6. [SCS] Timers

The `setTimeout` and `setInterval` methods allow authors to schedule timer-based events.

The `setTimeout(handler, timeout[, arguments...])` method takes a reference to a `TimeoutHandler` object and a length of time in milliseconds. It must return a handle to the timeout created, and then asynchronously wait `timeout` milliseconds and then invoke `handleEvent()` on the `handler` object. If any `arguments...` were provided, they must be passed to the `handler` as arguments to the `handleEvent()` function.

In the ECMAScript DOM binding, the ECMAScript native `Function` type must implement the `TimeoutHandler` interface such that invoking the `handleEvent()` method of that interface on the object from another language binding invokes the function itself, with the arguments passed to `handleEvent()` as the arguments passed to the function. In the ECMAScript binding itself, however, the `handleEvent()` method of the interface is not directly accessible on `Function` objects. Such functions must be called in the global scope.

Alternatively, `setTimeout(code, timeout[, language])` may be used. This variant takes a string instead of a `TimeoutHandler` object. That string must be parsed using the specified `language` (defaulting to ECMAScript if the third argument is omitted) and executed in the global scope.

Need to define `language` values.

The `setInterval(...)` variants must work in the same way as the `setTimeout` variants except that the `handler` or `code` must be invoked again every `timeout` milliseconds, not just the once.

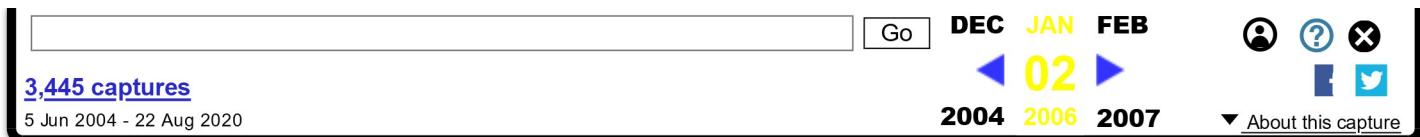

The `clearTimeout()` and `clearInterval()` methods take one integer (the value returned by `setTimeout` and `setInterval` respectively) and must cancel the specified timeout. When called with a value that does not correspond to an active timeout or interval, the methods must return without doing anything.

Timeouts must never fire while another script is executing. (Thus the HTML scripting model is strictly single-threaded and not reentrant.)

4.7. [SCS] Session history and navigation

4.7.1. The session history of browsing contexts

`History` objects provide a representation of the pages in the session history of their `Window` object's `browsing context`. Each browsing context (frame, iframe, etc) has a distinct session history.

interface for that [Window](#) object's associated [DocumentWindow](#) object.

[History](#) objects represent their [browsing context](#)'s session history as a flat list of URIs and [state objects](#). (This does not imply that the UI need be linear. See the [notes below](#).)

Typically, the history list will consist of only URIs. However, a page can [add state objects](#) between its entry in the session history and the next ("forward") entry. These are then [returned to the script](#) when the user (or script) goes back in the history, thus enabling authors to use the "navigation" metaphor even in one-page applications.

Entries that consist of [state objects](#) share the same [DocumentWindow](#) as the entry for the URI itself. Contiguous entries that differ just by fragment identifier must also share the same [DocumentWindow](#).

Note: All entries that share the same [DocumentWindow](#) (and that are therefore merely different states of one particular document) are contiguous by definition.

At any point, one of the entries in the session history is the [current entry](#). This is the entry representing the page in this [browsing context](#) that is considered the "current" page by the UA. The [current entry](#) is usually an entry for the [location](#) of the [DocumentWindow](#). However, it can also be one of the entries for [state objects](#) added to the history by that document.

When the browser's navigation model differs significantly from the sequential model represented by the [History](#) interface, for example if separate [DocumentWindow](#) objects in the session history are all simultaneously displayed and active, then the [current entry](#) could even be an entry unrelated to the [History](#) object's own [DocumentWindow](#) object. If, when a method is invoked on a [History](#) object, the [current entry](#) for that [browsing context](#)'s session history has a different [DocumentWindow](#) object than the [History](#) object's own [DocumentWindow](#) object, then the user agent must raise a `NO_MODIFICATION_ALLOWED_ERR` DOM exception. (This can only happen if scripts are allowed to run in documents that are not the current document. Typically, however, user agents only allow scripts from the [current entry](#) to execute.)

User agents may [discard](#) the DOMs of entries other than the [current entry](#), reloading the pages afresh when the user or script navigates back to such pages. This specification does not specify when user agents should discard pages' DOMs and when they should cache them. See the section on the [load](#) and [unload](#) events for more details.

Entries that have had their DOM discarded must, for the purposes of the algorithms given below, act as if they had not. When the user or script navigates back or forwards to a page which has no in-memory DOM objects, any other entries that shared the same [DocumentWindow](#) object with it must share the new object as well.

When a user agent discards the DOM from an entry in the session history, it must also discard all the entries from the first state object entry for that [DocumentWindow](#) object up to and including the last entry for that [DocumentWindow](#) object (including any non-state-object entries in that range, such as entries where the user navigated using fragment identifiers). These entries are not recreated if the user or script navigates back to the page. If there are no state object entries for that [DocumentWindow](#) object then no entries are removed.

4.7.2. The [History](#) interface

Go DEC JAN FEB
 02 2004 2006 2007 ▶ About this capture

[3,445 captures](#)
 5 Jun 2004 - 22 Aug 2020

```
void go();
void back();
void forward();
void pushState(in DOMObject data);
void clearState();
};
```

The `length` attribute of the `History` interface must return the number of entries in this session history.

The actual entries are not accessible from script.

The `go(delta)` method causes the UA to move the number of steps specified by `delta` in the session history.

If the index of the `current entry` plus `delta` is less than zero or greater than or equal to the `number of items in the session history`, then the user agent must do nothing.

If the `delta` is zero, then the user agent must act as if the `location.reload()` method was called instead.

Otherwise, the user agent must cause the current `browsing context` to navigate to the specified entry, as described below. The specified entry is the one whose index equals the index of the `current entry` plus `delta`.

If there are any entries with state objects between the current entry and the specified entry (not inclusive), then the user agent must iterate through every entry between the current entry and the specified entry, starting with the entry closest to the current entry, and ending with the one closest to the specified entry. For each entry, if the entry is a state object, the user agent must [activate the state object](#).

If the specified entry has a different `DocumentWindow` object than the `current entry` then the user agent must make that `DocumentWindow` object the user's "current" one for that `browsing context`.

If the specified entry is a state object, the user agent must [activate that state object](#). Otherwise, the user agent must update the current `location` object to the new location.

User agents may also update other aspects of the document view when the location changes in this way, for instance the scroll position, values of form fields, etc.

When the user navigates through a `browsing context`, e.g. using a browser's back and forward buttons, the user agent must translate this action into the equivalent invocations of the `history.go(delta)` method on the various affected `window` objects.

Some of the other members of the `History` interface are defined in terms of the `go()` method, as follows:

Member	Definition
<code>go()</code>	Must do the same as <code>go(0)</code>
<code>back()</code>	Must do the same as <code>go(-1)</code>
<code>forward()</code>	Must do the same as <code>go(1)</code>

About this capture

history that references the same DocumentWindow object, if any. If the current entry is the last entry in the session history, or if there are no entries after the current entry that reference the same DocumentWindow object, then no entries are removed.

Then, the user agent must add a state object entry to the session history, after the current entry, with the specified *data* as the state object.

Finally, the user agent must update the current entry to be the this newly added entry.

There has been a suggestion that `pushState()` should take a URI and a string; the URI to allow for the page to be bookmarked, and the string to allow the UA to give the page a meaningful title in the history state, if it shows history state.

User agents may limit the number of state objects added to the session history per page. If a page hits the UA-defined limit, user agents must remove the entry immediately after the first entry for that DocumentWindow object in the session history after having added the new entry. (Thus the state history acts as a FIFO buffer for eviction, but as a LIFO buffer for navigation.)

The `clearState()` method removes all the state objects for the DocumentWindow object from the session history.

When this method is invoked, the user agent must remove from the session history all the entries from the first state object entry for that DocumentWindow object up to the last entry that references that same DocumentWindow object, if any.

Then, if the current entry was removed in the previous step, the current entry must be set to the last entry for that DocumentWindow object in the session history.

4.7.3. Activating state objects

When a state object in the session history is activated (which happens in the cases described above), the user agent must fire a `popstate` event in the `http://www.w3.org/2001/XMLSchema#events` namespace on the the body element using the PopStateEvent interface, with the state object in the state attribute. This event bubbles but is not cancelable and has no default action.

If there is no "the body element" then the event must be fired on the document's Document object instead.

```
interface PopStateEvent : Event {
    readonly attribute DOMObject state;
    void           initPopStateEvent(in DOMString typeArg,
                                      in boolean canBubbleArg,
                                      in boolean cancelableArg,
                                      in DOMObject statetArg);
    void           initPopStateEventNS(in DOMString namespaceURIArg,
                                       in DOMString typeArg,
                                       in boolean canBubbleArg,
                                       in boolean cancelableArg,
                                       in DOMObject stateArg);
```

[3,445 captures](#)
 5 Jun 2004 - 22 Aug 2020

a manner analogous to the similarly named methods in the DOM Events interfaces.
[\[DOM3EVENTS\]](#)

The `state` attribute represents the context information for the event.

4.7.4. The Location interface

The `location` attribute of the Window interface must return an object implementing the Location interface.

For historical reasons, the `location` attribute of the DocumentWindow interface must return the same object as the `location` attribute on its associated Window object.

Location objects provide a representation of the URI of their document, and allow the current entry of the browsing context's session history to be changed, by adding or replacing entries in the history object.

```
interface Location {
  readonly attribute DOMString hash;
  readonly attribute DOMString host;
  readonly attribute DOMString hostname;
  readonly attribute DOMString href;
  readonly attribute DOMString pathname;
  readonly attribute DOMString port;
  readonly attribute DOMString protocol;
  readonly attribute DOMString search;
  void assign(in DOMString url);
  void replace(in DOMString url);
  void reload();
};
```

In the ECMAScript DOM binding, objects implementing this interface must stringify to the same value as the `href` attribute.

In the ECMAScript DOM binding, the `location` members of the DocumentWindow and Window interfaces behave as if they had a setter: user agents must treat attempts to set these `location` attribute as attempts at setting the `href` attribute of the relevant Location object instead.

The `href` attribute returns the address of the page represented by the associated DocumentWindow object, as an absolute IRI reference.

On setting, the user agent must act as if the `assign()` method had been called with the new value as its argument.

When the `assign(url)` method is invoked, the UA must remove all the entries after the current entry in its DocumentWindow's History object, add a new entry, with the given `url`, at the end of the list (asynchronously loading the new page if necessary), and then advance to that page as if the `history.forward()` method had been invoked.

When the `replace(url)` method is invoked, the UA must act as if the `assign()` method had been invoked, but with the additional step of removing the entry that was the current entry before the

About this capture

only in terms of the fragment identifier, then the user agent must use the same `DocumentWindow` object, updating only the scroll position in the document's view(s) appropriately.

Relative `url` arguments for `assign()` and `replace()` must be resolved relative to the base URI of the script that made the method call.

The component parts and `.reload()` are yet to be defined. If anyone can come up with a decent definition, let me know.

4.7.5. Implementation notes for session history

This section is non-normative.

The `History` interface is not meant to place restrictions on how implementations represent the session history to the user.

For example, session history could be implemented in a tree-like manner, with each page having multiple "forward" pages. This specification doesn't define how the linear list of pages in the `history` object are derived from the actual session history as seen from the user's perspective.

Similarly, a page containing two `iframes` has a `history` object distinct from the `iframes'` `history` objects, despite the fact that typical Web browsers present the user with just one "Back" button, with a session history that interleaves the navigation of the two inner frames and the outer page.

Security: It is suggested that to avoid letting a page "hijack" the history navigation facilities of a UA by abusing `pushState()`, the UA provide the user with a way to jump back to the previous page (rather than just going back to the previous state). For example, the back button could have a drop down showing just the pages in the session history, and not showing any of the states. Similarly, an aural browser could have two "back" commands, one that goes back to the previous state, and one that jumps straight back to the previous page.

In addition, a user agent could ignore calls to `pushState()` that are invoked on a timer, or from event handlers that do not represent a clear user action, or that are invoked in rapid succession.

4.8. [SCS] Client-side session and persistent storage

4.8.1. Introduction

This section is non-normative.

This specification introduces two related mechanisms, similar to HTTP session cookies [[RFC2965](#)], for storing structured data on the client side.

The first is designed for scenarios where the user is carrying out a single transaction, but could be carrying out multiple transactions in different windows at the same time.

Cookies don't really handle this case well. For example, a user could be buying plane tickets in two different windows, using the same site. If the site used cookies to keep track of which ticket the user was buying, then as the user clicked from page to page in both windows, the ticket currently being

◀ 02 ▶
2004 2006 2007

About this capture

data to the session storage, and it will be accessible to any page from that domain opened in that window.

For example, a page could have a checkbox that the user ticks to indicate that he wants insurance:

```
<label>
  <input type="checkbox" onchange="sessionStorage.insurance = checked">
    I want insurance on this trip.
</label>
```

A later page could then check, from script, whether the user had checked the checkbox or not:

```
if (sessionStorage.insurance) { ... }
```

If the user had multiple windows opened on the site, each one would have its own individual copy of the session storage object.

The second storage mechanism is designed for storage that spans multiple windows, and lasts beyond the current session.

The globalStorage DOM attribute is used to access the global storage areas.

The site at example.com can display a count of how many times the user has loaded its page by putting the following at the bottom of its page:

```
<p>
  You have viewed this page
  <span id="count">an untold number of</span>
  time(s).
</p>
<script>
  var storage = globalStorage['example.com'];
  if (!storage.pageLoadCount)
    storage.pageLoadCount = 0;
  storage.pageLoadCount += 1;
  document.getElementById('count').textContent = storage.pageLoadCount
</script>
```

Each domain and each subdomain has its own separate storage area. Subdomains can access the storage areas of parent domains, and domains can access the storage areas of subdomains.

- `globalStorage['']` is accessible to all domains.
- `globalStorage['com']` is accessible to all .com domains
- `globalStorage['example.com']` is accessible to example.com and any of its subdomains
- `globalStorage['www.example.com']` is accessible to www.example.com and example.com, but not www2.example.com.

Storage areas (both session storage and global storage) can store most simple data types

3,445 captures
5 Jun 2004 - 22 Aug 2020

DEC JAN FEB
02 2004 2006 2007

About this capture

```
// DOMUserData is defined in DOM3 Core [DOM3CORE]
interface Storage {
    readonly attribute unsigned long length;
    DOMString key(in unsigned long index);
    DOMUserData getItem(in DOMString key);
    void setItem(in DOMString key, in DOMUserData data);
    void removeItem(in DOMString key);
};
```

Each `Storage` object provides access to a list of key/value pairs, which are sometimes called items. Keys are strings, and any string (including the empty string) is a valid key. Values can be of any type.

In the ECMAScript binding, enumerating the object must enumerate through the currently stored keys (not the values, and not the actual members of the interface). In the ECMAScript binding, `Storage` objects must support dereferencing such that getting a property that is not a member of the object (i.e. is neither a member of the `Storage` interface nor of `Object`) must invoke the `getItem()` method with the property's name as the argument, and setting such a property must invoke the `setItem()` method with the property's name as the first argument and the given value as the second argument.

Each `Storage` object is associated with a list of key/value pairs when it is created, as defined in the sections on the `sessionStorage` and `globalStorage` attributes. Multiple separate objects implementing the `Storage` interface can all be associated with the same list of key/value pairs simultaneously.

The `length` attribute must return the number of key/value pairs currently present in the list associated with the object.

The `key(n)` method must return the name of the `n`th key in the list. The order of keys is user-agent defined, but must be consistent within an object between changes to the number of keys. (Thus, adding or removing a key may change the order of the keys, but merely changing the value of an existing key must not.) If `n` is less than zero or greater than or equal to the number of key/value pairs in the object, then this method must raise an `INDEX_SIZE_ERR` exception.

The `getItem(key)` method must return the `restored value` for the key/value pair with the given `key`. If the given `key` does not exist in the list associated with the object, then this method must return null.

The `setItem(key, value)` method must first check if a key/value pair with the given `key` already exists in the list associated with the object. If it does not, then a new key/value pair must be added to the list, with the given `key`. Then, the key/value pair with the given `key` must have its value updated so that if it is retrieved it will return the restored value for the given `original value`, the value given in the `value` argument.

When the `setItem()` method is invoked, events are fired on other `DocumentWindow` objects that can access the newly stored data, as defined in the sections on the `sessionStorage` and `globalStorage` attributes.

The `removeItem(key)` method must cause the key/value pair with the given `key` to be removed

◀ 02 ▶
2004 2006 2007

About this capture

changes to the data storage area must either be successful, or the data storage area must not be changed at all.

The **restored value** (returned by `getItem()`) of a given **original value** (as passed to `setItem()`) is defined as follows, depending on the type of the **original value**:

↳ **Numbers, Booleans, DOMTimeStamp, DOMStrings, undefined, null, and other "plain old data" types**

The restored value must be the same as the original value.

↳ **DOM Node objects**

The restored value must be a new DOM Node, which has the same `nodeType`, `nodeName`, `nodeValue`, `namespaceURI`, and `baseURI` as the original. In addition, for each entry in the original node's `attributes` and `childNodes` lists, the new object must have a corresponding entry that has been restored in the same way, in the same order. (In other words, the restoring recurses.) The `ownerDocument` attributes of the restored Node objects must be set to the value of the `document` attribute of the `Window` object that the `Storage` object is associated with. User agents must not restore any other state. In particular, `user data`, event handlers, and other DOM attributes on the original Nodes (e.g. `isId` or specified on attributes, or `domConfig` on documents) are not restored on the new Nodes. [DOM3CORE]

Note: The contents of the bitmaps of `canvas` elements and the value and state of form controls are therefore not stored when a node is placed in a `Storage` object, as those aspects are not represented in the core DOM Node interface.

↳ **E4X XML objects**

...

↳ **Arrays**

...

↳ **Other objects**

The restored value must be a new object, where for each enumerable property without a custom getter in the original object, the new object has a property with the same name and a value restored as if the property on the original object was itself treated as an original value to restore (i.e. the restoring recurses through all the properties of the object). If, while recursing through objects in this way, a reference to an object occurs more than once, only the occurrence that is found first in a depth-first search of the original value must be restored; all other occurrences must be restored as `null`.

Subsequent calls to `getItem()` for the same item must return new objects each time.

4.8.3. The `sessionStorage` attribute

3,445 captures
5 Jun 2004 - 22 Aug 2020

DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

User agents should not expire data from a browsing context's session storage areas, but may do so when the user requests that such data be deleted, or when the UA detects that it has limited storage space, or for security reasons. User agents should always avoid deleting data while a script that could access that data is running. When a top-level browsing context is destroyed (and therefore permanently inaccessible to the user) the data stored in its session storage areas can be discarded with it, as the API described in this specification provides no way for that data to ever be subsequently retrieved.

Note: *The lifetime of a browsing context can be unrelated to the lifetime of the actual user agent process itself, as the user agent may support resuming sessions after a restart.*

When a new `DocumentWindow` is created, the user agent must check to see if the document's `top-level browsing context` has allocated a session storage area for that `document's domain`. If it has not, a new storage area for that document's domain must be created.

The `Storage` object for the document's associated `Window` object's `sessionStorage` attribute must then be associated with the domain's session storage area.

When a new `top-level browsing context` is created by cloning an existing `browsing context`, the new browsing context must start with the same session storage areas as the original, but the two sets must from that point on be considered separate, not affecting each other in any way.

When a new `top-level browsing context` is created by a script in an existing `browsing context`, or by the user following a link in an existing browsing context, or in some other way related to a specific `DocumentWindow`, then, if the new context's first `DocumentWindow` has the same `domain` as the `DocumentWindow` from which the new context was created, the new browsing context must start with a single session storage area. That storage area must be a copy of that domain's session storage area in the original browsing context, which from that point on must be considered separate, with the two storage areas not affecting each other in any way.

When the `setItem()` method is called on a `Storage` object `x` that is associated with a session storage area, then in every `DocumentWindow` object whose `Window` object's `sessionStorage` attribute's `Storage` object is associated with the same storage area, other than `x`, a `storage` event must be fired, as [described below](#).

4.8.4. The `globalStorage` attribute

```
interface StorageList {
  Storage getDomain(in DOMString domain);
};
```

The `globalStorage` object provides a `Storage` object for each domain.

In the ECMAScript binding, `StorageList` objects must support dereferencing such that getting a property that is not a member of the object (i.e. is neither a member of the `StorageList` interface nor of `Object`) must invoke the `getDomain()` method with the property's name as the argument.

User agents must have a set of global storage areas, one for each domain.

◀ 02 ▶
2004 2006 2007

About this capture

storing user-written documents.

The `getDomain(domain)` method tries to returns a `Storage` object associated with the given domain, according to the rules that follow.

The `domain` must first be split into an array of strings, by splitting the string at "." characters (U+002E FULL STOP). If the `domain` argument is the empty string, then the array is empty as well. If the `domain` argument is not empty but has no dots, then the array has one item, which is equal to the `domain` argument. If the `domain` argument contains consecutive dots, there will be empty strings in the array (e.g. the string "hello..world" becomes split into the three strings "hello", "", and "world", with the middle one being the empty string).

Each component of the array must then have the IDNA ToASCII algorithm applied to it, with both the `AllowUnassigned` and `UseSTD3ASCIIRules` flags set. [RFC3490] If ToASCII fails to convert one of the components of the string, e.g. because it is too long or because it contains invalid characters, then the user agent must raise a `SYNTAX_ERR` exception. [DOM3CORE] The components after this step consist of only US-ASCII characters.

The components of the array must then be converted to lowercase. Since only US-ASCII is involved at this step, this only requires converting characters in the range A-Z to the corresponding characters in the range a-z.

The resulting array is used in a comparison with another array, as described below. In addition, its components are concatenated together, each part separated by a dot (U+002E), to form the **normalised requested domain**.

If the original `domain` was "Åsgård.Example.Com", then the resulting array would have the three items "xn--sgrd-poac", "example", and "com", and the normalised requested domain would be "xn--sgrd-poac.example.com".

Next, the `script's own domain` is processed to find if it is allowed to access the requested domain.

If the script's domain name is not known, e.g. if only the server's IP address is known, and the **normalised requested domain** is not the empty string, then the user agent must raise a security exception.

Note: If the **normalised requested domain** is the empty string, then the rest of this algorithm can be skipped. This is because in that situation, the comparison of the two arrays below will always find them to be the same — the first array in such a situation is also empty and so permission to access that storage area will always be given.

If the script's domain contains no dots (U+002E) then the string ".localdomain" must be appended to the script's domain.

Then, the script's domain must be turned into an array, being split, converted to ASCII, and lowercased as described for the `domain` argument [above](#).

Of the two arrays, the longest one must then be shortened to the length of the shorter one, by dropping items from the start of the array.

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

If the two arrays are not component-for-component identical in literal string comparisons, then the user agent must then raise a security exception.

Otherwise, the user agent must check to see if it has allocated global storage area for the [normalised requested domain](#). If it has not, a new storage area for that domain must be created.

The user agent must then create a [Storage](#) object associated with that domain's global storage area, and return it.

When the requested *domain* is a top level domain, or the empty string, or a country-specific sub-domain like "co.uk" or "ca.us", the associated global storage area is known as **public storage area**

The [setItem\(\)](#) method might be called on a [Storage](#) object that is associated with a global storage area for a domain *d*, created by a [StorageList](#) object associated with a [Window](#) object *x*. Whenever this occurs, a [storage](#) event must be fired, as described below, in every [DocumentWindow](#) object that matches the following conditions:

- Its [Window](#) object is not *x*, and
- Its [Window](#) object's [globalStorage](#) attribute's [StorageList](#) object's [getDomain\(\)](#) method would not raise a security exception according to the rules above if it was invoked with the domain *d*.

In other words, every other document that has access to that domain's global storage area is notified of the change.

4.8.5. The [storage](#) event

The [storage](#) event is fired in a [DocumentWindow](#) when a storage area changes, as described in the previous two sections ([for session storage](#), [for global storage](#)).

When this happens, a [storage](#) event in the <http://www.w3.org/2001/xml-events> namespace, which bubbles, is not cancelable, has no default action, and which uses the [StorageEvent](#) interface described below, must be fired on [the body element](#), or, if there isn't one, on the [DocumentWindow](#) object itself.

However, it is possible (indeed, for session storage areas, likely) that the target [DocumentWindow](#) object is not active at that time. For example, it might not be the [current entry](#) in the session history; user agents typically stop scripts from running in pages that are in the history. In such cases, the user agent must instead delay the firing of the event until such time as the [DocumentWindow](#) object in question becomes active again.

When there are multiple delayed [storage](#) events for the same [DocumentWindow](#) object, user agents should coalesce events with the same [domain](#) value (dropping duplicates).

If the DOM of a page that has delayed [storage](#) events queued up is [discarded](#), then the delayed events are dropped as well.

```
interface StorageEvent : Event {
  readonly attribute DOMString domain;
```

```
void initStorageEventNS(in DOMString namespaceURIArg,
                        in DOMString typeArg,
                        in boolean canBubbleArg,
                        in boolean cancelableArg,
                        in DOMString domainArg);
};
```

The `initStorageEvent()` and `initStorageEventNS()` methods must initialise the event in a manner analogous to the similarly-named methods in the DOM3 Events interfaces. [\[DOM3EVENTS\]](#)

The `domain` attribute of the `StorageEvent` event object must be set to the name of the domain associated with the storage area that changed if that storage area is a global storage area, or the string "`#session`" if it was a session storage area.

4.8.6. Miscellaneous implementation requirements for storage areas

4.8.6.1. Disk space

User agents should limit the total amount of space allowed for a domain based on the domain of the page setting the value.

User agents should not limit the total amount of space allowed on a per-storage-area basis, otherwise a site could just store data in any number of subdomains, e.g. storing up to the limit in `a1.example.com`, `a2.example.com`, `a3.example.com`, etc, circumventing per-domain limits.

User agents should consider additional quota mechanisms (for example limiting the amount of space provided to a domain's subdomains as a group) so that hostile authors can't run scripts from multiple subdomains all adding data to the global storage area in an attempted denial-of-service attack.

User agents may prompt the user when per-domain space quotas are reached, allowing the user to grant a site more space. This enables sites to store many user-created documents on the user's computer, for instance.

User agents should allow users to see how much space each domain is using.

If the storage area space limit is reached during a `setItem()` call, the user agent should raise an exception.

A mostly arbitrary limit of five megabytes per domain is recommended. Implementation feedback is welcome and will be used to update this suggestion in future.

4.8.6.2. Threads

Multiple browsing contexts must be able to access the global storage areas simultaneously in a predictable manner. Scripts must not be able to detect any concurrent script execution.

This is required to guarantee that the `length` attribute of a `Storage` object never changes while a script is executing, other than in a way that is predictable by the script itself.

There are various ways of implementing this requirement. One is that if a script running in one browsing context accesses a global storage area, the UA blocks scripts in other browsing contexts

About this capture

efficient but probably more complex) implementation strategy is to use optimistic transactional script execution. This specification does not require any particular implementation strategy, so long as the requirement above is met.

4.8.7. Security and privacy

4.8.7.1. User tracking

A third-party advertiser (or any entity capable of getting content distributed to multiple sites) could use a unique identifier stored in its domain's global storage area to track a user across multiple sessions, building a profile of the user's interests to allow for highly targeted advertising. In conjunction with a site that is aware of the user's real identity (for example an e-commerce site that requires authenticated credentials), this could allow oppressive groups to target individuals with greater accuracy than in a world with purely anonymous Web usage.

The `globalStorage` object also introduces a way for sites to cooperate to track users over multiple domains, by storing identifying data in "`public`" top-level domain storage area, accessible by any domain.

There are a number of techniques that can be used to mitigate the risk of user tracking:

- Blocking third-party storage: user agents may restrict access to the `globalStorage` object to scripts originating at the domain of the top-level document of the `browsing context`.

This blocks a third-party site from using its private storage area for tracking a user, but top-level sites could still cooperate with third parties to perform user tracking by using the "`public`" storage area.

- Expiring stored data: user agents may automatically delete stored data after a period of time.

For example, a user agent could treat the global storage area as session-only storage, deleting the data once the user had closed all the browsing contexts that could access it.

This can restrict the ability of a site to track a user, as the site would then only be able to track the user across multiple sessions when he authenticates with the site itself (e.g. by making a purchase or logging in to a service).

- Blocking access to the top-level domain ("`public`") storage areas: user agents may prevent domains from storing data in and reading data from the top-level domain entries in the `globalStorage` object.

In practice this requires a detailed list of all the "public" second-level (and third-level) domains. For example, content at the domain `www.example.com` would be allowed to access `example.com` data but not `.com` data; content at the domain `example.co.uk` would be allowed access to `example.co.uk` but not `.co.uk` or `uk`; and content at `example.chiyoda.tokyo.jp` would be allowed access to `example.chiyoda.tokyo.jp` but not `chiyoda.tokyo.jp`, `tokyo.jp`, or `jp`, while content at `example.metro.tokyo.jp` would be allowed access to both `example.metro.tokyo.jp` and `metro.tokyo.jp` but not `tokyo.jp` or `jp`. The problem is even more convoluted when one considers private domains with third-party subdomains such as `dyndns.org` or `uk.com`.

About this capture

feature to the user in a way that does not distinguish it from HTTP session cookies.

[RFC2965]

This might encourage users to view persistent storage with healthy suspicion.

- Site-specific white-listing of access to "[public](#)" storage area: user agents may allow sites to access persistent storage for their own domain and subdomains in an unrestricted manner, but require the user to authorise access to the storage area of higher-level domains.

For example, code at `example.com` would be always allowed to read and write data for `www.example.com` and `example.com`, but if it tried to access `.com`, the user agent could display a non-modal message informing the user that the page requested access to `.com` and offering to allow it.

- Origin-tracking of persistent storage data: user agents may record the domain of the script that caused data to be stored.

If this information is then used to present the view of data currently in persistent storage, it would allow the user to make informed decisions about which parts of the persistent storage to prune. Combined with a blacklist ("delete this data and prevent this domain from ever storing data again"), the user can restrict the use of persistent storage to sites that he trusts.

- Shared blacklists: user agents may allow users to share their persistent storage domain blacklists.

This would allow communities to act together to protect their privacy.

While these suggestions prevent trivial use of this API for user tracking, they do not block it altogether. Within a single domain, a site can continue to track the user across multiple sessions, and can then pass all this information to the third party along with any identifying information (names, credit card numbers, addresses) obtained by the site. If a third party cooperates with multiple sites to obtain such information, a profile can still be created.

However, user tracking is to some extent possible even with no cooperation from the user agent whatsoever, for instance by using session identifiers in URLs, a technique already commonly used for innocuous purposes but easily repurposed for user tracking (even retroactively). This information can then be shared with other sites, using visitors' IP addresses and other user-specific data (e.g. user-agent headers and configuration settings) to combine separate sessions into coherent user profiles.

4.8.7.2. *Cookie resurrection*

If the user interface for persistent storage presents data in the persistent storage feature separately from data in HTTP session cookies, then users are likely to delete data in one and not the other. This would allow sites to use the two features as redundant backup for each other, defeating a user's attempts to protect his privacy.

4.8.7.3. *Integrity of "public" storage areas*

Since the "[public](#)" global storage areas are accessible by content from many different parties, it is possible for third-party sites to delete or change information stored in those areas in ways that the originating sites may not expect.

2004 2006 2007

About this capture

This API makes no distinction between content served over HTTP, HTTPS, FTP, or other host-based protocols, and does not distinguish between content served from different ports at the same host.

Thus, for example, data stored in the global persistent storage for domain "secure.example.com" by a page served over SSL from <https://secure.example.com/> will be accessible from a page served in plain text from <http://example.com/>.

Since the data is not sent over the wire by the user agent, this is not a security risk in its own right. However, authors must take proper steps to ensure that all hosts that have fully qualified host names that are subsets of hosts dealing with sensitive information are as secure as the secure hosts themselves.

Similarly, authors must ensure that all Web servers on a host, regardless of the port, are equally trusted if any of them are to use persistent storage. For instance, if a Web server runs a production service that makes use of the persistent storage feature, then other users that have access to that machine and that can run a Web server on another port will be able to access the persistent storage added by the production service (assuming they can trick a user into visiting their page).

However, if one is able to trick users into visiting a Web server with the same host name but on a different port as a production service used by these users, then one could just as easily fake the look of the site and thus trick users into authenticating with the fake site directly, forwarding the request to the real site and stealing the credentials in the process. Thus, the persistent storage feature is considered to only minimally increase the risk involved.

4.8.7.5. Cross-directory attacks

Different authors sharing one host name, for example users hosting content on geocities.com, all share one persistent storage object. There is no feature to restrict the access by pathname. Authors on shared hosts are therefore recommended to avoid using the persistent storage feature, as it would be trivial for other authors to read from and write to the same storage area.

4.8.7.6. Implementation risks

The two primary risks when implementing this persistent storage feature are letting hostile sites read information from other domains, and letting hostile sites write information that is then read from other domains.

Letting third-party sites read data that is not supposed to be read from their domain causes *information leakage*. For example, a user's shopping wishlist on one domain could be used by another domain for targeted advertising; or a user's work-in-progress confidential documents stored by a word-processing site could be examined by the site of a competing company.

Letting third-party sites write data to the storage areas of other domains can result in *information spoofing*, which is equally dangerous. For example, a hostile site could add items to a user's wishlist; or a hostile site could set a user's session identifier to a known ID that the hostile site can then use to track the user's actions on the victim site.

A risk is also presented by servers on local domains having host names matching top-level domain names, for instance having a host called "com" or "net". Such hosts might, if implementations fail to correctly implement the `.localdomain` suffixing, have full access to all the data stored in a UA's

About this capture

4.9. [SCS] Browser state

The `navigator` attribute of the `Window` interface must return an instance of the `ClientInformation` interface, which represents the identity and state of the user agent (the client):

```
interface ClientInformation {
    readonly attribute boolean onLine;
};
```

The `navigator.onLine` attribute must return false if the user agent will not contact the network when the user follows links or when a script requests a remote page (or knows that such an attempt would fail), and must return true otherwise.

The `offline` event must be fired when the value of the `navigator.onLine` attribute of the `Window` changes from true to false.

The `online` event must be fired when the value of the `navigator.onLine` attribute of the `Window` changes from false to true.

These events are in the `http://www.w3.org/2001/xml-events` namespace, do bubble, are not cancelable, have no default action, and use the normal Event interface. They must be fired on `the body element`, or, if there isn't a "`the body element`", on the `DocumentWindow` object. (As the events bubble, they will reach the `Window` object.)

4.10. [SCS] Alternate style sheets: the `DocumentStyle` interface

This specification extends the `DocumentStyle` interface introduced in DOM2 Style. [\[DOM2STYLE\]](#)

```
// Introduced in DOM Level 2: [DOM2STYLE]
interface DocumentStyle {
    readonly attribute StyleSheetList styleSheets;

    // New in this specification:
    attribute DOMString selectedStylesheetSet;
    readonly attribute DOMString lastStylesheetSet;
    readonly attribute DOMString preferredStylesheetSet;
    readonly attribute DOMStringList stylesheetSets;
    void enableStylesheetsForSet(in DOMString name);
};
```

For this interface, the `DOMString` values "null" and "the empty string" are distinct, and must not be considered equivalent.

The new members are defined as follows:

`selectedStylesheetSet` of type `DOMString`

3,445 captures
5 Jun 2004 - 22 Aug 2020

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

the value of this attribute shall be exactly equal to the title of the first enabled style sheet with a title in the `styleSheets` list. If style sheets from different sets are enabled, then the return value shall be `null` (there is no way to determine what the currently selected style sheet set is in those conditions). Otherwise, either all style sheets are disabled, or there are no alternate style sheets, and `selectedStylesheetSet` must return the empty string.

Setting this attribute to the `null` value shall have no effect.

Setting this attribute to a non-`null` value must call `enableStylesheetsForSet()` with that value as the function's argument, then set `lastStylesheetSet` to that value.

From the DOM's perspective, all views have the same `selectedStylesheetSet`. If a UA supports multiple views with different selected alternate style sheets, then this attribute (and the `StyleSheet` interface's `disabled` attribute) must return and set the value for the default view.

`lastStylesheetSet` of type `DOMString`, `readonly`

This property shall return the last value that `selectedStylesheetSet` was set to, or, if none, `null`.

`preferredStylesheetSet` of type `DOMString`, `readonly`

This attribute shall indicate the preferred style sheet set as set by the author. It is determined from the order of style sheet declarations and the `Default-Style` HTTP headers. [HTML4]. If there is no preferred style sheet set, this attribute must return the empty string. The case of this attribute must exactly match the case given by the author where the preferred style sheet is specified or implied. This attribute must never return `null`.

`stylesheetSets` of type `DOMStringList`, `readonly`

This must return the live list of the currently available style sheet sets. This list is constructed by enumerating all the style sheets for this document available to the implementation, in the order they are listed in the `styleSheets` attribute, adding the title of each style sheet with a title to the list, avoiding duplicates by dropping titles that match (case insensitively) titles that have already been added to the list.

`enableStylesheetsForSet(name)`, `method`

Calling this method must change the `disabled` attribute on each `StyleSheet` object with a title attribute with a length greater than 0 in the `styleSheets` attribute, so that all those whose title matches the `name` argument are enabled, and all others are disabled. Title matches are case insensitive. Calling this method with the empty string disables all alternate and preferred style sheets (but does not change the state of persistent style sheets, that is those with no title attribute).

Calling this method with a `null` value must have no effect.

Style Sheets that have no title are never affected by this method. This method does not change the values of the `lastStylesheetSet` or `preferredStylesheetSet` attributes.

4.10.1. Dynamically adding new style sheets

If new style sheets with titles are added to the document, the UA must decide whether or not the

3,445 captures
5 Jun 2004 - 22 Aug 2020

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

First, if the style sheet is a preferred style sheet (it has a title, but is not marked as alternate), and there is no current preferred style sheet (the `preferredstylesheetSet` attribute is equal to the empty string) then the `preferredstylesheetSet` attribute is set to the exact value of this style sheet's title. (This changes the preferred style sheet set, which causes further changes — see below.)

Then, for all sheets, if any of the following is true, then the style sheet must be enabled:

- The style sheet has an empty title.
- The `laststylesheetSet` is null, and the style sheet's title matches (by case insensitive match) the value of the `preferredstylesheetSet` attribute.
- The style sheet's title matches (by case insensitive match) the value of the `laststylesheetSet` attribute.

Otherwise, the style sheet must be disabled.

4.10.1.2. Changing the preferred style sheet set

If the UA has the preferred style sheet set changed, for example if it receives a "Default-Style:" HTTP header after it receives HTTP "Link:" headers implying another preferred style sheet, then the `preferredstylesheetSet` attribute's value must be changed appropriately, and, if the `laststylesheetSet` is null, the `enableStylesheetsForSet()` method must be called with the new `preferredstylesheetSet` value. (The `laststylesheetSet` attribute is not changed.)

4.10.1.3. Examples

Thus, in the following HTML snippet:

```
<link rel="alternate stylesheet" title="foo" href="a">
<link rel="alternate stylesheet" title="bar" href="b">
<script>
    document.selectedstylesheetSet = 'foo';
    document.styleSheets[1].disabled = false;
</script>
<link rel="alternate stylesheet" title="foo" href="c">
<link rel="alternate stylesheet" title="bar" href="d">
```

...the style sheets that end up enabled are style sheets "a", "b", and "c", the `selectedstylesheetSet` attribute would return null, `laststylesheetSet` would return "foo", and `preferredstylesheetSet` would return "".

Similarly, in the following HTML snippet:

```
<link rel="alternate stylesheet" title="foo" href="a">
<link rel="alternate stylesheet" title="bar" href="b">
<script>
    var before = document.preferredstylesheetSet;
    document.styleSheets[1].disabled = false;
</script>
```

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

```
</script>
```

...the "before" variable will be equal to the empty string, the "after" variable will be equal to "foo", and style sheets "a" and "c" will be enabled. This is the case even though the first script block sets style sheet "b" to be enabled, because upon parsing the following `<link>` element, the `preferredstylesheetSet` is set and the `enableStylesheetsForSet()` method is called (since `selectedstylesheetSet` was never set explicitly, leaving `laststylesheetSet` at null throughout), which changes which style sheets are enabled and which are not.

4.10.2. Interaction with the User Interface

The user interface of Web browsers that support style sheets should list the style sheet titles given in the `stylesheetSets` list, showing the `selectedstylesheetSet` as the selected style sheet set, leaving none selected if it is null or the empty string, and selecting an extra option "Basic Page Style" (or similar) if it is the empty string and the `preferredstylesheetSet` is the empty string as well.

Selecting a style sheet from this list should set the `selectedstylesheetSet` attribute.

4.10.2.1. Persisting the selected style sheet set

If UAs persist the selected style sheet set, they should use the value of the `selectedstylesheetSet` attribute, or if that is null, the `laststylesheetSet` attribute, when leaving the page (or at some other time) to determine the set name to store. If that is null then the style sheet set should not be persisted.

When re-setting the style sheet set to the persisted value (which can happen at any time, typically at the first time the style sheets are needed for styling the document, after the `<head>` of the document has been parsed, after any scripts that are not dependent on computed style have executed), the style sheet set should be set by setting the `selectedstylesheetSet` attribute as if the user had selected the set manually.

Note: This specification does not give any suggestions on how UAs should decide to persist the style sheet set or whether or how to persist the selected set across pages.

4.10.3. Future compatibility

Future versions of CSS may introduce ways of having alternate style sheets declared at levels lower than the top level, i.e. embedded within other style sheets. Implementations of this specification that also support this proposed declaration of alternate style sheets are expected to perform depth-first traversals of the `styleSheets` list, not simply enumerations of the `styleSheets` list that only contains the top level.

5. Browser environment integration

The screenshot shows a search bar at the top left, followed by a 'Go' button, month abbreviations (DEC, JAN, FEB) with arrows for navigation, and user icons. Below this is a date range selector showing '02' in yellow, '2004', '2006', and '2007'. A 'About this capture' link is also present.

If an HTML element has a `contenteditable` attribute set to the empty string or the exact literal value `true`, or if its nearest ancestor with the `contenteditable` attribute set has its attribute set to the empty string or the exact the literal value `true`, then the UA must treat the element as **editable** (as described below).

If an HTML element has a `contenteditable` attribute set but the value of the attribute is not the empty string or the literal value `true`, or if its nearest ancestor with the `contenteditable` attribute set is not **editable**, or if it has no ancestor with the `contenteditable` attribute set, then the element is not editable.

Authors must only use the values `true` and `false` with the `contenteditable` attribute.

If an element is **editable** and its parent element is not, then the element is an **editing host**. Editable elements can be nested. User agents must make editing hosts focusable (which typically means they enter the `tab order`). An editing host can contain non-editable sections, these are handled as described below. An editing host can contain non-editable sections that contain further editing hosts.

When an editing host has focus, it must have a **caret position** that specifies where the current editing position is. It may also have a **selection**.

Note: How the caret and selection are represented depends entirely on the UA.

5.1.1. User editing actions

There are several actions that the user agent should allow the user to perform while the user is interacting with an editing host. How exactly each action is triggered is not defined for every action, but when it is not defined, suggested key bindings are provided to guide implementors.

Move the caret

User agents must allow users to move the caret to any position within an editing host, even into nested editable elements. This could be triggered as the default action of `keydown` events with various key identifiers and as the default action of `mousekeydown` events.

Change the selection

User agents must allow users to change **the selection** within an editing host, even into nested editable elements. This could be triggered as the default action of `keydown` events with various key identifiers and as the default action of `mousekeydown` events.

Insert text

This action must be triggered as the default action of a `textInput` event, and may be triggered by other commands as well. It must cause the user agent to insert the specified text (given by the event object's `data` attribute in the case of the `textInput` event) at the caret.

If the caret is positioned somewhere where **inline-level content** is not allowed (e.g. because the element accepts "both block-level and inline-level content but not both", and the element already contains block-level content), then the user agent must not insert the text directly at the caret position. In such cases the behaviour is UA-dependent, but user agents must not, in response to a request to insert text, generate a DOM that is less conformant than the DOM prior to the request.

3,445 captures
5 Jun 2004 - 22 Aug 2020

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

```
<section>
  <dl>
    <dt> Ben </dt>
    <dd> Goat </dd>
  </dl>
</section>
```

...the user agent should allow the user to insert p elements before and after the dl element, as children of the section element.

Break block

UAs should offer a way for the user to request that the current block be broken at the caret, e.g. as the default action of a `keydown` event whose identifier is the "Enter" key and that has no modifiers set.

The exact behaviour is UA-dependent, but user agents must not, in response to a request to break a block, generate a DOM that is less conformant than the DOM prior to the request.

Insert a line separator

UAs should offer a way for the user to request an explicit line break at the caret position without breaking the block, for example as in a poem verse or an address. To insert a line break, the user agent must insert a br element.

If the caret is positioned somewhere where inline-level content is not allowed (e.g. because the element accepts "both block-level and inline-level content but not both", and the element already contains block-level content), then the user agent must not insert the br element directly at the caret position. In such cases the behaviour is UA-dependent, but user agents must not, in response to a request to insert a line separator, generate a DOM that is less conformant than the DOM prior to the request.

Delete

UAs should offer a way for the user to delete text and elements, e.g. as the default action of `keydown` events whose identifiers are "U+0008" or "U+007F".

Five edge cases in particular need to be considered carefully when implementing this feature: backspacing at the start of an element, backspacing when the caret is immediately after an element, forward-deleting at the end of an element, forward-deleting when the caret is immediately before an element, and deleting a selection whose start and end points do not share a common parent node.

In any case, the exact behaviour is UA-dependent, but user agents must not, in response to a request to delete text or an element, generate a DOM that is less conformant than the DOM prior to the request.

Insert, and wrap text in, semantic elements

UAs should offer a way for the user to mark text as having stress emphasis and as being important, and may offer the user the ability to mark text and blocks with other semantics.

UAs should similarly offer a way for the user to insert empty semantic elements (such as, again, em, strong, and others) to subsequently fill by entering text manually.

The screenshot shows a navigation bar with a search input field, a 'Go' button, and month abbreviations (DEC, JAN, FEB) with arrows for navigation. Below the search is a link to '3,445 captures' and a date range from '5 Jun 2004 - 22 Aug 2020'. A large blue '02' indicates the current day. The year '2004' is in red, '2006' is in green, and '2007' is in blue. Social media links for GitHub, FAQ, and Twitter are at the top right. A 'About this capture' link is at the bottom right.

wrap semantics around some text or to insert or remove a semantic element, generate a DOM that is less conformant than the DOM prior to the request.

Select and move non-editable elements nested inside editing hosts

UAs should offer a way for the user to move images and other non-editable parts around the content within an editing host. This may be done using the [drag and drop](#) mechanism. User agents must not, in response to a request to move non-editable elements nested inside editing hosts, generate a DOM that is less conformant than the DOM prior to the request.

Edit form controls nested inside editing hosts

When an [editable](#) form control is edited, the changes must be reflected in both its current value *and* its default value. For `input` elements this means updating the `defaultValue` DOM attribute as well as the `value` DOM attribute; for `select` elements it means updating the `option` elements' `defaultSelected` DOM attribute as well as the `selected` DOM attribute; for `textarea` elements this means updating the `defaultValue` DOM attribute as well as the `value` DOM attribute. (Updating the `default*` DOM attributes causes content attributes to be updated as well.)

User agents may perform several commands per user request; for example if the user selects a block of text and hits `Enter`, the UA might interpret that as a request to delete the content of [the selection](#) followed by a request to break the block at that position.

5.2. [SCS] Drag and drop

This section defines an event-based drag-and-drop mechanism.

This specification does not define exactly what a *drag and drop operation* actually is.

On a visual medium with a pointing device, a drag operation could be the default action of a `mousedown` event that is followed by a series of `mousemove` events, and the drop could be triggered by the mouse being released.

On media without a pointing device, the user would probably have to explicitly indicate his intention to perform a drag-and-drop operation, stating what he wishes to drag and what he wishes to drop, respectively.

However it is implemented, drag and drop operations must have a starting point (e.g. where the mouse was clicked, or the start of [the selection](#) or element that was selected for the drag), may have any number of intermediate steps (elements that the mouse moves over during a drag, or elements that the user picks as possible drop points as he cycles through possibilities), and must either have an end point (the element above which the mouse button was released, or the element that was finally selected), or be canceled. The end point must be the last element selected as a possible drop point before the drop occurs (so if the operation is not canceled, there must be at least one element in the middle step).

5.2.1. Drag-and-drop processing model

There are two processing models for drag-and-drop: one for when a drag is initiated within the document, and one for when a drag is initiated in another (DOM-based) document or another application altogether, but the user has selected a node in the document as a drop target.

3,445 captures
5 Jun 2004 - 22 Aug 2020

DEC JAN FEB
02 2004 2006 2007

About this capture

dragged. Otherwise, it is the first element, going up the ancestor chain, starting at the node that the user tried to drag, that has the DOM attribute `draggable` set to true. If there is no such element, then nothing is being dragged, the drag-and-drop operation is never started, and the user agent must not continue with this algorithm.

If the user agent determines that something can be dragged, a `dragstart` event must then be fired.

If it is a selection that is being dragged, then this event must be fired on the node that the user started the drag on (typically the text node that the user originally clicked). If the user did not specify a particular node, for example if the user just told the user agent to begin a drag of "the selection", then the event must be fired on the deepest node that is a common ancestor of all parts of the selection.

If it is not a selection that is being dragged, then the event must be fired on the element that is being dragged.

The node on which the event is fired is the **source node**. Multiple events are fired on this node during the course of the drag-and-drop operation.

The `dataTransfer` member of the event must initially contain no nodes if a selection is being dragged, and just the **source node** otherwise.

If the event is canceled, then the drag and drop operation must not occur; the user agent must not continue with this algorithm.

If it is not canceled, then the drag and drop operation must be initiated.

Note: Since events with no event handlers registered are, almost by definition, never canceled, drag and drop is always available to the user if the author does not specifically prevent it.

The drag-and-drop feedback must be generated from the selection if the user is dragging a selection, or from the nodes that were in the `dataTransfer` object's list after the event has been handled otherwise. In visual media, if an image was specified, then that image must be used instead.

The user agent must take a note of the data that was placed in the `dataTransfer` object.

From this point until the end of the drag-and-drop operation, mouse and key events must be suppressed. In addition, the user agent must track all DOM changes made during the drag-and-drop operation, and add them to its `undo history` as one atomic operation once the drag-and-drop operation has ended.

During the drag operation, the element directly indicated by the user as the drop target is called the **immediate user selection**. (Only elements can be selected by the user; other nodes must not be made available as drop targets.)

However, the `immediate user selection` is not necessarily the element the **current target element**, the element currently selected for the drop part of the drag-and-drop operation.

The `immediate user selection` changes as the user selects different elements (either by pointing at

3,445 captures

◀ 02 ▶
2004 2006 2007

About this capture

Both the [current target element](#) and the [immediate user selection](#) can be null, which means no target element is selected. They can also both be elements in other (DOM-based) documents, or other (non-Web) programs altogether. (For example, a user could drag text to a word-processor.) The [current target element](#) is initially null.

In addition, there is also a **current drag operation**, which can take on the values "none", "copy", "link", and "move". Initially it has the value "none". It is updated by the user agent as described in the steps below.

User agents must, every 350ms ($\pm 200\text{ms}$), perform the following steps in sequence. (If the user agent is still performing the previous iteration of the sequence when the next iteration becomes due, the user agent must not execute the overdue iteration, effectively "skipping missed frames" of the drag and drop operation.)

1. First, the user agent must fire a [drag](#) event at the [source node](#).
2. Next, if the [drag](#) event was not canceled and the user has not ended the drag-and-drop operation, the user agent must check the state of the drag-and-drop operation, as follows:
 1. First, if the user is indicating a different [immediate user selection](#) than during the last iteration (or if this is the first iteration), and if this [immediate user selection](#) is not the same as the [current target element](#), then the [current target element](#) must be updated, as follows:
 1. If the new [immediate user selection](#) is null, or is in a non-DOM document or application, then set the [current target element](#) to the same value.
 2. Otherwise, the user agent must fire a [dragenter](#) event at the [immediate user selection](#).
 3. If the event is canceled, then the [current target element](#) must be set to the [immediate user selection](#).
 4. Otherwise, if the [current target element](#) is not [the body element](#), the user agent must fire a [dragenter](#) event at [the body element](#), and the [current target element](#) must be set to [the body element](#), regardless of whether the event was canceled or not.
 2. If the previous step caused the [current target element](#) to change, and if the previous target element was not null or a part of a non-DOM document, the user agent must fire a [dragleave](#) event at the previous target element.
 3. If the [current target element](#) is a DOM element, the user agent must fire a [dragover](#) event at this [current target element](#).

If the [dragover](#) event is not canceled, the [dataTransfer](#) object's `dropEffect` attribute must then be reset to the value it was given when the event was fired.

Then, regardless of whether the event was canceled or not, the drag feedback (e.g. the mouse cursor) must be updated to match the kind of drag-and-drop operation indicated by the event's [dataTransfer](#) object's `dropEffect` attribute, as follows:

3,445 captures
5 Jun 2004 - 22 Aug 2020

link	Data will be linked.
move	Data will be moved.

The drag operation in question is the new [current drag operation](#).

4. Otherwise, if the [current target element](#) is not a DOM element, the user agent must use platform-specific mechanisms to determine what drag operation is being performed (none, copy, link, or move). This sets the [current drag operation](#).
3. Otherwise, if the user ended the drag and drop operation (e.g. by releasing the mouse button in a mouse-driven drag-and-drop interface), then this will be the last iteration. The user agent should follow the following steps, then stop looping.
 1. If the [current drag operation](#) is none (no drag operation), or, if the user ended the drag-and-drop operation by canceling it (e.g. by hitting the `Escape` key), or if the [current target element](#) is null, then the drag operation failed. If the [current target element](#) is a DOM element, the user agent must fire a [dragleave](#) event at it; otherwise, if it is not null, it must use platform-specific conventions for drag cancellation.
 2. Otherwise, the drag operation was as success. If the [current target element](#) is a DOM element, the user agent must fire a [drop](#) event at it; otherwise, it must use platform-specific conventions for indicating a drop.

When the target is a DOM element, the `dropEffect` attribute of the event's `dataTransfer` object must be given the value representing the [current drag operation](#) (copy, link, or move), and the object must be set up so that the `getData()` method will return the data that was added during the [dragstart](#) event.

Some elements have a default behaviour for "drop", e.g. `textarea` receives new text.
Cancelable.

3. Finally, the user agent must fire a [dragend](#) event at the [source node](#).

Some elements have a default behaviour for "dragend", e.g. `textarea` deletes source text in a move. NOT cancelable.

The events must be fired as described above, even if the nodes are in different documents (assuming those are DOM-based). User agents should handle cases where the target is not in a DOM-based document according to the platform conventions.

5.2.1.2. For drags initiated in other documents or applications [TBW]

...

5.2.2. The `draggable` attribute [TBW]

...

Go DEC JAN FEB

elements, the default is false.

5.2.3. The DragEvent interface and the dataTransfer object [WIP]

Need to define DragEvent interface.

```
interface DataTransfer {
    attribute DOMString dropEffect;
    attribute DOMString effectAllowed;
    void clearData(in DOMString format);
    void setData(in DOMString format, in DOMString data);
    DOMString getData(in DOMString format);

    // XXX addElement, dragImage, etc
};
```

Need to define DataTransfer members

When a `DragEvent` event object is initialised by the user agent for the purposes of the drag-and-drop model described above (as opposed to when a custom `DragEvent` event object is created by author script), the object must be initialised as follows.

- Its `dataTransfer` member must be initialised to a new instance of a `DataTransfer` object.
- That object must initially contain no elements and have no associated image.
- The `dataTransfer` object's `effectAllowed` attribute must be set to "uninitialized" for `dragstart` events, and to whatever value the field had after the last drag-and-drop event was fired for all other events (only counting events fired by the user agent for the purposes of the drag-and-drop model described above).
- The `dropEffect` attribute must be set to "none" for `dragstart`, `drag`, `dragleave`, and `dragend` events (except when stated otherwise in the algorithms given in the earlier sections), and to a value based on the `effectAllowed` attribute's value and to the drag-and-drop source, as given by the following table, for other events:

effectAllowed	dropEffect
none	none
copy, copyLink, copyMove, all	copy
link, linkMove	link
move	move
uninitialised when what is being dragged is a selection from a text field	move
uninitialised when what is being dragged is a selection	copy
uninitialised when what is being dragged is an <code>a</code> element with an <code>href</code> attribute	link
Any other case	copy

The following events are involved in the drag-and-drop model. They all use the `DragEvent` interface.

Event Name	Target	Bubbles?	Cancelable?	dataTransfer	effectAllowed	dropEffect
<code>dragstart</code>	Source node	✓ Bubbles	✓ Cancelable	Contains source node unless a selection is being dragged, in which case it is empty	uninitialized	none
<code>drag</code>	Source node	✓ Bubbles	✓ Cancelable	—	Same as last event	none
<code>dragenter</code>	Immediate user selection or the body element	✓ Bubbles	✓ Cancelable	—	Same as last event	Based on effectAllowed value
<code>dragleave</code>	Previous target element	✓ Bubbles	—	—	Same as last event	none
<code>dragover</code>	Current target element	✓ Bubbles	✓ Cancelable	—	Same as last event	Based on effectAllowed value
<code>drop</code>	Current target element	✓ Bubbles	✓ Cancelable	getData () returns data set in dragstart event	Same as last event	Current drag operation
<code>dragend</code>	Source node	✓ Bubbles	✓ Cancelable	—	Same as last event	none

5.3. [SCS] Undo history

There has got to be a better way of doing this, surely.

The user agent must associate an **undo transaction history** with each [DocumentWindow](#) object.

The [undo transaction history](#) is a list of entries. The entries are of two type: [DOM changes](#) and [undo objects](#).

Each **DOM changes** entry in the [undo transaction history](#) consists of batches of one or more of the

3,445 captures
5 Jun 2004 - 22 Aug 2020

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

- Changes to the [DOM attributes](#) of a Node.
- Changes to the DOM hierarchy of nodes that are descendants of the [DocumentWindow](#) object (`parentNode`, `childNodes`).

Undo object entries consist of objects representing state that scripts running in the document are managing. For example, a Web mail application could use an [undo object](#) to keep track of the fact that a user has moved an e-mail to a particular folder, so that the user can undo the action and have the e-mail return to its former location.

Broadly speaking, [DOM changes](#) entries are handled by the UA in response to user edits of form controls and editing hosts on the page, and [undo object](#) entries are handled by script in response to higher-level user actions (such as interactions with server-side state, or in the implementation of a drawing tool).

5.3.1. The [UndoManager](#) interface

This API sucks. Seriously. It's a terrible API. Really bad. I hate it. Here are the requirements:

- Has to cope with cases where the server has undo state already when the page is loaded, that can be stuffed into the undo buffer onload.
- Has to support undo/redo.
- Has to cope with the "undo" action being "contact the server and tell it to undo", rather than it being the opposite of the "redo" action.
- Has to cope with some undo states expiring from the undo history (e.g. server can only remember one undelete action) but other states not expiring (e.g. client can undo arbitrary amounts of local edits).

To manage [undo object](#) entries in the [undo transaction history](#), the [UndoManager](#) interface can be used:

```
interface UndoManager {
    unsigned long add(in DOMObject data, in DOMString title);
    void remove(in unsigned long index);
    void clearUndo();
    void clearRedo();
    DOMObject item(in unsigned long index);
    readonly attribute unsigned long length;
    readonly attribute unsigned long position;
};
```

The `undoManager` attribute of the [Window](#) interface must return the object implementing the [UndoManager](#) interface for that [Window](#) object's associated [DocumentWindow](#) object.

In the ECMAScript binding, objects implementing this interface must also support being dereferenced using the square bracket notation, such that dereferencing with an integer index is

3,445 captures

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

are visible with this API, but this does not mean that [DOM changes](#) entries are absent from the [undo transaction history](#).

The `length` attribute must return the number of [undo object](#) entries in the [undo transaction history](#).

The `item(n)` method must return the *n*th [undo object](#) entry in the [undo transaction history](#).

The [undo transaction history](#) has a **current position**. This is the position between two entries in the [undo transaction history](#)'s list where the previous entry represents what needs to happen if the user invokes the "undo" command (the "undo" side, lower numbers), and the next entry represents what needs to happen if the user invokes the "redo" command (the "redo" side, higher numbers).

The `position` attribute must return the index of the [undo object](#) entry nearest to the [undo position](#), on the "redo" side. If there are no [undo object](#) entries on the "redo" side, then the attribute must return the same as the `length` attribute. If there are no [undo object](#) entries on the "undo" side of the [undo position](#), the `position` attribute returns zero.

Note: Since the [undo transaction history](#) contains both [undo object](#) entries and [DOM changes](#) entries, but the `position` attribute only returns indices relative to [undo object](#) entries, it is possible for several "undo" or "redo" actions to be performed without the value of the `position` attribute changing.

The `add(data, title)` method's behaviour depends on the current state. Normally, it must insert the `data` object passed as an argument into the [undo transaction history](#) immediately before the [undo position](#), optionally remembering the given `title` to use in the UI. If the method is called [during an undo operation](#), however, the object must instead be added immediately *after* the [undo position](#).

If the method is called and there is neither [an undo operation in progress](#) nor [a redo operation in progress](#) then any entries in the [undo transaction history](#) after the [undo position](#) must be removed (as if `clearRedo()` had been called).

We could fire events when someone adds something to the undo history -- one event per undo object entry before the position (or after, during redo addition), allowing the script to decide if that entry should remain or not. Or something. Would make it potentially easier to expire server-held state when the server limitations come into play.

The `remove(index)` method must remove the [undo object](#) entry with the specified `index`. If the index is less than zero or greater than or equal to `length` then the method must raise an `INDEX_SIZE_ERR` exception. [DOM changes](#) entries are unaffected by this method.

The `clearUndo()` method must remove all entries in the [undo transaction history](#) before the [undo position](#), be they [DOM changes](#) entries or [undo object](#) entries.

The `clearRedo()` method must remove all entries in the [undo transaction history](#) after the [undo position](#), be they [DOM changes](#) entries or [undo object](#) entries.

Another idea is to have a way for scripts to say "startBatchingDOMChangesForUndo()" and after that the changes to the DOM go in as if the user had done them.

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

If the [undo position](#) is at the start of the [undo transaction history](#), then the user agent must do nothing.

If the entry immediately before the [undo position](#) is a [DOM changes](#) entry, then the user agent must remove that [DOM changes](#) entry, reverse the DOM changes that were listed in that entry, and, if the changes were reversed with no problems, add a new [DOM changes](#) entry (consisting of the opposite of those DOM changes) to the [undo transaction history](#) on the other side of the [undo position](#).

If the DOM changes cannot be undone (e.g. because the DOM state is no longer consistent with the changes represented in the entry), then the user agent must simply remove the [DOM changes](#) entry, without doing anything else.

If the entry immediately before the [undo position](#) is an [undo object](#) entry, then the user agent must first remove that [undo object](#) entry from the [undo transaction history](#), and then must fire an [undo](#) event on the `Document` object, using the [undo object](#) entry's associated undo object as the event's data.

Any calls to `add()` while the event is being handled will be used to populate the redo history, and will then be used if the user invokes the "redo" command to undo his undo.

5.3.3. Redo: moving forward in the undo transaction history

When the user invokes a redo operation, or when the `execCommand()` method is called with the `redo` command, the user agent must perform a redo operation.

This is mostly the opposite of an [undo operation](#), but the full definition is included here for completeness.

If the [undo position](#) is at the end of the [undo transaction history](#), then the user agent must do nothing.

If the entry immediately after the [undo position](#) is a [DOM changes](#) entry, then the user agent must remove that [DOM changes](#) entry, reverse the DOM changes that were listed in that entry, and, if the changes were reversed with no problems, add a new [DOM changes](#) entry (consisting of the opposite of those DOM changes) to the [undo transaction history](#) on the other side of the [undo position](#).

If the DOM changes cannot be redone (e.g. because the DOM state is no longer consistent with the changes represented in the entry), then the user agent must simply remove the [DOM changes](#) entry, without doing anything else.

If the entry immediately after the [undo position](#) is an [undo object](#) entry, then the user agent must first remove that [undo object](#) entry from the [undo transaction history](#), and then must fire a `redo` event on the `Document` object, using the [undo object](#) entry's associated undo object as the event's data.

5.3.4. The `UndoManagerEvent` interface and the `undo` and `redo` events

```
interface UndoManagerEvent : Event {
  readonly attribute DOMObject data;
  void initUndoManagerEvent(in DOMString typeArg,
                           in boolean canBubbleArg,
```

The screenshot shows a Wayback Machine interface. At the top, there's a search bar, a 'Go' button, and navigation links for 'DEC', 'JAN', and 'FEB'. Below that, a date range '2004 2006 2007' is shown with '02' highlighted in yellow. To the right are icons for user profile, help, and sharing. A link 'About this capture' is also present. The main content area contains a block of code:

```

in boolean canBubbleArg,
in boolean cancelableArg,
in DOMObject dataArg);
};

```

The `initUndoManagerEvent()` and `initUndoManagerEventNS()` methods must initialise the event in a manner analogous to the similarly-named methods in the DOM3 Events interfaces.

[\[DOM3EVENTS\]](#)

The `data` attribute represents the [undo object](#) for the event.

The `undo` and `redo` events do not bubble, cannot be canceled, and have no default action. When the user agent fires one of these events it must use the [UndoManagerEvent](#) interface, with the `data` field containing the relevant [undo object](#).

5.3.5. Implementation notes

How user agents present the above conceptual model to the user is not defined. The undo interface could be a filtered view of the [undo transaction history](#), it could manipulate the [undo transaction history](#) in ways not described above, and so forth. For example, it is possible to design a UA that appears to have separate [undo transaction histories](#) for each form control; similarly, it is possible to design systems where the user has access to more undo information than is present in the official (as described above) [undo transaction history](#) (such as providing a tree-based approach to document state). Such UI models should be based upon the single [undo transaction history](#) described in this section, however, such that to a script there is no detectable difference.

5.4. [SCS] Command APIs

The `execCommand(commandID, doShowUI, value)` method on the [DocumentWindow](#) interface allows scripts to perform actions on the [current selection](#) or at the current caret position. Generally, these commands would be used to implement editor UI, for example having a "delete" button on a toolbar.

There are three variants to this method, with one, two, and three arguments respectively. The `doShowUI` and `value` parameters, even if specified, are ignored unless otherwise stated.

Note: In this specification, in fact, the `doShowUI` parameter is always ignored, regardless of its value. It is included for historical reasons only.

When any of these methods are invoked, user agents must act as described in the list below.

For actions marked "**editing hosts only**", if the selection is not entirely within an [editing host](#), or if there is no selection and the caret is not inside an [editing host](#), then the user agent must do nothing.

If the `commandID` is `undo`

The user agent must [move back one step](#) in its [undo transaction history](#), restoring the associated state. If there is no further undo information the user agent must do nothing. See the [undo history](#).

3,445 captures
5 Jun 2004 - 22 Aug 2020

nothing. See the [undo history](#).

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

If the `commandID` is `selectAll`

The user agent must change the selection so that all the content in the currently focused [editing host](#) is selected. If no [editing host](#) is focused, then the content of the entire document must be selected.

If the `commandID` is `unselect`

The user agent must change the selection so that nothing is selected.

We need some sort of way in which the user can make a selection without risk of script clobbering it.

If the `commandID` is `superscript`

[Editing hosts only.](#) The user agent must act as if the user had requested that the selection [be wrapped in the semantics](#) of the `sup` element (or unwrapped, or, if there is no selection, have that semantic inserted or removed — the exact behaviour is UA-defined).

If the `commandID` is `subscript`

[Editing hosts only.](#) The user agent must act as if the user had requested that the selection [be wrapped in the semantics](#) of the `sub` element (or, again, unwrapped, or have that semantic inserted or removed, as defined by the UA).

If the `commandID` is `formatBlock`

[Editing hosts only.](#) This command changes the semantics of the blocks containing the selection.

If there is no selection, then, where in the description below refers to the selection, the user agent must act as if the selection was an empty range at the caret position.

If the `value` parameter is not specified or has a value other than one of the following literal strings:

- `<address>`
- `<aside>`
- `<h1>`
- `<h2>`
- `<h3>`
- `<h4>`
- `<h5>`
- `<h6>`
- `<nav>`
- `<p>`
- `<pre>`

...then the user agent must do nothing.

Otherwise, the user agent must, for every position in the selection, take the furthest [block-level element](#) ancestor of that position that contains only [inline-level content](#) and is not being used as a [structured inline-level element](#), and, if that element is a descendant of the editing host, rename it according to the `value`, by stripping the leading `<` character and the trailing `>` character and using the rest as the new tag name.

About this capture

If the **commandID** is `forwardDelete`

[Editing hosts only.](#) The user agent must act as if the user had performed [a forward delete operation](#).

If the **commandID** is `insertLineBreak`

[Editing hosts only.](#) The user agent must act as if the user had [requested a line separator](#).

If the **commandID** is `insertParagraph`

[Editing hosts only.](#) The user agent must act as if the user had performed a [break block](#) editing action.

If the **commandID** is `insertText`

[Editing hosts only.](#) The user agent must act as if the user had [inserted text](#) corresponding to the `value` parameter.

If the **commandID** is `vendorID-customCommandID`

User agents may implement vendor-specific extensions to this API. Vendor-specific extensions to the list of commands should use the syntax `vendorID-customCommandID` so as to prevent clashes between extensions from different vendors and future additions to this specification.

If the **commandID** is something else

User agents must do nothing.

5.5. [SCS] The text selection APIs

Every [browsing context](#) has a **selection**. The selection may be empty, and the selection may have more than one range (a disjointed selection). The user should be able to change the selection. User agents are not required to let the user select more than one range, and may collapse multiple ranges in the selection to a single range when the user interacts with the selection. (But, of course, the user agent may let the user create selections with multiple ranges.)

This one selection must be shared by all the content of the browsing context (though not by nested browsing contexts), including any editing hosts in the document. (Editing hosts that are not inside a document cannot have a selection.)

If the selection is empty (collapsed, so that it has only one segment and that segment's start and end points are the same) then the selection's position should equal the caret position. When the selection is not empty, this specification does not define the caret position; user agents should follow platform conventions in deciding whether the caret is at the start of the selection, the end of the selection, or somewhere else.

On some platforms (such as those using Wordstar editing conventions), the caret position is totally independent of the start and end of the selection, even when the selection is empty. On such platforms, user agents may ignore the requirement that the cursor position be linked to the position of the selection altogether.

Mostly for historical reasons, in addition to the [browsing context's selection](#), each `textarea` and `input` element has an independent selection. These are the **text field selections**.

[3,445 captures](#)
 5 Jun 2004 - 22 Aug 2020

Note: This specification does not specify how Selections are presented to the user.

The Selectors specification, in conjunction with CSS, can be used to style text selections using the `::selection` pseudo-element. [SELECTORS] [CSS21]

5.5.1. APIs for the browsing context selection

The `getSelection()` method on the `Window` interface must return the `Selection` object representing the selection of that `Window` object's browsing context.

For historical reasons, the `getSelection()` method on the `DocumentWindow` interface must return the same `Selection` object.

```
interface Selection {
    readonly attribute Node anchorNode;
    readonly attribute long anchorOffset;
    readonly attribute Node focusNode;
    readonly attribute long focusOffset;
    readonly attribute boolean isCollapsed;
    void collapse(in Node parentNode, in long offset);
    void collapseToStart();
    void collapseToEnd();
    void selectAllChildren(in Node parentNode);
    void deleteFromDocument();
    readonly attribute long rangeCount;
    Range getRangeAt(in long index);
    void addRange(in Range range);
    void removeRange(in Range range);
    void removeAllRanges();
    DOMString toString();
};
```

The `Selection` interface represents a list of `Range` objects. The first item in the list has index 0, and the last item has index `count`-1, where `count` is the number of ranges in the list. [DOM2RANGE]

All of the members of the `Selection` interface are defined in terms of operations on the `Range` objects represented by this object. These operations can raise exceptions, as defined for the `Range` interface; this can therefore result in the members of the `Selection` interface raising exceptions as well, in addition to any explicitly called out below.

The `anchorNode` attribute must return the value returned by the `startContainer` attribute of the last `Range` object in the list, or null if the list is empty.

The `anchorOffset` attribute must return the value returned by the `startOffset` attribute of the last `Range` object in the list, or 0 if the list is empty.

The `focusNode` attribute must return the value returned by the `endContainer` attribute of the last `Range` object in the list, or null if the list is empty.

The `focusOffset` attribute must return the value returned by the `endOffset` attribute of the last `Range` object in the list, or 0 if the list is empty.

◀ 02 ▶
2004 2006 2007

About this capture

exception if `parentNode`'s `ownerDocument` is not the `DocumentWindow` object with which the `Selection` object is associated. Otherwise it is, and the method must remove all the ranges in the `Selection` list, then create a new `Range` object, add it to the list, and invoke its `setStart()` and `setEnd()` methods with the `parentNode` and `offset` values as their arguments.

The `collapseToStart()` method must raise an `INVALID_STATE_ERR` DOM exception if there are no ranges in the list. Otherwise, it must invoke the `collapse()` method with the `startContainer` and `startOffset` values of the first `Range` object in the list as the arguments.

The `collapseToEnd()` method must raise an `INVALID_STATE_ERR` DOM exception if there are no ranges in the list. Otherwise, it must invoke the `collapse()` method with the `endContainer` and `endOffset` values of the last `Range` object in the list as the arguments.

The `selectAllChildren(parentNode)` method must invoke the `collapse()` method with the `parentNode` value as the first argument and 0 as the second argument, and must then invoke the `selectNodeContents()` method on the first (and only) range in the list with the `parentNode` value as the argument.

The `deleteFromDocument()` method must invoke the `deleteContents()` method on each range in the list, if any, from first to last.

The `rangeCount` attribute must return the number of ranges in the list.

The `getRangeAt(index)` method must return the `index`th range in the list. If `index` is less than zero or greater or equal to the value returned by the `rangeCount` attribute, then the method must raise an `INDEX_SIZE_ERR` DOM exception.

The `addRange(range)` method must add the given `range` `Range` object to the list of selections, at the end (so the newly added range is the new last range). Duplicates are not prevented; a range may be added more than once in which case it appears in the list more than once, which (for example) will cause `toString()` to return the range's text twice.

The `removeRange(range)` method must remove the first occurrence of `range` in the list of ranges, if it appears at all.

The `removeAllRanges()` method must remove all the ranges from the list of ranges, such that the `rangeCount` attribute returns 0 after the `removeAllRanges()` method is invoked (and until a new range is added to the list, either through this interface or via user interaction).

The `toString()` method must return a concatenation of the results of invoking the `toString()` method of the `Range` object on each of the ranges of the selection, in the order they appear in the list (first to last).

In language bindings where this is supported, objects implementing the `Selection` interface must stringify to the value returned by the object's `toString()` method.

In the following document fragment, the emphasised parts indicate the selection.

```
<p>The cute girl likes the <cite>Oxford English Dictionary</cite>.</p>
```

If a script invoked `window.getSelection().toString()`, the return value would be "the

5.5.2. APIs for the text field selections

This section will refer to the IDLs for `HTMLTextAreaElement` and `HTMLInputElement`, most notably their `select()` method, the `selectionStart` and `selectionEnd` attributes, and the `setSelectionRange()` method.

6. Multimedia

should we move all the img, object, embed, iframe, etc, elements here?

6.1. [SCS] Dynamic graphics: The bitmap canvas

This needs to be reviewed for normative criteria. As it stands there is terrible abuse of the word "should", for example.

The `canvas` element represents a resolution-dependent bitmap canvas, which can be used for rendering graphs, game graphics, or other visual images on the fly.

When authors use the `canvas` element, they should also provide content that, when presented to the user, conveys essentially the same function or purpose as the bitmap canvas. This content may be placed as content of the `canvas` element.

Authors should not use the `canvas` element in a document when a more suitable element is available. For example, it is inappropriate to use a `canvas` element to render a page heading: if the desired presentation of the heading is graphically intense, it should be marked up using appropriate elements (typically `h1`) and then styled using CSS and supporting technologies such as XBL.

In non-visual media, and in visual media with scripting disabled, the `canvas` element should be treated as an ordinary block-level element and the fallback content should therefore be used instead.

In non-interactive, static, visual media, if the `canvas` element has been previously painted on (e.g. if the page was viewed in an interactive visual media and is now being printed, or if some script that ran during the page layout process painted on the element), then the `canvas` element should be treated as a replaced block-level element with the current image and size. Otherwise, the element should be treated as an ordinary block-level element and the fallback content should therefore be used instead.

In interactive visual media with scripting enabled, the `canvas` element is a block-level replaced element.

In CSS-aware user agents, this should be achieved by including the following rules, or their equivalent, in the UA's user agent style sheet:

About this capture

width. These attributes each take a positive integer value (one digit in the range 1-9 followed by zero or more digits in the range 0-9, interpreted in base ten). If an attribute is missing, or if it has a value that does not match this syntax, then the default values must be used instead. The width attribute defaults to 300, and the height attribute defaults to 150.

The intrinsic dimensions of the `canvas` element equal the size of the coordinate space, with the numbers interpreted in CSS pixels. However, the element can be sized arbitrarily by a style sheet. During rendering, the image is scaled to fit this layout size.

The size of the coordinate space does not necessarily represent the size of the actual bitmap that the user agent will use internally or during rendering. On high-definition displays, for instance, the user agent may internally use a bitmap with two device pixels per unit in the coordinate space, so that the rendering remains at high quality throughout.

If the width and height attributes are dynamically modified, the bitmap and any associated contexts must be cleared back to their initial state and reinitialised with the newly specified coordinate space dimensions.

The canvas is initially fully transparent black. Whenever the width and height attributes are changed, the canvas must be cleared back to this state.

As with any replaced element, the CSS background properties do apply to `canvas` elements; they are rendered below the canvas image.

```
interface HTMLCanvasElement : HTMLElement {  
  
    // returns the values of the width and height attributes, or the assumption  
    // defaults if the attributes were not specified or invalid  
    // sets the relevant content attributes on setting  
    // attribute long width;  
    // attribute long height;  
  
    // returns a data: URI representing the current image as a PNG  
    DOMString toDataURL();  
  
    // returns a data: URI representing the current image in the specified  
    // DOMString toDataURL(in DOMString type);  
  
    // returns the context with which to paint, see below  
    DOMObject getContext(in DOMString contextID);  
  
};
```

To draw on the canvas, authors must first obtain a reference to a **context** using the `getContext` method of the `canvas` element.

This specification only defines one context, with the name "`2d`". If `getContext()` is called with that exact string, then the UA must return a reference to an object implementing `CanvasRenderingContext2D`. Other specifications may define their own contexts, which would return different objects.

About this capture

it must return null. String comparisons should be literal and case sensitive.

Note: A future version of this specification will probably define a 3d context (probably based on the OpenGL ES API).

The `toDataURL()` method must, when called with no arguments, return a `data:` URI containing a representation of the image as a PNG file. [\[PNG\]](#).

The `toDataURL(type)` method (when called with one or more arguments) must return a `data:` URI containing a representation of the image in the format given by `type`. The possible values are MIME types with no parameters, for example `image/png`, `image/jpeg`, or even maybe `image/svg+xml` if the implementation actually keeps enough information to reliably render an SVG image from the canvas.

Only support for `image/png` is required. User agents may support other types. If the user agent does not support the requested type, it must return the image using the PNG format.

User agents must convert the provided type to lower case before establishing if they support that type and before creating the `data:` URL.

Note: When trying to use types other than `image/png`, authors can check if the image was really returned in the requested format by checking to see if the returned string starts with the exact string "`data:image/png`" or not. If it does, the image is PNG, and thus the requested type was not supported.

Arguments other than the `type` must be ignored, and must not cause the user agent to raise an exception (as would normally occur if a method was called with the wrong number of arguments). A future version of this specification will probably allow extra parameters to be passed to `toDataURL()` to allow authors to more carefully control compression settings, image metadata, etc.

Security: To prevent *information leakage*, the `toDataURL()` methods should raise a security exception if the canvas ever had images painted on it that originate from a domain other than the [script's domain](#).

6.1.1. The 2D context

When the `getContext()` method of a `canvas` element is invoked with `2d` as the argument, a `CanvasRenderingContext2D` object is returned.

There is only one `CanvasRenderingContext2D` object per canvas, so calling the `getContext()` method with the `2d` argument a second time must return the same object.

```
interface CanvasRenderingContext2D {
    // back-reference to the canvas
    readonly attribute HTMLCanvasElement canvas;
    // state

The `canvas` attribute returns the `canvas` element that the context paints on.

6.1.1.1. The `canvas` state

Each context maintains a stack of drawing states. **Drawing states** consist of:

- The current transformation matrix.
- The current clip region.
- The current values of the following attributes: `strokeStyle`, `fillStyle`, `globalAlpha`, `lineWidth`, `lineCap`, `lineJoin`, `miterLimit`, `shadowOffsetX`, `shadowOffsetY`, `shadowBlur`, `shadowColor`, `globalCompositeOperation`.

Note: *The current path and the current bitmap are not part of the drawing state. The current path is persistent, and can only be reset using the `beginPath()` method. The current bitmap is a property of the canvas, not the context.*

The `save()` method pushes a copy of the current drawing state onto the drawing state stack.

The `restore()` method pops the top entry in the drawing state stack, and resets the drawing state it describes. If there is no saved state, the method does nothing.

6.1.1.2. Transformations

The transformation matrix is applied to all drawing operations prior to their being rendered. It is also applied when creating the clip region.

When the context is created, the transformation matrix is initially the identity transform. It may then be adjusted using the three transformation methods.

The transformations are performed in reverse order. For instance, if a scale transformation that doubles the width is applied, followed by a rotation transformation that rotates drawing operations by

3,445 captures

DEC JAN FEB

2004 2006 2007 02

About this capture

argument represents the scale factor in the horizontal direction and the `y` argument represents the scale factor in the vertical direction. The factors are multiples.

The `rotate(angle)` method adds a rotation transformation to the transformation matrix. The `angle` argument represents a clockwise rotation angle expressed in radians.

The `translate(x, y)` method adds a translating transformation to the transformation matrix. The `x` argument represents the translation distance in the horizontal direction and the `y` argument represents the translation distance in the vertical direction. The arguments are in coordinate space units.

6.1.1.3. Compositing

All drawing operations are affected by the global compositing attributes, `globalAlpha` and `globalCompositeOperation`.

The `globalAlpha` attribute gives an alpha value that is applied to shapes and images before they are composited onto the canvas. The valid range of values is from 0.0 (fully transparent) to 1.0 (no additional transparency). If the attribute is set to values outside this range, they are ignored. When the context is created, the `globalAlpha` attribute must initially have the value 1.0.

The `globalCompositeOperation` attribute sets how shapes and images are drawn onto the existing bitmap, once they have had `globalAlpha` and the current transformation matrix applied. It may be set to any of the values in the following list. In the descriptions below, the source image is the shape or image being rendered, and the destination image is the current state of the bitmap.

`source-atop`

Display the source image wherever both images are opaque. Display the destination image wherever the destination image is opaque but the source image is transparent. Display transparency elsewhere.

`source-in`

Display the source image wherever both the source image and destination image are opaque. Display transparency elsewhere.

`source-out`

Display the source image wherever the source image is opaque and the destination image is transparent. Display transparency elsewhere.

`source-over (default)`

Display the source image wherever the source image is opaque. Display the destination image elsewhere.

`destination-atop`

Same as `source-atop` but using the destination image instead of the source image and vice versa.

`destination-in`

Same as `source-in` but using the destination image instead of the source image and vice versa.

About this capture

destination-over

Same as `source-over` but using the destination image instead of the source image and vice versa.

darker

Display the sum of the source image and destination images, with color values approaching 0 as a limit.

lighter

Display the sum of the source image and destination image, with color values approaching 1 as a limit.

copy

Display the source image instead of the destination image.

xor

Exclusive OR of the source and destination images.

vendorName-operationName

Vendor-specific extensions to the list of composition operators should use this syntax.

If the user agent does not recognise the specified value, it must be ignored, leaving the value of `globalCompositeOperation` unaffected.

When the context is created, the `globalCompositeOperation` attribute must initially have the value `source-over`.

6.1.1.4. Colours and styles

The `strokeStyle` attribute represents the colour or style to use for the lines around shapes, and the `fillStyle` attribute represents the colour or style to use inside the shapes.

Both attributes can be either strings, `CanvasGradients`, or `CanvasPatterns`. On setting, strings should be parsed as CSS `<color>` values. [\[CSS3COLOR\]](#) If the value is a string but is not a valid colour, or is neither a string, a `CanvasGradient`, nor a `CanvasPattern`, then it must be ignored, and the attribute must retain its previous value.

On getting, if the value is a color, then: if it has alpha equal to 1.0, then the colour must be returned as an uppercase six-digit hex value, prefixed with a "#" character (U+0023 NUMBER SIGN), with the first two digits representing the red component, the next two digits representing the green component, and the last two digits representing the blue component, the digits being in the range 0-9 A-F (U+0030 to U+0039 and U+0041 to U+0046). If the value has alpha less than 1.0, then the value must instead be returned in the CSS `rgba()` functional-notation format: the literal string `rgba` (U+0072 U+0067 U+0062 U+0061) followed by a U+0028 LEFT PARENTHESIS, a base-ten integer in the range 0-255 representing the red component (using digits 0-9, U+0030 to U+0039), a literal U+0020 SPACE and U+002C COMMA, an integer for the green component, a space and a comma, an integer for the blue component, another space and comma, a U+0030 DIGIT ZERO, a U+002E FULL STOP (representing the decimal point), one or more digits in the range 0-9 (U+0030 to U+0039) representing the fractional part of the alpha value, and finally a U+0029 RIGHT PARENTHESIS.

[3,445 captures](#)
5 Jun 2004 - 22 Aug 2020

When the context is created, the `strokeStyle` and `fillStyle` attribute smust initially have the string value #000000.

There are two types of gradients, linear gradients and radial gradients, both represented by objects implementing the opaque `CanvasGradient` interface.

Once a gradient has been created (see below), stops must be placed along it to define how the colours are distributed along the gradient. Between each such stop, the colours and the alpha component are interpolated over the RGBA space to find the colour to use at that offset. Immediately before the 0 offset and immediately after the 1 offset, transparent black stops are assumed.

The `addColorStop(offset, color)` method on the `CanvasGradient` interface adds a new stop to a gradient. If the `offset` is less than 0 or greater than 1 then an `INDEX_SIZE_ERR` exception is raised. If the `color` cannot be parsed as a CSS colour, then a `SYNTAX_ERR` exception is raised. Otherwise, the gradient is updated with the new stop information.

The `createLinearGradient(x0, y0, x1, y1)` method takes four arguments, representing the start point (x_0, y_0) and end point (x_1, y_1) of the gradient, in coordinate space units, and returns a linear `CanvasGradient` initialised with that line.

Linear gradients are rendered such that at the starting point on the canvas the colour at offset 0 is used, that at the ending point the color at offset 1 is used, that all points on a line perpendicular to the line between the start and end points have the colour at the point where those two lines cross, and that any points beyond the start or end points are a transparent black. (Of course, the colours are only painted where the shape they are being painted on needs them.)

The `createRadialGradient(x0, y0, r0, x1, y1, r1)` method takes six arguments, the first three representing the start circle with origin (x_0, y_0) and radius r_0 , and the last three representing the end circle with origin (x_1, y_1) and radius r_1 . The values are in coordinate space units. The method returns a radial `CanvasGradient` initialised with those two circles.

Radial gradients are rendered such that a cone is created from the two circles, so that at the circumference of the starting circle the colour at offset 0 is used, that at the circumference around the ending circle the color at offset 1 is used, that the circumference of a circle drawn a certain fraction of the way along the line between the two origins with a radius the same fraction of the way between the two radii has the colour at that offset, that the end circle appear to be above the start circle when the end circle is not completely enclosed by the start circle, and that any points not described by the gradient are a transparent black.

If a gradient has no stops defined, then the gradient is treated as a solid transparent black. Gradients are, naturally, only painted where the stroking or filling effect requires that they be drawn.

Support for actually painting gradients is optional. Instead of painting the gradients, user agents may instead just paint the first stop's colour. However, `createLinearGradient()` and `createRadialGradient()` must always return objects when passed valid arguments.

Patterns are represented by objects implementing the opaque `CanvasPattern` interface.

To create objects of this type, the `createPattern(image, repetition)` method is used. The first argument gives the image to use as the pattern (either an `HTMLImageElement` or an `HTMLCanvasElement`). Modifying this image after calling the `createPattern()` method must not

3,445 captures
5 Jun 2004 - 22 Aug 2020

method returns a `CanvasPattern` object suitably initialised.

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

Patterns are painted so that the first image is centered in the middle of the coordinate space, and images are then repeated horizontally to the left and right (if the `repeat-x` string was specified) or vertically up and down (if the `repeat-y` string was specified) or in all four directions all over the canvas (if the `repeat` string was specified). The images shall not be scaled by this process; one CSS pixel of the image is painted on one coordinate space unit. Of course, patterns must only actually painted where the stroking or filling effect requires that they be drawn.

Support for patterns is optional. If the user agent doesn't support patterns, then `createPattern()` must return null.

6.1.1.5. Line styles

The `lineWidth` attribute gives the default width of lines, in coordinate space units. On setting, zero and negative values are ignored, and leave the value unchanged.

When the context is created, the `lineWidth` attribute must initially have the value 1.0.

The `lineCap` attribute defines the type of endings that UAs shall place on the end of lines. The three valid values are `butt`, `round`, and `square`. The `butt` value means that the end of each line is a flat edge perpendicular to the direction of the line. The `round` value means that a semi-circle with the diameter equal to the width of the line is then added on to the end of the line. The `square` value means that at the end of each line is a rectangle with the length of the line width and the width of half the line width, placed flat against the edge perpendicular to the direction of the line. On setting, any other value than the literal strings `butt`, `round`, and `square` are ignored and leave the value unchanged.

When the context is created, the `lineCap` attribute must initially have the value `butt`.

The `lineJoin` attribute defines the type of corners that that UAs shall place where two lines meet. The three valid values are `round`, `bevel`, and `miter`.

On setting, any other value than the literal strings `round`, `bevel` and `miter` are ignored and leave the value unchanged.

When the context is created, the `lineJoin` attribute must initially have the value `miter`.

The `round` value means that a filled arc connecting the corners on the outside of the join, with the diameter equal to the line width, and the origin at the point where the inside edges of the lines touch, is rendered at the join. The `bevel` value means that a filled triangle connecting those two corners with a straight line, the third point of the triangle being the point where the lines touch on the inside of the join, is rendered at the join. The `miter` value means that a filled four- or five-sided polygon is placed at the join, with two of the lines being the perpendicular edges of the joining lines, and the other two being continuations of the outside edges of the two joining lines, as long as required to intersect without going over the miter limit.

The miter length is the distance from the point where the lines touch on the inside of the join to the intersection of the line edges on the outside of the join. The miter limit is the maximum allowed ratio of the miter length to the line width. If the miter limit would be exceeded, then a fifth line is added to the polygon, connecting the two outside lines, such that the distance from the inside point of the join

3,445 captures
5 Jun 2004 - 22 Aug 2020

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

When the context is created, the `miterLimit` attribute must initially have the value 10.0.

6.1.1.6. Shadows

All drawing operations are affected by the four global shadow attributes. Shadows form part of the source image during composition.

The `shadowColor` attribute sets the colour of the shadow.

When the context is created, the `shadowColor` attribute initially is fully-transparent black.

The `shadowOffsetX` and `shadowOffsetY` attributes specify the distance that the shadow should be offset in the positive horizontal and positive vertical distance respectively. Their values are in coordinate space units.

When the context is created, the shadow offset attributes initially have the value 0.

The `shadowBlur` attribute specifies the number of coordinate space units that the blurring should cover. On setting, negative numbers are ignored and leave the attribute unmodified.

When the context is created, the `shadowBlur` attribute must initially have the value 0.

Support for shadows is optional.

6.1.1.7. Shapes

There are three methods that immediately draw rectangles to the bitmap. They each take four arguments; the first two give the x and y coordinates of the top left of the rectangle, and the second two give the width and height of the rectangle, respectively.

Shapes are painted without affecting the current path, and are subject to [transformations](#), [shadow effects](#), [global alpha](#), [clipping paths](#), and [global composition operators](#).

Negative values for width and height must cause the implementation to raise an `INDEX_SIZE_ERR` exception.

The `clearRect()` method clears the pixels in the specified rectangle to a fully transparent black, erasing any previous image.

The `fillRect()` method paints the specified rectangular area using the `fillStyle`.

The `strokeRect()` method draws a rectangular outline of the specified size using the `strokeStyle`, `lineWidth`, `lineJoin`, and (if appropriate) `miterLimit` attributes.

6.1.1.8. Paths

The context always has a current path. There is only one current path, it is not part of the [drawing state](#).

A **path** has a list of subpaths and a current position. Each subpath consists of a list of points, some of which may be connected by straight and curved lines, and a flag indicating whether the subpath is closed or not.

3,445 captures
5 Jun 2004 - 22 Aug 2020

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

subpath with that point as its first (and only) point. If there was a previous subpath, and it consists of just one point, then that subpath is removed from the path.

The `closePath()` method adds a straight line from the current position to the first point in the last subpath and marks the subpath as closed, if the last subpath isn't closed, and if it has more than one point in its list of points. If the last subpath is not open or has only one point, it does nothing.

The `lineTo(x, y)` method adds the given coordinate (x, y) to the list of points of the subpath, and connects the current position to that point with a straight line. It then sets the current position to the given coordinate (x, y) .

The `quadraticCurveTo(cpx, cpy, x, y)` method adds the given coordinate (x, y) to the list of points of the subpath, and connects the current position to that point with a quadratic curve with control point (cpx, cpy) . It then sets the current position to the given coordinate (x, y) .

The `bezierCurveTo(cp1x, cp1y, cp2x, cp2y, x, y)` method adds the given coordinate (x, y) to the list of points of the subpath, and connects the two points with a bezier curve with control points $(cp1x, cp1y)$ and $(cp2x, cp2y)$. It then sets the current position to the given coordinate (x, y) .

The `arcTo(x1, y1, x2, y2, radius)` method adds an arc to the current path. The arc is given by the circle that has one point tangent to the line from the current position to point $(x1, y1)$, one point tangent to the line from the point $(x1, y1)$ to the point $(x2, y2)$, and that has radius $radius$. The points at which this circle touches these two lines are called the start and end tangent points respectively.

If the point $(x2, y2)$ is on the line from the current position to point $(x1, y1)$ then this method does nothing. Otherwise, the arc is the shortest path along the circle's circumference between those two points. If the first tangent point is not equal to the current position then the first tangent point is added to the list of points of the subpath and the current position is joined to that point by a straight line. Then, the second tangent point is added to the list of points and the two tangent points are joined by the arc described above. Finally, the current position is set to the second tangent point.

Negative or zero values for $radius$ must cause the implementation to raise an `INDEX_SIZE_ERR` exception.

The `arc(x, y, radius, startAngle, endAngle, anticlockwise)` method adds an arc to the current path. The arc is given by the circle that has its origin at (x, y) and that has radius $radius$. The points at `startAngle` and `endAngle` along the circle, measured in radians clockwise from the positive x-axis, are the start and end points. The arc is the path along the circumference of the circle from the start point to the end point going anti-clockwise if the `anticlockwise` argument is true, and clockwise otherwise.

The start point is added to the list of points of the subpath and the current position is joined to that point by a straight line. Then, the end point is added to the list of points and these last two points are joined by the arc described above. Finally, the current position is set to the end point.

Negative or zero values for $radius$ must cause the implementation to raise an `INDEX_SIZE_ERR` exception.

The `rect(x, y, w, h)` method creates a new subpath containing just the rectangle with top left coordinate (x, y) , width w and height h , and marks it as closed. It then calls `moveTo` with the point

The screenshot shows a top navigation bar with a search input, a 'Go' button, and month abbreviations (DEC, JAN, FEB) with arrows for navigation. Below this is a date display showing '02' in large yellow font, 'JAN' in green, and '2006' in blue. To the right are icons for user profile, help, and sharing (Facebook, Twitter). A link 'About this capture' is also present.

The `fill()` method fills each subpath of the current path in turn, using `fillStyle`, and using the non-zero winding number rule. Open subpaths are implicitly closed when being filled (without affecting the actual subpaths).

The `stroke()` method strokes each subpath of the current path in turn, using the `strokeStyle`, `lineWidth`, `lineJoin`, and (if appropriate) `miterLimit` attributes.

Paths, when filled or stroked, are painted without affecting the current path, and are subject to [transformations](#), [shadow effects](#), [global alpha](#), [clipping paths](#), and [global composition operators](#).

The `clip()` method creates a new **clipping path** by calculating the intersection of the current clipping path and the area described by the current path, using the non-zero winding number rule. Open subpaths are implicitly closed without affecting the actual subpaths).

When the context is created, the initial clipping path is the rectangle with the top left corner at (0,0) and the width and height of the coordinate space.

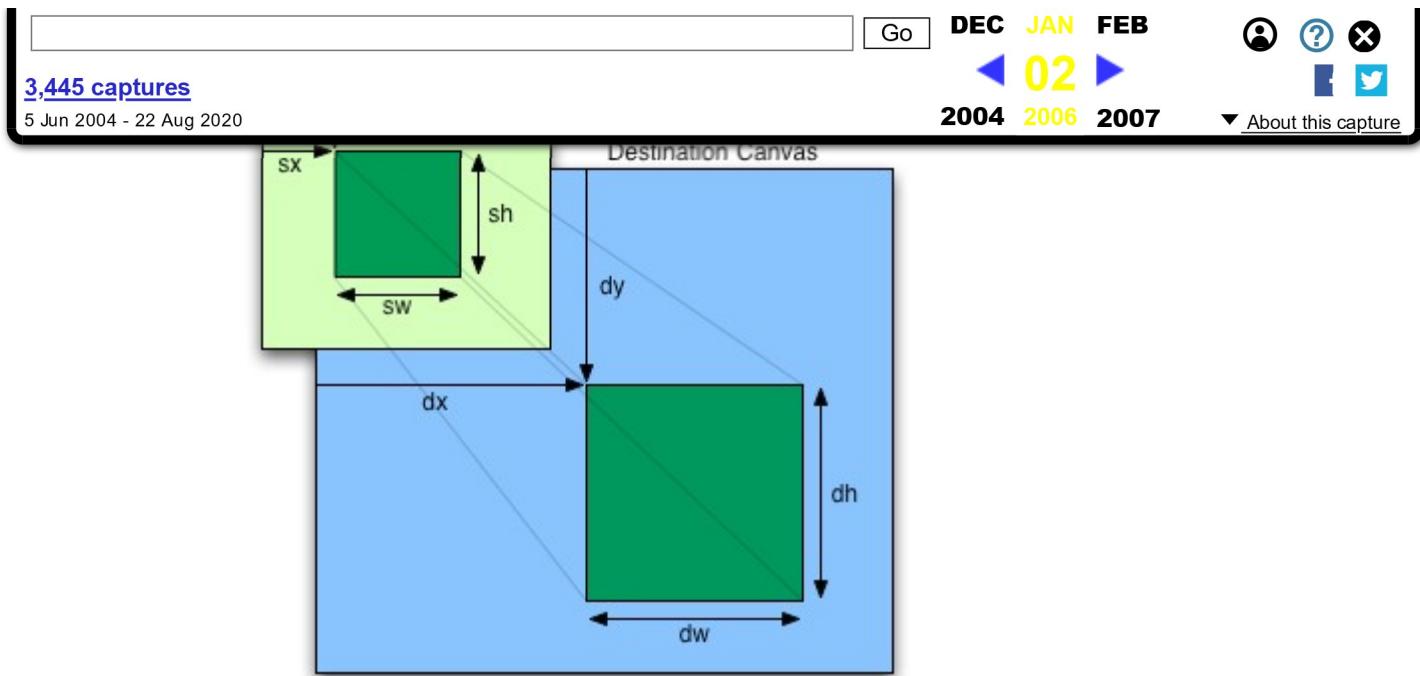

6.1.1.9. Images

To draw images onto the canvas, the `drawImage` method may be used.

This method is overloaded with three variants: `drawImage(image, dx, dy)`, `drawImage(image, dx, dy, dw, dh)`, and `drawImage(image, sx, sy, sw, sh, dx, dy, dw, dh)`. (Actually it is overloaded with six; each of those three can take either an [HTMLImageElement](#) or an [HTMLCanvasElement](#) for the `image` argument.) If not specified, the `dw` and `dh` arguments default to the values of `sw` and `sh`, interpreted such that one CSS pixel in the image is treated as one unit in the canvas coordinate space. If the `sx`, `sy`, `sw`, and `sh` arguments are omitted, they default to 0, 0, the image's intrinsic width in image pixels, and the image's intrinsic height in image pixels, respectively.

The `image` argument must be an instance of an [HTMLImageElement](#) or [HTMLCanvasElement](#). If the `image` is of the wrong type, the implementation must raise a `TYPE_MISMATCH_ERR` exception. If one of the `sy`, `sw`, `sw`, and `sh` arguments is outside the size of the image, or if one of the `dw` and `dh` arguments is negative, the implementation must raise an `INDEX_SIZE_ERR` exception.

When `drawImage` is invoked, the specified region of the image specified by the source rectangle (`sx, sy, sw, sh`) is painted on the region of the canvas specified by the destination rectangle (`dx, dy, dw, dh`).

Images are painted without affecting the current path, and are subject to [transformations](#), [shadow effects](#), [global alpha](#), [clipping paths](#), and [global composition operators](#).

6.1.1.10. Drawing model

When a shape or image is painted, user agents shall follow these steps, in the order given (or act as if they do):

1. The coordinates are transformed by the current transformation matrix.
2. The shape or image is rendered, creating image *A*.
3. The shadow is rendered from image *A*, creating image *B*.
4. Image *A* is composited over image *B* creating the source image.
5. The source image has its alpha adjusted by `globalAlpha`.
6. Within the clip region, the source image is composited over the current canvas bitmap using the composition operator.

6.1.2. The 3D context

Well, one day.

6.2. [SCS] Sound

The `Audio` interface allows scripts to play sound clips.

There is no markup element that corresponds to `Audio` objects, they are only accessible from script.

User agents should allow users to dynamically enable and disable sound output, but doing so must not affect how `Audio` objects act in any way other than whether sounds are physically played back

Go DEC JAN FEB
02
 2004 2006 2007 ▾ About this capture

3,445 captures
 5 Jun 2004 - 22 Aug 2020

When multiple sounds are played simultaneously, the user agent must mix the sounds together.

```
interface Audio {
    attribute EventListener onload;
    void play();
    void loop();
    void loop(in unsigned long repeatCount);
    void stop();
};
```

Audio objects must also implement the EventTarget interface. [[DOM3EVENTS](#)]

In ECMAScript, an instance of Audio can be created using the `Audio(uri)` constructor:

```
|| var a = new Audio("test.wav");
```

The **Audio()** constructor takes a single argument, a URI (or IRI), which is resolved using the script context's `window.location.href` value as the base, and which returns an Audio object that will, at the completion of the current script, start loading that URI.

Once the URI is loaded, a `load` event must be fired on the Audio object.

Audio objects have a current position and a repeat count. Both are initially zero.

The Audio interface has the following members:

onload

An event listener that is invoked along with any other appropriate event listeners that are registered on this object when a `load` event is fired on it.

play()

Begins playing the sound at the current position, setting the repeat count to 1.

loop()

Begins playing the sound at the current position, setting the repeat count to infinity.

loop(*repeatCount*)

Begins playing the sound at the current position, setting the repeat count to *repeatCount*.

stop()

Stops playing the clip and resets the current position and repeat count to zero.

When playback of the sound reaches the end of the available data, its current position is reset to the start of the clip, and the repeat count is decreased by one (unless it is infinite). If the repeat count is greater than zero, then the sound is played again.

7. Communication

7.1. [SCS] Server-sent DOM events

DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

To specify an event source in an HTML document authors use a new (empty) element `event-source`, with an attribute `src=""` that takes a URI (or IRI) to open as a stream and, if the data found at that URI is of the appropriate type, treat as an event source.

The `event-source` element may also have an `onevent=""` attribute. If present, the attribute must be treated as script representing an event handler registered as non-capture listener of events with name `event` and the namespace `uuid:755e2d2d-a836-4539-83f4-16b51156341f` or null, that are targeted at or bubble through the element.

UAs must also support all the common attributes on the `event-source` element.

7.1.2. The `RemoteEventTarget` interface

Any object that implements the `EventTarget` interface shall also implement the `RemoteEventTarget` interface.

```
interface RemoteEventTarget {
    void addEventSource(in DOMString src);
    void removeEventSource(in DOMString src);
};
```

The `addEventSource (src)` method shall register the URI (or IRI) specified in `src` as an event source on the object. The `removeEventSource (src)` method shall remove the URI (or IRI) specified in `src` from the list of event sources for that object. If a single URI is added multiple times, each instance must be handled individually. Removing a URI must only remove one instance of that URI. If the specified URI cannot be added or removed, the method must return without doing anything or raising an exception.

7.1.3. Processing model

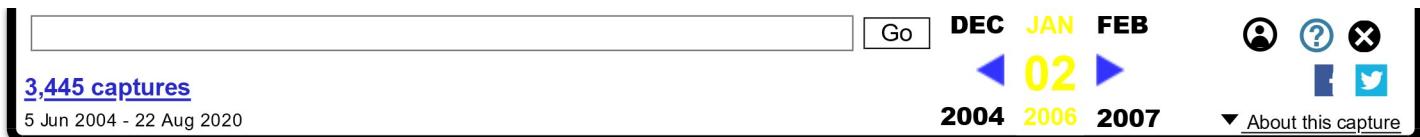

When an `event-source` element in a document has a `src` attribute set, the UA should fetch the resource indicated by the attribute's value.

Similarly, when the `addEventSource ()` method is invoked on an object, the UA should, at the completion of the script's current execution, fetch the resource identified by the method's argument (unless the `removeEventSource ()` was called removing the URI from the list first).

When an `event-source` element is removed from the document, or when an event source is removed from the list of event sources for an object using the `removeEventSource ()` method, the relevant connection must be closed (and not reopened unless the element is returned to the document or the `addEventSource ()` method is called with the same URI again).

Since connections established to remote servers for such resources are expected to be long-lived, UAs should ensure that appropriate buffering is used. In particular, while line buffering may be safe if lines are defined to end with a single U+000A LINE FEED character, block buffering or line buffering with different expected line endings can cause delays in event dispatch.

In general, the semantics of the transport protocol specified by the "src" attribute must be followed. Clients should re-open `event-source` connections that get closed after a short interval (such as 5

event-source.

HTTP 200 OK responses that have a Content-Type other than `application/x-dom-event-stream` must be ignored and must prevent the user agent from reopening the connection for that event-source. HTTP 200 OK responses with the right MIME type, however, should, when closed, be reopened after a small delay.

Resource with the type `application/x-dom-event-stream` must be processed line by line [as described below](#).

HTTP 201 Created, 202 Accepted, 203 Non-Authoritative Information, and 206 Partial Content responses must be treated like HTTP 200 OK responses for the purposes of reopening event-source connections. They are, however, likely to indicate an error has occurred somewhere and may cause the user agent to emit a warning.

HTTP 204 No Content, and 205 Reset Content responses must be treated as if they were 200 OK responses with the right MIME type but no content, and should therefore cause the user agent to reopen the connection after a short delay.

HTTP 300 Multiple Choices responses should be handled automatically if possible (treating the responses as if they were 302 Moved Permanently responses pointing to the appropriate resource), and otherwise must be treated as HTTP 404 responses.

HTTP 301 Moved Permanently responses must cause the user agent to use the server specified URI instead of the one specified in the event-source's "src" attribute for future connections.

HTTP 302 Found, 303 See Other, and 307 Temporary Redirect responses must cause the user agent to use the server specified URI instead of the one specified in the event-source's "src" attribute for the next connection, but if the user agent needs to reopen the connection at a later point, it must once again start from the "src" attribute (or the last URI given by a 301 Moved Permanently response in complicated cases where such responses are chained).

HTTP 304 Not Modified responses should be handled like HTTP 200 OK responses, with the content coming from the user agent cache. A new connection attempt should then be made after a short wait.

HTTP 305 Use Proxy, HTTP 401 Unauthorized, and 407 Proxy Authentication Required should be treated transparently as for any other subresource.

HTTP 400 Bad Request, 403 Forbidden, 404 Not Found, 405 Method Not Allowed, 406 Not Acceptable, 408 Request Timeout, 409 Conflict, 410 Gone, 411 Length Required, 412 Precondition Failed, 413 Request Entity Too Large, 414 Request-URI Too Long, 415 Unsupported Media Type, 416 Requested Range Not Satisfiable, 417 Expectation Failed, 500 Internal Server Error, 501 Not Implemented, 502 Bad Gateway, 503 Service Unavailable, 504 Gateway Timeout, and 505 HTTP Version Not Supported responses, and any other HTTP response code not listed here, should cause the user agent to stop trying to process this event-source element.

For non-HTTP protocols, UAs should act in equivalent ways.

7.1.4. The event stream format

The event stream MIME type is `application/x-dom-event-stream`.

Go DEC JAN FEB
02 2004 2006 2007     

3,445 captures
 5 Jun 2004 - 22 Aug 2020 ▾ About this capture

```

<stream> ::= <event>*
<event> ::= [ <comment> | <command> | <field> ]* <newline>

<comment> ::= ';' <data> <newline>
<command> ::= ':' <data> <newline>
<field> ::= <name> [ ':' <space>? <data> ]? <newline>

<name> ::= one or more UNICODE characters other than ':', ';', and U+(U+000A-LINE FEED)
<data> ::= zero or more UNICODE characters other than U+000A LINE FEED
<space> ::= a single U+0020 SPACE character (' ')
<newline> ::= a single U+000A LINE FEED character
  
```

Bytes that are not valid UTF-8 sequences must be interpreted as the U+FFFD REPLACEMENT CHARACTER.

The stream is parsed by reading everything line by line, in blocks separated by blank lines (blank lines are those consisting of just a single lone line feed character). Comment lines (those starting with the character ';') and command lines (those starting with the character ':') are ignored. Command lines are reserved for future use and should not be used.

For each non-blank, non-comment line, the field name is first taken. This is everything on the line up to but not including the first colon (':') or the line feed, whichever comes first. Then, if there was a colon, the data for that line is taken. This is everything after the colon, ignoring a single space after the colon if there is one, up to the end of the line. If there was no colon the data is the empty string.

Examples:

```

Field name: Field data

This is a blank field

1. These two lines: have the same data
2. These two lines:have the same data

1. But these two lines: do not
2. But these two lines: do not
  
```

If a field name occurs multiple times, the data values for those lines are concatenated with a newline between them.

For example, the following:

```

Test: Line 1
Foo: Bar
Test: Line 2
  
```

...is treated as having two fields, one called `Test` with the value `Line 1\nLine 2` (where `\n` represents a newline), and one called `Foo` with the value `Bar`.

Note: Since any random stream of characters matches the above format, there is no need to define any error handling.

◀ 02 ▶
2004 2006 2007

About this capture

- Event is the name of the event. For example, load, DOMActivate, updateTicker. If there is no field with this name, then no event will be synthesised, and the other data will be ignored.
- Namespace is the DOM3 namespace for the event. For normal DOM events this would be <http://www.w3.org/2001/xml-events>. If it isn't specified the event namespace is null.
- Class is the interface used for the event, for instance Event, UIEvent, MutationEvent, KeyboardEvent, etc. For compatibility with DOM3 Events, the values UIEvents, MouseEvents, MutationEvents, and HTMLEvents are valid values and must be treated respectively as meaning the interfaces UIEvent, MouseEvent, MutationEvent, and Event. (This value can therefore be used as the argument to `createEvent()`.) If the value is not specified it is defaulted based on the event name as follows:

- If Namespace is <http://www.w3.org/2001/xml-events> or null and the Event field exactly matches one of the events specified by DOM3 Events in [section 1.4.2 "Complete list of event types"](#), then the Class defaults to the interface relevant for that event type. [\[DOM3EVENTS\]](#)

For example:

Event: click

...would cause Class to be treated as MouseEvent.

- If Namespace is `uuid:755e2d2d-a836-4539-83f4-16b51156341f` or null and the Event doesn't match any of the known events, then the [RemoteEvent](#) interface (described below) is used.
- Otherwise, if the UA doesn't have special knowledge of which class to use for the given event in the given namespace, then the Event interface is used.

It is quite possible to give the wrong class for an event. This is equivalent to creating an event in the DOM using the DOM Event APIs, but using the wrong interface for it.

- Bubbles specifies whether the event is to bubble. If it is specified and has the value No, the event does not bubble. If it is specified and has any other value (including no or No\n) then the event bubbles. If it is not specified it is defaulted based on the event name as follows:

- If Namespace is <http://www.w3.org/2001/xml-events> or null and the Event field exactly matches one of the events specified by DOM3 Events in [section 1.4.2 "Complete list of event types"](#), then whether the event bubbles depends on whether the DOM3 Events spec specifies that that event should bubble or not. [\[DOM3EVENTS\]](#)

For example:

Event: load

...would cause Bubbles to be treated as No.

- Otherwise, if the UA doesn't have special knowledge of which class to use for the

◀ 02 ▶
2004 2006 2007

About this capture

specified and has any other value (including no or No\n) then the event may be canceled. If it is not specified it is defaulted based on the event name as follows:

- If Namespace is `http://www.w3.org/2001/xml-events` or null and the Event field exactly matches one of the events specified by DOM3 Events in [section 1.4.2 "Complete list of event types"](#), then whether the event is cancelable depends on whether the DOM3 Events spec specifies that that event should be cancelable or not. [\[DOM3EVENTS\]](#)

For example:

Event: load

...would cause Cancelable to be treated as No.

- Otherwise, if the UA doesn't have special knowledge of which class to use for the given event in the given namespace, then the event may be canceled.
- Target is the element that the event is to be dispatched on. If its value starts with a # character then the remainder of the value represents an ID, and the event must be dispatched on the same node as would be obtained by the `getElementById()` method on the ownerDocument of the event-source element responsible for the event being dispatched.

For example,

Target: #test

...would target the element with ID test.

If the value does not start with a # but has the literal value Document, then the event is dispatched at the ownerDocument of the event-source element responsible for the event being dispatched.

Otherwise, the event is dispatched at the event-source element itself.

- Other fields depend on the interface specified (or possibly implied) by the Class field. If the specified interface has an attribute that exactly matches the name of the field, and the value of the field can be converted (using the type conversions defined in ECMAScript) to the type of the attribute, then it must be used. Any attributes (other than the Event interface attributes) that do not have matching fields are initialised to zero, null, false, or the empty string.

For example:

```
; ...some other fields...
Class: MouseEvent
button: 2
```

...would result in a MouseEvent event that had button set to 2 but screenX, screenY, etc, set to 0, false, or null as appropriate.

If a field does not match any of the attributes on the event, it is ignored.

3,445 captures
5 Jun 2004 - 22 Aug 2020

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

```
keyIdentifier: 0
```

...would result in a `MouseEvent` event with its fields all at their default values, with the event name being `keypress`. The `ctrlKey` field would be ignored. (If the author had not included the `Class` field explicitly, it would have just worked, since the class would have defaulted as described above.)

Once a blank line is reached, an event of the appropriate type is synthesized and dispatched to the appropriate node as described by the fields above. No event is dispatched until a blank line has been received.

If the `Event` field was omitted, then no event is synthesised and the data is ignored.

The following stream contains four blocks yet synthesizes no events, since none of the blocks have a field called `Event`. (The first block has just a comment, the second block has two fields with names "load" and "Target" respectively, the third block is empty, and the fourth block has two comments.)

```
; test

load
Target: #image1

; if any real events follow this block, they will not be affected by
; the "Target" and "load" fields above.
```

7.1.6. The `RemoteEvent` interface

The `RemoteEvent` interface is defined as follows:

```
interface RemoteEvent : Event {
    readonly attribute DOMString          data;
    void               initRemoteEvent(in DOMString typeArg,
                                       in boolean canBubbleArg,
                                       in boolean cancelableArg,
                                       in DOMString dataArg);
    void               initRemoteEventNS(in DOMString namespaceURI,
                                         in DOMString typeArg,
                                         in boolean canBubbleArg,
                                         in boolean cancelableArg,
                                         in DOMString dataArg);
};
```

Events that use the `RemoteEvent` interface never have any default action associated with them.

7.1.7. Example

The following event description, once followed by a blank line:

```
Event: stock change
```

[Go](#) DEC JAN FEB
02
 2004 2006 2007 ▾ [About this capture](#)

[3,445 captures](#)
 5 Jun 2004 - 22 Aug 2020

...would cause an event stock change with the interface `RemoteEvent` to be dispatched on the `event-source` element, which would then bubble up the DOM, and whose `data` attribute would contain the string `YHOO\n-2\n10` (where `\n` again represents a newline).

This could be used as follows:

```
<event-source src="http://stocks.example.com/ticker.php" id="stock">
<script type="text/javascript">
document.getElementById('stock').addEventListener('stock change',
    function () {
        var data = event.data.split('\n');
        updateStocks(data[0], data[1], data[2]);
    }, false);
</script>
```

...where `updateStocks` is a function defined as:

```
function updateStocks(symbol, delta, value) { ... }
```

...or some such.

7.2. [SCS] Scripted HTTP: `XMLHttpRequest`

To allow scripts to programmatically connect back to their originating server via HTTP, the following interface may be used.

```
interface XMLHttpRequest {
    attribute EventListener onreadystatechange;
    readonly attribute int readyState;
    void open(in DOMString method, in DOMString uri);
    void open(in DOMString method, in DOMString uri, in boolean async);
    void open(in DOMString method, in DOMString uri, in boolean async, in
    void open(in DOMString method, in DOMString uri, in boolean async, in
    void setRequestHeader(in DOMString header, in DOMString value);
    void send();
    void send(in DOMString body);
    void send(in Document body);
    void abort();
    DOMString getAllResponseHeaders();
    DOMString getResponseHeader(in DOMString header);
    readonly attribute DOMString responseText;
    readonly attribute Document responseXML;
    readonly attribute int status;
    readonly attribute DOMString statusText;
};
```

`XMLHttpRequest` objects must also implement the `EventTarget` interface. [\[DOM3EVENTS\]](#)

In ECMAScript, an instance of `XMLHttpRequest` can be created using the `XMLHttpRequest()`

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

3,445 captures
5 Jun 2004 - 22 Aug 2020

The XMLHttpRequest interface has the following members:

onreadystatechange

An event listener that is invoked along with any other appropriate event listeners that are registered on this object when a `readystatechange` event is fired on it.

readyState

The state of the object. The values have the following meanings:

0 Uninitialised

The initial value.

1 Open

The `open()` method has been successfully called.

2 Sent

The `send()` method has been successfully called, but no data has yet been received.

3 Receiving

Data is being received, but the data transfer is not yet complete.

4 Loaded

The data transfer has been completed.

A `readystatechange` event shall immediately be dispatched at the object whenever the `readyState` attribute changes value. The `readystatechange` event must never be dispatched by the UA if the `readyState` attribute did not change. The `readystatechange` event has no default action.

open(*method*, *uri*, [*async*, [*user*, [*password*]]])

Initialises the object by remembering the *method*, *uri*, *async* (defaulting to true if omitted), *user* (defaulting to null if omitted), and *password* (defaulting to null if omitted) arguments, setting the `readyState` attribute to 1 (Open), resetting the `responseText`, `responseXML`, `status`, and `statusText` attributes to their initial values, and resetting the list of request headers.

The *uri* argument is resolved to an absolute URI using the script context's `window.location.href` value as the base.

Same-origin security restrictions should apply.

If the URI given to this method contains a username and a password (the latter potentially being the empty string), then these must be used if the *user* and *password* arguments are omitted. If the arguments are not omitted, they take precedence, even if they are null.

setRequestHeader(*header*, *value*)

If the `readyState` attribute has a value other than 1 (Open), raises an exception. If the *header* or *value* arguments contain any U+000A LINE FEED or U+000D CARRIAGE RETURN characters, or if the *header* argument contains any U+0020 SPACE or U+003A COLON characters, does nothing. Otherwise, the request header *header* is set to *value*. If the request header *header* had already been set, then the new *value* is concatenated to the existing value after a comma and a space.

The following script:

```
var r = new XMLHttpRequest;
r.open('get', 'demo.cgi');
```

3,445 captures

◀ 02 ▶
2004 2006 2007

About this capture

...would result in the following header being sent:

```
...
X-Test: one, two
...
```

The list of request headers must be reset when the `open()` method is called.

User agents must not set any headers other than the headers set by the author using this method, with the following exceptions:

- UAs must set the `Host` header appropriately (see `open()`) and not allow it to be overridden.
- UAs must set the `Authorization` header according to the values passed to the `open()` method (but must allow calls to `setRequestHeader()` to append values to it).
- UAs may set the `Accept-Charset` and `Accept-Encoding` headers and must not allow them to be overridden.
- UAs may set the `If-Modified-Since`, `If-None-Match`, `If-Range`, and `Range` headers if the resource is cached and has not expired (as allowed by HTTP), and must not allow those headers to be overridden.
- UAs must set the `Connection` and `Keep-Alive` headers as described by the HTTP specification, and must not allow those headers to be overridden.
- UAs should set the proxy-related headers according to proxy settings of the environment, and must not allow those headers to be overridden.
- UAs may give the `User-Agent` header an initial value, but must allow authors to append values to it.
- UAs should set `Cookie` and `Cookie2` headers appropriately for the given URI and given the user's current cookies, and must allow authors to append values to these headers.

In particular, UAs must not automatically set the `Cache-Control` or `Pragma` headers to defeat caching. [\[HTTP\]](#)

`send([data])`

If the `readyState` attribute has a value other than 1 (Open), raises an exception. Otherwise, sets the `readyState` attribute to 2 (Sent) and sends a request to `uri` using method `method`, authenticating using `user` and `password` as appropriate. If the `async` flag is set to false, then the method does not return until the request has completed. Otherwise, it returns immediately. (See: `open()`.)

If the `method` is `post` or `put`, then the `data` passed to the `send()` method is used for the entity body. If `data` is a string, the data is encoded as UTF-8 for transmission. If the `data` is a `Document`, then the document is serialised using the encoding given by `data.xmlEncoding`, if specified, or UTF-8 otherwise. [\[DOM3CORE\]](#)

3,445 captures
5 Jun 2004 - 22 Aug 2020

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

Once the final HTTP status line has been received, the `readyState` attribute should be set to 3 (Receiving). When the request has completed loading, the `readyState` attribute should be set to 4 (Loaded).

abort

Cancels any network activity for which the object is responsible and returns `readyState` to 0 (Uninitialised).

getAllResponseHeaders()

If the `readyState` attribute has a value other than 3 (Receiving) or 4 (Loaded), returns null. Otherwise, returns the HTTP headers that have been received so far for the last request sent, as a single string, with each header line separated by a CR (U+000D) LF (U+000A) pair. The status line is not included.

The following script:

```
var r = new XMLHttpRequest;
r.open('get', 'test.txt', false);
r.send();
alert(r.getAllResponseHeaders());
```

...should display a dialog with text similar to the following:

```
Date: Sun, 24 Oct 2004 04:58:38 GMT
Server: Apache/1.3.31 (Unix)
Keep-Alive: timeout=15, max=99
Connection: Keep-Alive
Transfer-Encoding: chunked
Content-Type: text/plain; charset=utf-8
```

getResponseHeader(header)

If the `readyState` attribute has a value other than 3 (Receiving) or 4 (Loaded), returns an empty string. Otherwise, returns the value of the given HTTP header in the data received so far for the last request sent, as a single string. If more than one header of the given name was received, then the values should be concatenated, separated from each other by a comma and a space. If no headers of that name were received, then returns the empty string. Header names must be compared case-insensitively to the method argument (`header`).

responseText

If the `readyState` attribute has a value other than 3 (Receiving) or 4 (Loaded), returns an empty string. Otherwise, returns the body of the data received so far, interpreted using the character encoding specified in the response, or UTF-8 if no character encoding was specified. Invalid bytes must be converted to U+FFFD REPLACEMENT CHARACTER.

responseXML

If the `readyState` attribute has a value other than 4 (Loaded), returns null. Otherwise, if the Content-Type header is either `text/xml`, `application/xml`, or ends in `+xml`, returns an object that implements the Document interface representing the parsed document. If the document was not an XML document, or if the document could not be parsed (due to an XML well-formedness error or unsupported character encoding, for instance), returns null.

status

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

statusText

If the `readyState` attribute has a value other than 3 (Receiving) or 4 (Loaded), raises an exception. Otherwise, returns the HTTP status text sent by the server after the status code.

If an exception is raised due to an attribute or method being used when `readyState` has an inappropriate value, it should be a `INVALID_STATE_ERR` DOM Exception.

HTTP requests sent from multiple different `XMLHttpRequest` objects in succession should be pipelined into shared HTTP connections.

7.3. [SCS] Network connections

To enable Web applications to communicate with each other in local area networks, and to maintain bidirectional communications with their originating server, this specification introduces the `Connection` interface.

The `Window` interface provides three constructors for creating `Connection` objects: `TCPConnection()`, for creating a direct (possibly encrypted) link to another node on the Internet using TCP/IP; `LocalBroadcastConnection()`, for creating a connection to any listening peer on a local network (which could be a local TCP/IP subnet using UDP, a Bluetooth PAN, or another kind of network infrastructure); and `PeerToPeerConnection()`, for a direct peer-to-peer connection (which could again be over TCP/IP, Bluetooth, IrDA, or some other type of network).

Note: This interface does not allow for raw access to the underlying network. For example, this interface could not be used to implement an IRC client without proxying messages through a custom server.

7.3.1. Introduction [TBW]

This section is non-normative.

An introduction to the client-side and server-side of using the direct connection APIs.

An example of a party-line implementation of a broadcast service, and direct peer-to-peer chat for direct local connections.

7.3.2. The `Connection` interface

```
interface Connection {
    readonly attribute DOMString network;
    readonly attribute DOMString peer;
    readonly attribute int readyState;
        attribute EventListener onopen;
        attribute EventListener onread;
        attribute EventListener onclose;
    void send(in DOMString data);
```

5 Jun 2004 - 22 Aug 2020

DEC JAN FEB
◀ 02 ▶
2004 2006 2007

About this capture

Connection objects must also implement the EventTarget interface. [DOMEvents]

When a `Connection` object is created, the UA must try to establish a connection, as described in the sections below describing each connection type.

The `network` attribute represents the name of the network connection (the value depends on the kind of connection being established). The `peer` attribute identifies the remote host for direct (non-broadcast) connections.

The `network` attribute must be set as soon as the `Connection` object is created, and keeps the same value for the lifetime of the object. The `peer` attribute must initially be set to the empty string and must be updated once, when the connection is established, after which point it must keep the same value for the lifetime of the object.

The `readyState` attribute represents the state of the connection. When the object is created it must be set to 0. It can have the following values:

0 Connecting

The connection has not yet been established.

1 Connected

The connection is established and communication is possible.

2 Closed

The connection has been closed.

Once a connection is established, the `readyState` attribute's value must be changed to 1, and the `open` event must be fired on the `Connection` object.

When data is received, the `read` event will be fired on the `Connection` object.

When the connection is closed, the `readyState` attribute's value must be changed to 2, and the `close` event must be fired on the `Connection` object.

The `onopen`, `onread`, and `onclose` attributes must, when set, register their new value as an event listener for their respective events (namely `open`, `read`, and `close`), and unregister their previous value if any.

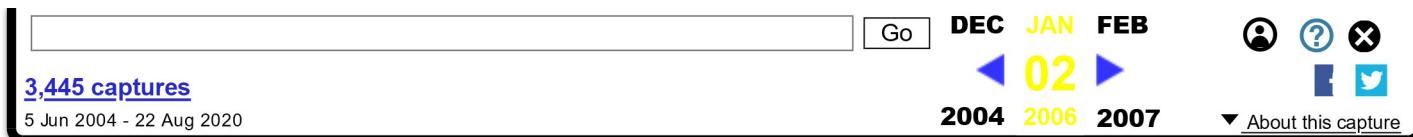

The `send()` method transmits data using the connection. If the connection is not yet established, it must raise an `INVALID_STATE_ERR` exception. If the connection is established, then the behaviour depends on the connection type, as described below.

The `disconnect()` method must close the connection, if it is open. If the connection is already closed, it must do nothing. Closing the connection causes a `close` event to be fired and the `readyState` attribute's value to change, as [described above](#).

7.3.3. Connection Events

All the events described in this section are events in the `http://www.w3.org/2001/XMLSchema#events` namespace, which do not bubble, are not cancelable, and have no default action.

The `open` event is fired when the connection is established. UAs must use the normal `Event`

interface when firing this event as well.

Note: No information regarding why the connection was closed is passed to the application in this version of this specification.

The `read` event is fired when data is received for a connection. UAs must use the `ConnectionReadEvent` interface for this event.

```
interface ConnectionReadEvent : Event {
    readonly attribute DOMString data;
    readonly attribute DOMString source;
    void           initConnectionReadEvent(in DOMString typeArg,
                                         in boolean canBubbleArg,
                                         in boolean cancelableArg,
                                         in DOMString dataArg);
    void           initConnectionReadEventNS(in DOMString namespaceURI
                                         in DOMString typeArg,
                                         in boolean canBubbleArg,
                                         in boolean cancelableArg,
                                         in DOMString dataArg);
};
```

The `data` attribute must contain the data that was transmitted from the peer.

The `source` attribute must contain the name of the peer. This is primarily useful on broadcast connections; on direct connections it is equal to the `peer` attribute on the `Connection` object.

The `initConnectionReadEvent()` and `initConnectionReadEventNS()` methods must initialise the event in a manner analogous to the similarly-named methods in the DOM3 Events interfaces. [\[DOM3EVENTS\]](#)

Events that would be fired during script execution (e.g. between the connection object being created — and thus the connection being established — and the current script completing; or, during the execution of a `read` event handler) must be buffered, and those events queued up and each one individually fired after the script has completed.

7.3.4. TCP connections

The `TCPCConnection(subdomain, port, secure)` constructor on the `Window` interface returns a new object implementing the `Connection` interface, set up for a direct connection to a specified host on the page's domain.

When this constructor is invoked, the following steps must be followed.

First, if the `script's domain` is not a host name (e.g. it is an IP address) then the UA must raise a security exception.

Then, if the `subdomain` argument is null or the empty string, the target host is the `script's domain`. Otherwise, the `subdomain` argument is prepended to the `script's domain` with a dot separating the two strings, and that is the target host.

[format](#) can be obtained without errors. If it cannot, then the user agent must raise a security exception.

The user agent may also raise a security exception at this time if, for some reason, permission to create a direct TCP connection to the relevant host is denied. Reasons could include the UA being instructed by the user to not allow direct connections, or the UA establishing (for instance using UPnP) that the network topology will cause connections on the specified port to be directed at the wrong host.

If no exceptions are raised by the previous steps, then a new [Connection](#) object must be created, its [peer](#) attribute must be set to a string consisting of the name of the target host, a colon (U+003A COLON), and the port number as decimal digits, and its [network](#) attribute must be set to the same value as the [peer](#) attribute.

This object must then be returned.

The user agent must then begin trying to establish a connection with the target host and specified port. (This typically would begin in the background, while the script continues to execute.)

If the [secure](#) boolean argument is set to true, then the user agent must establish a secure connection with the target host and specified port using TLS or another protocol, negotiated with the server. [\[RFC2246\]](#) If this fails the user agent must act as if it had [closed the connection](#).

Once a secure connection is established, or if the [secure](#) boolean argument is not set to true, then the user agent must continue to connect to the server using the protocol described in the section entitled [clients connecting over TCP](#). All data on connections made using TLS must be sent as "application data".

Once the connection is established, the UA must act as described in the section entitled [sending and receiving data over TCP](#).

User agents should allow multiple TCP connections to be established per host. In particular, user agents should not apply per-host HTTP connection limits to connections established with the [TCPConnection](#) constructor.

7.3.5. Broadcast connections

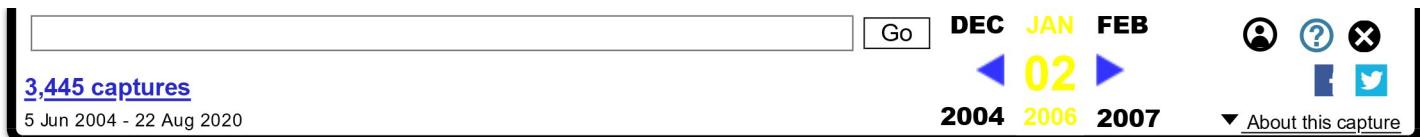

The [LocalBroadcastConnection\(\)](#) constructor on the [Window](#) interface returns a new object implementing the [Connection](#) interface, set up to broadcast on the local network.

When this constructor is invoked, a new [Connection](#) object must be created.

The [network](#) attribute of the object must be set to [the string representing the script's domain in IDNA format](#). If this string cannot be obtained, then the user agent must raise a security exception exception when the constructor is called.

The [peer](#) attribute must be set to the empty string.

The object must then be returned, unless, for some reason, permission to broadcast on the local network is to be denied. In the latter case, a security exception must be raised instead. User agents may deny such permission for any reason, for example a user preference.

on before beginning broadcasting.

UAs may broadcast and listen on multiple networks at once. For example, the UA could broadcast on both Bluetooth and Wifi at the same time.

As soon as the object is returned, the connection [has been established](#), which implies that the [open](#) event must be fired. Broadcast connections are never closed.

7.3.5.1. Broadcasting over TCP/IP

We need to register a UDP port for this. For now this spec refers to port 18080/udp.

Note: Since this feature requires that the user agent listen to a particular port, typically only one user agent per IP address can use this feature at any one time.

On TCP/IP networks, broadcast connections transmit data using UDP over port 18080.

When the [send\(data\)](#) method is invoked on a [Connection](#) object that was created by the [LocalBroadcastConnection\(\)](#) constructor, the user agent must follow these steps:

1. Create a string consisting of the value of the [network](#) attribute of the [Connection](#) object, a U+0020 SPACE character, a U+0002 START OF TEXT character, and the [data](#) argument.
2. Encode the string as UTF-8.
3. If the resulting byte stream is longer than 65487 bytes, raise an [INDEX_SIZE_ERR](#) DOM exception and stop.
4. Create a UDP packet whose data is the byte stream, with the source and destination ports being 18080, and with appropriate length and checksum fields. Transmit this packet to IPv4 address 255.255.255.255 or IPv6 address ff02::1, as appropriate. **IPv6 applications will also have to enable reception from this address.**

When a broadcast connection is opened on a TCP/IP network, the user agent should listen for UDP packets on port 18080.

When the user agent receives a packet on port 18080, the user agent must attempt to decode that packet's data as UTF-8. If the data is not fully correct UTF-8 (i.e. if there are decoding errors) then the packet must be ignored. Otherwise, the user agent must check to see if the decoded string contains a U+0020 SPACE character. If it does not, then the packet must again be ignored (it might be a peer discovery packet from a [PeerToPeerConnection\(\)](#) constructor). If it does then the user agent must split the the string at the first space character. All the characters before the space are then known as *d*, and all the characters after the space are known as *s*. If *s* is not at least one character long, or if the first character of *s* is not a U+0002 START OF TEXT character, then the packet must be ignored. (This allows for future extension of this protocol.)

Otherwise, for each [Connection](#) object that was created by the [LocalBroadcastConnection\(\)](#) constructor and whose [network](#) attribute exactly matches *d*, a [read](#) event must be fired on the [Connection](#) object. The string *s*, with the first character removed, must be used as the [data](#), and the source IP address of the packet as the [source](#).

IP addresses secret while still allowing for applications to distinguish between multiple participants?

7.3.5.2. Broadcasting over Bluetooth

Does anyone know enough about Bluetooth to write this section?

7.3.5.3. Broadcasting over IrDA

Does anyone know enough about IrDA to write this section?

7.3.6. Peer-to-peer connections

The `PeerToPeerConnection()` constructor on the `Window` interface returns a new object implementing the `Connection` interface, set up for a direct connection to a user-specified host.

When this constructor is invoked, a new `Connection` object must be created.

The `network` attribute of the object must be set to [the string representing the script's domain in IDNA format](#). If this string cannot be obtained, then the user agent must raise a security exception exception when the constructor is called.

The `peer` attribute must be set to the empty string.

The object must then be returned, unless, for some reason, permission to establish peer-to-peer connections is generally disallowed, for example due to administrator settings. In the latter case, a security exception must be raised instead.

The user agent must then, typically while the script resumes execution, find a remote host to establish a connection to. To do this it must start broadcasting and listening for peer discovery messages and listening for incoming connection requests on all the supported networks. How this is performed depends on the type of network and is described below.

The UA should inform the user of the clients that are detected, and allow the user to select one to connect to. UAs may also allow users to explicit specify hosts that were not detected, e.g. by having the user enter an IP address.

If an incoming connection is detected before the user specifies a target host, the user agent should ask the user to confirm that this is the host they wish to connect to. If it is, the connection should be accepted and the UA will act as the `server` in this connection. (Which UA acts as the server and which acts as the client is not discernible at the DOM API level.)

If no incoming connection is detected and if the user specifies a particular target host, a connection should be established to that host, with the UA acting as the `client` in the connection.

No more than one connection must be established per `Connection` object, so once a connection has been established, the user agent must stop listening for further connections (unless, or until such time as, another `Connection` object is being created).

If at any point the user cancels the connection process or the remote host refuses the connection,

About this capture

We need to register ports for this. For now this spec refers to port 18080/udp and 18080/tcp.

Note: Since this feature requires that the user agent listen to a particular port, typically only one user agent per IP address can use this feature at any one time.

When using TCP/IP, broadcasting peer discovery messages must be done by creating UDP packets every few seconds containing as their data the value of the connection's `network` attribute, encoded as UTF-8, with the source and destination ports being set to 18080 and appropriate length and checksum fields, and sending these packets to address (in IPv4) 255.255.255.255 or (in IPv6) ff02::1, as appropriate.

Listening for peer discovery messages must be done by examining incoming UDP packets on port 18080. **IPv6 applications will also have to enable reception from the ff02::1 address.** If their payload is exactly byte-for-byte equal to a UTF-8 encoded version of the value of the connection's `network` attribute, then the source address of that packet represents the address of a host that is ready to accept a peer-to-peer connection, and it should therefore be offered to the user.

Incoming connection requests must be listened for on TCP port 18080. If an incoming connection is received, the UA acts as a *server*, as described in the section entitled [servers accepting connections over TCP](#).

If no incoming connection requests are accepted and the user instead specifies a target host to connect to, the UA acts as a *client*: the user agent must attempt to connect to the user-specified host on port 18080, as described in the section entitled [clients connecting over TCP](#).

Once the connection is established, the UA must act as described in the section entitled [sending and receiving data over TCP](#).

Note: This specification does not include a way to establish secure (encrypted) peer-to-peer connections at this time. **If you can see a good way to do this, let me know.**

7.3.6.2. Peer-to-peer connections over Bluetooth

Does anyone know enough about Bluetooth to write this section?

7.3.6.3. Peer-to-peer connections over IrDA

Does anyone know enough about IrDA to write this section?

7.3.7. The common protocol for TCP-based connections

The same protocol is used for `TCPConnection` and `PeerToPeerConnection` connection types. This section describes how such connections are established from the client and server sides, and then describes how data is sent and received over such connections (which is the same for both

This section defines the client-side requirements of the protocol used by the [TCPConnection](#) and [PeerToPeerConnection](#) connection types.

If a TCP connection to the specified target host and port cannot be established, for example because the target host is a domain name that cannot be resolved to an IP address, or because packets cannot be routed to the host, the user agent should retry creating the connection. If the user agent gives up trying to connect, the user agent must act as if it had [closed the connection](#).

Note: *No information regarding the state of the connection is passed to the application while the connection is being established in this version of this specification.*

Once a TCP/IP connection to the remote host is established, the user agent must transmit the following sequence of bytes, represented here in hexadecimal form:

0x48 0x65 0x6C 0x6C 0x6F 0x0A

Note: *This represents the string "Hello" followed by a newline, encoded in UTF-8.*

The user agent must then read all the bytes sent from the remote host, up to the first 0x0A byte (inclusive). That string of bytes is then compared byte-for-byte to the following string of bytes:

0x57 0x65 0x6C 0x63 0x6F 0x6E 0x65 0x0A

Note: *This says "Welcome".*

If the server sent back a string in any way different to this, then the user agent must [close the connection](#) and give up trying to connect.

Otherwise, the user agent must then take [the string representing the script's domain in IDNA format](#), encode it as UTF-8, and send that to the remote host, followed by a 0x0A byte (a U+000A LINE FEED in UTF-8).

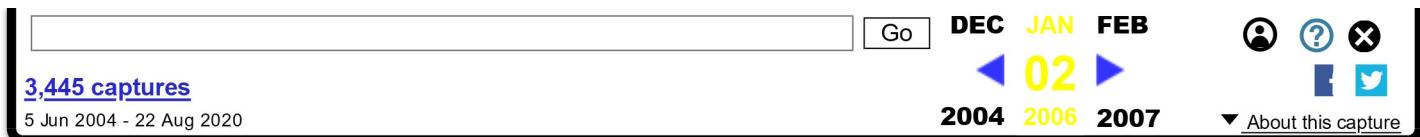

The user agent must then read all the bytes sent from the remote host, up to the first 0x0A byte (inclusive). That string of bytes must then be compared byte-for-byte to the string that was just sent to the server (the one with the IDNA domain name and ending with a newline character). If the server sent back a string in any way different to this, then the user agent must [close the connection](#) and give up trying to connect.

Otherwise, the connection [has been established](#) (and events and so forth get fired, as described above).

If at any point during this process the connection is closed prematurely, then the user agent must [close the connection](#) and give up trying to connect.

7.3.7.2. Servers accepting connections over TCP

This section defines the server side of the protocol described in the previous section. For authors, it should be used as a guide for how to implement servers that can communicate with Web pages over TCP. For UAs these are the requirements for the server part of [PeerToPeerConnections](#).

Note: This says "Welcome" and a newline in UTF-8.

The user agent must then read all the bytes sent from the remote host, up to the first 0x0A byte (inclusive). That string of bytes is then compared byte-for-byte to the following string of bytes:

```
0x48 0x65 0x6C 0x6C 0x6F 0x0A
```

Note: "Hello" and a newline.

If the remote host sent back a string in any way different to this, then the user agent must [close the connection](#) and give up trying to connect.

Otherwise, the user agent must then take [the string representing the script's domain in IDNA format](#), encode it as UTF-8, and send that to the remote host, followed by a 0x0A byte (a U+000A LINE FEED in UTF-8).

The user agent must then read all the bytes sent from the remote host, up to the first 0x0A byte (inclusive). That string of bytes must then be compared byte-for-byte to the string that was just sent to that host (the one with the IDNA domain name and ending with a newline character). If the remote host sent back a string in any way different to this, then the user agent must [close the connection](#) and give up trying to connect.

Otherwise, the connection [has been established](#) (and events and so forth get fired, as described above).

Note: For author-written servers (as opposed to the server side of a peer-to-peer connection), the script's domain would be replaced by the hostname of the server. Alternatively, such servers might instead wait for the client to send its domain string, and then simply echo it back. This would allow connections from pages on any domain, instead of just pages originating from the same host. The client compares the two strings to ensure they are the same before allowing the connection to be used by author script.

If at any point during this process the connection is closed prematurely, then the user agent must [close the connection](#) and give up trying to connect.

7.3.7.3. Sending and receiving data over TCP

When the `send(data)` method is invoked on the connection's corresponding `Connection` object, the user agent must take the `data` argument, replace any U+0000 NULL and U+0017 END OF TRANSMISSION BLOCK characters in it with U+FFFD REPLACEMENT CHARACTER characters, then transmit a U+0002 START OF TEXT character, this new `data` string and a single U+0017 END OF TRANSMISSION BLOCK character (in that order) to the remote host, all encoded as UTF-8.

When the user agent receives bytes on the connection, the user agent must buffer received bytes until it receives a 0x17 byte (a U+0017 END OF TRANSMISSION BLOCK character). If the first buffered byte is not a 0x02 byte (a U+0002 START OF TEXT character encoded as UTF-8) then all the data up to the 0x17 byte, inclusive, must be dropped. (This allows for future extension of this protocol.) Otherwise, all the data from (but not including) the 0x02 byte and up to (but not including)

About this capture

Note: This protocol does not yet allow binary data (e.g. an image or video data) to be efficiently transmitted. A future version of this protocol might allow this by using the prefix character U+001F INFORMATION SEPARATOR ONE, followed by binary data which uses a particular byte (e.g. 0xFF) to encode byte 0x17 somehow (since otherwise 0x17 would be treated as transmission end by down-level UAs).

7.3.8. Security

Need to write this section.

If you have an unencrypted page that is (through a man-in-the-middle attack) changed, it can access a secure service that is using IP authentication and then send that data back to the attacker. Ergo we should probably stop unencrypted pages from accessing encrypted services, on the principle that the actual level of security is zero. Then again, if we do that, we prevent insecure sites from using SSL as a tunneling mechanism.

Should consider dropping the subdomain-only restriction. It doesn't seem to add anything, and prevents cross-domain chatter.

7.3.9. Relationship to other standards

Should have a section talking about the fact that we blithely ignoring IANA's port assignments here.

Should explain why we are not reusing HTTP for this. (HTTP is too heavy-weight for such a simple need; requiring authors to implement an HTTP server just to have a party line is too much of a barrier to entry; cannot rely on prebuilt components; having a simple protocol makes it much easier to do RAD; HTTP doesn't fit the needs and doesn't have the security model needed; etc)

7.4. [SCS] Cross-document messaging

Web browsers, for security and privacy reasons, prevent documents in different domains from affecting each other; that is, cross-site scripting is disallowed.

While this is an important security feature, it prevents pages from different domains from communicating even when those pages are not hostile. This section introduces a messaging system that allows documents to communicate with each other regardless of their source domain, in a way designed to not enable cross-site scripting attacks.

7.4.1. Definitions

Any `Document` object that supports this cross-document messaging API must implement the `DocumentMessaging` interface.

Such Document objects must also implement the EventTarget interface. [\[DOM3EVENTS\]](#)

The [postMessage\(\)](#) method causes an event to be dispatched (as defined below). This event uses the following interface:

```
interface CrossDocumentMessageEvent : Event {
  readonly attribute DOMString data;
  readonly attribute DOMString domain;
  readonly attribute DOMString uri;
  readonly attribute Document source;
  void initCrossDocumentMessageEvent(in DOMString typeArg,
                                      in boolean canBubbleArg,
                                      in boolean cancelableArg,
                                      in DOMString dataArg,
                                      in DOMString domainArg,
                                      in DOMString uriArg,
                                      in Document documentArg);
  void initCrossDocumentMessageEventNS(in DOMString namespaceURI,
                                       in DOMString typeArg,
                                       in boolean canBubbleArg,
                                       in boolean cancelableArg,
                                       in DOMString dataArg,
                                       in DOMString domainArg,
                                       in DOMString uriArg,
                                       in Document documentArg);
};
```

7.4.2. Processing model

When a script invokes the [postMessage\(\)](#) method on a document, the user agent must create an event that uses the [CrossDocumentMessageEvent](#) interface, with the event name [message](#) in the [uuid:7f37e11a-3a5c-4f3d-a82e-83b611439f37](#) namespace, which bubbles, is cancelable, and has no default action. The [data](#) attribute must be set to the value passed as the argument to the [postMessage\(\)](#) method, the [domain](#) attribute must be set to the domain of the document that the script that invoked the methods is associated with, the [uri](#) attribute must be set to the URI of that document, and the [source](#) attribute must be set to the object representing that document.

⚠Warning! Authors should check the [domain](#) attribute to ensure that messages are only accepted from domains that they expect to receive messages from. Otherwise, bugs in the author's message handling code could be exploited by hostile sites.

For example, if document A contains an [object](#) element that contains document B, and script in document A calls [postMessage\(\)](#) on document B, then a message event will be fired on that element, marked as originating from document A. The script in document A might look like:

```
var o = document.getElementsByTagName('object')[0];
o.contentDocument.postMessage('Hello world');
```

3,445 captures

Go DEC JAN FEB
◀ 02 ▶
2004 2006 2007
▼ About this capture

```
function receiver(e) {
    if (e.domain == 'example.com') {
        if (e.data == 'Hello world') {
            e.source.postMessage('Hello');
        } else {
            alert(e.data);
        }
    }
}
```

This script first checks the domain is the expected domain, and then looks at the message, which it either displays to the user, or responds to by sending a message back to the document which sent the message in the first place.

Note: *Implementors are urged to take extra care in the implementation of this feature. It allows authors to transmit information from one domain to another domain, which is normally disallowed for security reasons. It also requires that UAs be careful to allow access to certain properties but not others.*

The `initCrossDocumentMessageEvent()` and `initCrossDocumentMessageEventNS()` methods must initialise an event object in a manner analogous to other `initXXXEvent` methods.

8. The HTML syntax

8.1. Writing HTML documents [TBW]

This section only applies to authors and markup generators.

This section needs writing.

8.2. [SCS] Parsing HTML documents [WIP]

This section only applies to user agents.

The rules for parsing [XHTML](#) documents into DOM trees are covered by the XML and Namespaces in XML specifications, and are out of scope of this specification.

For [HTML](#) documents, user agents must use the parsing rules described in this section to generate the DOM trees.

This specification mainly defines the parsing rules for syntactically valid HTML documents. When user agents encounter something described as a **hard parse error** in the rules below, they may use any error correction algorithm to handle the error. Such error correction should not result in DOMs that are not strictly trees. User agents are reluctantly encouraged to reverse engineer the error handling behaviour of the prevalent user agent in order to foster interoperability.

About this capture

but may apply error correction algorithms (those described in the spec for easy errors, and those reverse-engineered from other UAs for hard errors) in an attempt to continue past the location of the error and find the remaining errors.

While the HTML form of HTML5 bears a close resemblance to SGML and XML, it is a separate language with its own parsing rules.

Past versions of HTML (in particular from HTML2 to HTML4) were based on SGML and used SGML parsing rules. However, few (if any) web browsers ever implemented true SGML parsing for HTML documents; the only user agents to strictly handle HTML as an SGML application have historically been validators. The resulting confusion — with validators claiming documents to have one representation while widely deployed Web browsers interoperably implemented a different representation — has resulted in this version of HTML returning to a non-SGML basis.

Authors interested in using SGML tools in their authoring pipeline are encouraged to use the XML serialisation of HTML5 instead of the HTML serialisation.

The input to the HTML parsing process consists of a stream of Unicode characters. Bytes or sequences of bytes in the original byte stream that could not be converted to Unicode characters must be converted to U+FFFD REPLACEMENT CHARACTER code points.

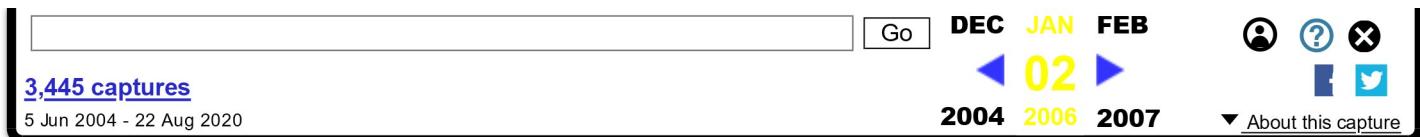

For HTML, user agents must use the following algorithm in determining the character encoding of a document:

1. If the transport layer specifies an encoding, use that.
2. Otherwise, if the user agent can find a `meta` element that [specifies character encoding information](#), then use that. (The exact parsing rules for using this information are not yet described in this specification.)
3. Otherwise, if the user agent can autodetect the character encoding from applying frequency analysis or other algorithms to the data stream, then use that.
4. Otherwise, use an implementation-defined or user-specified default character encoding (ISO-8859-1, windows-1252, and UTF-8 are recommended as defaults, and can in many cases be identified by inspection as they have different ranges of valid bytes).

Note: For XML documents, the algorithm user agents must use to determine the character encoding is given by the XML specification. [XML]

U+000D CARRIAGE RETURN (CR) characters, and U+000A LINE FEED (LF) characters, are treated specially. Any CR characters that are followed by LF characters must be removed, and any CR characters not followed by LF characters must be converted to LF characters. Thus, newlines in HTML DOMs are represented by LF characters.

Parsing an HTML document consists of a [tokenisation](#) stage (lexical analysis) followed by a [tree construction](#) stage (semantic analysis). The output is a `Document` object.

8.2.1. Tokenisation

Implementations must act as if they used the following state machine to tokenise HTML. The state machine must start in the [data state](#). Each state consumes a single character, which may have various side-effects, and either switches the state machine to a new state to *reconsume* the same character, or switches it to a new state (to consume the next character), or repeats the same state (to consume the next character). The "EOF" character in the tables below is a conceptual character representing the end of the input file. It is not a real character in the stream, but rather the lack of any further characters.

The output of the tokenisation step is a series of zero or more of the following tokens: DOCTYPE, start tag, end tag, comment, character, entity.

Data state

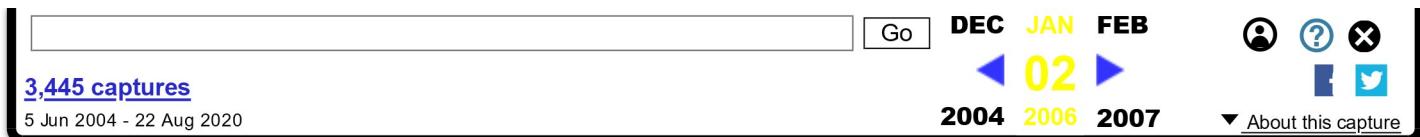

- ↪ **U+003C LESS-THAN SIGN**
Switch to the [tag open state](#).
- ↪ **U+0026 AMPERSAND**
Switch to the entity open state.
- ↪ **EOF**
Stop tokenising.
- ↪ **Anything else**
Emit the input character as a character token.

Tag open state

- ↪ **U+0021 EXCLAMATION MARK**
Switch to the marked section open state.
- ↪ **U+002F SOLIDUS**
Switch to the close tag open state.
- ↪ **U+003E GREATER-THAN SIGN**
Emit a U+003C LESS-THAN SIGN character token and a U+003E GREATER-THAN SIGN character token, then switch to the [data state](#).
- ↪ **U+003F QUESTION MARK**
- ↪ **U+0041 LATIN CAPITAL LETTER A through to U+005A LATIN CAPITAL LETTER Z**
- ↪ **U+0061 LATIN SMALL LETTER A through to U+007A LATIN SMALL LETTER Z**
Create a new start tag token, set its tag name to the input character, then switch to the tagname state. (Don't emit the token yet; further details will be filled in before it is emitted.)
- ↪ **EOF**
Emit a U+003C LESS-THAN SIGN character token and stop tokenising.
- ↪ **Anything else**
Emit a U+003C LESS-THAN SIGN character token and reconsume the current input character in the [data state](#).

...

8.2.2. Tree construction

/1999/xhtml namespace to elements in that are parsed in documents labelled as text/html, at least for the purposes of the DOM and CSS.

9. Rendering [\[TBW\]](#)

This section will probably include details on how to render DATAGRID, drag-and-drop, etc, in a visual media, in concert with CSS.

CSS UAs in visual media must, when scrolling a page to a fragment identifier, align the top of the viewport with the target element's top border edge.

9.1. Rendering and the DOM

This section is wrong. mediaMode will end up on Window, I think. All views implement Window.

Any object implement the `AbstractView` interface must also implement the `MediaModeAbstractView` interface.

```
interface MediaModeAbstractView {
    readonly attribute DOMString mediaMode;
};
```

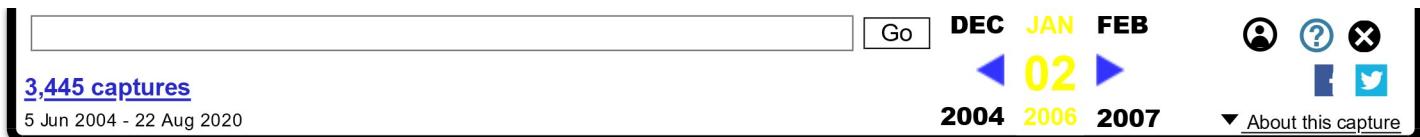

The `mediaMode` attribute on objects implementing the `MediaModeAbstractView` interface must return the string that represents the canvas' current rendering mode (screen, print, etc). This is a lowercase string, as defined by the CSS specification. [\[CSS21\]](#)

Some user agents may support multiple media, in which case there will exist multiple objects implementing the `AbstractView` interface. Only the default view implements the `Window` interface. The other views can be reached using the `view` attribute of the `UIEvent` interface, during event propagation. There is no way currently to enumerate all the views.

10. Things that you can't do with this specification because they are better handled using other technologies that are further described herein

This section is non-normative.

There are certain features that are not handled by this specification because a client side markup language is not the right level for them, or because the features exist in other languages that can be integrated into this one. This section covers some of the more common requests.

10.2. Declarative 2D vector graphics and animation

Embedding vector graphics into XHTML documents is the domain of SVG.

10.3. Declarative 3D scenes

Embedding 3D imagery into XHTML documents is the domain of X3D, or technologies based on X3D that are namespace-aware.

References [TBW]

This section will be written in a future draft.

Mike Dierken, Shaun Inman, Simon Pieters, Steven Garrity, Stuart Parmenter, Tantek Çelik, Thomas O'Connor, Tim Altman, Vladimir Vukićević, and everyone on the WHATWG mailing list for their useful and substantial comments.

Special thanks to Richard Williamson for creating the first implementation of canvas in Safari, from which the canvas feature was designed.

Special thanks also to the Microsoft employees who first implemented the XMLHttpRequest interface, the event-based drag-and-drop mechanism, and other features first widely deployed by the Windows Internet Explorer browser.

Thanks also to the Microsoft blogging community for some ideas, to the attendees of the W3C Workshop on Web Applications and Compound Documents for inspiration, and to the #mrt crew, the #mrt.no crew, and the cabal for their ideas and support.
