Full table of contents

1	Introduction
1.1	Where does this specification fit?
1.2	What is HTML? [S]
1.3	Background
1.4	Audience
1.5	Scope
1.6	History
1.7	Design goals
1.8	Serializability of script execution
1.9	Compatibility with other specifications
1.10	Extensibility
1.11	HTML vs XML syntax
1.12	Structure of this specification
1.13	How to use this specification
1.14	Typeographic conventions
1.15	A quick introduction to HTML
1.16	Writing secure applications with HTML
1.17	Common pitfalls to avoid when using the scripting APIs
1.18	How to catch mistakes when writing HTML validators and conformance checkers
1.19	Conformance requirements for authors
1.20	Prescriptive markup
1.21	Syntax errors
1.22	Restrictions on content models and on attribute values
1.23	Suggested reading
2	Common infrastructure
2.1	Terminology
2.1.1	Parsability
2.1.2	Resources
2.1.3	XML compatibility
2.1.4	DOM trees
2.1.5	Charsets
2.1.6	Plurals
2.1.7	Character encodings
2.1.8	Conformance classes
2.1.9	Dependencies
2.1.10	Extensibility
2.1.11	Interactions with XPath and XSLT
2.2	Case-sensitivity and string comparison
2.3	Policy-controlled features
2.4	Common microsyntaxes
2.4.1	Common parser atoms
2.4.2	String-separated tokens
2.4.3	Keywords and enumerated attributes
2.4.4	Numbers
2.4.4.1	Signed integers
2.4.4.2	Non-negative integers
2.4.4.3	Floating-point numbers
2.4.4.4	Percentages and lengths
2.4.4.5	Lists of floating-point numbers
2.4.4.6	Lists of dimensions
2.4.5	Dates and times
2.4.5.1	Moments
2.4.5.2	Dates
2.4.5.3	Yearless dates
2.4.5.4	Times
2.4.5.5	Local dates and times
2.4.5.6	Global zones
2.4.5.7	Global dates and times
2.4.5.8	Weeks
2.4.5.9	Durations
2.4.5.10	Vague moments in time
2.4.6	Colors
2.4.7	Space-separated tokens
2.4.8	Comma-separated tokens
2.4.9	References
2.4.10	Media queries
2.5	URLs
2.5.1	Terminology
2.5.2	Parsing URLs
2.5.3	Dynamic changes to base URLs
2.6	Fetching resources
2.6.1	Terminology
2.6.2	Determining the type of a resource
2.6.3	Decoding character encodings from <code>meta</code> elements
2.6.4	CORS settings attributes
2.6.5	Referrer policy attributes
2.6.6	Nonce attributes
2.7	Common DOM interfaces
2.7.1	Reflecting content attributes in IDL_attributes
2.7.2	Collective interfaces
2.7.2.1	The <code>HTMLCollection</code> interface
2.7.2.2	The <code>HTMLFormControlsCollection</code> interface
2.7.2.3	The <code>HTMLScriptElementCollection</code> interface
2.7.2.4	The <code>HTMLStyleElementCollection</code> interface
2.8	Storage management of structured data
2.8.1	Serializable objects
2.8.2	Transferable objects
2.8.3	StructuredSerialize(<code>value</code> , <code>storage</code> , <code>memory</code>)
2.8.4	StructuredDeserialize(<code>storage</code> , <code>value</code>)
2.8.5	StructuredSerialize(<code>storage</code> , <code>value</code>)
2.8.6	StructuredDeserialize(<code>serialized</code> , <code>targetRealm</code> , <code>memory</code>)
2.8.7	StructuredSerializeWithTransfer(<code>value</code> , <code>transferList</code>)
2.8.8	StructuredDeserializeWithTransfer(<code>serializedWithTransferResult</code> , <code>targetRealm</code>)
2.8.9	Performing serialization and transferring from other specifications
3	Semantics, structure, and APIs of HTML documents
3.1	Document object
3.1.1	The <code>Document</code> object
3.1.2	The <code>documentOrShadowRoot</code> interface
3.1.3	Resource metadata management
3.1.4	DOM tree accessors
3.2	HTML elements
3.2.1	Elements in the DOM
3.2.2	HTML element constructors
3.2.3	Element definitions
3.2.4	Element attributes
3.2.5	Content models
3.2.5.1	The “nothing” content model
3.2.5.2	Kinds of content
3.2.5.2.1	Metadata content
3.2.5.2.2	Flow content
3.2.5.2.3	Text content
3.2.5.2.4	Heading content
3.2.5.2.5	Phrasing content
3.2.5.2.6	Embedded content
3.2.5.2.7	Interactive content
3.2.5.2.8	Placeholder content
3.2.5.2.9	Translating content elements
3.2.5.3	Transparent content models
3.2.5.4	Paragraphs
3.2.6	Global attributes
3.2.6.1	The <code>title</code> attribute
3.2.6.2	The <code>lang</code> and <code>dir</code> attributes
3.2.6.3	The <code>translate</code> attribute
3.2.6.4	The <code>aria</code> attribute
3.2.6.5	The <code>role</code> attribute
3.2.6.6	Embedding custom non-visible data with the <code>data-</code> * attributes
3.2.7	The <code>nearestID</code> attribute
3.2.8	Requirements relating to the bidirectional algorithm

3.2.9 Requirements related to ARIA and to platform accessibility APIs

4 The document element

4.1 The `html` element

4.1.1 The `html` element

4.1.2 Document metadata

4.2.1 The `head` element

4.2.2 The `title` element

4.2.3 The `meta` element

4.2.4 The `link` element

4.2.4.1 Processing the `media` attribute

4.2.4.2 Processing the `type` attribute

4.2.4.3 Fetching and processing a resource from a `link` element

4.2.4.4 Providing users with a means to follow hyperlinks created using the `link` element

4.2.5 The `script` element

4.2.5.1 Standard metadata name

4.2.5.2 Other metadata name

4.2.5.3 Primary attributes

4.2.5.4 Specifying the document's character encoding

4.2.6 The `style` element

4.2.7 Interactions of style and scripting

4.3 Sections

4.3.1 The `body` element

4.3.2 The `div` element

4.3.3 The `section` element

4.3.4 The `nav` element

4.3.5 The `aside` element

4.3.6 The `h1`, `h2`, `h3`, `h4`, `h5`, and `h6` elements

4.3.7 The `hgroup` element

4.3.8 The `h1` element

4.3.9 The `h2` element

4.3.10 The `h3` element

4.3.11 Headings and sections

4.3.11.1 Creating an outline

4.3.11.2 Creating outlines

4.3.11.3 Providing outlines to users

4.3.12 Usage summary

4.3.12.1 Article or section*

4.4 Grouping content

4.4.1 The `s` element

4.4.2 The `del` element

4.4.3 The `ins` element

4.4.4 The `blockquote` element

4.4.5 The `ol` element

4.4.6 The `ul` element

4.4.7 The `li` element

4.4.8 The `ul` element

4.4.9 The `ol` element

4.4.10 The `ol` element

4.4.11 The `ul` element

4.4.12 The `ol` element

4.4.13 The `ul` element

4.4.14 The `ol` element

4.4.15 The `div` element

4.5 Text-level semantics

4.5.1 The `a` element

4.5.2 The `area` element

4.5.3 The `img` element

4.5.4 The `area` element

4.5.5 The `a` element

4.5.6 The `area` element

4.5.7 The `a` element

4.5.8 The `a` element

4.5.9 The `area` element

4.5.10 The `area` element

4.5.11 The `a` element

4.5.12 The `a` element

4.5.13 The `a` element

4.5.14 The `a` element

4.5.15 The `a` element

4.5.16 The `a` element

4.5.17 The `a` element

4.5.18 The `a` element

4.5.19 The `a` element

4.5.20 The `a` element

4.5.21 The `a` element

4.5.22 The `a` element

4.5.23 Sequential link types

4.6.23.1 Link type "none"

4.6.23.2 Link type "ugc"

4.6.24 Other link types

4.6 Links

4.6.1 Introduction

4.6.2 Links created by `a` and `area` elements

4.6.3 API for `a` and `area` elements

4.6.4 Following hyperlinks

4.6.5 Downloading resources

4.6.6 Hyperlink auditing

4.6.6 Link types

4.6.6.1 Link type "alternate"

4.6.6.2 Link type "author"

4.6.6.3 Link type "bookmark"

4.6.6.4 Link type "checkbox"

4.6.6.5 Link type "controlset"

4.6.6.6 Link type "external"

4.6.6.7 Link type "help"

4.6.6.8 Link type "icon"

4.6.6.9 Link type "image-set"

4.6.6.10 Link type "internal"

4.6.6.11 Link type "mailto"

4.6.6.12 Link type "noopener"

4.6.6.13 Link type "noopener"

4.6.6.14 Link type "noreferrer"

4.6.6.15 Link type "noreferrer noopener"

4.6.6.16 Link type "tag"

4.6.6.17 Link type "uri-set"

4.6.6.18 Link type "visualset"

4.6.6.19 Link type "wsganda"

4.6.6.20 Link type "wsgaud"

4.6.6.21 Link type "wsgauda"

4.6.6.22 Link type "tag"

4.6.6.23 Sequential link types

4.6.23.1 Link type "none"

4.6.23.2 Link type "ugc"

4.6.24 Other link types

4.7 Edits

4.7.1 The `ins` element

4.7.2 The `del` element

4.7.3 Attributes common to `ins` and `del` elements

4.7.4 Edits and paragraphs

4.7.5 Edits and lists

4.7.6 Edits and tables

4.8 Embedded content

4.8.1 The `picture` element

4.8.2 The `source` element

4.8.3 The `img` element

4.8.4 Images

4.8.4.1 Introduction

4.8.4.1.1 Adaptive images

4.8.4.2 Attributes common to `source`, `img`, and `link` elements

4.8.4.2.1 `srcset` attributes

4.8.4.2.2 `src` attributes

4.8.4.2.3 `size` attributes

4.8.4.2.4 `width` and `height` attributes

4.8.4.2.5 `density` attributes

4.8.4.2.6 `alt` attributes

4.8.4.2.7 `crossorigin` attributes

4.8.4.2.8 `loading` attributes

4.8.4.2.9 `referrerpolicy` attributes

4.8.4.2.10 `type` attributes

4.8.4.2.11 `decoding` attributes

4.8.4.2.12 `fetch` attributes

4.8.4.2.13 `get` attributes

4.8.4.2.14 `is` attributes

4.8.4.2.15 `loading` attributes

4.8.4.2.16 `referrerpolicy` attributes

4.8.4.2.17 `type` attributes

4.8.4.2.18 `decoding` attributes

4.8.4.2.19 `get` attributes

4.8.4.2.20 `is` attributes

4.8.4.2.21 `loading` attributes

4.8.4.2.22 `referrerpolicy` attributes

4.8.4.2.23 `type` attributes

4.8.4.2.24 `decoding` attributes

4.8.4.2.25 `get` attributes

4.8.4.2.26 `is` attributes

4.8.4.2.27 `loading` attributes

4.8.4.2.28 `referrerpolicy` attributes

4.8.4.2.29 `type` attributes

4.8.4.2.30 `decoding` attributes

4.8.4.2.31 `get` attributes

4.8.4.2.32 `is` attributes

4.8.4.2.33 `loading` attributes

4.8.4.2.34 `referrerpolicy` attributes

4.8.4.2.35 `type` attributes

4.8.4.2.36 `decoding` attributes

4.8.4.2.37 `get` attributes

4.8.4.2.38 `is` attributes

4.8.4.2.39 `loading` attributes

4.8.4.2.40 `referrerpolicy` attributes

4.8.4.2.41 `type` attributes

4.8.4.2.42 `decoding` attributes

4.8.4.2.43 `get` attributes

4.8.4.2.44 `is` attributes

4.8.4.2.45 `loading` attributes

4.8.4.2.46 `referrerpolicy` attributes

4.8.4.2.47 `type` attributes

4.8.4.2.48 `decoding` attributes

4.8.4.2.49 `get` attributes

4.8.4.2.50 `is` attributes

4.8.4.2.51 `loading` attributes

4.8.4.2.52 `referrerpolicy` attributes

4.8.4.2.53 `type` attributes

4.8.4.2.54 `decoding` attributes

4.8.4.2.55 `get` attributes

4.8.4.2.56 `is` attributes

4.8.4.2.57 `loading` attributes

4.8.4.2.58 `referrerpolicy` attributes

4.8.4.2.59 `type` attributes

4.8.4.2.60 `decoding` attributes

4.8.4.2.61 `get` attributes

4.8.4.2.62 `is` attributes

4.8.4.2.63 `loading` attributes

4.8.4.2.64 `referrerpolicy` attributes

4.8.4.2.65 `type` attributes

4.8.4.2.66 `decoding` attributes

4.8.4.2.67 `get` attributes

4.8.4.2.68 `is` attributes

4.8.4.2.69 `loading` attributes

4.8.4.2.70 `referrerpolicy` attributes

4.8.4.2.71 `type` attributes

4.8.4.2.72 `decoding` attributes

4.8.4.2.73 `get` attributes

4.8.4.2.74 `is` attributes

4.8.4.2.75 `loading` attributes

4.8.4.2.76 `referrerpolicy` attributes

4.8.4.2.77 `type` attributes

4.8.4.2.78 `decoding` attributes

4.8.4.2.79 `get` attributes

4.8.4.2.80 `is` attributes

4.8.4.2.81 `loading` attributes

4.8.4.2.82 `referrerpolicy` attributes

4.8.4.2.83 `type` attributes

4.8.4.2.84 `decoding` attributes

4.8.4.2.85 `get` attributes

4.8.8 The <code><var></code> element
4.8.9 The <code><script></code> element
4.8.10 The <code><audio></code> element
4.8.11 The <code><track></code> element
4.8.12 Media elements
4.8.12.1 Error codes
4.8.12.2 States of the media resource
4.8.12.3 MIME types
4.8.12.4 Network states
4.8.12.5 Loading the media resource
4.8.12.6 Offsets into the media resource
4.8.12.7 Ready states
4.8.12.8 State of the media resource
4.8.12.9 Seeking
4.8.12.10 Media resources with multiple media tracks
4.8.12.10.1 <code>audioTrackList</code> and <code>videoTrackList</code> objects
4.8.12.10.2 Selecting specific audio and video tracks declaratively
4.8.12.11 Time-based tracks
4.8.12.11.1 Text track model
4.8.12.11.2 Sources in-band text tracks
4.8.12.11.3 Sources out-of-band text tracks
4.8.12.11.4 Guidelines for exposing cues in various formats as text track cues
4.8.12.11.5 TextTrack API
4.8.12.11.6 Best practices for objects of the text track API
4.8.12.11.7 Best practices for metadata text tracks
4.8.12.12 Identifying a track kind through a URL
4.8.12.13 User interface
4.8.12.14 Time ranges
4.8.12.15 TextTrackList interface
4.8.12.16 Events summary
4.8.12.17 Security and privacy considerations
4.8.12.18 Best practices for authors using media elements
4.8.12.19 Best practices for implementers of media elements
4.8.13 The <code><nav></code> element
4.8.14 The <code><area></code> element
4.8.15 Images
4.8.15.1 Authoring
4.8.15.2 Processing model
4.8.16 MathML
4.8.17 SVG
4.8.18 The <code><math></code> element
4.9 Tables
4.9.1 The <code><table></code> element
4.9.1.1 Techniques for describing tables
4.9.1.2 Techniques for table design
4.9.2 The <code><caption></code> element
4.9.3 The <code><thead></code> element
4.9.4 The <code><tbody></code> element
4.9.5 The <code><tfoot></code> element
4.9.6 The <code><tr></code> element
4.9.7 The <code><td></code> element
4.9.8 The <code><th></code> element
4.9.9 The <code><th></code> element
4.9.10 The <code><col></code> element
4.9.11 Attributes common to <code><td></code> and <code><th></code> elements
4.9.12 Processing model
4.9.13 Forming a table
4.9.13.1 Forming relationships between data cells and header cells
4.9.13.2 Forming relationships between data cells and header cells
4.9.13 Examples
4.10 Forms
4.10.1 Introduction
4.10.1.1 Writing a form user interface
4.10.1.2 Implementing the server-side processing for a form
4.10.1.3 Configuring a form to communicate with a server
4.10.1.4 Client-side form validation
4.10.1.5 Enabling client-side automatic filling of form controls
4.10.1.6 Improving the user experience on mobile devices
4.10.1.7 The difference between the field type, the <code>autofill</code> field name, and the <code>input</code> modality
4.10.1.8 Date-time and number formats
4.10.2 Categories
4.10.2.1 The <code><input></code> element
4.10.2.2 The <code><label></code> element
4.10.2.3 The <code><select></code> element
4.10.2.4 The <code><button></code> element
4.10.2.5 The <code><form></code> element
4.10.2.6 The <code><input type="checkbox"></code> attribute
4.10.2.6.1 Hidden state (<code>type="checkbox"</code>)
4.10.2.6.2 Text (<code>type="text"</code>) state and Search state (<code>type="search"</code>)
4.10.2.6.3 Telephone state (<code>type="tel"</code>)
4.10.2.6.4 URL state (<code>type="url"</code>)
4.10.2.6.5 Email state (<code>type="email"</code>)
4.10.2.6.6 Password state (<code>type="password"</code>)
4.10.2.6.7 Date state (<code>type="date"</code>)
4.10.2.6.8 Month state (<code>type="month"</code>)
4.10.2.6.9 Week state (<code>type="week"</code>)
4.10.2.6.10 Time state (<code>type="time"</code>)
4.10.2.6.11 Local Date/Time/DateTime state (<code>type="date-local"</code>)
4.10.2.6.12 Number state (<code>type="number"</code>)
4.10.2.6.13 Range state (<code>type="range"</code>)
4.10.2.6.14 Color state (<code>type="color"</code>)
4.10.2.6.15 Checkbox state (<code>type="checkbox"</code>)
4.10.2.6.16 Radio state (<code>type="radio"</code>)
4.10.2.6.17 File Upload state (<code>type="file"</code>)
4.10.2.6.18 Submit Button state (<code>type="submit"</code>)
4.10.2.6.19 Image Button state (<code>type="image"</code>)
4.10.2.6.20 Reset Button state (<code>type="reset"</code>)
4.10.2.6.21 Button state (<code>type="button"</code>)
4.10.2.7 Form control element binding and normalization of form controls
4.10.2.8 Common <code><input></code> element attributes
4.10.2.8.1 The <code>maxlength</code> and <code>minlength</code> attributes
4.10.2.8.2 The <code>size</code> attribute
4.10.2.8.3 The <code>readonly</code> attribute
4.10.2.8.4 The <code>required</code> attribute
4.10.2.8.5 The <code>disabled</code> attribute
4.10.2.8.6 The <code>pattern</code> attribute
4.10.2.8.7 The <code>step</code> attribute
4.10.2.8.8 The <code>list</code> attribute
4.10.2.8.9 The <code>aria-labelledby</code> attribute
4.10.2.8.10 The <code>aria-describedby</code> attribute
4.10.2.8.11 The <code>aria-errormessage</code> attribute
4.10.2.8.12 The <code>aria-invalid</code> attribute
4.10.2.8.13 The <code>aria-required</code> attribute
4.10.2.8.14 The <code>aria-autocomplete</code> attribute
4.10.2.8.15 The <code>aria-haspopup</code> attribute
4.10.2.8.16 The <code>aria-expanded</code> attribute
4.10.2.8.17 The <code>aria-controls</code> attribute
4.10.2.8.18 The <code>aria-owns</code> attribute
4.10.2.8.19 The <code>aria-pressed</code> attribute
4.10.2.8.20 The <code>aria-checked</code> attribute
4.10.2.8.21 The <code>aria-current</code> attribute
4.10.2.8.22 The <code>aria-relevant</code> attribute
4.10.2.8.23 The <code>aria-label</code> attribute
4.10.2.8.24 The <code>aria-labelledby</code> attribute
4.10.2.8.25 The <code>aria-describedby</code> attribute
4.10.2.8.26 The <code>aria-errormessage</code> attribute
4.10.2.8.27 The <code>aria-invalid</code> attribute
4.10.2.8.28 The <code>aria-required</code> attribute
4.10.2.8.29 The <code>aria-autocomplete</code> attribute
4.10.2.8.30 The <code>aria-haspopup</code> attribute
4.10.2.8.31 The <code>aria-expanded</code> attribute
4.10.2.8.32 The <code>aria-controls</code> attribute
4.10.2.8.33 The <code>aria-owns</code> attribute
4.10.2.8.34 The <code>aria-pressed</code> attribute
4.10.2.8.35 The <code>aria-checked</code> attribute
4.10.2.8.36 The <code>aria-current</code> attribute
4.10.2.8.37 The <code>aria-relevant</code> attribute
4.10.2.8.38 The <code>aria-label</code> attribute
4.10.2.8.39 The <code>aria-labelledby</code> attribute
4.10.2.8.40 The <code>aria-describedby</code> attribute
4.10.2.8.41 The <code>aria-errormessage</code> attribute
4.10.2.8.42 The <code>aria-invalid</code> attribute
4.10.2.8.43 The <code>aria-required</code> attribute
4.10.2.8.44 The <code>aria-autocomplete</code> attribute
4.10.2.8.45 The <code>aria-haspopup</code> attribute
4.10.2.8.46 The <code>aria-expanded</code> attribute
4.10.2.8.47 The <code>aria-controls</code> attribute
4.10.2.8.48 The <code>aria-owns</code> attribute
4.10.2.8.49 The <code>aria-pressed</code> attribute
4.10.2.8.50 The <code>aria-checked</code> attribute
4.10.2.8.51 The <code>aria-current</code> attribute
4.10.2.8.52 The <code>aria-relevant</code> attribute
4.10.2.8.53 The <code>aria-label</code> attribute
4.10.2.8.54 The <code>aria-labelledby</code> attribute

4.16.2 Case-sensitivity of selectors

4.16.3 Pseudo-classes

5 Microdata
5.1 Introduction
5.1.1 Overview
5.1.2 The basic syntax
5.1.3 Typed items
5.1.4 Global identifiers for items
5.1.5 Selecting names when defining vocabularies
5.2 Encoding microdata
5.2.1 The microdata model
5.2.2 Items
5.2.3 Names, the <code>itemprop</code> attribute
5.2.4 Values
5.2.5 Associating names with items
5.2.6 Microdata and other namespaces
5.3 Shared microdata vocabularies

5.3.1 <code>vCard</code>

5.3.1.1 Conversion to vCard

5.3.1.2 Examples

5.3.2 <code>vEvent</code>

5.3.2.1 Conversion to iCalendar

5.3.2.2 Examples

5.3.3 Licensing works

5.3.3.1 Examples

5.4 Converting HTML to other formats

5.4.1 JSON

6 User interaction

6.1 The <code>hidden</code> attribute

6.2 Insert subrees

6.3 Tracking user activation

6.3.1 Data model

6.3.2 Application model

6.3.3 APIs used by user activation

6.4 Activation behavior of elements

6.5 Focus

6.5.1 Introduction

6.5.2 Item model

6.5.3 The <code>focusable</code> attribute
--

6.5.4 Processing model

6.5.5 Sequential focus navigation

6.5.6 Focus management APIs

6.5.7 The <code>tabindex</code> attribute

6.6 Accessibility key and shortcuts

6.6.1 Introduction

6.6.2 The <code>accesskey</code> attribute
--

6.6.3 Processing model

6.7 Editing

6.7.1 Making document regions editable: The <code>contentEditable</code> content attribute
--

6.7.2 Making entire documents editable: the <code>documentEditable</code> IDL attribute

6.7.3 Best practices for in-page editors
--

6.7.4 Editing APIs

6.7.5 Spelling and grammar checking

6.7.6 Autocapitalization

6.7.7 The <code>spellcheck</code> attribute

6.7.8 Input modifications: the <code>enterkeyhint</code> attribute
--

6.7.9 Security risks in the drag-and-drop model

6.8 Drag and drop

6.8.1 Introduction

6.8.2 The drag data store

6.8.3 The <code>DataTransfer</code> interface

6.8.3.1 The <code>DataTransferItemList</code> interface

6.8.3.2 The <code>DataTransferItem</code> interface

6.8.4 The <code>DataView</code> interface

6.8.5 Processing model

6.8.6 Events summary

6.8.7 The <code>dropzone</code> attribute

6.8.8 Security risks in the drag-and-drop model

7 Loading Web pages

7.1 Browsing contexts

7.1.1 Creating browsing contexts

7.1.2 Reloading browsing contexts

7.1.2.1 Creating/reloading browsing contexts in the DOM

7.1.3 Security

7.1.4 Groupings of browsing contexts

7.1.5 Browsing context names

7.2 Security infrastructure for <code>window</code> , <code>WindowProxy</code> , and <code>Location</code> objects
--

7.2.1 API for working with <code>window</code>
--

7.2.2 Shared iterator slot: the <code>CrossOriginPropertyDescriptorMap</code>

7.2.3 Shared abstract operations

7.2.3.1 <code>CrossOriginProperties</code> (O)
--

7.2.3.2 <code>CrossOriginPropertyFallback</code> (P)
--

7.2.3.3 <code>isPlatformObject</code> (<code>isOrigin</code>) (O)

7.2.3.4 <code>getCrossOriginPropertyDescriptor</code> (O, P)
--

7.2.3.5 <code>CrossOriginSet</code> ($O, P, I, Receiver$)

7.2.3.6 <code>CrossOriginOwnProperties</code> (O)

7.2.3.7 <code>CrossOriginOwnPropertyKeys</code> (O)

7.3 The <code>script</code> object

7.3.1 API for creating and navigating browsing contexts by name

7.3.2 Accessing other browsing contexts

7.3.3 Named access on the <code>Window</code> object
--

7.3.4 Discarding browsing contexts

7.3.5 Closing browsing contexts

7.3.6 Browser interface elements

7.3.7 Script execution objects

7.4 The <code>script</code> and <code>exec</code> object
--

1 Introduction

1.1 Where does this specification fit?

This specification defines a big part of the Web platform, in lots of detail. Its place in the Web platform specification stack relative to other specifications can be best summed up as follows:

1.2 Is this HTML5?

This section is non-normative.

In short: Yes.

In more length: the term “HTML5” is widely used as a buzzword to refer to modern web technologies, many of which (though by no means all) are developed at the WHATWG. This document is one such; others are available from the [WHATWG Standards overview](#).

1.3 Background

This section is non-normative.

HTML is the World Wide Web’s core markup language. Originally, HTML was primarily designed as a language for semantically describing scientific documents. Its general design, however, has enabled it to be adapted, over the subsequent years, to describe a number of other types of documents and even applications.

1.4 Audience

This section is non-normative.

This specification is intended for authors of documents and scripts that use the features defined in this specification, implementers of tools that operate on pages that use the features defined in this specification, and individuals wishing to establish the correctness of documents or implementations with respect to the requirements of this specification.

This document is probably not suited to readers who do not already have at least a passing familiarity with Web technologies, as in places it sacrifices clarity for precision, and brevity for completeness. More approachable tutorials and authoring guides can provide a gentler introduction to the topic.

In particular, familiarity with the basics of DOM is necessary for a complete understanding of some of the more technical parts of this specification. An understanding of Web IDL, HTTP, XML, Unicode, character encodings, JavaScript, and CSS will also be helpful in places but is not essential.

1.5 Scope

This section is non-normative.

This specification is limited to providing a semantic-level markup language and associated semantic-level scripting APIs for authoring accessible pages on the Web ranging from static documents to dynamic applications.

The scope of this specification does not include providing mechanisms for media-specific customization of presentation (although default rendering rules for Web browsers are included at the end of this specification, and several mechanisms for hooking into CSS are provided as part of the language).

EXPAND

The scope of this specification is not to describe an entire operating system. In particular, hardware configuration software, image manipulation tools, and applications that users would be expected to use with high-end workstations on a daily basis are out of scope. In terms of applications, this specification is targeted specifically at applications that would be expected to be used by users on an occasional basis, or regularly but from disparate locations, with low CPU requirements. Examples of such applications include online purchasing systems, searching systems, games (especially multiplayer online games), public telephone books or address books, communications software (e-mail clients, instant messaging clients, discussion software), document editing software, etc.

1.0 History

This section is non-normative.

For its first five years (1990–1995), HTML went through a number of revisions and experienced a number of extensions, primarily hosted first at CERN, and then at the IETF.

With the creation of the W3C, HTML's development changed venue again. A first abortive attempt at extending HTML in 1995 known as HTML 3.0 then made way to a more pragmatic approach known as HTML 3.2, which was completed in 1997. HTML4 quickly followed later that same year.

The following year, the W3C membership decided to stop evolving HTML, and instead begin work on an XML-based equivalent, called XHTML. This effort started with a reformation of HTML4 in XML, known as XHTML 1.0, which added no new features except the new serialization, and which was completed in 2000. After XHTML 1.0, the W3C's focus turned to making it easier for other working groups to extend XHTML under the banner of XHTML Modularization. In parallel with this, the W3C also worked on a new language that was not compatible with the earlier HTML and XHTML languages, calling it XHTMIL2.

Around the time that HTML's evolution was stopped in 1998, parts of the API for HTML developed by browser vendors were specified and published under the name DOM Level 1 (in 1998) and DOM Level 2 Core and DOM Level 2 HTML (starting in 2000 and culminating in 2003). These efforts then petered out, with some DOM Level 3 specifications published in 2004 but the working group being closed before all the Level 3 drafts were completed.

In 2003, publication of XForms, a technology which was positioned as the next generation of Web forms, sparked a renewed interest in evolving HTML itself, rather than finding replacements for it. This interest was borne from the realization that XML's deployment as a Web technology was limited to entirely new technologies (like RSS and later Atom), rather than as a replacement for existing deployed technologies (like HTML).

A proof of concept to show that it was possible to extend HTML4's forms to provide many of the features that XForms 1.0 introduced, without requiring browsers to implement rendering engines that were incompatible with existing HTML Web pages, was the first result of this renewed interest. At this early stage, while the draft was already publicly available, and input was already being solicited from all sources, the specification was only under Opera Software's copyright.

The idea that HTML's evolution should be reopened was tested at a W3C workshop in 2004, where some of the principles that underlie the HTML5 work (described below), as well as the aforementioned early draft proposal covering just forms-related features, were presented to the W3C jointly by Mozilla and Opera. The proposal was rejected on the grounds that the proposal conflicted with the previously chosen direction for the Web's evolution; the W3C staff and members voted to continue developing XML-based replacements instead.

Shortly thereafter, Apple, Mozilla, and Opera jointly announced their intent to continue working on the effort under the umbrella of a new venue called the WHATWG. A public mailing list was created, and the draft was moved to the WHATWG site. The copyright was subsequently amended to be jointly owned by all three vendors, and to allow reuse of the specification.

The WHATWG was based on several core principles, in particular that technologies need to be backwards compatible, that specifications and implementations need to match even if this means changing the specification rather than the implementations, and that specifications need to be detailed enough that implementations can achieve complete interoperability without reverse-engineering each other.

The latter requirement in particular required that the scope of the HTML5 specification include what had previously been specified in three separate documents: HTML4, XHTML1, and DOM2 HTML. It also meant including significantly more detail than had previously been considered the norm.

In 2006, the W3C indicated an interest to participate in the development of HTML5 after all, and in 2007 formed a working group chartered to work with the WHATWG on the development of the HTML5 specification. Apple, Mozilla, and Opera allowed the W3C to publish the specification under the W3C copyright, while keeping a version with the less restrictive license on the WHATWG site.

For a number of years, both groups then worked together. In 2011, however, the groups came to the conclusion that they had different goals: the W3C wanted to publish a "finished" version of "HTML5", while the WHATWG wanted to continue working on a Living Standard for HTML, continuously maintaining the specification rather than freezing it in a state with known problems, and adding new features as needed to evolve the platform.

In 2019, the WHATWG and W3C signed an agreement to collaborate on a single version of HTML going forward: this document.

1.7 Design notes

This section is non-normative.

It must be admitted that many aspects of HTML appear at first glance to be nonsensical and inconsistent.

HTML, its supporting DOM APIs, as well as many of its supporting technologies, have been developed over a period of several decades by a wide array of people with different priorities who, in many cases, did not know of each other's existence.

Features have thus arisen from many sources, and have not always been designed in especially consistent ways. Furthermore, because of the unique characteristics of the Web, implementation bugs have often become de-facto, and now de-jure, standards, as content is often unintentionally written in ways that rely on them before they can be fixed.

Despite all this, efforts have been made to adhere to certain design goals. These are described in the next few subsections.

1.7.1 Serializability of script execution

This section is non-normative.

To avoid exposing Web authors to the complexities of multithreading, the HTML and DOM APIs are designed such that no script can ever detect the simultaneous execution of other scripts. Even with `workers`, the intent is that the behavior of implementations can be thought of as completely serializing the execution of all scripts in all [executing contexts](#).

The exception to this general design principle is the JavaScript `SharedArrayBuffer` class. Using `SharedArrayBuffer` objects, it can in fact be observed that scripts in other `agents` are executing simultaneously. Furthermore, due to the JavaScript memory model, there are situations which not only are un-representable via serialized `script` execution, but also un-representable via serialized `statement` execution among those scripts.

1.7.2 Compliance with other specifications

This section is non-normative.

This specification interacts with and relies on a wide variety of other specifications. In certain circumstances, unfortunately, conflicting needs have led to this specification violating the requirements of these other specifications. Whenever this has occurred, the transgressions have each been noted as a "wilful violation", and the reason for the violation has been noted.

1.7.3 Extensibility

This section is non-normative.

HTML has a wide array of extensibility mechanisms that can be used for adding semantics in a safe manner:

- Authors can use the `data` attribute to extend elements, effectively creating their own elements, while using the most applicable existing "real" HTML element, so that browsers and other tools that don't know of the extension can still support it somewhat well. This is the tack used by microformats, for example.
- Authors can include data for inline client-side scripts or server-side site-wide scripts to process using the `data-*` attributes. These are guaranteed to never be touched by browsers, and allow scripts to include data on HTML elements that scripts can then look for and process.
- Authors can use the `meta name="content-type"` mechanism to include page-wide metadata.
- Authors can use the `rel="*` mechanism to annotate links with specific meanings by registering [extensions to the predefined set of link types](#). This is also used by microformats.
- Authors can embed raw data using the `script type="text/plain"` mechanism with a custom type, for further handling by inline or server-side scripts.
- Authors can create `plugins` and invoke them using the `embed` element. This is how Flash works.
- Authors can extend APIs using the JavaScript prototyping mechanism. This is widely used by script libraries, for instance.
- Authors can use the microdata feature (the `itemprop="*" and itemtype="*" attributes) to embed nested name-value pairs of data to be shared with other applications and sites.`

1.8 HTML vs XML syntax

This section is non-normative.

This specification defines an abstract language for describing documents and applications, and some APIs for interacting with in-memory representations of resources that use this language.

The in-memory representation is known as "DOM HTML", or "the DOM" for short.

There are various concrete syntaxes that can be used to transmit resources that use this abstract language, two of which are defined in this specification.

The first such concrete syntax is the HTML syntax. This is the format suggested for most authors. It is compatible with most legacy Web browsers. If a document is transmitted with the `text/html` [MIME type](#), then it will be processed as an HTML document by Web browsers. This specification defines the latest HTML syntax, known simply as "HTML".

The second concrete syntax is XML. When a document is transmitted with an [XML MIME type](#), such as `application/xhtml+xml`, then it is treated as an XML document by Web browsers, to be parsed by an XML processor. Authors are reminded that the processing for XML and HTML differs; in particular, even minor syntax errors will prevent a document labeled as XML from being rendered fully, whereas they would be ignored in the HTML syntax.

Note

The XML syntax for HTML was formerly referred to as "XHTML", but this specification does not use that term (among other reasons, because no such term is used for the HTML syntaxes of MathML and SVG).

The DOM, the HTML syntax, and the XML syntax cannot all represent the same content. For example, namespaces cannot be represented using the HTML syntax, but they are supported in the DOM and in the XML syntax. Similarly, documents that use the `prescription` feature can be represented using the HTML syntax, but cannot be represented with the DOM or in the XML syntax. Comments that contain the string "`-->`" can only be represented in the DOM, not in the HTML and XML syntaxes.

1.9 Structure of this specification

This section is non-normative.

This specification is divided into the following major sections:

Introduction

Non-normative materials providing a context for the HTML standard.

Conformance

The conformance classes, algorithms, definitions, and the common underpinnings of the rest of the specification.

Semantics, structure, and APIs of HTML documents

Documents are built from elements. These elements form a tree using the DOM. This section defines the features of this DOM, as well as introducing the features common to all elements, and the concepts used in defining elements.

The elements of HTML

Each element has a predefined meaning, which is explained in this section. Rules for authors on how to use the element, along with user agent requirements for how to handle each element, are also given. This includes large signature features of HTML such as video playback and subtitles, form controls and form submission, and a 2D graphics API known as the HTML canvas.

Microdata

This specification introduces a mechanism for adding machine-readable annotations to documents, so that tools can extract trees of name-value pairs from the document. This section describes this mechanism and some algorithms that can be used to convert HTML documents into other formats. This section also defines some sample Microdata vocabularies for contact information, calendar events, and licensing works.

User interface

HTML documents can provide a number of mechanisms for users to interact with and modify content, which are described in this section, such as how focus works, and drag-and-drop.

Loading Web pages

HTML documents do not exist in a vacuum — this section defines many of the features that affect environments that deal with multiple pages, such as Web browsers and offline caching of Web applications.

Web application APIs

This section introduces basic features for scripting of applications in HTML.

Web workers

This section defines an API for background threads in JavaScript.

The communication APIs

This section describes some mechanisms that applications written in HTML can use to communicate with other applications from different domains running on the same client. It also introduces a server-push event stream mechanism known as Server Sent Events or `EventSource`, and a two-way full-duplex socket protocol for scripts known as Web Sockets.

Web storage

This section defines a client-side storage mechanism based on name-value pairs.

The HTML syntax

All of these features would be for naught if they couldn't be represented in a serialized form and sent to other people, and so these sections define the syntaxes of HTML and XML, along with rules for how to parse content using those syntaxes.

Reading

This section defines the default rendering rules for Web browsers.

There are also some appendices, listing [obsolete features](#) and [IANA considerations](#), and several indices.

1.9.1 How to read this specification

This specification should be read like all other specifications. First, it should be read cover-to-cover, multiple times. Then, it should be read backwards at least once. Then it should be read by picking random sections from the contents list and following all the cross-references.

As described in the conformance requirements section below, this specification describes conformance criteria for a variety of conformance classes. In particular, there are conformance requirements that apply to *producers*, for example authors and the documents they create, and there are conformance requirements that apply to *consumers*, for example Web browsers. They can be distinguished by what they are requiring: a requirement on a producer states what is allowed, while a requirement on a consumer states how software is to act.

Example

For example, "the `foo` attribute's value must be a `valid integer`" is a requirement on producers, as it lays out the allowed values; in contrast, the requirement "the `foo` attribute's value must be parsed using the `rules for parsing integers`" is a requirement on consumers, as it describes how to process the content.

Requirements on producers have no bearing whatsoever on consumers.

Example

Continuing the above example, a requirement stating that a particular attribute's value is constrained to being a [valid integer](#) emphatically does *not* imply anything about the requirements on consumers. It might be that the consumers are in fact required to treat the attribute as an opaque string, completely unaffected by whether the value conforms to the requirements or not. It might be (as in the previous example) that the consumers are required to parse the value using specific rules that define how invalid (non-numeric in this case) values are to be processed.

1.9.2 Typographic conventions

This is a definition, requirement, or explanation.

Note

This is a note.

Example

This is an example.

This is an open issue.

⚠Warning!

This is a warning.

```
IDL (Forwards-Window)
interface Example {
  // this is an IDL definition
};
```

For web developers (non-normative)

`variable = object . method [optionalArgument]`

This is a note to authors describing the usage of an interface.

CSS/* this is a CSS fragment */

The defining instance of a term is marked up like `this`. Uses of that term are marked up like `this` or like `this`.

The defining instance of an element, attribute, or API is marked up like `this`. References to that element, attribute, or API are marked up like `this`.

Other code fragments are marked up like `this`.

Variables are marked up like `this`.

In an algorithm steps in [synchronous sections](#) are marked with `☒`.

In some cases, requirements are given in the form of lists with conditions and corresponding requirements. In such cases, the requirements that apply to a condition are always the first set of requirements that follow the condition, even in the case of there being multiple sets of conditions for those requirements. Such cases are presented as follows:

This is a condition.

This is another condition.

This is the requirement that applies to the conditions above.

This is a third condition.

This is the requirement that applies to the third condition.

1.10 A quick introduction to HTML

This section is *non-normative*.

A basic HTML document looks like this:

```
<!DOCTYPE html>
<html lang="en">
  <head>
    <title>Sample page</title>
  </head>
  <body>
    <p>This is a sample page.</p>
    <p>This is a <a href="demo.html">simple</a> sample.</p>
    <!-- this is a comment -->
  </body>
</html>
```

HTML documents consist of a tree of elements and text. Each element is denoted in the source by a [start tag](#), such as "`<body>`", and an [end tag](#), such as "`</body>`". (Certain start tags and end tags can in certain cases be [omitted](#) and are implied by other tags.)

Tags have to be nested such that elements are all completely within each other, without overlapping:

```
<p>This is <em>very <strong>wrong</em></strong></p>
<p>This <em>is <strong>correct</strong></em></p>
```

This specification defines a set of elements that can be used in HTML, along with rules about the ways in which the elements can be nested.

Elements can have attributes, which control how the elements work. In the example below, there is a [hyperlink](#), formed using the `a` element and its `href` attribute:

```
<a href="demo.html">simple</a>
```

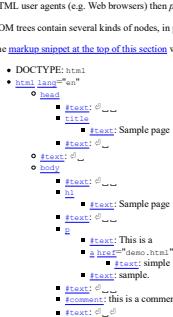

[Attributes](#) are placed inside the start tag, and consist of a `name` and a `value`, separated by an "`=`" character. The attribute value can remain [unquoted](#) if it doesn't contain [ASCII whitespace](#) or any of "`<`" "`>`" "`=`" or "`&`". Otherwise, it has to be quoted using either single or double quotes. The value, along with the "`=`" character, can be omitted altogether if the value is the empty string.

```
<!-- empty attributes -->
<input type="text" name="address" disabled="disabled">
<!-- attributes with a value -->
<input type="text" name="address" maxlength="200">
<input type="text" name="address" maxlength="200">
<input type="text" name="address" maxlength="200">
```

HTML user agents (e.g. Web browsers) then *parse* this markup, turning it into a DOM (Document Object Model) tree. A DOM tree is an in-memory representation of a document.

DOM trees contain several kinds of nodes, in particular a `DocumentType` node, `Element` nodes, `Text` nodes, `Comment` nodes, and in some cases `ProcessingInstruction` nodes.

The [markup snippet at the top of this section](#) would be turned into the following DOM tree:

The [document element](#) of this tree is the `html` element, which is the element always found in that position in HTML documents. It contains two elements, `head` and `body`, as well as a `Text` node between them.

There are many more `Text` nodes in the DOM tree than one would initially expect, because the source contains a number of spaces (represented here by "") and line breaks ("`\n`") that all end up as `Text` nodes in the DOM. However, for historical reasons not all of the spaces and line breaks in the original markup appear in the DOM. In particular, all the whitespace before `head` start tag ends up being dropped silently, and all the whitespace after the `body` end tag ends up placed at the end of the `body`.

The `head` element contains a `title` element, which itself contains a `Text` node with the text "Sample page". Similarly, the `body` element contains an `h1` element, a `p` element, and a comment.

This DOM tree can be manipulated from scripts in the page. Scripts (typically in JavaScript) are small programs that can be embedded using the `script` element or using [event handler content attributes](#). For example, here is a form with a script that sets the value of the form's `input` element to say "Hello World":

```
<form name="main">
  <input type="text" name="result">/>output>
  <script>
    document.form_main.getElementById('result').value = 'Hello World';
  </script>
</form>
```

Each element in the DOM tree is represented by an object, and these objects have APIs so that they can be manipulated. For instance, a link (e.g. the `a` element in the tree above) can have its `href` attribute changed in several ways:

```
var a = document.links[0]; // obtain the first link in the document
a.href = 'http://example.com'; // change the href attribute of the link
a.protocol = 'https'; // change just the scheme part of the URL
a.setAttribute('href', 'https://example.com/'); // change the content attribute directly
```

Since DOM trees are used as the way to represent HTML documents when they are processed and presented by implementations (especially interactive implementations like Web browsers), this specification is mostly phrased in terms of DOM trees, instead of the markup described above.

HTML documents represent a media-independent description of interactive content. HTML documents might be rendered to a screen, or through a speech synthesizer, or on a braille display. To influence exactly how such rendering takes place, authors can use a styling language such as CSS.

In the following example, the page has been made yellow-on-blue using CSS.

```
<!DOCTYPE html>
<html lang="en">
  <head>
    <title>Sample styled page</title>
    <style>
      body { background: navy; color: yellow; }
    </style>
  </head>
  <body>
    <h1>Sample styled page</h1>
    <p>This page is just a demo.</p>
  </body>
</html>
```

For more details on how to use HTML, authors are encouraged to consult tutorials and guides. Some of the examples included in this specification might also be of use, but the novice author is cautioned that this specification, by necessity, defines the language with a level of detail that might be difficult to understand at first.

1.10.1 Writing secure applications with HTML

This section is *non-normative*.

When HTML is used to create interactive sites, care needs to be taken to avoid introducing vulnerabilities through which attackers can compromise the integrity of the site itself or of the site's users.

A comprehensive study of this matter is beyond the scope of this document, and authors are strongly encouraged to study the matter in more detail. However, this section attempts to provide a quick introduction to some common pitfalls in HTML application development.

The security model of the Web is based on the concept of "origins", and correspondingly many of the potential attacks on the Web involve cross-origin actions. [ORIGIN]

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Not validating user input
Cross-site scripting (XSS)
SQL injection

When accepting untrusted input, e.g. user-generated content such as text comments, values in URL parameters, messages from third-party sites, etc, it is imperative that the data be validated before use, and properly escaped when displayed. Failing to do this can allow a hostile user to perform a variety of attacks, ranging from the potentially benign, such as providing bogus user information like a negative age, to the serious, such as running scripts every time a user looks at a page that includes the information, potentially propagating the attack in the process, to the catastrophic, such as deleting all data in the server.

When writing filters to validate user input, it is imperative that filters always be safelist-based, allowing known-safe constructs and disallowing all other input. Blocklist-based filters that disallow known-bad inputs and allow everything else are not secure, as not everything that is bad is yet known (for example, because it might be invented in the future).

Example

For example, suppose a page looked at its URL's query string to determine what to display, and the site then redirected the user to that page to display a message, as in:

```
<?><a href="#message.cgi?say>Hello">Say Hello</a>
<?><a href="#message.cgi?say>Welcome">Say Welcome</a>
<?><a href="#message.cgi?say>Kittens">Say Kittens</a>
</?>
```

If the message was just displayed to the user without escaping, a hostile attacker could then craft a URL that contained a script element:

```
https://example.com/message.cgi?say=3$alert%20%27oh%20ok%21%27%23%2fscript%3B
```

If the attacker then convinced a victim user to visit this page, a script of the attacker's choosing would run on the page. Such a script could do any number of hostile actions, limited only by what the site offers: if the site is an e-commerce shop, for instance, such a script could cause the user to unknowingly make arbitrarily many unwanted purchases.

This is called a cross-site scripting attack.

There are many constructs that can be used to try to trick a site into executing code. Here are some that authors are encouraged to consider when writing safelist filters:

- When filtering cross-scripting elements like `img`, it is important to safelist any provided attributes as well. If one allowed all attributes then an attacker could, for instance, use the `src` attribute to run arbitrary script.
- When allowing URLs to be provided (e.g. for links), the scheme of each URL also needs to be explicitly safelisted, as there are many schemes that can be abused. The most prominent example is "`javascript`", but user agents can implement (and indeed, have historically implemented) others.
- Allowing a `script` element to be inserted means any `script` elements in the page with relative links can be hijacked, and similarly that any form submissions can get redirected to a hostile site.

Cross-site request forgery (CSRF)

If a site allows a user to make form submissions with user-specific side-effects, for example posting messages on a forum under the user's name, making purchases, or applying for a passport, it is important to verify that the request was made by the user intentionally, rather than by another site tricking the user into making the request unknowingly.

This problem exists because HTML forms can be submitted to other origins.

Sites can prevent such attacks by populating forms with user-specific hidden tokens, or by checking '`origin`' headers on all requests.

Clickjacking

A page that provides users with an interface to perform actions that the user might not wish to perform needs to be designed so as to avoid the possibility that users can be tricked into activating the interface.

One way that a user could be so tricked is if a hostile site places the victim site in a small `iframe` and then convinces the user to click, for instance by having the user play a reaction game. Once the user is playing the game, the hostile site can quickly position the `iframe` under the mouse cursor just as the user is about to click, thus tricking the user into clicking the victim site's interface.

To avoid this, sites that do not expect to be used in frames are encouraged to only enable their interface if they detect that they are not in a frame (e.g. by comparing the `window` object to the value of the `top` attribute).

1.10.2 Common pitfalls to avoid when using the scripting APIs

This section is non-normative.

Scripts in HTML have "run-to-completion" semantics, meaning that the browser will generally run the script uninterrupted before doing anything else, such as firing further events or continuing to parse the document.

On the other hand, parsing of HTML files happens incrementally, meaning that the parser can pause at any point to let scripts run. This is generally a good thing, but it does mean that authors need to be careful to avoid hooking event handlers after the events could have possibly fired.

There are two techniques for doing this reliably: use `event handler content attributes`, or create the element and add the event handlers in the same script. The latter is safe because, as mentioned earlier, scripts are run to completion before further events can fire.

Example

One way this could manifest itself is with `img` elements and the `load` event. The event could fire as soon as the element has been parsed, especially if the image has already been cached (which is common).

Here, the author uses the `onload` handler on an `img` element to catch the `load` event:

```

```

If the element is being added by script, then so long as the event handlers are added in the same script, the event will still not be missed:

```
<script>
var img = new Image();
img.src = "games.png";
img.alt = "Games";
img.onload = gamesLogoHasLoaded;
// img.addEventListener("load", gamesLogoHasLoaded, false); // would work also
</script>
```

However, if the author first created the `img` element and then in a separate script added the event listeners, there's a chance that the `load` event would be fired in between, leading it to be missed:

```
<!-- Do not use this style, it has a race condition! -->

<!-- the 'load' event might fire here while the parser is taking a
break, in which case you will not see it! -->
<script>
var img = document.getElementById("games");
img.onload = gamesLogoHasLoaded; // might never fire!
</script>
```

1.10.3 How to catch mistakes when writing HTML: validators and conformance checkers

This section is non-normative.

Authors are encouraged to make use of conformance checkers (also known as *validators*) to catch common mistakes. The WHATWG maintains a list of such tools at: <https://whatwg.org/validator/>

1.11 Conformance requirements for authors

This section is non-normative.

The majority of presentation features from previous versions of HTML are no longer allowed. Presentation markup in general has been found to have a number of problems:

The use of presentational elements leads to poorer accessibility

While it is possible to use presentational markup in a way that provides users of assistive technologies (ATs) with an acceptable experience (e.g. using ARIA), doing so is significantly more difficult than doing so when using semantically-appropriate markup. Furthermore, even using such techniques doesn't help make pages accessible for non-AT non-graphical users, such as users of text-mode browsers.

Using media-independent markup, on the other hand, provides an easy way for documents to be authored in such a way that they work for more users (e.g. users of text browsers).

Higher cost of maintenance

It is significantly easier to maintain a site written in such a way that the markup is style-independent. For example, changing the color of a site that uses `` throughout requires changes across the entire site, whereas a similar change to a site based on CSS can be done by changing a single file.

Larger document sizes

Presentation markup tends to be much more redundant, and thus results in larger document sizes.

For those reasons, presentational markup has been removed from HTML in this version. This change should not come as a surprise; HTML4 deprecated presentational markup many years ago and provided a mode (HTML4 Transitional) to help authors move away from presentational markup; later, XHTML 1.1 went further and obsoleted those features altogether.

The only remaining presentational markup features in HTML are the `style` attribute and the `style` element. Use of the `style` attribute is somewhat discouraged in production environments, but it can be useful for rapid prototyping (where its rules can be directly moved into a separate style sheet later) and for providing specific styles in unusual cases where a separate style sheet would be inconvenient. Similarly, the `style` element can be useful in syndication or for page-specific styles, but in general an external style sheet is likely to be more convenient when the styles apply to multiple pages.

It is also worth noting that some elements that were previously presentational have been redefined in this specification to be media-independent: `p`, `h1`, `h2`, `a`, `img`, and `u`.

1.11.1 Presentational markup

This section is non-normative.

The majority of presentation features from previous versions of HTML are no longer allowed. Presentation markup in general has been found to have a number of problems:

The use of presentational elements leads to poorer accessibility

While it is possible to use presentational markup in a way that provides users of assistive technologies (ATs) with an acceptable experience (e.g. using ARIA), doing so is significantly more difficult than doing so when using semantically-appropriate markup. Furthermore, even using such techniques doesn't help make pages accessible for non-AT non-graphical users, such as users of text-mode browsers.

Using media-independent markup, on the other hand, provides an easy way for documents to be authored in such a way that they work for more users (e.g. users of text browsers).

Higher cost of maintenance

It is significantly easier to maintain a site written in such a way that the markup is style-independent. For example, changing the color of a site that uses `` throughout requires changes across the entire site, whereas a similar change to a site based on CSS can be done by changing a single file.

Larger document sizes

Presentation markup tends to be much more redundant, and thus results in larger document sizes.

For those reasons, presentational markup has been removed from HTML in this version. This change should not come as a surprise; HTML4 deprecated presentational markup many years ago and provided a mode (HTML4 Transitional) to help authors move away from presentational markup; later, XHTML 1.1 went further and obsoleted those features altogether.

The only remaining presentational markup features in HTML are the `style` attribute and the `style` element. Use of the `style` attribute is somewhat discouraged in production environments, but it can be useful for rapid prototyping (where its rules can be directly moved into a separate style sheet later) and for providing specific styles in unusual cases where a separate style sheet would be inconvenient. Similarly, the `style` element can be useful in syndication or for page-specific styles, but in general an external style sheet is likely to be more convenient when the styles apply to multiple pages.

It is also worth noting that some elements that were previously presentational have been redefined in this specification to be media-independent: `p`, `h1`, `h2`, `a`, `img`, and `u`.

1.11.2 Syntax errors

This section is non-normative.

The syntax of HTML is constrained to avoid a wide variety of problems.

Intuitive error-handling behavior

Certain invalid syntax constructs, when parsed, result in DOM trees that are highly unintuitive.

Example

For example, the following markup fragment results in a DOM with an `hr` element that is an *earlier* sibling of the corresponding `table` element:

```
<table><hr>...</table>
```

Errors with optional error recovery

To allow user agents to be used in controlled environments without having to implement the more bizarre and convoluted error handling rules, user agents are permitted to fail whenever encountering a `parse_error`.

Errors where the error-handling behavior is not compatible with streaming user agents

Some error-handling behavior, such as the behavior for the `<table><hr>...</table>` example mentioned above, are incompatible with streaming user agents (user agents that process HTML files in one pass, without storing state). To avoid interoperability problems with such user agents, any syntax resulting in such behavior is considered invalid.

Errors that can result in infostack coercion

When a user agent based on XML is connected to an HTML parser, it is possible that certain invariants that XML enforces, such as element or attribute names never contain multiple colons, will be violated by an HTML file. Handling this can require that the parser coerce the HTML DOM into an XML-compatible infostack. Most syntax constructs that require such handling are considered invalid. (Comments containing two consecutive hyphens, or ending with a hyphen, are exceptions that are allowed in the HTML syntax.)

Errors that result in disproportionately poor performance

Certain syntax constructs can result in disproportionately poor performance. To discourage the use of such constructs, they are typically made non-conforming.

Example

For example, the following markup results in poor performance, since all the unclosed `_` elements have to be reconstructed in each paragraph, resulting in progressively more elements in each paragraph:

```
<p>I<_>She dreamt.
<p>I<_>She dreamt that she ate breakfast.
<p>I<_>Then lunch.
<p>I<_>And finally dinner.
```

The resulting DOM for this fragment would be:

```

      • #text: She dreamt.
      • E   o 1   □ 1   □ #text: She dreamt that she ate breakfast.
      • E   o 1   □ 1   □ #text: Then lunch.
      • E   o 1   □ 1   □ #text: And finally dinner.

```

Errors involving fragile syntax constructs

There are syntax constructs that, for historical reasons, are relatively fragile. To help reduce the number of users who accidentally run into such problems, they are made non-conforming.

Example

For example, the parsing of certain named character references in attributes happens even with the closing semicolon being omitted. It is safe to include an ampersand followed by letters that do not form a named character reference, but if the letters are changed to a string that does form a named character reference, they will be interpreted as that character instead.

In this fragment, the attribute's value is "?billiated":

```
<a href="#?billiated">Bill and Ted</a>
```

In the following fragment, however, the attribute's value is actually "?art©", nor the intended "?art©", because even without the final semicolon, "©" is handled the same as "©" and thus gets interpreted as "o":

```
<a href="#?art&copy">Art and Copy</a>
```

To avoid this problem, all named character references are required to end with a semicolon, and uses of named character references without a semicolon are flagged as errors.

Thus, the correct way to express the above cases is as follows:

```
<a href="#?billiated">Bill and Ted</a> <!-- &ted is ok, since it's not a named character reference -->
<a href="#?art&copy">Art and Copy</a> <!-- the & has to be escaped, since &copy is a named character reference -->
```

Errors involving known interoperability problems in legacy user agents

Certain syntax constructs are known to cause especially subtle or serious problems in legacy user agents, and are therefore marked as non-conforming to help authors avoid them.

Example

For example, this is why the U+0060 GRAVE ACCENT character (`) is not allowed in unquoted attributes. In certain legacy user agents, it is sometimes treated as a quote character.

Example

Another example of this is the DOCTYPE, which is required to trigger [no-quirks mode](#), because the behavior of legacy user agents in [quirks mode](#) is often largely undocumented.

Errors that risk exposing authors to security attacks

Certain restrictions exist purely to avoid known security problems.

Example

For example, the restriction on using UTF-7 exists purely to avoid authors falling prey to a known cross-site-scripting attack using UTF-7. ([\[UFE7\]](#))

Cases where the author's intent is unclear

Markup where the author's intent is very unclear is often made non-conforming. Correcting these errors early makes later maintenance easier.

Example

For example, it is unclear whether the author intended the following to be an [h1](#) heading or an [h2](#) heading:

```
<h1>Contact details</h2>
```

Cases that are likely to be typos

When a user makes a simple typo, it is helpful if the error can be caught early, as this can save the author a lot of debugging time. This specification therefore usually considers it an error to use element names, attribute names, and so forth, that do not match the names defined in this specification.

Example

For example, if the author typed [<caption>](#) instead of [<caption>](#), this would be flagged as an error and the author could correct the typo immediately.

Errors that could interfere with new syntax in the future

In order to allow the language syntax to be extended in the future, certain otherwise harmless features are disallowed.

Example

For example, "attributes" in end tags are ignored currently, but they are invalid, in case a future change to the language makes use of that syntax feature without conflicting with already-deployed (and valid!) content.

Some authors find it helpful to be in the practice of always quoting all attributes and always including all optional tags, preferring the consistency derived from such custom over the minor benefits of terseness afforded by making use of the flexibility of the HTML syntax. To aid such authors, conformance checkers can provide modes of operation wherein such conventions are enforced.

1.11.3 Restrictions on content models and on attribute values

This section is non-normative.

Beyond the syntax of the language, this specification also places restrictions on how elements and attributes can be specified. These restrictions are present for similar reasons:

Errors involving content with dubious semantics

To avoid misuse of elements with defined meanings, content models are defined that restrict how elements can be nested when such nestings would be of dubious value.

Example

For example, this specification disallows nesting a [section](#) element inside a [h1](#) element, since it is highly unlikely for an author to indicate that an entire section should be keyed in.

Errors that involve a conflict in expressed semantics

Similarly, to draw the author's attention to mistakes in the use of elements, clear contradictions in the semantics expressed are also considered conformance errors.

Example

In the fragments below, for example, the semantics are nonsensical: a separator cannot simultaneously be a cell, nor can a radio button be a progress bar.

```
<hr role="cell">
<input type="radio" role="progressbar">
```

Example

Another example is the restrictions on the content models of the [ul](#) element, which only allows [li](#) element children. Lists by definition consist just of zero or more list items, so if a [ul](#) element contains something other than an [li](#) element, it's not clear what was meant.

Cases where the default styles are likely to lead to confusion

Certain elements have default styles or behaviors that make certain combinations likely to lead to confusion. Where these have equivalent alternatives without this problem, the confusing combinations are disallowed.

Example

For example, [div](#) elements are rendered as [block boxes](#), and [span](#) elements as [inline boxes](#). Putting a [block box](#) in an [inline box](#) is unnecessarily confusing: since either nesting just [div](#) elements, or nesting just [span](#) elements, or nesting [span](#) elements inside [div](#) elements all serve the same purpose as nesting a [div](#) element in a [span](#) element, but only the latter involves a [block box](#) in an [inline box](#), the latter combination is disallowed.

Example

Another example would be the way [interactive content](#) cannot be nested. For example, a [button](#) element cannot contain a [textarea](#) element. This is because the default behavior of such nesting [interactive](#) elements would be highly confusing to users. Instead of nesting these elements, they can be placed side by side.

Errors that indicate a likely misunderstanding of the specification

Sometimes, something is disallowed because allowing it would likely cause author confusion.

Example

For example, setting the [disabled](#) attribute to the value "false" is disallowed, because despite the appearance of meaning that the element is enabled, it in fact means that the element is [disabled](#) (what matters for implementations is the presence of the attribute, not its value).

Errors involving limits that have been imposed merely to simplify the language

Some conformance errors simplify the language that authors need to learn.

Example

For example, the [area](#) element's [shape](#) attribute, despite accepting both [circle](#) and [square](#) values in practice as synonyms, disallows the use of the [circle](#) value, so as to simplify tutorials and other learning aids. There would be no benefit to allowing both, but it would cause extra confusion when teaching the language.

Errors that involve peculiarities of the parser

Certain elements are parsed in somewhat eccentric ways (typically for historical reasons), and their content model restrictions are intended to avoid exposing the author to these issues.

Example

For example, a [form](#) element isn't allowed inside [phrasing content](#), because when parsed as HTML, a [form](#) element's start tag will imply a [p](#) element's end tag. Thus, the following markup results in two [paragraphs](#), not one:

```
<p>Hello, <form><label>Name:</label> <input></form>
```

It is parsed exactly like the following:

```
<p>Hello, </p><form><label>Name:</label> <input></form>
```

Errors that would likely result in scripts failing in hard-to-debug ways

Some errors are intended to help prevent script problems that would be hard to debug.

Example

This is why, for instance, it is non-conforming to have two [id](#) attributes with the same value. Duplicate IDs lead to the wrong element being selected, with sometimes disastrous effects whose cause is hard to determine.

Errors that waste authoring time

Some constructs are disallowed because historically they have been the cause of a lot of wasted authoring time, and by encouraging authors to avoid making them, authors can save time in future efforts.

Example

For example, a [script](#) element's [src](#) attribute causes the element's contents to be ignored. However, this isn't obvious, especially if the element's contents appear to be executable script — which can lead to authors spending a lot of time trying to debug the inline script without realizing that it is not executing. To reduce this problem, this specification makes it non-conforming to have executable script in a [script](#) element when the [src](#) attribute is present. This means that authors who are validating their documents are less likely to waste time with this kind of mistake.

Errors that involve areas that affect authors migrating between the HTML and XML syntaxes

Example

For example, there are somewhat complicated rules surrounding the `lang` and `xml:lang` attributes intended to keep the two synchronized.

Example

Another example would be the restrictions on the values of `names` attributes in the HTML serialization, which are intended to ensure that elements in conforming documents end up in the same namespaces whether processed as HTML or XML.

Errors that involve areas reserved for future expansion

As with the restrictions on the syntax intended to allow for new syntax in future revisions of the language, some restrictions on the content models of elements and values of attributes are intended to allow for future expansion of the HTML vocabulary.

Example

For example, limiting the values of the `cursor` attribute that start with an U+005E LOW LINE character () to only specific predefined values allows new predefined values to be introduced at a future time without conflicting with author-defined values.

Errors that indicate a mis-use of other specifications

Certain restrictions are intended to support the restrictions made by other specifications.

Example

For example, requiring that attributes that take media query lists use only valid media query lists reinforces the importance of following the conformance rules of that specification.

1.12 Suggested reading

This section is non-normative.

The following documents might be of interest to readers of this specification.

Character Model for the World Wide Web 1.0: Fundamentals [CHARMOD]

This Architectural Specification provides authors of specifications, software developers, and content developers with a common reference for interoperable text manipulation on the World Wide Web, building on the Universal Character Set, defined jointly by the Unicode Standard and ISO/IEC 10646. Topics addressed include use of the terms 'character', 'encoding' and 'string', a reference processing model, choice and identification of character encodings, character escaping, and string indexing.

Unicode Security Considerations [UTR36]

Because Unicode contains such a large number of characters and incorporates the varied writing systems of the world, incorrect usage can expose programs or systems to possible security attacks. This is especially important as more and more products are internationalized. This document describes some of the security considerations that programmers, system analysts, standards developers, and users should take into account, and provides specific recommendations to reduce the risk of problems.

Web Content Accessibility Guidelines (WCAG) 2.0 [WCAG]

Web Content Accessibility Guidelines (WCAG) 2.0 covers a wide range of recommendations for making Web content more accessible. Following these guidelines will make content accessible to a wider range of people with disabilities, including blindness and low vision, deafness and hearing loss, learning disabilities, cognitive limitations, limited movement, speech disabilities, photosensitivity and combinations of these. Following these guidelines will also often make your Web content more usable to users in general.

Authoring Tool Accessibility Guidelines (ATAG) 2.0 [ATAG]

This specification provides guidelines for designing Web content authoring tools that are more accessible for people with disabilities. An authoring tool that conforms to these guidelines will promote accessibility by providing an accessible user interface to authors with disabilities as well as by enabling, supporting, and promoting the production of accessible Web content by all authors.

User Agent Accessibility Guidelines (UAAG) 2.0 [UAAG]

This document provides guidelines for designing user agents that lower barriers to Web accessibility for people with disabilities. User agents include browsers and other types of software that retrieve and render Web content. A user agent that conforms to these guidelines will promote accessibility through its own user interface and through other internal facilities, including its ability to communicate with other technologies (especially assistive technologies). Furthermore, all users, not just users with disabilities, should find conforming user agents to be more usable.

2 Common infrastructure

This specification depends on *Infra*. [INFRA]

2.1 Terminology

This specification refers to both HTML and XML attributes and IDL attributes, often in the same context. When it is not clear which is being referred to, they are referred to as *content attributes* for HTML and XML attributes, and *IDL attributes* for those defined on IDL interfaces. Similarly, the term "properties" is used for both JavaScript object properties and CSS properties. When these are ambiguous they are qualified as *object properties* and *CSS properties* respectively.

Generally, when the specification states that a feature applies to the `HTML syntax` or the `XML syntax`, it also includes the other. When a feature specifically only applies to one of the two languages, it is called out by explicitly stating that it does not apply to the other format, as in "for HTML, ... (this does not apply to XML)".

This specification uses the term *document* to refer to any use of HTML, ranging from short static documents to long essays or reports with rich multimedia, as well as to fully-fledged interactive applications. The term is used to refer both to *Document* objects and their descendant DOM trees, and to serialized byte streams using the `HTML syntax` or the `XML syntax`, depending on context.

In the context of the DOM structures, the terms `HTML document` and `XML document` are used as defined in *DOM*, and refer specifically to two different modes that `Document` objects can find themselves in. [DOM] (Such uses are always hyperlinked to their definition.)

In the context of byte streams, the term `HTML document` refers to resources labeled as `text/html`, and the term `XML document` refers to resources labeled with an `XML MIME type`.

For simplicity, terms such as *shown*, *displayed*, and *visible* might sometimes be used when referring to the way a document is rendered to the user. These terms are not meant to imply a visual medium; they must be considered to apply to other media in equivalent ways.

2.1.1 Parallelism

To run steps in *parallel* means those steps are to be run, one after another, at the same time as other logic in the standard (e.g., at the same time as the `event loop`). This standard does not define the precise mechanism by which this is achieved, be it time-sharing cooperative multitasking, fibers, threads, processes, using different hyperthreads, cores, CPUs, machines, etc. By contrast, an operation that is to run *immediately* must interrupt the currently running task, run itself, and then resume the previously running task.

Note

For guidance on writing specifications that leverage parallelism, see *Dealing with the event loop from other specifications*.

To avoid race conditions between different `in parallel` algorithms that operate on the same data, a `parallel queue` can be used.

A `parallel queue` represents a queue of algorithm steps that must be run in series.

A `parallel queue` has an *algorithm queue* (a `queue`), initially empty.

To enqueue steps to a `parallel queue`, enqueue the algorithm steps to the `parallel queue's algorithm queue`.

To start a new *parallel queue*, run the following steps:

1. Let `parallelQueue` be a new `parallel queue`.
2. Run the following steps `in parallel`:

1. While true:

1. Let `steps` be the result of `dequeueing` from `parallelQueue's algorithm queue`.
2. If `steps` is not nothing, then run `steps`.
3. Assert: running `steps` did not throw an exception, as steps running `in parallel` are not allowed to throw.

Note

Implementations are not expected to implement this as a continuously running loop. Algorithms in standards are to be easy to understand and are not necessarily great for battery life or performance.

3. Return `parallelQueue`.

Note

Steps running `in parallel` can themselves run other steps `in parallel`. E.g., inside a `parallel queue` it can be useful to run a series of steps `in parallel` with the queue.

Example

Imagine a standard defined `nameList` (a `list`), along with a method to add a `name` to `nameList`, unless `nameList` already `contains` `name`, in which case it rejects.

The following solution suffers from race conditions:

1. Let `p` be a new promise.
2. Run the following steps `in parallel`:
 1. If `nameList` `contains` `name`, reject `p` with a `TypeError` and abort these steps.
 2. Do some potentially lengthy work.
 3. `Append` `name` to `nameList`.
 4. Resolve `p` with undefined.
3. Return `p`.

Two invocations of the above could run simultaneously, meaning `name` isn't in `nameList` during step 2.1, but it *might be added* before step 2.3 runs, meaning `name` ends up in `nameList` twice.

Parallel queues solve this. The standard would let `nameListQueue` be the result of *starting a new parallel queue*, then:

1. Let `p` be a new promise.
2. `Enqueue the following steps` to `nameListQueue`.
 1. If `nameList` `contains` `name`, reject `p` with a `TypeError` and abort these steps.
 2. Do some potentially lengthy work.
 3. `Append` `name` to `nameList`.
 4. Resolve `p` with undefined.
3. Return `p`.

The steps would now queue and the race is avoided.

2.1.2 Resources

The specification uses the term *supported* when referring to whether a user agent has an implementation capable of decoding the semantics of an external resource. A format or type is said to be *supported* if the implementation can process an external resource of that format or type without critical aspects of the resource being ignored. Whether a specific resource is *supported* can depend on what features of the resource's format are in use.

Example

For example, a PNG image would be considered to be in a *supported format* if its pixel data could be decoded and rendered, even if, unbeknownst to the implementation, the image also contained animation data.

Example

An MPEG-4 video file would not be considered to be in a *supported format* if the compression format used was not supported, even if the implementation could determine the dimensions of the movie from the file's metadata.

What some specifications, in particular the HTTP specifications, refer to as a *representation* is referred to in this specification as a *resource*. [HTTP]

A resource's *critical subresources* are those that the resource needs to have available to be correctly processed. Which resources are considered critical or not is defined by the specification that defines the resource's format.

For `CSS style sheets`, we tentatively define here that their critical subresources are other style sheets imported via `@import` rules, including those indirectly imported by other imported style sheets.

This definition is not fully interoperable; furthermore, some user agents seem to count resources like background images or web fonts as critical subresources. Ideally, the CSS Working Group would define this; see [w3c/csswg-drafts-issue-#108](https://www.w3.org/2014/09/08-csswg-drafts-issue-#108) to track progress on that front.

2.1.3 XML compatibility

Some XML processors, such as the one used by the WHATWG, do not support XML 1.1 features.

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Except where otherwise stated, all elements defined or mentioned in this specification are in the [HTML namespace](http://www.w3.org/1999/xhtml) ("`http://www.w3.org/1999/xhtml`"), and all attributes defined or mentioned in this specification have no namespace.

The term *element type* is used to refer to the set of elements that have a given local name and namespace. For example, `button` elements are elements with the element type `button`, meaning they have the local name "`button`" and (implicitly as defined above) the [HTML namespace](http://www.w3.org/1999/xhtml).

Attribute names are said to be *XML-compatible* if they match the `name` production defined in XML and they contain no U+003A COLON characters (:). [\[XML\]](#)

2.1.4 DOM trees

When it is stated that some element or attribute is *ignored*, or treated as some other value, or handled as if it was something else, this refers only to the processing of the node after it is in the DOM. A user agent must not mutate the DOM in such situations.

A content attribute is said to *change value* only if its new value is different than its previous value; setting an attribute to a value it already has does not change it.

The term `empty`, when used for an attribute value, `text` node, or string, means that the length of the text is zero (i.e., not even containing `controls` or U+0020 SPACE).

A node *A* is *inserted* into a node *B* when the *insertion steps* are invoked with *A* as the argument and *A*'s new parent is *B*. Similarly, a node *A* is *removed* from a node *B* when the *removing steps* are invoked with *A* as the *removedNode* argument and *B* as the *oldParent* argument.

A node is *inserted* into a document when the *insertion steps* are invoked with it as the argument and it is now [in a document tree](#). Analogously, a node is *removed* from a document when the *removing steps* are invoked with it as the argument and it is now no longer [in a document tree](#).

A node becomes *connected* when the *insertion steps* are invoked with it as the argument and it is now [connected](#). Analogously, a node becomes *disconnected* when the *removing steps* are invoked with it as the argument and it is now no longer [connected](#).

A node is *browsing-context connected* when it is [connected](#) and its *browsing context* is non-null. A node becomes *browsing-context connected* when the *insertion steps* are invoked with it as the argument and it is now [browsing-context connected](#). A node becomes *browsing-context disconnected* either when the *removing steps* are invoked with it as the argument and it is now no longer [browsing-context connected](#), or when its *browsing context* becomes null.

2.1.5 Scripting

The construction "a `Foo` object", where `Foo` is actually an interface, is sometimes used instead of the more accurate "an object implementing the interface `Foo`".

An IDL attribute is said to be *getting* when its value is being retrieved (e.g. by author script), and is said to be *setting* when a new value is assigned to it.

If a DOM object is said to be *live*, then the attributes and methods on that object must operate on the actual underlying data, not a snapshot of the data.

2.1.6 Plugins

The term `plugin` refers to a user-agent defined set of content handlers used by the user agent that can take part in the user agent's rendering of a `document` object, but that neither act as [child browsing contexts](#) of the `Document`, nor introduce any `Node` objects to the `Document`'s DOM.

Typically such content handlers are provided by third parties, though a user agent can also designate built-in content handlers as plugins.

A user agent must not consider the types `text/plain` and `application/octet-stream` as having a registered `plugin`.

Example

One example of a plugin would be a PDF viewer that is instantiated in a [browsing context](#) when the user navigates to a PDF file. This would count as a plugin regardless of whether the party that implemented the PDF viewer component was the same as that which implemented the user agent itself. However, a PDF viewer application that launches separate from the user agent (as opposed to using the same interface) is not a plugin by this definition.

Note

This specification does not define a mechanism for interacting with plugins, as it is expected to be user-agent- and platform-specific. Some UAs might opt to support a plugin mechanism such as the Netscape Plugin API; others might use remote content converters or have built-in support for certain types. Indeed, this specification doesn't require user agents to support plugins at all. [\[NPAPI\]](#)

A plugin can be *secured* if it honors the semantics of the `sandbox` attribute.

Example

For example, a secured plugin would prevent its contents from creating pop-up windows when the plugin is instantiated inside a sandboxed `iframe`.

⚠ Warning!

Browsers should take extreme care when interacting with external content intended for `plugins`. When third-party software is run with the same privileges as the user agent itself, vulnerabilities in the third-party software become as dangerous as those in the user agent.

Since different users having different sets of `plugins` provides a tracking vector that increases the chances of users being uniquely identified, user agents are encouraged to support the exact same set of `plugins` for each user.

2.1.7 Character encodings

A *character encoding*, or just *encoding* where that is not ambiguous, is a defined way to convert between byte streams and Unicode strings, as defined in *Encoding*. An `encoding` has an *encoding name* and one or more *encoding labels*, referred to as the encoding's *name* and *labels* in the Encoding standard. [\[ENCODING\]](#)

A `UTF-16` encoding is `UTF-16BE` or `UTF-16LE`. [\[ENCODING\]](#)

An ASCII-compatible encoding is any `encoding` that is not a `UTF-16` encoding. [\[ENCODING\]](#)

Note

Since support for encodings that are not defined in *Encoding* is prohibited, `UTF-16` encodings are the only encodings that this specification needs to treat as not being ASCII-compatible encodings.

2.1.8 Conformance classes

This specification describes the conformance criteria for user agents (relevant to implementers) and documents (relevant to authors and authoring tool implementers).

Conforming documents are those that comply with all the conformance criteria for documents. For readability, some of these conformance requirements are phrased as conformance requirements on authors; such requirements are implicitly requirements on documents: by definition, all documents are assumed to have had an author. (In some cases, that author may itself be a user agent — such user agents are subject to additional rules, as explained below.)

Example

For example, if a requirement states that "authors must not use the `foobar` element", it would imply that documents are not allowed to contain elements named `foobar`.

Note

There is no implied relationship between document conformance requirements and implementation conformance requirements. User agents are not free to handle non-conformant documents as they please; the processing model described in this specification applies to implementations regardless of the conformity of the input documents.

User agents fall into several (overlapping) categories with different conformance requirements.

Web browsers and other interactive user agents

Web browsers that support `the XML syntax` must process elements and attributes from the [HTML namespace](http://www.w3.org/1999/xhtml) found in XML documents as described in this specification, so that users can interact with them, unless the semantics of those elements have been overridden by other specifications.

Example
A conforming Web browser would, upon finding a `<script>` element in an XML document, execute the script contained in that element. However, if the element is found within a transformation expressed in XSLT (assuming the user agent also supports XSLT), then the processor would instead treat the `<script>` element as an opaque element that forms part of the transform.

Web browsers that support `the XML syntax` must process documents labeled with an `HTML MIME type` as described in this specification, so that users can interact with them.

User agents that support scripting must also be conforming implementations of the IDL fragments in this specification, as described in [Web IDL](#). [\[WEBIDL\]](#)

Note
Unless explicitly stated, specifications that override the semantics of HTML elements do not override the requirements on DOM objects representing those elements. For example, the `aria_label` element in the example above would still implement the `scriptableElement` interface.

Non-interactive presentation user agents

User agents that process HTML and XML documents purely to render non-interactive versions of them must comply to the same conformance criteria as Web browsers, except that they are exempt from requirements regarding user interaction.

Note

Typical examples of non-interactive presentation user agents are printers (static UAs) and overhead displays (dynamic UAs). It is expected that most static non-interactive presentation user agents will also opt to [lack scripting support](#).

Example

A non-interactive but dynamic presentation UA would still execute scripts, allowing forms to be dynamically submitted, and so forth. However, since the concept of "focus" is irrelevant when the user cannot interact with the document, the UA would not need to support any of the focus-related DOM APIs.

Visual user agents support the suggested default rendering

User agents, whether interactive or not, may be designated (possibly as a user option) as supporting the suggested default rendering defined by this specification.

This is not required. In particular, even user agents that do implement the suggested default rendering are encouraged to offer settings that override this default to improve the experience for the user, e.g. changing the color contrast, using different focus styles, or otherwise making the experience more accessible and usable to the user.

User agents that are designated as supporting the suggested default rendering must, while so designated, implement the rules `the rendering section` defines as the behavior that user agents are *expected* to implement.

User agents with no scripting support

Implementations that do not support scripting (or which have their scripting features disabled entirely) are exempt from supporting the events and DOM interfaces mentioned in this specification. For the parts of this specification that are defined in terms of an events model or in terms of the DOM, such user agents must still act as if events and the DOM were supported.

Note

Scripting can form an integral part of an application. Web browsers that do not support scripting, or that have scripting disabled, might be unable to fully convey the author's intent.

Conformance checkers

Conformance checkers must verify that a document conforms to the applicable conformance criteria described in this specification. Automated conformance checkers are exempt from detecting errors that require interpretation of the author's intent (for example, while a document is non-conforming if the content of a `blockquote` element is not a quote, conformance checkers running without the input of human judgement do not have to check that `blockquote` elements only contain quoted material).

Conformance checkers must check that the input document conforms when parsed without a [browsing context](#) (meaning that no scripts run, and that the parser's `scripting flag` is disabled), and should also check that the input document conforms when parsed with a [browsing context](#) in which scripts execute, and that the scripts never cause non-conforming states to occur other than transiently during script execution itself. (This is only a "SHOULD" and not a "MUST" requirement because it has been proven to be impossible. [\[COMPUTABLE\]](#))

The term "HTML validator" can be used to refer to a conformance checker that itself conforms to the applicable requirements of this specification.

Note

XML DTDs cannot express all the conformance requirements of this specification. Therefore, a validating XML processor and a DTD cannot constitute a conformance checker. Also, since neither of the two authoring formats defined in this specification are applications of SGML, a validating SGML system cannot constitute a conformance checker either.

To put it another way, there are three types of conformance criteria:

1. Criteria that can be expressed in a DTD.
2. Criteria that cannot be expressed by a DTD, but can still be checked by a machine.
3. Criteria that can only be checked by a human.

A conformance checker must check for the first two. A simple DTD-based validator only checks for the first class of errors and is therefore not a conforming conformance checker according to this specification.

Data mining tools

Applications and tools that process HTML and XML documents for reasons other than to either render the documents or check them for conformance should act in accordance with the semantics of the documents that they process.

Example

A tool that generates `document outlines` but increases the nesting level for each paragraph and does not increase the nesting level for each section would not be conforming.

Authoring tools and markup generators

Authoring tools and markup generators must generate [conforming documents](#). Conformance criteria that apply to authors also apply to authoring tools, where appropriate.

Authoring tools are exempt from the strict requirements of using elements only for their specified purpose, but only to the extent that authoring tools are not yet able to determine author intent. However, authoring tools must not automatically misuse elements or encourage their users to do so.

Example

For example, it is not conforming to use an `address` element for arbitrary contact information; that element can only be used for marking up contact information for its nearest `article` or `body` element ancestor. However, since an authoring tool is likely unable to determine the difference, an authoring tool is exempt from that requirement. This does not mean, though, that authoring tools can use `address` elements for any block of text (for instance); it just means that the authoring tool doesn't have to verify that when the user uses a tool for inserting contact information for an `article` element, that the user really is doing that and not inserting something else instead.

Note

In terms of conformance checking, an editor has to output documents that conform to the same extent that a conformance checker will verify.

When an authoring tool is used to edit a non-conforming document, it may preserve the conformance errors in sections of the document that were not edited during the editing session (i.e. an editing tool is allowed to round-trip erroneous content). However, an authoring tool must not claim that the output is conformant if errors have been so preserved.

► **THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.**

Authoring tools are expected to come in two broad varieties: tools that work from structure or semantic data, and tools that work on a What-You-See-Is-What-You-Get media-specific editing basis (WYSIWYG).

The former is the preferred mechanism for tools that author HTML, since the structure in the source information can be used to make informed choices regarding which HTML elements and attributes are most appropriate.

However, WYSIWYG tools are legitimate. WYSIWYG tools should use elements they know are appropriate, and should not use elements that they do not know to be appropriate. This might in certain extreme cases mean limiting the use of flow elements to just a few elements, like `div`, `p`, and `span` and making liberal use of the `style` attribute.

All authoring tools, whether WYSIWYG or not, should make a best effort attempt at enabling users to create well-structured, semantically rich, media-independent content.

User agents may impose implementation-specific limits on otherwise unconstrained inputs, e.g., to prevent denial of service attacks, to guard against running out of memory, or to work around platform-specific limitations.

For compatibility with existing content and prior specifications, this specification describes two authoring formats: one based on [XML](#), and one using a [custom format](#) inspired by SGML (referred to as [the HTML syntax](#)). Implementations must support at least one of these two formats, although supporting both is encouraged.

Some conformance requirements are phrased as requirements on elements, attributes, methods or objects. Such requirements fall into two categories: those describing content model restrictions, and those describing implementation behavior. Those in the former category are requirements on documents and authoring tools. Those in the second category are requirements on user agents. Similarly, some conformance requirements are phrased as requirements on authors; such requirements are to be interpreted as conformance requirements on the documents that authors produce. (In other words, this specification does not distinguish between conformance criteria on authors and conformance criteria on documents.)

2.1.9 Dependencies

This specification relies on several other underlying specifications.

[Infra](#)

The following terms are defined in [Infra](#): [\[INFRA\]](#)

- The general iteration terms `while`, `continue`, and `break`
- `trackable vector`
- `code point` and its synonym `character`
- `comment`
- `scalar value`
- `tuple`
- `noncharacter`
- `JavaScript string`, `code unit`, and `JavaScript string length`
- `code unit range`
- `string length`
- `ASCII whitespace`
- `control`
- `ASCII digit`
- `ASCII lower hex digit`
- `ASCII lower hex digits`
- `ASCII hex digit`
- `ASCII lower alpha`
- `ASCII lower alpha`
- `ASCII upper alpha`
- `ASCII numeric`
- `isomorphic decode`
- `ASCII lowercase`
- `ASCII uppercase`
- `ASCII case-insensitive`
- `isolate newlines`
- `strip newlines`
- `strip leading and trailing ASCII whitespace`
- `strip and collapse ASCII whitespace`
- `split a string on ASCII whitespace`
- `split a string on commas`
- `collapse adjacent code points` and its associated `position variable`
- `skip ASCII whitespace`
- The `ordered map` data structure and the associated definitions for `value`, `entry`, `exists`, `getting the value of an entry`, `setting the value of an entry`, `removing an entry`, `getting the keys`, and `iterate`
- The `list` data structure and the associated definitions for `push` and `pop`
- The `queue` data structure and the associated definitions for `push` and `dequeue`
- The `set` data structure and the associated definition for `item`
- The `strict` specification type and the associated definition for `item`
- The `foraging-base64 encode` and `foraging-base64 decode` algorithms
- `HTML namespace`
- `MathML namespace`
- `SVG namespace`
- `XLink namespace`
- `XMI namespace`
- `XMNS namespace`

[Unicode and Encoding](#)

The Unicode character set is used to represent textual data, and `Encoding` defines requirements around `character encodings`. [\[UNICODE\]](#)

[Note](#)

This specification introduces terminology based on the terms defined in those specifications, as described earlier.

The following terms are used as defined in `Encoding`: [\[ENCODING\]](#)

- `Getting an encoding`
- `Decoding a stream`
- The generic `decode` algorithm which takes a byte stream and an encoding and returns a character stream
- The `UTF-8 decode` algorithm which takes a byte stream and returns a character stream, additionally stripping one leading UTF-8 Byte Order Mark (BOM), if any
- The `UTF-8 decode without BOM` algorithm which is identical to `UTF-8 decode` except that it does not strip one leading UTF-8 Byte Order Mark (BOM)
- The `encode` algorithm which takes a character stream and an encoding and returns a byte stream
- The `UTF-8 encode` algorithm which takes a character stream and returns a byte stream

[XML and related specifications](#)

Implementations that support the `XML syntax` for HTML must support some version of XML, as well as its corresponding namespaces specification, because that syntax uses an XML serialization with namespaces. [\[XML\]](#) [\[XMLNS\]](#)

Data mining tools and other user agents that perform operations on content without running scripts, evaluating CSS or XPath expressions, or otherwise exposing the resulting DOM to arbitrary content, may "support namespaces" by just asserting that their DOM node analogues are in certain namespaces, without actually exposing the namespace strings.

[Note](#)

In the `HTML syntax`, namespace prefixes and namespace declarations do not have the same effect as in XML. For instance, the colon has no special meaning in HTML element names.

The attribute with the tag name `xml:space` in the `XML namespace` is defined by [Extensible Markup Language \(XML\)](#): [\[XML\]](#)

The `xml` production is defined in `XML`: [\[XML\]](#)

This specification also references the `<xmlelement>` processing instruction, defined in [Associating Style Sheets with XML documents](#): [\[XMLSSP\]](#)

This specification also non-normatively mentions the `XSLTProcessor` interface and its `transformToFragment()` and `transformToDocument()` methods: [\[XSLTP\]](#)

[URLs](#)

The following terms are defined in `URL`: [\[URL\]](#)

- `host`
- `public suffix`
- `domain`
- `IPv4 address`
- `IPv6 address`
- `URI`
- `Origin of URLs`
- `Absolute URI`
- `Relative URI`
- `resolvable domain`
- The `parse` and `basic-URI-parser` as well as these parser states:
 - `scheme start state`
 - `host state`
 - `hostname state`
 - `port state`
 - `path start state`
 - `query state`
 - `fragment state`
- `URI record`, as well as its individual components:
 - `scheme`
 - `username`
 - `password`
 - `host`
 - `port`
 - `path`
 - `query`
 - `fragment`
 - `can-be-a-base-URL flag`
 - `object`
- `valid-URI-string`
- The `cannot have a username/password/port` concept
- The `URI serializer`
- The `URI resolver`
- The `host serializer`
- `Host equals`
- `URI equals`
- `serialize-as-an-integer`
- `Default encode-set`
- `UTF-8 encode-set`
- `String percent decode`
- `set the username`
- `set the password`
- The `application/x-www-form-urlencoded` format
- The `application/x-www-form-urlencodedkeyvalue`

A number of schemes and protocols are referenced by this specification also:

- The `about` scheme ([\[ABOUT\]](#))
- The `file` scheme ([\[FILEAPI\]](#))
- The `data` scheme ([\[RFC2397\]](#))
- The `http` scheme ([\[HTTP\]](#))
- The `https` scheme ([\[HTTP\]](#))
- The `mailto` scheme ([\[MAILTO\]](#))
- The `im` scheme ([\[IM\]](#))
- The `xrce` scheme ([\[XRCE\]](#))

`Media fragment syntax` is defined in `Media Fragments URI`: [\[MEDIAFRAG\]](#)

[HTTP and related specifications](#)

[Content negotiation and HTTP's conditional requests](#): [\[HTTP\]](#)

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

- `accept` header
- `accept-encoding` header
- `content-length` header
- `Content-Type` header
- `Content-Language` header
- `Last-Modified` header
- `Referrer` header

The following terms are defined in *HTTP State Management Mechanism*: [\[COOKIES\]](#)

- `cookie-string`
- receives a set-cookie-string
- `Cookie` header

The following term is defined in *Web Linking*: [\[WEBLINK\]](#)

- `Link` header

The following terms are defined in *MIME Sniffing*: [\[MIMESNIFF\]](#)

- `MIME-type`
- `valid MIME-type string`
- `valid MIME-type string with no parameters`
- `HTML MIME-type`
- `JavaScript MIME-type` and `JavaScript MIME-type essence match`
- `JSON MIME-type`
- `XML MIME-type`

Fetch

The following terms are defined in *Fetch*: [\[FETCH\]](#)

- `about:blank`
- A `HTTP/1 scheme`
- A `network scheme`
- A `fetch scheme`
- `HTTP/2 connection value`
- `CORS protocol`
- `default-user-agent-value`
- `extract a MIME type`
- `fetch`
- `HTTP-prefetch`
- `ok status`
- `navigation request`
- `network error`
- `prefetch` header
- `process response`
- `set`
- `terminate`
- the `RequestCredentials` enumeration
- the `RequestDestination` enumeration
- the `fetch()` method
- `request` and its associated:
 - `url`

 - `referrer-policy`
 - `cryptographic-nonce-metadata`
 - `integrity-metadata`
 - `load-navigation-flag`
 - `reload-navigation-flag`
 - `history-navigation-flag`

The following terms are defined in *Referrer Policy*: [\[REFERRERPOLICY\]](#)

- `referrer policy`
- The `Referrer-Policy` HTTP header
- The `parse a referrer policy from a Referrer-Policy header` algorithm
- The `"no-referrer", "no-referrer-when-downgrade", "strict-origin-when-downgrade", and "unsafe-url"` referrer policies

The following terms are defined in *Mixed Content*: [\[MIX\]](#)

- `a priori authenticated URL`

Paint Timing

The following terms are defined in *Paint Timing*: [\[PAINTTIMING\]](#)

- `mark paint timing`

Long Tasks

The following terms are defined in *Long Tasks*: [\[LONGTASKS\]](#)

- `report long tasks`

Web IDL

The IDL fragments in this specification must be interpreted as required for conforming IDL fragments, as described in *Web IDL*: [\[WEBIDL\]](#)

The following terms are defined in *Web IDL*:

- `extended attribute`
- `named constructor`
- `named operation`
- `overridden constructor steps`
- `internally create a new object implementing the interface`
- `array-index property name`
- `supported property indices`
- `create a new indexed property`
- `set the value of an existing indexed property`
- `set the value of a new indexed property`
- `support named properties`
- `supported property names`
- `get the value of a named property`
- `set the value of a named property`
- `set the value of a new named property`
- `delete an existing named property`
- `perform a security check`
- `platform object`
- `top-level object`
- `primary interface`
- `interface object`
- `interface prototype object`
- `IRealm`
- `callback context`
- `freeze` and `creating a frozen array`
- `callback this value`
- `converting` between Web IDL types and JS types
- `invoking` and `constructing` callback functions
- `converting to a sequence of Unicode scalar values`
- `overload resolution algorithm`
- `enum`

The *Web IDL* also defines the following types that are used in Web IDL fragments in this specification:

- `any`
- `any-but-error`
- `any-but-error-or-view`
- `any-view`
- `DOMString`
- `double`
- `enumeration`
- `float`
- `Function`
- `long`
- `object`
- `scriptable-name-string`
- `restricted-double`
- `unrestricted-long`
- `unrestricted-number`

The following features are defined in [UI Events](#): [\[UIEVENTS\]](#)

- The [MouseEvents](#) interface
- The [MouseEvents](#) interface's [relatedTarget](#) attribute
- [mouseEventTarget](#) dictionary type
- The [FocusEvent](#) interface
- The [FocusEvent](#) interface's [relatedTarget](#) attribute
- The [UIEvent](#) interface
- The [UIEvent](#) interface's [view](#) attribute
- [dragging](#) event
- [drag](#) event
- [dblclick](#) event
- [mousedown](#) event
- [mouseup](#) event
- [mouseover](#) event
- [mouseout](#) event
- [mousemove](#) event
- [wheel](#) event
- [swipe](#) event
- [pan](#) event
- [panstart](#) event
- [panmove](#) event
- [panend](#) event
- [swipeend](#) event

The following features are defined in [Touch Events](#): [\[TOUCH\]](#)

- [touchstart](#) interface
- [Touch start](#) concept
- [touchend](#) event

The following features are defined in [Pointer Events](#): [\[POINTEREVENTS\]](#)

- [pointerup](#) event

This specification sometimes uses the term [name](#) to refer to the event's [type](#); as in, "an event named [click](#)" or "if the event name is [keypress](#)". The terms "name" and "type" for events are synonymous.

The following features are defined in [DOM Parsing and Serialization](#): [\[DOMPARSING\]](#)

- [parseHTML](#)
- [parseXML](#)

The [Selection](#) interface is defined in the [Selection API](#) specification. [\[SELECTION\]](#)

Note: User agents are encouraged to implement the features described in [execCommand](#): [\[EXECCOMMAND\]](#)

The following parts of [Fullscreen API](#) are referenced from this specification, in part to define the rendering of [dialog](#) elements, and also to define how the Fullscreen API interacts with HTML: [\[FULLSCREEN\]](#)

- [top layer](#) (an [ordered set](#)) and its [add](#) operation
- [topLayerForAncestor\(\)](#)
- [run the fullscreen steps](#)

High Resolution Time provides the [current high resolution time](#) and the [DOMHighResTimeStamp](#) typedef: [\[HRT\]](#)

File API

This specification uses the following features defined in [File API](#): [\[FILEAPI\]](#)

- The [File](#) interface and its [name](#) attribute
- The [FileList](#) interface and its [name](#) and [lastModified](#) attributes
- The [FileReader](#) interface
- The concept of a [File](#)'s [snapshot state](#)
- The concept of [read errors](#)
- [Blob](#) [URL](#) [Store](#)

Indexed Database API

This specification uses [cleanup Indexed Database transactions](#) defined by [Indexed Database API](#). [\[INDEXEDDB\]](#)

Media Source Extensions

The following terms are defined in [Media Source Extensions](#): [\[MEDIASOURCE\]](#)

- [MediaSource](#) interface
- [Detaching from a media element](#)

Media Capture and Streams

The following terms are defined in [Media Capture and Streams](#): [\[MEDIASTREAM\]](#)

- [MediaStream](#) interface

XMLHttpRequest

The following features and terms are defined in [XMLHttpRequest](#): [\[XHR\]](#)

- [XMLHttpRequest](#) interface
- [XMLHttpRequest.readyState](#) attribute
- [XMLHttpRequest.onreadystatechange](#) attribute
- [XMLHttpRequest.responseText](#) attribute
- [XMLHttpRequest.responseText](#) attribute
- [XMLHttpRequest.responseText](#) attribute
- The concept of [error](#)
- [error](#) [entry](#)

Battery Status

The following features are defined in [Battery Status API](#): [\[BATTERY\]](#)

Implementations must support *Media Queries*. The [`@media-condition`](#) feature is defined therein. [MO]

CSS modules

While support for CSS as a whole is not required of implementations of this specification (though it is encouraged, at least for Web browsers), some features are defined in terms of specific CSS requirements.

When this specification requires that something be [parsed according to a particular CSS grammar](#), the relevant algorithm in *CSS Syntax* must be followed, including error handling rules. [CSSSYNTAX]

Example
For example, user agents are required to close all open constructs upon finding the end of a style sheet unexpectedly. Thus, when parsing the string "`z:0(0,0,0,0)`" (with a missing close-parenthesis for a color value, the close parenthesis is implied by this error handling rule, and a value is obtained (the color "black"). However, the similar construct "`z:0(0,0,0,"` (with both a missing parenthesis and a missing "blue" value) cannot be parsed, as closing the open construct does not result in a viable value.

To parse a CSS `<color>` value, given a string input with an optional element *element*, run these steps:

1. Let *color* be the result of [parsing](#) *input* as a CSS `<color>`. [CSSCOLOR]
2. If *color* is failure, then return failure.
3. If *color* is [`currentcolor`](#), then:
 1. If *element* is not given, then set *color* to `transparent`.
 2. Otherwise, set *color* to the computed value of the `<color>` property of *element*.
4. Return *color*.

The following terms and features are defined in *Cascading Style Sheets (CSS)*: [CSS]

- `viewport`
- `line_box`
- `out-of-flow`
- `in-flow`
- `intrinsic_dimensions`
- `content_area`
- `content_box`
- `border_box`
- `margin_box`
- `border-edge`
- `margin-edge`
- `collapsing_margins`
- `containing_block`
- `inline_box`
- `block_box`
- The `margin-top`, `margin-bottom`, `margin-left`, and `margin-right` properties
- The `padding-top`, `padding-bottom`, `padding-left`, and `padding-right` properties
- The `top`, `bottom`, `left`, and `right` properties
- The `float` property
- The `clear` property
- The `display` property
- The `table` property
- The `table-cell` property
- The `table-row` property
- The `table-column` property
- The `table-row-group` property
- The `table-column-group` property
- The `table-border-spacing` property
- The `table-layout` value of the `display` property
- The `table-view` property

CSS also defines the following border properties: [CSS]

	Top	Bottom	Left	Right
Width	<code>border-top-width</code>	<code>border-bottom-width</code>	<code>border-left-width</code>	<code>border-right-width</code>
Style	<code>border-top-style</code>	<code>border-bottom-style</code>	<code>border-left-style</code>	<code>border-right-style</code>
Color	<code>border-top-color</code>	<code>border-bottom-color</code>	<code>border-left-color</code>	<code>border-right-color</code>

The terms *intrinsic width* and *intrinsic height* refer to the width dimension and the height dimension, respectively, of *intrinsic dimensions*.

The basic version of the `display` property is defined in CSS, and the property is extended by other CSS modules. [CSS] [CSSRUBY] [CSSTABLE]

The following terms and features are defined in *CSS Logical Properties*: [CSSLOGICAL]

- The `margin-block-start`, `margin-block-end`, `margin-inline-start`, and `margin-inline-end` properties
- The `padding-block-start`, `padding-block-end`, `padding-inline-start`, and `padding-inline-end` properties
- The `border-block-start-width` property
- The `border-block-end-width` property
- The `block-size` property
- The `block-size` property
- The `block-size` property
- The `block-size` property

The following terms and features are defined in *CSS Color*: [CSSCOLOR]

- `named_color`
- `color`
- The `color` property
- The `color` value
- `green`
- `black`
- `transparent`

The term *intrinsic aspect ratio* is used as defined in *CSS Image Values and Replaced Content* to define the sizing of replaced content. [CSSIMAGES]

The term `paint-source` is used as defined in *CSS Image Values and Replaced Content* to define the interaction of certain HTML elements with the CSS'element()' function. [CSSIMAGES]

The term `default-object-type` and the `object-fit` property are also defined in *CSS Image Values and Replaced Content*: [CSSIMAGES]

The following features are defined in *CSS Backgrounds and Borders*: [CSSBG]

- The `background-color` property
- The `background-image` property
- The `border-radius` property

The following features are defined in *CSS Box Alignment*: [CSSALIGN]

- The `align-content` property
- The `align-items` property
- The `align-self` property
- The `justify-self` property
- The `justify-content` property
- The `justify-items` property

The following terms and features are defined in *CSS Display*: [CSSDISPLAY]

- `block-display-type`
- `block-level`
- `block-container`
- `formatting_context`
- `block-formatting-context`
- `inline-formatting-context`
- `absolute-positioned`
- `replaced-element`
- `CSSText`

The following features are defined in *CSS Flexible Box Layout*: [CSSFLEXBOX]

- The `flex-direction` property
- The `flex-wrap` property

The following features are defined in *CSS Fonts*: [CSSFONTS]

- The `font-family` property
- The `font-weight` property
- The `font-style` property
- The `font` property

The following features are defined in *CSS Grid Layout*: [CSSGRID]

- The `grid-auto-columns` property
- The `grid-auto-flow` property
- The `grid-auto-rows` property
- The `grid-column-gap` property
- The `grid-row-gap` property
- The `grid-template-areas` property
- The `grid-template-columns` property
- The `grid-template-rows` property

The following terms and features are defined in *CSS Intrinsic & Extrinsic Sizing*: [CSSSIZING]

- `fit-content inline-size`

The `list-style-type` property is defined in *CSS Lists and Counters*: [CSSLISTS]

The following features are defined in *CSS Overflow*: [CSSOVERFLOW]

- The `overflow` property and its `hidden` value
- The `text-overflow` property

The following features are defined in *CSS Positioned Layout*: [CSSPOSITION]

- The `position` property and its `static` value

The following features are defined in *CSS Multi-column Layout*: [CSSMULTICOL]

- The `columns-count` property
- The `columns-fill` property
- The `columns-equal` property
- The `column-reverse` property
- The `column-width` property

The `ruby-base` value of the `display` property is defined in *CSS Ruby Layout*: [CSSRUBY]

The following features are defined in *CSS Table*: [CSSTABLE]

- The `border-spacing` property
- The `border-collapse` property

The following features are defined in CSS Text: [\[CSSTEXT\]](#)

- The `text-transform` property
- The `white-space` property
- The `text-align` property
- The `letter-spacing` property

The following features are defined in CSS Writing Modes: [\[CSSWM\]](#)

- The `direction` property
- The `unicode-bidi` property
- The `block-flow-direction`, `block-size`, `inline-size`, `block-start`, `block-end`, `inline-start`, `line-left`, and `line-right` concepts

The following features are defined in CSS Basic User Interface: [\[CSSUI\]](#)

- The `outline` property
- The `cursor` property
- The `appearance` property

The algorithm to `update_animations_and_send_events` is defined in Web Animations: [\[WEBANIMATIONS\]](#)

Implementations that support scripting must support the CSS Object Model. The following features and terms are defined in the CSSOM specifications: [\[CSSOM\]](#) [\[CSSOMVIEW\]](#)

- `cssom` interface
- `cssrule` interface
- `CSSStyleDeclaration` interface
- `cssText` attribute of `CSSStyleDeclaration`
- `cssValue` interface
- `create a CSS style sheet`
- `remove a CSS style sheet`
- `associated CSS style sheet`
- `CSS style sheet` and their properties:
 - `type`
 - `location`
 - `parent CSS style sheet`
 - `media`
 - `owner CSS rule`
 - `media`
 - `title`
 - `alternate flag`
 - `disabled flag`
 - `CSS value`
 - `origin-clean flag`
- `CSS style sheet set`
- `CSS style sheet set name`
- `parented CSS style sheet set name`
- `sharing a common CSS style sheet set name`
- `Serialize a CSS value`
- `run the resize steps`
- `run the scroll steps`
- `evaluate media queries and report changes`
- `scroll the document into view`
- `Scroll to the beginning of the document`
- The `resize` event
- The `scroll` event
- `set up browsing context features`

The following features and terms are defined in CSS Syntax: [\[CSSSYNTAX\]](#)

- `conformant style sheet`
- `parse a comma-separated list of component values`
- `component value`
- `environment encoding`
- `whitespace tokens`

The following terms are defined in Selectors: [\[SELECTORS\]](#)

- `type selector`
- `attribute selector`
- `pseudo-class`

The following features are defined in CSS Values and Units: [\[CSSVALUES\]](#)

- `length`
 - The `em` unit
 - The `ex` unit
 - The `pc` unit
 - The `pc` unit
 - The `in` unit
 - The `px` unit
 - The `in` function
 - The `math` functions

The term `style attribute` is defined in CSS Style Attributes: [\[CSSATTR\]](#)

The following terms are defined in the CSS Cascading and Inheritance: [\[CSSCASCADE\]](#)

- `specified value`
- `computed value`
- `used value`

The `CanvasRenderingContext2D` object's use of fonts depends on the features described in the CSS Fonts and Font Loading specifications, including in particular `FontFace` objects and the `font source` concept: [\[CSSFONTS\]](#) [\[CSSFONTLOAD\]](#)

The following interfaces and terms are defined in Geometry Interfaces: [\[GEOOMETRY\]](#)

- `geometry` interface, and associated `m11_element`, `m12_element`, `m21_element`, `m22_element`, `m41_element`, and `m42_element`
- `geometricMatrix` and `geometricMatrix` dictionaries
- The `create a geometric entry from a dictionary` and `create a geometric from a 2D dictionary` algorithms for `DOMMatrixInit` or `DOMMatrixInit`

The following terms are defined in the CSS Scoping: [\[CSSSCOPING\]](#)

- `flat tree`

Intersection Observer

The following term is defined in Intersection Observer: [\[INTERSECTIONOBSERVER\]](#)

- `run the update intersection observations steps`

WebGL

The following interfaces are defined in the WebGL specifications: [\[WEBGL\]](#)

- `WebGL2RenderingContext` interface
- `WebGL2RenderingContext` interface
- `WebGL2RenderingContext` dictionary

WebVTT

Implementations may support WebVTT as a text track format for subtitles, captions, metadata, etc., for media resources: [\[WEBVTT\]](#)

The following terms, used in this specification, are defined in WebVTT:

- `WebVTT file`
- `WebVTT using cue text`
- `WebVTT file using only nested cues`
- `WebVTT parser`
- The `rules for updating the display of WebVTT text tracks`
- The `WebVTT text track cue writing direction`
- `cueText` interface

The WebSockets protocol

The following terms are defined in Fetch: [\[FETCH\]](#)

- `establish a WebSocket connection`

The following terms are defined in The WebSocket protocol: [\[WSP\]](#)

- `the WebSocket connection is established`
- `extensions in use`
- `subprotocol in use`
- `a WebSocket message has been received`
- `send a WebSocket Message`
- `fail the WebSocket connection`
- `close the WebSocket connection`
- `start the WebSocket closing handshake`
- `the WebSocket connection is closed (possibly cleanly)`
- `the WebSocket connection close code`
- `the WebSocket connection close reason`
- `Set-WebSocket-Protocol` field

ARIA

The `role` attribute is defined in Accessible Rich Internet Applications (ARIA), as are the following roles: [\[ARIA\]](#)

- `button`
- `checkbox`

In addition, the following `aria-` content attributes are defined in ARIA: [\[ARIA\]](#)

- `aria-describedby`
- `aria-disabled`
- `aria-label`

Finally, the following terms are defined ARIA: [\[ARIA\]](#)

- `accessible name`

Content Security Policy

The following terms are defined in Content Security Policy: [\[CSP\]](#)

- `Content-Security-Policy`
- `Content-Security-Policy directive`
- `CSP list`

- The [parse a serialized Content Security Policy](#) algorithm
- The [Initialize a Document's CSP list](#) algorithm
- The [Initialize a Document's CSP list](#) algorithm
- The [Should element's inline behavior be blocked by Content Security Policy?](#) algorithm
- The [Should navigation request of type from source in target be blocked by Content Security Policy?](#) algorithm
- The [Should navigation response to navigation request of type from source in target be blocked by Content Security Policy?](#) algorithm
- The [parse a CSPDocument](#) abstract operation
- The [Is base allowed for Document?](#) algorithm
- The [frame-ancestor directive](#)
- The [sandbox directive](#)
- The [Should element be blocked a priori by Content Security Policy?](#) algorithm
- The [contains a header-delivered Content Security Policy](#) property.

Service Workers

The following terms are defined in [Service Workers](#): [SW]

- [active worker](#)
- [client message queue](#)
- [control](#)
- [handle fetch](#)
- [match service worker registration](#)
- [registration](#)
- [service worker client](#)
- [service-worker-interface](#) interface
- [service-worker-connection-interface](#) interface
- [service-worker-global-issuing-interface](#) interface

Secure Contexts

The following algorithm is defined in [Secure Contexts](#): [SECURE-CONTEXTS]

- [Is environment settings object a secure context?](#)

Feature Policy

The following terms are defined in [Feature Policy](#): [FEATUREPOLICY]

- [feature policy](#)
- [feature policy](#)
- [container policy](#)
- [serialized feature policy](#)
- [default allowlist](#)
- The [read feature policy](#) algorithm
- The [return a feature policy from a response](#) algorithm
- The [Is feature enabled by policy for origin](#) algorithm
- The [Process feature policy attributes](#) algorithm

Payment Request API

The following feature is defined in [Payment Request API](#): [PAYMENTREQUEST]

- [PaymentRequest](#) interface

MathML

While support for MathML as a whole is not required by this specification (though it is encouraged, at least for Web browsers), certain features depend upon small parts of MathML being implemented: [MATHML]

The following features are defined in [Mathematical Markup Language \(MathML\)](#):

- [MathML_annotation-xml](#) element
- [MathML_math](#) element
- [MathML_merror](#) element
- [MathML_mi](#) element
- [MathML_mn](#) element
- [MathML_mtext](#) element
- [MathML_ms](#) element
- [MathML_msub](#) element
- [MathML_msubsup](#) element
- [MathML_msubsupr](#) element
- [MathML_mfrac](#) element
- [MathML_msubscript](#) element
- [MathML_msuperscript](#) element
- [MathML_msubsupr](#) element
- [MathML_msubscript](#) element
- [MathML_msuperscript](#) element
- [MathML_msubsupr](#) element
- [MathML_msubscript](#) element
- [MathML_msuperscript](#) element
- [MathML_msubsupr](#) element

SVG

While support for SVG as a whole is not required by this specification (though it is encouraged, at least for Web browsers), certain features depend upon parts of SVG being implemented.

User agents that implement SVG must implement the [SVG 2](#) specification, and not any earlier revisions.The following features are defined in the [SVG 2](#) specification: [SVG]

- [SVGElement](#) interface
- [SVGImageElement](#) interface
- [SVGScriptElement](#) interface
- [SVGSVGElement](#) interface
- [SVGTextElement](#)
- [SVG_a_element](#)
- [SVG_dbase_element](#)
- [SVG_fallback_element](#)
- [SVG_image_element](#)
- [SVG_line_element](#)
- [SVG_rect_element](#)
- [SVG_use_element](#)
- [SVG_zindex_element](#)
- [SVG_was_element](#)

Filter Effects

The following feature is defined in [Filter Effects](#): [FILTERS]

- [filter-function-list](#)

Workers

The following feature is defined in [Workers](#): [WORKLETS]

- [WorkerGlobalScope](#)
- A [WorkerGlobalScope's owner document](#)

Cooperative Scheduling of Background Tasks

The following features are defined in [Cooperative Scheduling of Background Tasks](#): [REQUESTIDLCALLBACK]

- [requestAnimationFrame\(\)](#)
- [start an idle period algorithm](#)

This specification does not require support of any particular network protocol, style sheet language, scripting language, or any of the DOM specifications beyond those required in the list above. However, the language described by this specification is biased towards CSS as the styling language, JavaScript as the scripting language, and HTTP as the network protocol, and several features assume that those languages and protocols are in use.

A user agent that implements the HTTP protocol must implement [HTTP State Management Mechanism \(Cookies\)](#) as well: [HTTP] [COOKIES]

Note

This specification might have certain additional requirements on character encodings, image formats, audio formats, and video formats in the respective sections.

2.1.10 Extensibility

Vendor-specific proprietary user agent extensions to this specification are strongly discouraged. Documents must not use such extensions, as doing so reduces interoperability and fragments the user base, allowing only users of specific user agents to access the content in question.

All extensions must be defined so that the use of extensions neither contradicts nor causes the non-conformance of functionality defined in the specification.

Example

For example, while strongly discouraged from doing so, an implementation could add a new IDL attribute "`typeTime`" to a control that returned the time it took the user to select the current value of a control (say). On the other hand, defining a new control that appears in a form's `elements` array would be in violation of the above requirement, as it would violate the definition of `elements` given in this specification.When vendor-neutral extensions to this specification are needed, either this specification can be updated accordingly, or an extension specification can be written that overrides the requirements in this specification. When someone applying this specification to their activities decides that they will recognize the requirements of such an extension specification, it becomes an *applicable specification* for the purposes of conformance requirements in this specification.

Note

Someone could write a specification that defines any arbitrary byte stream as conforming, and then claim that their random junk is conforming. However, that does not mean that their random junk actually is conforming for everyone's purposes: if someone else decides that that specification does not apply to their work, then they can quite legitimately say that the aforementioned random junk is just, well, junk, and not conforming at all. As far as conformance goes, what matters in a particular community is what that community agrees is applicable.

User agents must treat elements and attributes that they do not understand as semantically neutral; leaving them in the DOM (for DOM processors), and styling them according to CSS (for CSS processors), but not inferring any meaning from them.

When support for a feature is disabled (e.g. as an emergency measure to mitigate a security problem, or to aid in development, or for performance reasons), user agents must act as if they had no support for the feature whatsoever, and as if the feature was not mentioned in this specification. For example, if a particular feature is accessed via an attribute in a Web IDL interface, the attribute itself would be omitted from the objects that implement that interface — leaving the attribute on the object but making it return null or throw an exception is insufficient.

2.1.11 Interactions with XPath and XSLT

Implementations of XPath 1.0 that operate on [HTML documents](#) parsed or created in the manners described in this specification (e.g. as part of the `document.evaluate()` API) must act as if the following edit was applied to the XPath 1.0 specification.

First, remove this paragraph:

A QName in the node test is expanded into an expanded-name using the namespace declarations from the expression context. This is the same way expansion is done for element type names in start and end-tags except that the default namespace declared with `xmlns` is not used: if the `QName` does not have a prefix, then the namespace URI is null (this is the same way attribute names are expanded). It is an error if the `QName` has a prefix for which there is no namespace declaration in the expression context.

Then, insert in its place the following:

A QName in the node test is expanded into an expanded-name using the namespace declarations from the expression context. If the QName has a prefix, then there must be a namespace declaration for this prefix in the expression context, and the corresponding namespace URI is the one that is associated with this prefix. It is an error if the QName has a prefix for which there is no namespace declaration in the expression context.

If the QName has no prefix and the principal node type of the axis is element, then the default element namespace is used. Otherwise if the QName has no prefix, the namespace URI is null. The default element namespace is a member of the context for the XPath expression. The value of the default element namespace when executing an XPath expression through the DOM3 XPath API is determined in the following way:

1. If the context node is from an HTML DOM, the default element namespace is "<http://www.w3.org/1999/xhtml>".
2. Otherwise, the default element namespace URI is null.

This is equivalent to adding the default element namespace feature of XPath 2.0 to XPath 1.0, and using the HTML namespace as the default element namespace for HTML documents. It is motivated by the desire to have implementations be compatible with legacy HTML content while still supporting the changes that this specification introduces to HTML regarding the namespace used for HTML elements. [XPATH10]

Note

This change is a *willful violation* of the XPath 1.0 specification, motivated by desire to have implementations be compatible with legacy content while still supporting the changes that this specification introduces to HTML regarding which namespace is used for HTML elements. [XPATH10]

XSLT 1.0 processors outputting to a DOM when the output method is "html" (either explicitly or via the defaulting rule in XSLT 1.0) are affected as follows:

If the transformation program outputs an element in no namespace, the processor must, prior to constructing the corresponding DOM element node, change the namespace of the element to the `HTML_namespace`, `ASCII-lowercase` the element's local name, and `ASCII-lowercase` the names of any non-namedpaced attributes on the element.

Note

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

This specification does not specify precisely how XSLT processing interacts with the [HTML_parse](#) infrastructure (for example, whether an XSLT processor acts as if it puts any elements into a [stack of open elements](#)). However, XSLT processors must [stop parsing](#) if they successfully complete, and must set the [current document readiness](#) first to "interactive" and then to "complete" if they are aborted.

This specification does not specify how XSLT interacts with the [navigation](#) algorithm, how it fits in with the [event loop](#), nor how error pages are to be handled (e.g. whether XSLT errors are to replace an incremental XSLT output, or are rendered inline, etc).

Note

There are also additional non-normative comments regarding the interaction of XSLT and HTML in the [script element section](#), and of XSLT, XPath, and HTML in the [translate element section](#).

2.2 Case-sensitivity and string comparison

Comparing two strings in a *case-sensitive* manner means comparing them exactly, code point for code point.

Except where otherwise stated, string comparisons must be performed in a [case-sensitive](#) manner.

A *string pattern* is a *prefix match* for a string *s* when *pattern* is not longer than *s* and truncating *s* to *pattern*'s length leaves the two strings as matches of each other.

2.3 Policy-controlled features

This document defines the following [policy-controlled features](#):

MDN

[Headers/Feature-Policy/document-domain](#)

Firefox74+SafariNoChrome77+

Opera64+Edg79+

Edge Legacy>NoInternet ExplorerNo

Firefox, Android 65+Safari iOSNoChrome AndroidNoWebView AndroidNoSamsung InternetNoOpera AndroidNo

- "autoplay", which has a [default allowlist](#) of "+",
- "document-domain", which has a [default allowlist](#) of "-".

2.4 Common microsyntaxes

There are various places in HTML that accept particular data types, such as dates or numbers. This section describes what the conformance criteria for content in those formats is, and how to parse them.

Note

Implementors are strongly urged to carefully examine any third-party libraries they might consider using to implement the parsing of syntaxes described below. For example, date libraries are likely to implement error handling behavior that differs from what is required in this specification, since error-handling behavior is often not defined in specifications that describe date syntaxes similar to those used in this specification, and thus implementations tend to vary greatly in how they handle errors.

2.4.1 Common parser idioms

Some of the micro-parsers described below follow the pattern of having an *input* variable that holds the string being parsed, and having a *position* variable pointing at the next character to parse in *input*.

2.4.2 Boolean attributes

A number of attributes are *boolean attributes*. The presence of a boolean attribute on an element represents the true value, and the absence of the attribute represents the false value.

If the attribute is present, its value must either be the empty string or a value that is an [ASCII case-insensitive](#) match for the attribute's canonical name, with no leading or trailing whitespace.

Note

The values "true" and "false" are not allowed on boolean attributes. To represent a false value, the attribute has to be omitted altogether.

Example

Here is an example of a checkbox that is checked and disabled. The [checked](#) and [disabled](#) attributes are the boolean attributes.

```
<label><input type="checkbox" checked="" name="cheese" disabled=""> Cheese</label>
```

This could be equivalently written as this:

```
<label><input type="checkbox" checked="checked" name="cheese" disabled="disabled"> Cheese</label>
```

You can also mix styles; the following is still equivalent:

```
<label><input type="checkbox" checked="" name="cheese" disabled=""> Cheese</label>
```

2.4.3 Keywords and enumerated attributes

Some attributes are defined as taking one of a finite set of keywords. Such attributes are called *enumerated attributes*. The keywords are each defined to map to a particular *state* (several keywords might map to the same state, in which case some of the keywords are synonyms of each other; additionally, some of the keywords can be said to be non-conforming, and are only in the specification for historical reasons). In addition, two default states can be given. The first is the *invalid value default*, the second is the *missing value default*.

If an enumerated attribute is specified, the attribute's value must be an [ASCII case-insensitive](#) match for one of the given keywords that are not said to be non-conforming, with no leading or trailing whitespace.

When the attribute is specified, if its value is an [ASCII case-insensitive](#) match for one of the given keywords then that keyword's state is the state that the attribute represents. If the attribute value matches none of the given keywords, but the attribute has an [invalid value default](#), then the attribute represents that state. Otherwise, there is no default, and invalid values mean that there is no state represented.

When the attribute is not specified, if there is a [missing value default](#) state defined, then that is the state represented by the (missing) attribute. Otherwise, the absence of the attribute means that there is no state represented.

Note

The empty string can be a valid keyword.

2.4.4 Numbers

2.4.4.1 Signed integers

A string is a *valid integer* if it consists of one or more [ASCII digits](#), optionally prefixed with a U+002D HYPHEN-MINUS character (-).

A [valid integer](#) without a U+002D HYPHEN-MINUS (-) prefix represents the number that is represented in base ten by that string of digits. A [valid integer](#) with a U+002D HYPHEN-MINUS (-) prefix represents the number represented in base ten by the string of digits that follows the U+002D HYPHEN-MINUS, subtracted from zero.

The rules for parsing integers are as given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either an integer or an error.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Let *sign* have the value "positive".
4. [Skip ASCII whitespace](#) within *input* given *position*.
5. If *position* is past the end of *input*, return an error.
6. If the character indicated by *position* (the first character) is a U+002D HYPHEN-MINUS character (-):
 1. Let *sign* be "negative".
 2. Advance *position* to the next character.
 3. If *position* is past the end of *input*, return an error.
- Otherwise, if the character indicated by *position* (the first character) is a U+002B PLUS SIGN character (+):
 1. Advance *position* to the next character. (The "+" is ignored, but it is not conforming.)
 2. If *position* is past the end of *input*, return an error.
7. If the character indicated by *position* is not an [ASCII digit](#), then return an error.
8. Collect a sequence of [code points](#) that are [ASCII digits](#) from *input* given *position*, and interpret the resulting sequence as a base-ten integer. Let *value* be that integer.
9. If *sign* is "positive", return *value*, otherwise return the result of subtracting *value* from zero.

2.4.4.2 Non-negative integers

A string is a *valid non-negative integer* if it consists of one or more [ASCII digits](#).

A [valid non-negative integer](#) represents the number that is represented in base ten by that string of digits.

The rules for parsing non-negative integers are as given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either zero, a positive integer, or an error.

1. Let *input* be the string being parsed.
2. Let *value* be the result of parsing *input* using the [rules for parsing integers](#).
3. If *value* is an error, return an error.
4. If *value* is less than zero, return an error.
5. Return *value*.

2.4.4.3 Floating-point numbers

A string is a *valid floating-point number* if it consists of:

1. Optionally, a U+002D HYPHEN-MINUS character (-).
2. One or both of the following, in the given order:
 1. A series of one or more [ASCII digits](#).
 2. Both of the following, in the given order:
 1. A single U+002E FULL STOP character (.)
 2. A series of one or more [ASCII digits](#).
3. Optionally:
 1. Either a U+0065 LATIN SMALL LETTER E character (e) or a U+0045 LATIN CAPITAL LETTER E character (E).
 2. Optionally, a U+002D HYPHEN-MINUS character (-) or U+002B PLUS SIGN character (+).
 3. A series of one or more [ASCII digits](#).

A [valid floating-point number](#) represents the number obtained by multiplying the significand by ten raised to the power of the exponent, where the significand is the first number, interpreted as base ten (including the decimal point and the number after the decimal point, if any, and interpreting the significand as a negative number if the whole string starts with a U+002D HYPHEN-MINUS character (-) and the number is not zero), and where the exponent is the number after the E, if any (interpreted as a negative number if there is a U+002D HYPHEN-MINUS character (-) between the E and the number and the number is not zero, or else ignoring a U+002B PLUS SIGN character (+) between the E and the number if there is one). If there is no E, then the exponent is zero.

Note

The [Infinity](#) and [Not-a-Number](#)(NaN) values are not [valid floating-point numbers](#).

Note

The [valid floating-point number](#) concept is typically only used to restrict what is allowed for authors, while the user agent requirements use the [rules for parsing floating-point number values](#) below (e.g. the [tag](#) attribute of the [process](#) element). However, in some cases the user agent requirements include checking if a string is a [valid floating-point number](#) (e.g., the [value sanitization algorithm](#) for the [Number](#) state of the [input](#) element, or the [parse-a-*reset* attribute](#) algorithm).

The best representation of the *number* as a *floating-point number* is the string obtained from running [ToString\(n\)](#). The abstract operation [ToString](#) is not uniquely determined. When there are multiple possible strings that could be obtained from [ToString](#) for a particular value, the user agent must always return the same string for that value (though it may differ from the value used by other user agents).

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

The rules for parsing floating-point number values are as given in the following algorithm. This algorithm must be aborted at the first step that returns something. This algorithm will return either a number or an error.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Let *value* have the value 1.
4. Let *divisor* have the value 1.
5. Let *exponent* have the value 1.
6. **Skip ASCII whitespace** within *input* given *position*.
7. If *position* is past the end of *input*, return an error.
8. If the character indicated by *position* is a U+002D HYPHEN-MINUS character (-):
 1. Change *value* and *divisor* to -1.
 2. Advance *position* to the next character.
 3. If *position* is past the end of *input*, return an error.
- Otherwise, if the character indicated by *position* (the first character) is a U+002B PLUS SIGN character (+):
 1. Advance *position* to the next character. (The "+" is ignored, but it is not conforming.)
 2. If *position* is past the end of *input*, return an error.
9. If the character indicated by *position* is a U+002E FULL STOP (.), and that is not the last character in *input*, and the character after the character indicated by *position* is an [ASCII digit](#), then set *value* to zero and jump to the step labeled *fraction*.
10. If the character indicated by *position* is not an [ASCII digit](#), then return an error.
11. **Collect a sequence of code points** that are [ASCII digits](#) from *input* given *position*, and interpret the resulting sequence as a base-ten integer. Multiply *value* by that integer.
12. If *position* is past the end of *input*, jump to the step labeled *conversion*.
13. **Fraction:** If the character indicated by *position* is a U+002E FULL STOP (.), run these substeps:
 1. Advance *position* to the next character.
 2. If *position* is past the end of *input*, or if the character indicated by *position* is not an [ASCII digit](#), U+0065 LATIN SMALL LETTER E (e), or U+0045 LATIN CAPITAL LETTER E (E), then jump to the step labeled *conversion*.
 3. If the character indicated by *position* is a U+0065 LATIN SMALL LETTER E character (e) or a U+0045 LATIN CAPITAL LETTER E character (E), skip the remainder of these substeps.
 4. **Fraction loop:** Multiply *divisor* by ten.
 5. Add the value of the character indicated by *position*, interpreted as a base-ten digit (0..9) and divided by *divisor*, to *value*.
 6. Advance *position* to the next character.
 7. If *position* is past the end of *input*, then jump to the step labeled *conversion*.
 8. If the character indicated by *position* is an [ASCII digit](#), jump back to the step labeled *fraction loop* in these substeps.
14. If the character indicated by *position* is U+0065 (e) or a U+0045 (E), then:
 1. Advance *position* to the next character.
 2. If *position* is past the end of *input*, then jump to the step labeled *conversion*.
 3. If the character indicated by *position* is a U+002D HYPHEN-MINUS character (-):
 1. Change *exponent* to -1.
 2. Advance *position* to the next character.
 3. If *position* is past the end of *input*, then jump to the step labeled *conversion*.
 - Otherwise, if the character indicated by *position* is a U+002B PLUS SIGN character (+):
 1. Advance *position* to the next character.
 2. If *position* is past the end of *input*, then jump to the step labeled *conversion*.
 4. If the character indicated by *position* is not an [ASCII digit](#), then jump to the step labeled *conversion*.
15. **Collect a sequence of code points** that are [ASCII digits](#) from *input* given *position*, and interpret the resulting sequence as a base-ten integer. Multiply *exponent* by that integer.
16. Multiply *value* by ten raised to the *exponent* power.
17. **Conversion:** Let *S* be the set of finite IEEE 754 double-precision floating-point values except -0, but with two special values added: 2^{1024} and -2^{1024} .
18. Let *rounded-value* be the number in *S* that is closest to *value*, selecting the number with an even significand if there are two equally close values. (The two special values 2^{1024} and -2^{1024} are considered to have even significands for this purpose.)
17. If *rounded-value* is 2^{1024} or -2^{1024} , return an error.
18. Return *rounded-value*.

2.4.4.4 Percentages and lengths

The rules for parsing dimension values are as given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either a number greater than or equal to 0.0, or failure; if a number is returned, then it is further categorized as either a percentage or a length.

1. Let *input* be the string being parsed.
2. Let *position* be a **position variable** for *input*, initially pointing at the start of *input*.
3. **Skip ASCII whitespace** within *input* given *position*.
4. If *position* is past the end of *input* or the code point at *position* within *input* is not an [ASCII digit](#), then return failure.
5. **Collect a sequence of code points** that are [ASCII digits](#) from *input* given *position*, and interpret the resulting sequence as a base-ten integer. Let *value* be that number.
6. If *position* is past the end of *input*, then return *value* as a length.
7. If the code point at *position* within *input* is U+002E (.), then:
 1. Advance *position* by 1.
 2. If *position* is past the end of *input* or the code point at *position* within *input* is not an [ASCII digit](#), then return the [current dimension value](#) with *value*, *input*, and *position*.
 3. Let *divisor* have the value 1.
 4. While true:
 1. Multiply *divisor* by ten.
 2. Add the value of the code point at *position* within *input*, interpreted as a base-ten digit (0..9) and divided by *divisor*, to *value*.
 3. Advance *position* by 1.
 4. If *position* is past the end of *input*, then return *value* as a length.
 5. If the code point at *position* within *input* is not an [ASCII digit](#), then **break**.
8. Return the [current dimension value](#) with *value*, *input*, and *position*.

The [current dimension value](#), given *value*, *input*, and *position*, is determined as follows:

1. If *position* is past the end of *input*, then return *value* as a length.
2. If the code point at *position* within *input* is U+0025 (%), then return *value* as a percentage.
3. Return *value* as a length.

2.4.4.5 Non-zero percentages and lengths

The rules for parsing nonzero dimension values are as given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either a number greater than 0.0, or an error; if a number is returned, then it is further categorized as either a percentage or a length.

1. Let *input* be the string being parsed.
2. Let *value* be the result of parsing *input* using the [rules for parsing dimension values](#).
3. If *value* is an error, return an error.
4. If *value* is zero, return an error.
5. If *value* is a percentage, return *value* as a percentage.
6. Return *value* as a length.

2.4.4.6 Lists of floating-point numbers

A valid list of floating-point numbers is a number of [valid floating-point numbers](#) separated by U+002C COMMA characters, with no other characters (e.g. no [ASCII whitespace](#)). In addition, there might be restrictions on the number of floating-point numbers that can be given, or on the range of values allowed.

The rules for parsing a list of floating-point numbers are as follows:

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Let *numbers* be an initially empty list of floating-point numbers. This list will be the result of this algorithm.
4. **Collect a sequence of code points** that are [ASCII whitespace](#), U+002C COMMA, or U+003B SEMICOLON characters from *input* given *position*. This skips past any leading delimiters.
5. While *position* is not past the end of *input*:
 1. **Collect a sequence of code points** that are not [ASCII whitespace](#), U+002C COMMA, U+003B SEMICOLON, [ASCII digits](#), U+002E FULL STOP, or U+002D HYPHEN-MINUS characters from *input* given *position*. This skips past leading garbage.
 2. **Collect a sequence of code points** that are not [ASCII whitespace](#), U+002C COMMA, or U+003B SEMICOLON characters from *input* given *position*, and let *unparsed number* be the result.
 3. Let *number* be the result of parsing *unparsed number* using the [rules for parsing floating-point number values](#).
 4. If *number* is an error, set *number* to zero.
 5. Append *number* to *numbers*.
6. **Collect a sequence of code points** that are [ASCII whitespace](#), U+002C COMMA, or U+003B SEMICOLON characters from *input* given *position*. This skips past the delimiter.

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

6. Return numbers.

2.4.4.7 Lists of dimensions

The rules for parsing a list of dimensions are as follows. These rules return a list of zero or more pairs consisting of a number and a unit, the unit being one of *percentage*, *relative*, and *absolute*.

1. Let *raw input* be the string being parsed.
2. If the last character in *raw input* is a U+002C COMMA character (,), then remove that character from *raw input*.
3. *Skip the string raw input on commas*. Let *raw tokens* be the resulting list of tokens.
4. Let *result* be an empty list of number/unit pairs.
5. For each token in *raw tokens*, run the following substeps:
 1. Let *input* be the token.
 2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
 3. Let *value* be the number 0.
 4. Let *unit* be *absolute*.
 5. If *position* is past the end of *input*, set *unit* to *relative* and jump to the last substep.
 6. If the character at *position* is an ASCII digit, collect a sequence of code points that are ASCII digits from *input* given *position*, interpret the resulting sequence as an integer in base ten, and increment *value* by that integer.
 7. If the character at *position* is U+002E (.), then:
 1. Collect a sequence of code points consisting of ASCII whitespace and ASCII digits from *input* given *position*. Let *s* be the resulting sequence.
 2. Remove all ASCII whitespace in *s*.
 3. If *s* is not the empty string, then:
 1. Let *length* be the number of characters in *s* (after the spaces were removed).
 2. Let *fraction* be the result of interpreting *s* as a base-ten integer, and then dividing that number by 10^{length} .
 3. Increment *value* by *fraction*.
 8. *Skip ASCII whitespace* within *input* given *position*.
 9. If the character at *position* is a U+0025 PERCENT SIGN character (%), then set *unit* to *percentage*. Otherwise, if the character at *position* is a U+002A ASTERISK character (*), then set *unit* to *relative*.
 10. Add an entry to *result* consisting of the number given by *value* and the unit given by *unit*.
 6. Return the list *result*.

2.4.5 Dates and times

In the algorithms below, the *number of days in month month of year* is: 31 if *month* is 1, 3, 5, 7, 8, 10, or 12; 30 if *month* is 4, 6, 9, or 11; 29 if *month* is 2 and *year* is a number divisible by 400, or if *year* is a number divisible by 4 but not by 100; and 28 otherwise. This takes into account leap years in the Gregorian calendar. [GREGORIAN]

When ASCII digits are used in the date and time syntaxes defined in this section, they express numbers in base ten.

Note

While the formats described here are intended to be subsets of the corresponding ISO8601 formats, this specification defines parsing rules in much more detail than ISO8601. Implementors are therefore encouraged to carefully examine any date parsing libraries before using them to implement the parsing rules described below; ISO8601 libraries might not parse dates and times in exactly the same manner. [ISO8601]

Where this specification refers to the *proleptic Gregorian calendar*, it means the modern Gregorian calendar, extrapolated backwards to year 1. A date in the *proleptic Gregorian calendar*, sometimes explicitly referred to as a *proleptic-Gregorian date*, is one that is described using that calendar even if that calendar was not in use at the time (or place) in question. [GREGORIAN]

Note

The use of the Gregorian calendar as the wire format in this specification is an arbitrary choice resulting from the cultural biases of those involved in the decision. See also the section discussing *date*, *time*, and *number formats* in forms (for authors), *implementation notes regarding localization of form controls*, and the *time* element.

2.4.5.1 Months

A *month* consists of a specific *proleptic-Gregorian date* with no time-zone information and no date information beyond a year and a month. [GREGORIAN]

A string is a *valid month string* representing a year and month *month* if it consists of the following components in the given order:

1. Four or more ASCII digits, representing year, where *year* > 0
2. A U+002D HYPHEN-MINUS character (-)
3. Two ASCII digits, representing the month *month*, in the range 1 ≤ *month* ≤ 12

The rules to *parse a month string* are as follows. This will return either a year and month, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. *Parse a month component* to obtain *year* and *month*. If this returns nothing, then fail.
4. If *position* is not beyond the end of *input*, then fail.
5. Return *year* and *month*.

The rules to *parse a month component*, given an *input* string and a *position*, are as follows. This will return either a year and a month, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Collect a sequence of code points that are ASCII digits from *input* given *position*. If the collected sequence is not at least four characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the *year*.
2. If *year* is not a number greater than zero, then fail.
3. If *position* is beyond the end of *input* or if the character at *position* is not a U+002D HYPHEN-MINUS character, then fail. Otherwise, move *position* forwards one character.
4. Collect a sequence of code points that are ASCII digits from *input* given *position*. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the *month*.
5. If *month* is not a number in the range 1 ≤ *month* ≤ 12, then fail.
6. Return *year* and *month*.

2.4.5.2 Dates

A *date* consists of a specific *proleptic-Gregorian date* with no time-zone information, consisting of a year, a month, and a day. [GREGORIAN]

A string is a *valid date string* representing a year *year*, month *month*, and day *day* if it consists of the following components in the given order:

1. A *valid month string*, representing *year* and *month*
2. A U+002D HYPHEN-MINUS character (-)
3. Two ASCII digits, representing *day*, in the range 1 ≤ *day* ≤ *maxday* where *maxday* is the *number of days in the month month and year year*

The rules to *parse a date string* are as follows. This will return either a date, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. *Parse a date component* to obtain *year*, *month*, and *day*. If this returns nothing, then fail.
4. If *position* is not beyond the end of *input*, then fail.
5. Let *date* be the date with *year*, *month*, and *day*.
6. Return *date*.

The rules to *parse a date component*, given an *input* string and a *position*, are as follows. This will return either a year, a month, and a day, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. *Parse a month component* to obtain *year* and *month*. If this returns nothing, then fail.
2. Let *maxday* be the *number of days in month month of year year*.
3. If *position* is beyond the end of *input* or if the character at *position* is not a U+002D HYPHEN-MINUS character, then fail. Otherwise, move *position* forwards one character.
4. Collect a sequence of code points that are ASCII digits from *input* given *position*. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the *day*.
5. If *day* is not a number in the range 1 ≤ *day* ≤ *maxday*, then fail.
6. Return *year*, *month*, and *day*.

2.4.5.3 Yearless dates

A *yearless date* consists of a Gregorian month and a day within that month, but with no associated year. [GREGORIAN]

A string is a *valid yearless date string* representing a month *month* and a day *day* if it consists of the following components in the given order:

1. Optionally, two U+002D HYPHEN-MINUS characters (-)
2. Two ASCII digits, representing the month *month*, in the range 1 ≤ *month* ≤ 12
3. A U+002D HYPHEN-MINUS character (-)
4. Two ASCII digits, representing *day*, in the range 1 ≤ *day* ≤ *maxday* where *maxday* is the *number of days* in the month *month* and any arbitrary leap year (e.g. 4 or 2000)

In other words, if the month is "02", meaning February, then the day can be 29, as if the year was a leap year.

The rules to *parse a yearless date string* are as follows. This will return either a month and a day, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. *Parse a yearless date component* to obtain *month* and *day*. If this returns nothing, then fail.
4. If *position* is not beyond the end of *input*, then fail.
5. Return *month* and *day*.

The rules to *parse a yearless date component*, given an *input* string and a *position*, are as follows. This will return either a month and a day, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Collect a sequence of code points that are U+002D HYPHEN-MINUS characters (-) from *input* given *position*. If the collected sequence is not exactly zero or two characters long, then fail.
2. Collect a sequence of code points that are ASCII digits from *input* given *position*. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the *month*.

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

4. Let `maxday` be the [number of days](#) in month `month` of any arbitrary leap year (e.g. 4 or 2000).
5. If `position` is beyond the end of `input` or if the character at `position` is not a U+002D HYPHEN-MINUS character, then fail. Otherwise, move `position` forwards one character.
6. [Collect a sequence of code points](#) that are [ASCII digits](#) from `input` given `position`. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the `day`.
7. If `day` is not a number in the range 1 ≤ `day` ≤ `maxday`, then fail.
8. Return `month` and `day`.

2.4.5.4 Times

A string is a valid time string representing an hour `hour`, a minute `minute`, and a second `second` if it consists of the following components in the given order:

1. Two [ASCII digits](#), representing `hour`, in the range 0 ≤ `hour` ≤ 23
2. A U+003A COLON character (:
3. Two [ASCII digits](#), representing `minute`, in the range 0 ≤ `minute` ≤ 59
4. If `second` is present, then:
 1. A U+003A COLON character (:
 2. Two [ASCII digits](#), representing the integer part of `second`, in the range 0 ≤ `second` ≤ 59
 3. If `second` is not an integer, or optionally if `second` is an integer:
 1. A U+002E FULL STOP character (.)
 2. One, two, or three [ASCII digits](#), representing the fractional part of `second`

Note

The `second` component cannot be 60 or 61; leap seconds cannot be represented.

The rules to parse a time string are as follows. This will return either a time, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let `input` be the string being parsed.
2. Let `position` be a pointer into `input`, initially pointing at the start of the string.
3. [Parse a time component](#) to obtain `hour`, `minute`, and `second`. If this returns nothing, then fail.
4. If `position` is not beyond the end of `input`, then fail.
5. Let `time` be the time with hour `hour`, minute `minute`, and second `second`.
6. Return `time`.

The rules to parse a time component, given an `input` string and a `position`, are as follows. This will return either an hour, a minute, and a second, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. [Collect a sequence of code points](#) that are [ASCII digits](#) from `input` given `position`. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the `hour`.
2. If `hour` is not a number in the range 0 ≤ `hour` ≤ 23, then fail.
3. If `position` is beyond the end of `input` or if the character at `position` is not a U+003A COLON character, then fail. Otherwise, move `position` forwards one character.
4. [Collect a sequence of code points](#) that are [ASCII digits](#) from `input` given `position`. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the `minute`.
5. If `minute` is not a number in the range 0 ≤ `minute` ≤ 59, then fail.
6. Let `second` be 0.

7. If `position` is not beyond the end of `input` and the character at `position` is U+003A (:), then:
 1. Advance `position` to the next character in `input`.
 2. If `position` is beyond the end of `input`, or at the last character in `input`, or if the next two characters in `input` starting at `position` are not both [ASCII digits](#), then fail.
 3. [Collect a sequence of code points](#) that are either [ASCII digits](#) or U+002E FULL STOP characters from `input` given `position`. If the collected sequence is three characters long, or if it is longer than three characters long and the third character is not a U+002E FULL STOP character, or if it has more than one U+002E FULL STOP character, then fail. Otherwise, interpret the resulting sequence as a base-ten number (possibly with a fractional part). Set `second` to that number.
 4. If `second` is not a number in the range 0 ≤ `second` < 60, then fail.

2.4.5.5 Local dates and times

A local date and time consists of a specific [proleptic-Gregorian date](#), consisting of a year, a month, and a day, and a time, consisting of an hour, a minute, a second, and a fraction of a second, but expressed without a time zone. [\[GREGORIAN\]](#)

A string is a valid local date and time string representing a date and time if it consists of the following components in the given order:

1. A [valid date string](#) representing the date
2. A U+0054 LATIN CAPITAL LETTER T character (T) or a U+0020 SPACE character
3. A [valid time string](#) representing the time

A string is a valid normalized local date and time string representing a date and time if it consists of the following components in the given order:

1. A [valid date string](#) representing the date
2. A U+0054 LATIN CAPITAL LETTER T character (T)
3. A [valid time string](#) representing the time, expressed as the shortest possible string for the given time (e.g. omitting the seconds component entirely if the given time is zero seconds past the minute)

The rules to parse a local date and time string are as follows. This will return either a date and time, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let `input` be the string being parsed.
2. Let `position` be a pointer into `input`, initially pointing at the start of the string.
3. [Parse a date component](#) to obtain `year`, `month`, and `day`. If this returns nothing, then fail.
4. If `position` is beyond the end of `input` or if the character at `position` is neither a U+0054 LATIN CAPITAL LETTER T character (T) nor a U+0020 SPACE character, then fail. Otherwise, move `position` forwards one character.
5. [Parse a time component](#) to obtain `hour`, `minute`, and `second`. If this returns nothing, then fail.
6. If `position` is not beyond the end of `input`, then fail.
7. Let `date` be the date with year `year`, month `month`, and day `day`.
8. Let `time` be the time with hour `hour`, minute `minute`, and second `second`.
9. Return `date` and `time`.

2.4.5.6 Time zones

A time-zone offset consists of a signed number of hours and minutes.

A string is a valid time-zone offset string representing a time-zone offset if it consists of either:

- A U+005A LATIN CAPITAL LETTER Z character (Z), allowed only if the time zone is UTC
- Or, the following components, in the given order:
 1. Either a U+002B PLUS SIGN character (+) or, if the time-zone offset is not zero, a U+002D HYPHEN-MINUS character (-), representing the sign of the time-zone offset
 2. Two [ASCII digits](#), representing the hours component `hour` of the time-zone offset, in the range 0 ≤ `hour` ≤ 23
 3. Optionally, a U+003A COLON character (:
 4. Two [ASCII digits](#), representing the minutes component `minute` of the time-zone offset, in the range 0 ≤ `minute` ≤ 59

Note

This format allows for time-zone offsets from -23:59 to +23:59. Right now, in practice, the range of offsets of actual time zones is -12:00 to +14:00, and the minutes component of offsets of actual time zones is always either 00, 30, or 45. There is no guarantee that this will remain so forever, however, since time zones are used as political footballs and are thus subject to very whimsical policy decisions.

Note

See also the usage notes and examples in the [global date and time](#) section below for details on using time-zone offsets with historical times that predate the formation of formal time zones.

The rules to parse a time-zone offset string are as follows. This will return either a time-zone offset, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let `input` be the string being parsed.
2. Let `position` be a pointer into `input`, initially pointing at the start of the string.
3. [Parse a time-zone offset component](#) to obtain `timezone_hours` and `timezone_minutes`. If this returns nothing, then fail.
4. If `position` is not beyond the end of `input`, then fail.
5. Return the time-zone offset that is `timezone_hours` hours and `timezone_minutes` minutes from UTC.

The rules to parse a time-zone offset component, given an `input` string and a `position`, are as follows. This will return either time-zone hours and time-zone minutes, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. If the character at `position` is a U+005A LATIN CAPITAL LETTER Z character (Z), then:
 1. Let `timezone_hours` be 0.
 2. Let `timezone_minutes` be 0.
 3. Advance `position` to the next character in `input`.

Otherwise, if the character at `position` is either a U+002B PLUS SIGN (+) or a U+002D HYPHEN-MINUS (-), then:

1. If the character at `position` is a U+002B PLUS SIGN (+), let `sign` be "positive". Otherwise, it's a U+002D HYPHEN-MINUS (-); let `sign` be "negative".
2. Advance `position` to the next character in `input`.
3. [Collect a sequence of code points](#) that are [ASCII digits](#) from `input` given `position`. Let `s` be the collected sequence.
4. If `s` is exactly two characters long, then:
 1. Interpret `s` as a base-ten integer. Let that number be the `timezone_hours`.
 2. If `position` is beyond the end of `input` or if the character at `position` is not a U+003A COLON character, then fail. Otherwise, move `position` forwards one character.
 3. [Collect a sequence of code points](#) that are [ASCII digits](#) from `input` given `position`. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the `timezone_minutes`.

If `s` is exactly four characters long, then:

1. Interpret the first two characters of `s` as a base-ten integer. Let that number be the `timezone_hours`.
2. Interpret the last two characters of `s` as a base-ten integer. Let that number be the `timezone_minutes`.

Otherwise, fail.

- 8. If `timezonehours` is not a number in the range $0 \leq \text{timezonehours} \leq 23$, then fail.
- 9. If sign is "negative", then negate `timezonehours`.
- 10. If `timzoneminutes` is not a number in the range $0 \leq \text{timzoneminutes} \leq 59$, then fail.
- 11. If sign is "negative", then negate `timzoneminutes`.

Otherwise, fail.

2. Return `timezonehours` and `timzoneminutes`.

2.4.5.7 Global dates and times

A *global date and time* consists of a specific [proleptic-Gregorian date](#), consisting of a year, a month, and a day, and a time, consisting of an hour, a minute, a second, and a fraction of a second, expressed with a time-zone offset, consisting of a signed number of hours and minutes. [\[GREGORIAN\]](#)

A string is a *valid global date and time string* representing a date, time, and a time-zone offset if it consists of the following components in the given order:

1. A [valid date string](#) representing the date.
2. A U+0054 LATIN CAPITAL LETTER T character (T) or a U+0020 SPACE character.
3. A [valid time string](#) representing the time.
4. A [valid time-zone offset string](#) representing the time-zone offset.

Times in before the formation of UTC in the mid twentieth century must be expressed and interpreted in terms of UT1 (contemporary Earth solar time at the 0° longitude), not UTC (the approximation of UT1 that ticks in SI seconds). Time before the formation of time zones must be expressed and interpreted as UT1 times with explicit time zones that approximate the contemporary difference between the appropriate local time and the time observed at the location of Greenwich, London.

Example

The following are some examples of dates written as [valid global date and time strings](#):

"0053-12-13 00:00:00"
Midnight in areas using London time on the birthday of Nero (the Roman Emperor). See below for further discussion on which date this actually corresponds to.

"1979-10-14T12:00:00.001-04:00"
One millisecond after noon on October 14th 1979, in the time zone in use on the east coast of the USA during daylight saving time.

"8592-01-01T02:09:02.09"
Midnight UTC on the 1st of January, 8592. The time zone associated with that time is two hours and nine minutes ahead of UTC, which is not currently a real time zone, but is nonetheless allowed.

Several notes are available about these dates:

- Years with fewer than four digits have to be zero-padded. The date "97-12-13" would not be a valid date.
- If the ":" is replaced by a space, it must be a single space character. The string "0053-12-13 12:00:00" (with two spaces between the components) would not be parsed successfully.
- To unambiguously identify a moment in time prior to the introduction of the Gregorian calendar (insofar as moments in time before the formation of UTC can be unambiguously identified), the date has to be first converted to the Gregorian calendar from the calendar in use at the time (e.g. from the Julian calendar). The date of Nero's birth is the 15th of December 37, in the Julian Calendar, which is the 13th of December 37 in the [proleptic Gregorian calendar](#).
- The time and time-zone offset components are not optional.
- Dates before the year one can't be represented as a datetime in this version of HTML.
- Times of specific events in ancient times are, at best, approximations, since time was not well coordinated or measured until relatively recent decades.
- Time-zone offsets differ based on daylight saving time.

The rules to *parse a global date and time string* are as follows. This will return either a time in UTC, with associated time-zone offset information for round-tripping or display purposes, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let `input` be the string being parsed.
2. Let `position` be a pointer into `input`, initially pointing at the start of the string.
3. Parse a [date component](#) to obtain `year`, `month`, and `day`. If this returns nothing, then fail.
4. If `position` is beyond the end of `input` or if the character at `position` is neither a U+0054 LATIN CAPITAL LETTER T character (T) nor a U+0020 SPACE character, then fail. Otherwise, move `position` forwards one character.
5. Parse a [time component](#) to obtain `hour`, `minute`, and `second`. If this returns nothing, then fail.
6. If `position` is beyond the end of `input`, then fail.
7. Parse a [time-zone offset component](#) to obtain `timezonehours` and `timzoneminutes`. If this returns nothing, then fail.
8. If `position` is not beyond the end of `input`, then fail.
9. Let `time` be the moment in time at `year`, `month`, `day`, `hour`, `minute`, `second`, subtracting `timezonehours` hours and `timzoneminutes` minutes. That moment in time is a moment in the UTC time zone.
10. Let `timezone` be `timezonehours` hours and `timzoneminutes` minutes from UTC.
11. Return `time` and `timezone`.

2.4.5.8 Weeks

A week consists of a week-year number and a week number representing a seven-day period starting on a Monday. Each week-year in this calendaring system has either 52 or 53 such seven-day periods, as defined below. The seven-day period starting on the Gregorian date Monday December 29th 1969 (1969-12-29) is defined as week number 1 in week-year 1970. Sequential weeks are numbered sequentially: the week before the number 1 week in a week-year is the last week in the previous week-year, and vice versa. [\[GREGORIAN\]](#)

A week-year with a number `y` has 53 weeks if it corresponds to either a year `y` in the [proleptic Gregorian calendar](#) that has a Thursday as its first day (January 1st), or a year `y` in the [proleptic Gregorian calendar](#) that has a Wednesday as its first day (January 1st) and where `y` is a number divisible by 400, or a number divisible by 4 but not by 100. All other week-years have 52 weeks.

The *week number of the last day* of a week-year with 53 weeks is 53; the week number of the last day of a week-year with 52 weeks is 52.

Note

The week-number of a particular day can be different than the number of the year that contains that day in the [proleptic Gregorian calendar](#). The first week in a week-year `y` is the week that contains the first Thursday of the Gregorian year `y`.

Note

For modern purposes, a `week` as defined here is equivalent to ISO weeks as defined in ISO 8601. [\[ISO8601\]](#)

A string is a *valid week string* representing a week-year number and week number if it consists of the following components in the given order:

1. Four or more [ASCII digits](#), representing `year`, where `year` $>$ 0
2. A U+002D HYPHEN-MINUS character (-)
3. A U+0057 LATIN CAPITAL LETTER W character (W)
4. Two [ASCII digits](#), representing the week week, in the range $1 \leq \text{week} \leq \text{maxweek}$, where `maxweek` is the [week number of the last day](#) of week-year `year`

The rules to *parse a week string* are as follows. This will return either a week-year number and week number, or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let `input` be the string being parsed.
2. Let `position` be a pointer into `input`, initially pointing at the start of the string.
3. Collect a sequence of code points that are [ASCII digits](#) from `input` given `position`. If the collected sequence is not at least four characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the `year`.
4. If `year` is not a number greater than zero, then fail.
5. If `position` is beyond the end of `input` or if the character at `position` is not a U+002D HYPHEN-MINUS character, then fail. Otherwise, move `position` forwards one character.
6. If `position` is beyond the end of `input` or if the character at `position` is not a U+0057 LATIN CAPITAL LETTER W character (W), then fail. Otherwise, move `position` forwards one character.
7. Collect a sequence of code points that are [ASCII digits](#) from `input` given `position`. If the collected sequence is not exactly two characters long, then fail. Otherwise, interpret the resulting sequence as a base-ten integer. Let that number be the `week`.
8. Let `maxweek` be the [week number of the last day](#) of `year`.
9. If `week` is not a number in the range $1 \leq \text{week} \leq \text{maxweek}$, then fail.
10. If `position` is not beyond the end of `input`, then fail.
11. Return the week-year number and the week number `week`.

2.4.5.9 Durations

A *duration* consists of a number of seconds.

Note

Since months and seconds are not comparable (a month is not a precise number of seconds, but is instead a period whose exact length depends on the precise day from which it is measured) a *duration* as defined in this specification cannot include months (or years, which are equivalent to twelve months). Only durations that describe a specific number of seconds can be described.

A string is a *valid duration string* representing a `duration` `t` if it consists of either of the following:

- A literal U+0050 LATIN CAPITAL LETTER P character followed by one or more of the following subcomponents, in the order given, where the number of days, hours, minutes, and seconds corresponds to the same number of seconds as in `t`:
 1. One or more [ASCII digits](#) followed by a U+0044 LATIN CAPITAL LETTER D character, representing a number of days.
 2. A U+0054 LATIN CAPITAL LETTER T character followed by one or more of the following subcomponents, in the order given:
 1. One or more [ASCII digits](#) followed by a U+0048 LATIN CAPITAL LETTER H character, representing a number of hours.
 2. One or more [ASCII digits](#) followed by a U+004D LATIN CAPITAL LETTER M character, representing a number of minutes.
 3. The following components:
 1. One or more [ASCII digits](#), representing a number of seconds.
 2. Optionally, a U+002E FULL STOP character (.) followed by one, two, or three [ASCII digits](#), representing a fraction of a second.
 3. A U+0053 LATIN CAPITAL LETTER S character.

This, as with a number of other date- and time-related microsyntaxes defined in this specification, is based on one of the formats defined in ISO 8601. [\[ISO8601\]](#)

- One or more [duration time components](#), each with a different [duration time component scale](#), in any order; the sum of the represented seconds being equal to the number of seconds in `t`.

A *duration time component* is a string consisting of the following components:

1. Zero or more [ASCII whitespace](#).
2. One or more [ASCII digits](#), representing a number of time units, scaled by the [duration time component scale](#) specified (see below) to represent a number of seconds.
3. If the [duration time component scale](#) specified is 1 (i.e. the units are seconds), then, optionally, a U+002E FULL STOP character (.) followed by one, two, or three [ASCII digits](#), representing a fraction of a second.
4. Zero or more [ASCII whitespace](#).
5. One of the following characters, representing the [duration time component scale](#) of the time unit used in the numeric part of the [duration time component](#):

U+0057 LATIN CAPITAL LETTER W character
U+0077 LATIN SMALL LETTER W character
U+0044 LATIN CAPITAL LETTER D character
U+0064 LATIN SMALL LETTER D character
Days. The scale is 86400.
U+0048 LATIN CAPITAL LETTER H character
U+0068 LATIN SMALL LETTER H character
Hours. The scale is 3600.

Minutes. The scale is 60.
 U+0053 LATIN CAPITAL LETTER S character
 U+0073 LATIN SMALL LETTER S character
 Seconds. The scale is 1.

6. Zero or more [ASCII whitespace](#).

Note
 This is not based on any of the formats in ISO 8601. It is intended to be a more human-readable alternative to the ISO 8601 duration format.

The rules to parse a duration string are as follows. This will return either a [duration](#) or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Let *months*, *seconds*, and *component count* all be zero.
4. Let *M-disambiguator* be minutes.

Note
 This flag's other value is *months*. It is used to disambiguate the "M" unit in ISO8601 durations, which use the same unit for months and minutes. Months are not allowed, but are parsed for future compatibility and to avoid misinterpreting ISO8601 durations that would be valid in other contexts.

5. Skip [ASCII whitespace](#) within *input* given position.
6. If *position* is past the end of *input*, then fail.

7. If the character in *input* pointed to by *position* is a U+0050 LATIN CAPITAL LETTER P character, then advance *position* to the next character, set *M-disambiguator* to *months*, and skip [ASCII whitespace](#) within *input* given *position*.

8. While true:

1. Let *units* be undefined. It will be assigned one of the following values: *years*, *months*, *weeks*, *days*, *hours*, *minutes*, and *seconds*.
2. Let *next character* be undefined. It is used to process characters from the *input*.
3. If *position* is past the end of *input*, then break.

4. If the character in *input* pointed to by *position* is a U+0054 LATIN CAPITAL LETTER T character, then advance *position* to the next character, set *M-disambiguator* to *minutes*, skip [ASCII whitespace](#) within *input* given *position*, and continue.

5. Set *next character* to the character in *input* pointed to by *position*.
6. If *next character* is a U+002E FULL STOP character (.), then let *N* equal zero. (Do not advance *position*. That is taken care of below.)

Otherwise, if *next character* is an [ASCII digit](#), then collect a sequence of code points that are [ASCII digits](#) from *input* given *position*, interpret the resulting sequence as a base-ten integer, and let *N* be that number.

Otherwise *next character* is not part of a number; fail.

7. If *position* is past the end of *input*, then fail.

8. Set *next character* to the character in *input* pointed to by *position*, and this time advance *position* to the next character. (If *next character* was a U+002E FULL STOP character (.) before, it will still be that character this time.)

9. If *next character* is a U+002E (.), then:

1. Collect a sequence of code points that are [ASCII digits](#) from *input* given *position*. Let *s* be the resulting sequence.

2. If *s* is the empty string, then fail.

3. Let *length* be the number of characters in *s*.

4. Let *fraction* be the result of interpreting *s* as a base-ten integer, and then dividing that number by 10^{length} .

5. Increment *N* by *fraction*.

6. Skip [ASCII whitespace](#) within *input* given *position*.

7. If *position* is past the end of *input*, then fail.

8. Set *next character* to the character in *input* pointed to by *position*, and advance *position* to the next character.

9. If *next character* is neither a U+0053 LATIN CAPITAL LETTER S character nor a U+0073 LATIN SMALL LETTER S character, then fail.

10. Set *units* to *seconds*.

Otherwise:

1. If *next character* is [ASCII whitespace](#), then skip [ASCII whitespace](#) within *input* given *position*, set *next character* to the character in *input* pointed to by *position*, and advance *position* to the next character.

2. If *next character* is a U+0059 LATIN CAPITAL LETTER Y character, or a U+0079 LATIN SMALL LETTER Y character, set *units* to *years* and set *M-disambiguator* to *months*.

If *next character* is a U+004D LATIN CAPITAL LETTER M character or a U+006D LATIN SMALL LETTER M character, and *M-disambiguator* is *months*, then set *units* to *months*.

If *next character* is a U+0057 LATIN CAPITAL LETTER W character or a U+0077 LATIN SMALL LETTER W character, set *units* to *weeks* and set *M-disambiguator* to *minutes*.

If *next character* is a U+0044 LATIN CAPITAL LETTER D character or a U+0064 LATIN SMALL LETTER D character, set *units* to *days* and set *M-disambiguator* to *minutes*.

If *next character* is a U+0048 LATIN CAPITAL LETTER H character or a U+0068 LATIN SMALL LETTER H character, set *units* to *hours* and set *M-disambiguator* to *minutes*.

If *next character* is a U+004D LATIN CAPITAL LETTER M character or a U+006D LATIN SMALL LETTER M character, and *M-disambiguator* is *minutes*, then set *units* to *minutes*.

If *next character* is a U+0053 LATIN CAPITAL LETTER S character or a U+0073 LATIN SMALL LETTER S character, set *units* to *seconds* and set *M-disambiguator* to *minutes*.

Otherwise if *next character* is none of the above characters, then fail.

10. Increment *component count*.

11. Let *multiplier* be 1.

12. If *units* is *years*, multiply *multiplier* by 12 and set *units* to *months*.

13. If *units* is *months*, add the product of *N* and *multiplier* to *months*.

Otherwise:

1. If *units* is *weeks*, multiply *multiplier* by 7 and set *units* to *days*.

2. If *units* is *days*, multiply *multiplier* by 24 and set *units* to *hours*.

3. If *units* is *hours*, multiply *multiplier* by 60 and set *units* to *minutes*.

4. If *units* is *minutes*, multiply *multiplier* by 60 and set *units* to *seconds*.

5. Forcibly, *units* is now *seconds*. Add the product of *N* and *multiplier* to *seconds*.

14. Skip [ASCII whitespace](#) within *input* given *position*.

9. If *component count* is zero, fail.

10. If *months* is not zero, fail.

11. Return the [duration](#) consisting of *seconds* *seconds*.

2.4.5.10 Vague moments in time

A string is a [valid date string](#) with optional [time](#) if it is also one of the following:

- A [valid date string](#)
- A [valid global date and time string](#)

The rules to parse a date or time string are as follows. The algorithm will return either a [date](#), a [time](#), a [global date and time](#), or nothing. If at any point the algorithm says that it "fails", this means that it is aborted at that point and returns nothing.

1. Let *input* be the string being parsed.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Set *start position* to the same position as *position*.
4. Set the [date present](#) and [time present](#) flags to true.

5. Parse a [date component](#) to obtain [year](#), [month](#), and [day](#). If this fails, then set the [date present](#) flag to false.

6. If [date present](#) is true, and *position* is not beyond the end of *input*, and the character at *position* is either a U+0054 LATIN CAPITAL LETTER T character (T) or a U+0020 SPACE character, then advance *position* to the next character in *input*.

Otherwise, if [date present](#) is true, and either *position* is beyond the end of *input* or the character at *position* is neither a U+0054 LATIN CAPITAL LETTER T character (T) nor a U+0020 SPACE character, then set [time present](#) to false.

Otherwise, if [date present](#) is false, set *position* back to the same position as *start position*.

7. If the [time present](#) flag is true, then parse a [time component](#) to obtain [hour](#), [minute](#), and [second](#). If this returns nothing, then fail.

8. If the [date present](#) and [time present](#) flags are both true, but *position* is beyond the end of *input*, then fail.

9. If the [date present](#) and [time present](#) flags are both true, parse a [time-zone offset component](#) to obtain [timezone_hours](#) and [timezone_minutes](#). If this returns nothing, then fail.

10. If *position* is not beyond the end of *input*, then fail.

11. If the [date present](#) flag is true and the [time present](#) flag is false, then let *date* be the date with [year](#), [month](#), and [day](#), and return *date*.

Otherwise, if the [time present](#) flag is true and the [date present](#) flag is false, then let *time* be the time with [hour](#), [minute](#), and [second](#), and return *time*.

Otherwise, let *time* be the moment in time at [year](#), [month](#), [day](#), [hour](#), [minute](#), [second](#), subtracting [timezone_hours](#) hours and [timezone_minutes](#) minutes, that moment in time being a moment in the UTC time zone; let *timezone* be [timezone_hours](#) hours and [timezone_minutes](#) minutes from UTC; and return *time* and *timezone*.

2.4.6 Colors

A [simple color](#) consists of three 8-bit numbers in the range 0..255, representing the red, green, and blue components of the color respectively, in the sRGB color space. [SRGB](#)

A string is a [valid simple color](#) if it is exactly seven characters long, and the first character is a U+0023 NUMBER SIGN character (#), and the remaining six characters are all [ASCII hex digits](#), with the first two digits representing the red component, the middle two digits representing the green component, and the last two digits representing the blue component, in hexadecimal.

A string is a [valid lowercase simple color](#) if it is a [valid simple color](#) and doesn't use any characters in the range U+0041 LATIN CAPITAL LETTER A to U+0046 LATIN CAPITAL LETTER F.

The rules for parsing simple color values are as given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either a [simple color](#) or an error.

1. Let *input* be the string being parsed.

2. If *input* is not exactly seven characters long, then return an error.

3. If the first character in *input* is not a U+0023 NUMBER SIGN character (#), then return an error.
4. If the last six characters of *input* are not all [ASCII hex digits](#), then return an error.
5. Let *result* be a [simple color](#).
6. Interpret the second and third characters as a hexadecimal number and let the result be the red component of *result*.
7. Interpret the fourth and fifth characters as a hexadecimal number and let the result be the green component of *result*.
8. Interpret the sixth and seventh characters as a hexadecimal number and let the result be the blue component of *result*.
9. Return *result*.

The rules for serializing simple color values given a [simple color](#) are as given in the following algorithm:

1. Let *result* be a string consisting of a single U+0023 NUMBER SIGN character (#).
2. Convert the red, green, and blue components in turn to two-digit hexadecimal numbers using [ASCII lower hex digits](#), zero-padding if necessary, and append these numbers to *result*, in the order red, green, blue.
3. Return *result*, which will be a [valid lowercase simple color](#).

Some obsolete legacy attributes parse colors in a more complicated manner, using the rules for parsing a legacy color value, which are given in the following algorithm. When invoked, the steps must be followed in the order given, aborting at the first step that returns a value. This algorithm will return either a [simple color](#) or an error.

1. Let *input* be the string being parsed.

2. If *input* is the empty string, then return an error.

3. Strip leading and trailing ASCII whitespace from *input*.

4. If *input* is an [ASCII case-insensitive](#) match for the string "transparent", then return an error.

5. If *input* is an [ASCII case-insensitive](#) match for one of the [named colors](#), then return the [simple color](#) corresponding to that keyword. [CSSCOLOR]

Note

CSS2 System Colors are not recognized.

6. If *input* is four characters long, and the first character in *input* is U+0023 (#), and the last three characters of *input* are all [ASCII hex digits](#), then:

1. Let *result* be a [simple color](#).
 2. Interpret the second character of *input* as a hexadecimal digit; let the red component of *result* be the resulting number multiplied by 17.
 3. Interpret the third character of *input* as a hexadecimal digit; let the green component of *result* be the resulting number multiplied by 17.
 4. Interpret the fourth character of *input* as a hexadecimal digit; let the blue component of *result* be the resulting number multiplied by 17.
 5. Return *result*.
7. Replace any characters in *input* that have a code point greater than U+FFFF (i.e., any characters that are not in the basic multilingual plane) with the two-character string "00".
8. If *input* is longer than 128 characters, truncate *input*, leaving only the first 128 characters.
9. If the first character in *input* is a U+0023 NUMBER SIGN character (#), remove it.
10. Replace any character in *input* that is not an [ASCII hex digit](#) with the character U+0030 DIGIT ZERO (0).
11. While *input*'s length is zero or not a multiple of three, append a U+0030 DIGIT ZERO (0) character to *input*.
12. Split *input* into three strings of equal length, to obtain three components. Let *length* be the length of those components (one third the length of *input*).
13. If *length* is greater than 8, then remove the leading *length*-8 characters in each component, and let *length* be 8.
14. While *length* is greater than two and the first character in each component is a U+0030 DIGIT ZERO (0) character, remove that character and reduce *length* by one.
15. If *length* is still greater than two, truncate each component, leaving only the first two characters in each.
16. Let *result* be a [simple color](#).
17. Interpret the first component as a hexadecimal number; let the red component of *result* be the resulting number.
18. Interpret the second component as a hexadecimal number; let the green component of *result* be the resulting number.
19. Interpret the third component as a hexadecimal number; let the blue component of *result* be the resulting number.
20. Return *result*.

Note

The 2D graphics context has a separate color syntax that also handles opacity.

2.4.7 Space-separated tokens

A set of space-separated tokens is a string containing zero or more words (known as tokens) separated by one or more [ASCII whitespace](#), where words consist of any string of one or more characters, none of which are [ASCII whitespace](#).

A string containing a [set of space-separated tokens](#) may have leading or trailing [ASCII whitespace](#).

An unordered set of unique space-separated tokens is a [set of space-separated tokens](#) where none of the tokens are duplicated.

An ordered set of unique space-separated tokens is a [set of space-separated tokens](#) where none of the tokens are duplicated but where the order of the tokens is meaningful.

Sets of space-separated tokens sometimes have a defined set of allowed values. When a set of allowed values is defined, the tokens must all be from that list of allowed values; other values are non-conforming. If no such set of allowed values is provided, then all values are conforming.

Note

How tokens in a [set of space-separated tokens](#) are to be compared (e.g. case-sensitively or not) is defined on a per-set basis.

2.4.8 Comma-separated tokens

A set of comma-separated tokens is a string containing zero or more tokens each separated from the next by a single U+002C COMMA character (,), where tokens consist of any string of zero or more characters, neither beginning nor ending with [ASCII whitespace](#), nor containing any U+002C COMMA characters (,), and optionally surrounded by [ASCII whitespace](#).

For instance, the string "a , b , c , d , e" consists of four tokens: "a", "b", the empty string, and "d e". Leading and trailing whitespace around each token doesn't count as part of the token, and the empty string can be a token.

Sets of comma-separated tokens sometimes have further restrictions on what counts as a valid token. When such restrictions are defined, the tokens must all fit within those restrictions; other values are non-conforming. If no such restrictions are specified, then all values are conforming.

2.4.9 References

A valid hash-name reference to an element of type *type* is a string consisting of a U+0023 NUMBER SIGN character (#) followed by a string which exactly matches the value of the *name* attribute of an element with type *type* in the same [tree](#).

The rules for parsing a hash-name reference to an element of type *type*, given a context node *scope*, are as follows:

1. If the string being parsed does not contain a U+0023 NUMBER SIGN character, or if the first such character in the string is the last character in the string, then return null.
2. Let *s* be the string from the character immediately after the first U+0023 NUMBER SIGN character in the string being parsed up to the end of that string.
3. Return the first element of type *type* in *scope*'s [tree](#), in [tree order](#), that has an [id](#) or *name* attribute whose value is *s*, or null if there is no such element.

Note

Although [id](#) attributes are accounted for when parsing, they are not used in determining whether a value is a [valid hash-name reference](#). That is, a hash-name reference that refers to an element based on [id](#) is a conformance error (unless that element also has a *name* attribute with the same value).

2.4.10 Media queries

A string is a [valid media query list](#) if it matches the `<media-query-list>` production of *Media Queries*. [MO]

A string matches the environment of the user if it is the empty string, a string consisting of only [ASCII whitespace](#), or a media query list that matches the user's environment according to the definitions given in *Media Queries*. [MO]

2.5 URLs

2.5.1 Terminology

A string is a [valid non-empty URL](#) if it is a [valid URL string](#) but it is not the empty string.

A string is a [valid URL potentially surrounded by spaces](#) if, after stripping leading and trailing [ASCII whitespace](#) from it, it is a [valid URL string](#).

A string is a [valid non-empty URL potentially surrounded by spaces](#) if, after stripping leading and trailing [ASCII whitespace](#) from it, it is a [valid non-empty URL](#).

This specification defines the URL `about:legacy-compat` as a reserved, though unresolvable, [about](#) URL, for use in `DOCTYPE`s in [HTML documents](#) when needed for compatibility with XML tools. [ABOUT]

This specification defines the URL `about:html-kind` as a reserved, though unresolvable, [about](#) URL, that is used as an identifier for kinds of media tracks. [ABOUT]

This specification defines the URL `about:srcdoc` as a reserved, though unresolvable, [about](#) URL, that is used as the URL of `<iframe srcdoc>` documents. [ABOUT]

The fallback base URL of a [document](#) object document is the [URL record](#) obtained by running these steps:

1. If *document* is an [`<iframe srcdoc>` document](#), then return the *document base URL* of *document*'s [browsing context](#)'s container document.
2. If *document*'s [URL](#) is [about:blank](#), and *document*'s [browsing context](#)'s [creator base URL](#) is non-null, then return that [creator base URL](#).
3. Return *document*'s [URL](#).

The document base URL of a [document](#) object is the [absolute URL](#) obtained by running these steps:

1. If there is a [base](#) element that has an [href](#) attribute in the [document](#), then return the *document*'s [fallback base URL](#).
2. Otherwise, return the [frozen base URL](#) of the first [base](#) element in the [document](#) that has an [href](#) attribute, in [tree order](#).

2.5.2 Parsing URLs

Parsing a URL is the process of taking a string and obtaining the [URL record](#) that it represents. While this process is defined in *URL*, the HTML standard defines a wrapper for convenience: [URL]

Note

This wrapper is only useful when the character encoding for the URL parser has to match that of the document or environment settings object for legacy reasons. When that is not the case the [URL parser](#) can be used directly.

To parse a URL, relative to either a *document* or *environment settings object*, the user agent must use the following steps. Parsing a URL either results in failure or a [resulting URL string](#) and [resulting URL record](#).

1. Let *encoding* be *document*'s [character encoding](#), if *document* was given, and *environment settings object*'s [API URL character encoding](#) otherwise.
2. Let *baseURL* be *document*'s [base URL](#), if *document* was given, and *environment settings object*'s [API base URL](#) otherwise.
3. Let *urlRecord* be the result of applying the [URL parser](#) to *url*, with *baseURL* and *encoding*.

5. Let `urlString` be the result of applying the `URL_serializer` to `uriRecord`.

6. Return `urlString` as the resulting `URL` string and `uriRecord` as the resulting `URL` record.

2.5.3 Dynamic changes to base URLs

When a document's `document_base_URL` changes, all elements in that document are affected by a base URL change.

The following are `base URL change steps`, which run when an element is affected by a base URL change (as defined by DOM):

If the element creates a `hyperlink`:

If the `URL` identified by the hyperlink is being shown to the user, or if any data derived from that `URL` is affecting the display, then the `href` attribute should be `reparsed` relative to the element's `node_document` and the UI updated appropriately.

Example
For example, the CSS `list-itemVisited pseudo-class` might have been affected.

If the hyperlink has a `ping` attribute and its `URL(s)` are being shown to the user, then the `ping` attribute's tokens should be `reparsed` relative to the element's `node_document` and the UI updated appropriately.

If the element is a `a`, `blockquote`, `img`, or `del` element with a `cite` attribute:

If the `URL` identified by the `cite` attribute is being shown to the user, or if any data derived from that `URL` is affecting the display, then the `URL` should be `reparsed` relative to the element's `node_document` and the UI updated appropriately.

Otherwise:

The element is not directly affected.

Example
For instance, changing the base URL doesn't affect the image displayed by `img` elements, although subsequent accesses of the `sse IDL` attribute from script will return a new `absolute URL` that might no longer correspond to the image being shown.

2.6 Fetching resources

2.6.1 Terminology

A `response` whose `type` is "basic", "cors", or "default" is CORS-same-origin. [FETCH]

A `response` whose `type` is "opaque" or "opaqueredirect" is CORS-cross-origin.

A `response`'s unsafe response is its `internal response` if it has one, and the `response` itself otherwise.

To create a potential-CORS request, given a `url`, `destination`, `corsAttributeState`, and an optional `same-origin-fallback` flag, run these steps:

1. Let `mode` be "no-cors" if `corsAttributeState` is `NoCORS`, and "cors" otherwise.

2. If `same-origin-fallback` flag is set and `mode` is "no-cors", set `mode` to "same-origin".

3. Let `credentialsMode` be "include".

4. If `corsAttributeState` is `Anonymous`, set `credentialsMode` to "same-origin".

5. Let `request` be a new `request` whose `url` is `url`, `destination` is `destination`, `mode` is `mode`, `credentials mode` is `credentialsMode`, and whose `use-URL-credentials` flag is set.

2.6.2 Determining the type of a resource

The `Content-Type` metadata of a resource must be obtained and interpreted in a manner consistent with the requirements of `MIME Sniffing`. [MIMESNIFF]

The computed `MIME type` of a resource must be found in a manner consistent with the requirements given in `MIME Sniffing`. [MIMESNIFF]

The `rules for sniffing images specifically`, the `rules for distinguishing if a resource is text or binary`, and the `rules for sniffing audio and video specifically` are also defined in `MIME Sniffing`. These rules return a `MIME type` as their result. [MIMESNIFF]

⚠️ Warning!

It is imperative that the rules in `MIME Sniffing` be followed exactly. When a user agent uses different heuristics for content type detection than the server expects, security problems can occur. For more details, see `MIME Sniffing`. [MIMESNIFF]

2.6.3 Extracting character encodings from `meta` elements

The algorithm for extracting a character encoding from a `meta` element, given a string `s`, is as follows.

1. Let `position` be a pointer into `s`, initially pointing at the start of the string.

2. *Loop:* Find the first seven characters in `s` after `position` that are an `ASCII case-insensitive` match for the word "charset". If no such match is found, return nothing.

3. Skip any `ASCII whitespace` that immediately follow the word "charset" (there might not be any).

4. If the next character is not a U+003D EQUALS SIGN (=), then move `position` to point just before that next character, and jump back to the step labeled `loop`.

5. Skip any `ASCII whitespace` that immediately follow the equals sign (there might not be any).

6. Process the next character as follows:

If it is a U+0022 QUOTATION MARK character (") and there is a later U+0022 QUOTATION MARK character (") in `s`

If it is a U+0027 APOSTROPHE character (') and there is a later U+0027 APOSTROPHE character (') in `s`

 Return the result of `getting an encoding` from the substring that is between this character and the next earliest occurrence of this character.

If it is an unmatched U+0022 QUOTATION MARK character (")

If it is an unmatched U+0027 APOSTROPHE character (')

If there is no next character

 Return nothing.

 Return the result of `getting an encoding` from the substring that consists of this character up to but not including the first `ASCII whitespace` or U+003B SEMICOLON character (;), or the end of `s`, whichever comes first.

Note

This algorithm is distinct from those in the HTTP specifications (for example, HTTP doesn't allow the use of single quotes and requires supporting a backslash-escape mechanism that is not supported by this algorithm). While the algorithm is used in contexts that, historically, were related to HTTP, the syntax as supported by implementations diverged some time ago. [HTTP]

2.6.4 CORS settings attributes

MDN

Attributes/crossorigin

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

A `CORS settings attribute` is an `enumerated attribute`. The following table lists the keywords and states for the attribute — the keywords in the left column map to the states in the cell in the second column on the same row as the keyword.

Keyword	State	Brief description
<code>anonymous</code>	<code>Anonymous</code>	Requests for the element will have their <code>mode</code> set to "cors" and their <code>credentials mode</code> set to "same-origin".
<code>use-credentials</code>	<code>Use Credentials</code>	Requests for the element will have their <code>mode</code> set to "cors" and their <code>credentials mode</code> set to "include".

The empty string is also a valid keyword, and maps to the `Anonymous` state. The attribute's `invalid value/default` is the `Anonymous` state. For the purposes of `reflection`, the canonical case for the `Anonymous` state is the `anonymous` keyword. The `missing value/default`, used when the attribute is omitted, is the `No CORS` state.

The majority of fetches governed by `CORS settings attributes` will be done via the `create a potential-CORS request` algorithm.

For `module script`, certain `CORS settings attributes` have been repurposed to have a slightly different meaning, wherein they only impact the `request's credentials mode` (since the `mode` is always "cors"). To perform this translation, we define the `module script credentials mode` for a given `CORS settings attribute` to be determined by switching on the attribute's state:

NoCORS

Anonymous

"same-origin"

Use Credentials

"include"

2.6.5 Referrer policy attributes

A `referrer policy attribute` is an `enumerated attribute`. Each `referrer policy`, including the empty string, is a keyword for this attribute, mapping to a state of the same name.

The attribute's `invalid value/default` and `missing value/default` are both the empty string state.

The impact of these states on the processing model of various `fetches` is defined in more detail throughout this specification, in `Fetch`, and in `Referrer Policy`. [FETCH] [REFERRERPOLICY]

Note

Several signals can contribute to which processing model is used for a given `fetch`; a `referrer policy attribute` is only one of them. In general, the order in which these signals are processed are:

1. First, the presence of a `referrer` link type;
2. Then, the value of a `referrer policy attribute`;
3. Then, the presence of any `meta` element with `name` attribute set to `referrer`;
4. Finally, the `'referrer-policy'` HTTP header.

2.6.6Nonce attributes

JSON

HTMLOrForeignElement/noncs

Support in all current engines.

Firefox 75+ Safari 10+ Chrome 61+

Opera Yes Edge 79+

Edge (Legacy) No Internet Explorer No

Firefox Android No Safari iOS 10+ Chrome Android 61+ WebView Android 61+ Samsung Internet 8.0+ Opera Android Yes

A `nonce` content attribute represents a cryptographic nonce ("number used once") which can be used by `Content Security Policy` to determine whether or not a given fetch will be allowed to proceed. The value is text. [CSP]

Elements that have a `nonce` content attribute ensure that the cryptographic nonce is only exposed to script (and not to side-channels like CSS attribute selectors) by extracting the value from the content attribute, moving it into an internal slot named `//CryptographicNonce//`, and exposing it to script via the `HTMLOrForeignElement` interface mixin. Unless otherwise specified, the slot's value is the empty string.

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

For web developers (non-normative)

`element.nonce`Returns the value of the element's `[ICryptographicNonce]` internal slot.

Can be set, to update that slot's value.

The `nonce` IDL attribute must, on getting, return the value of this element's `[ICryptographicNonce]`; and on setting, set this element's `[ICryptographicNonce]` to the given value.

Note

Note how the setter for the `nonce` IDL attribute does not update the corresponding content attribute. This, as well as the below setting of the `nonce` content attribute to the empty string when an element becomes `browsing-context connected`, is meant to prevent exfiltration of the nonce value through mechanisms that can easily read content attributes, such as selectors. Learn more in issue #7369, where this behavior was introduced.Whenever an element including `HTMLFormElement` has its `nonce` attribute is set or changed, set this element's `[ICryptographicNonce]` to the given value.Whenever an element including `HTMLFormElement` becomes `browsing-context connected`, the user agent must execute the following steps on the `element`:

1. Let `CSP list` be `element`'s shadow-including root's `CSP list`.
2. If `CSP list` contains a header-delivered Content Security Policy, and `element` has a `nonce` content attribute `attr` whose value is not the empty string, then:

1. Set an attribute value for `element` using "`nonce`" and the empty string.

Note

As each `Document`'s `CSP list` is append-only, user agents can optimize away the `contains a header-delivered Content Security Policy` check by, for example, holding a flag on the `Document`, set during `Document creation and initialization`.The `cloning steps` for elements that include `HTMLFormElement` must set the `[ICryptographicNonce]` slot on the copy to the value of the slot on the element being cloned.

2.7 Common DOM interfaces

2.7.1 Reflecting content attributes in IDL attributes

Some IDL attributes are defined to reflect a particular content attribute. This means that on getting, the IDL attribute returns the current value of the content attribute, and on setting, the IDL attribute changes the value of the content attribute to the given value.

In general, on getting, if the content attribute is not present, the IDL attribute must act as if the content attribute's value is the empty string; and on setting, if the content attribute is not present, it must first be added.

If a reflecting IDL attribute is a `URLString` attribute whose content attribute is defined to contain a `URL`, then on getting, if the content attribute is absent, the IDL attribute must return the empty string. Otherwise, the IDL attribute must `parse` the value of the content attribute relative to the element's `node document` and if that is successful, return the `resulting URL string`. If parsing fails, then the value of the content attribute must be returned instead, converted to a `URLString`. On setting, the content attribute must be set to the specified new value.If a reflecting IDL attribute is a `POBString` attribute whose content attribute is an `enumerated attribute`, and the IDL attribute is `limited to only known values`, then, on getting, the IDL attribute must return the conforming value associated with the state the attribute is in (in its canonical case), if any, or the empty string if the attribute is in a state that has no associated keyword value or if the attribute is not in a defined state (e.g. the attribute is missing and there is no `missing value default`). On setting, the content attribute must be set to the specified new value.If a reflecting IDL attribute is a nullable `contentString` attribute whose content attribute is an `enumerated attribute`, then, on getting, if the corresponding content attribute is in its `missing value default` then the IDL attribute must return null; otherwise, the IDL attribute must return the conforming value associated with the state the attribute is in (in its canonical case). On setting, if the new value is null, the content attribute must be removed, and otherwise, the content attribute must be set to the specified new value.If a reflecting IDL attribute is a `POBString` or `URLString` attribute, but doesn't fall into any of the above categories, then the getting and setting must be done in a transparent, case-preserving manner.If a reflecting IDL attribute is a `boolean` attribute, then on getting the IDL attribute must return true if the content attribute is set, and false if it is absent. On setting, the content attribute must be removed if the IDL attribute is set to false, and must be set to the empty string if the IDL attribute is set to true. (This corresponds to the rules for `boolean content attributes`.)If a reflecting IDL attribute has a signed integer type (`sint64`), then, on getting, the content attribute must be parsed according to the `rules for parsing signed integers`, and if that is successful, and the value is in the range of the IDL attribute's type, the resulting value must be returned. If, on the other hand, it fails or returns an out of range value, or if the attribute is absent, then the default value must be returned instead, or if there is no default value.If a reflecting IDL attribute has a signed integer type (`sint64`) that is `limited to only non-negative numbers`, then, on getting, the content attribute must be parsed according to the `rules for parsing non-negative integers`, and if that is successful, and the value is in the range of the IDL attribute's type, the resulting value must be returned. If, on the other hand, it fails or returns an out of range value, or if the attribute is absent, the default value must be returned instead, or -1 if there is no default value. On setting, if the value is negative, the user agent must throw an `"IndexSizeError"` `DOMException`. Otherwise, the given value must be converted to the shortest possible string representing the number as a `valid non-negative integer` and then that string must be used as the new content attribute value.If a reflecting IDL attribute has an unsigned integer type (`uint64`), then, on getting, the content attribute must be parsed according to the `rules for parsing non-negative integers`, and if that is successful, and the value is in the range 0 to 2147483647 inclusive, the resulting value must be returned. If, on the other hand, it fails or returns an out of range value, or if the attribute is absent, the default value must be returned instead, or 0 if there is no default value. On setting, first, if the new value is in the range 0 to 2147483647, then let `n` be the new value, otherwise let `n` be the default value, or 0 if there is no default value; then, `n` must be converted to the shortest possible string representing the number as a `valid non-negative integer` and that string must be used as the new content attribute value.If a reflecting IDL attribute has an unsigned integer type (`uint64`) that is `limited to only non-negative numbers greater than zero`, then the behavior is similar to the previous case, but zero is not allowed. On getting, the content attribute must first be parsed according to the `rules for parsing non-negative integers`, and if that is successful, and the value is in the range 1 to 2147483647, the resulting value must be returned. If, on the other hand, it fails or returns an out of range value, or if the attribute is absent, the default value must be returned instead, or 1 if there is no default value. On setting, if the value is zero, the user agent must throw an `"IndexSizeError"` `DOMException`. Otherwise, first, if the new value is in the range 1 to 2147483647, then let `n` be the new value, otherwise let `n` be the default value; then, `n` must be converted to the shortest possible string representing the number as a `valid non-negative integer` and that string must be used as the new content attribute value.If a reflecting IDL attribute has an unsigned integer type (`uint64`) that is `clamped to the range [min, max]`, then on getting, the content attribute must first be parsed according to the `rules for parsing non-negative integers`, and if that is successful, and the value is between `min` and `max` inclusive, the resulting value must be returned. If it fails, the default value must be returned. If it succeeds but the value is less than `min`, `min` must be returned. On setting, if the value is greater than `max`, `max` must be returned. On setting, if the value is less than `min` or setting a regular reflected unsigned integer.If a reflecting IDL attribute has a floating-point number type (`double` or `unrestricted double`), then, on getting, the content attribute must be parsed according to the `rules for parsing floating-point number values`, and if that is successful, the resulting value must be returned. If, on the other hand, it fails, or if the attribute is absent, the default value must be returned instead, or 0.0 if there is no default value. On setting, the given value must be converted to the `best representation of the number as a floating-point number` and then that string must be used as the new content attribute value.If a reflecting IDL attribute has a floating-point number type (`double` or `unrestricted double`) that is `limited to numbers greater than zero with fallback`, then the behavior is similar to the previous case, but disallowed values are converted to the default value. On getting, the content attribute must first be parsed according to the `rules for parsing non-negative integers`, and if that is successful, and the value is in the range 0 to 2147483647 inclusive, the resulting value must be returned. If, on the other hand, it fails or returns an out of range value, or if the attribute is absent, the default value must be returned instead. On setting, first, if the new value is in the range 1 to 2147483647, then let `n` be the new value; otherwise let `n` be the default value; then, `n` must be converted to the shortest possible string representing the number as a `valid non-negative integer` and that string must be used as the new content attribute value.If a reflecting IDL attribute has an unsigned integer type (`uint64`) that is `clamped to the range [min, max]`, then on getting, the content attribute must first be parsed according to the `rules for parsing non-negative integers`, and if that is successful, and the value is between `min` and `max` inclusive, the resulting value must be returned. If it fails, the default value must be returned. If it succeeds but the value is less than `min`, `min` must be returned. On setting, if the value is greater than `max`, `max` must be returned. On setting, if the value is less than `min` or setting a regular reflected unsigned integer.If a reflecting IDL attribute has a floating-point number type (`double` or `unrestricted double`), then, on getting, the content attribute must be parsed according to the `rules for parsing floating-point number values`, and if that is successful, the resulting value must be returned. If, on the other hand, it fails, or if the attribute is absent, the default value must be returned instead, or 0.0 if there is no default value. On setting, if the value is less than or equal to zero, then the value must be ignored. Otherwise, the given value must be converted to the `best representation of the number as a floating-point number` and then that string must be used as the new content attribute value.

Note

The values Infinity and Not-a-Number (NaN) values throw an exception on setting, as defined in Web IDL (WEBIDL).

If a reflecting IDL attribute has the type `DOMTokenList`, then on getting it must return a `DOMTokenList` object whose associated element is the element in question and whose associated attribute's local name is the name of the attribute in question.

2.7.2 Collections

The `HTMLFormControlsCollection` and `HTMLScriptElementCollection` interfaces are `collections` derived from the `HTMLCollection` interface. The `HTMLAllCollection` interface is a `collection`, but is not so derived.2.7.2.1 The `HTMLAllCollection` interfaceThe `HTMLAllCollection` interface is used for the legacy `document.all` attribute. It operates similarly to `HTMLCollection`; the main differences are that it allows a staggering variety of different (abuses of its methods to all end up returning something, and that it can be called as a function as an alternative to property access.

Note

All `HTMLAllCollection` objects are rooted at a `Document` and have a filter that matches all elements, so the elements represented by the collection of an `HTMLAllCollection` object consist of all the descendant elements of the root `Document`.Objects that implement the `HTMLAllCollection` interface are `legacy platform objects` with an additional `[[Call]]` internal method described in the section below. They also have an `[[IsHTMLDDA]]` internal slot.

Note

Objects that implement the `HTMLAllCollection` interface have several unusual behaviors, due of the fact that they have an `[[IsHTMLDDA]]` internal slot:

- The `ToBoolean` abstract operation in JavaScript returns false when given objects implementing the `HTMLAllCollection` interface.
- The `Abstract Equality Comparison` algorithm, when given objects implementing the `HTMLAllCollection` interface, returns true when compared to the `undefined` and `null` values. (Comparisons using the `Strict Equality Comparison` algorithm, and Abstract Equality comparisons to other values such as strings or objects, are unaffected.)
- The `typeof` operator in JavaScript returns the string `"undefined"` when applied to objects implementing the `HTMLAllCollection` interface.

These special behaviors are motivated by a desire for compatibility with two classes of legacy content: one that uses the presence of `document.all` as a way to detect legacy user agents, and one that only supports those legacy user agents and uses the `document.all` object without testing for its presence first. (JAVASCRIPT)

        └── getNamedItemNamesItemNameNameNameNameNameNameNameNameNameNameIndex(DOMString? name? optional DOMString nameOrIndex, unsigned long index?);
        └── getNamedItemNamesItemNameNameNameNameNameNameNameNameNameLength(unsigned long? name? optional DOMString nameOrIndex, unsigned long index?);
        └── getNamedItemNamesItemNameNameNameNameNameNameNameNameNameNameName(DOMString? name? optional DOMString nameOrIndex, unsigned long index</code
```

2. Let `subCollection` be an `HTMLCollection` object rooted at the same `Document` as `collection`, whose filter matches only elements that are either:

- "all"-named elements with a `name` attribute equal to `name`, or,
- elements with an `ID` equal to `name`.

3. If there is exactly one element in `subCollection`, then return that element.

4. Otherwise, if `subCollection` is empty, return null.

5. Otherwise, return `subCollection`.

To get the "all"-indexed or named element(s) from an `HTMLCollection` collection given `nameOrIndex`:

1. If `nameOrIndex`, converted to a JavaScript String value, is an `array index property name`, return the result of getting the "all"-indexed element from this `HTMLCollection` given the number represented by `nameOrIndex`.

2. Return the result of getting the "all"-named element(s) from this `HTMLCollection` given `nameOrIndex`.

2.7.1.1 [Call] (`thisArg`, `argNameList`)

1. If `argumentsList`'s `size` is zero, or if `argumentsList[0]` is undefined, return null.

2. Let `nameOrIndex` be the result of converting `argumentsList[0]` to a `String`.

3. Let `result` be the result of getting the "all"-indexed element(s) from this `HTMLCollection` given `nameOrIndex`.

4. Return the result of converting `result` to an ECMAScript value.

Note

The `thisArgument` is ignored, and thus code such as `function.prototype.call.call(document.all, null, "a")` will still search for elements. (`document.all.call` does not exist, since `document.all` does not inherit from `Function.prototype`.)

2.7.2.2 The `HTMLFormControlsCollection` interface

The `HTMLFormControlsCollection` interface is used for collections of listed elements in `form` elements.

MDN

[HTMLFormControlsCollection](#)

Support in all current engines.

Firefox?+Android?+Safari?+iOS?+Chrome?+Android?+WebView?+Android?+Yes?+Samsung?+Internet?+Yes?+Opera?+Android?+Yes

IDL Exposed=Window

```
interface HTMLFormControlsCollection : HTMLCollection {
  // Inherits length and item()
  getNamedItem([DOMString name])? namedItem(DOMString name); // shadows inherited namedItem()
};
```

```
[Exposed=Window]
interface RadioNodeList : NodeList {
  attribute DOMString value;
};
```

For web developers (non-normative)

`collection.length`

Returns the number of elements in the collection.

```
element = collection.item(index)
element = collection[index]
```

Returns the item with index `index` from the collection. The items are sorted in `tree_order`.

```
element = collection.namedItem(name)
radioNodeList = collection.namedItem(name)
element = collection[name]
radioNodeList = collection[name]
```

Returns the item with `ID` or `name` from the collection.

If there are multiple matching items, then a `RadioNodeList` object containing all those elements is returned.

`radioNodeList.value [= value]`

Returns the value of the first checked radio button represented by the object.

Can be set, to check the first radio button with the given value represented by the object.

The object's `supportedPropertyIndices` are as defined for `HTMLCollection` objects.

The `supportedPropertyNames` consist of the non-empty values of all the `ID` and `name` attributes of all the elements represented by the collection, in `tree_order`, ignoring later duplicates, with the `ID` of an element preceding its `name` if it contributes both, they differ from each other, and neither is the duplicate of an earlier entry.

The `namedItem(name)` method must act according to the following algorithm:

1. If `name` is the empty string, return null and stop the algorithm.
2. If, at the time the method is called, there is exactly one node in the collection that has either an `ID` attribute or a `name` attribute equal to `name`, then return that node and stop the algorithm.
3. Otherwise, if there are no nodes in the collection that have either an `ID` attribute or a `name` attribute equal to `name`, then return null and stop the algorithm.
4. Otherwise, create a new `RadioNodeList` object representing a `tree` view of the `HTMLFormControlsCollection` object, further filtered so that the only nodes in the `RadioNodeList` object are those that have either an `ID` attribute or a `name` attribute equal to `name`. The nodes in the `RadioNodeList` object must be sorted in `tree_order`.
5. Return that `RadioNodeList` object.

Members of the `RadioNodeList` interface inherited from the `NodeList` interface must behave as they would on a `NodeList` object.

The `value` IDL attribute on the `RadioNodeList` object, on getting, must return the value returned by running the following steps:

1. Let `element` be the first element in `tree_order` represented by the `RadioNodeList` object that is an `input` element whose `type` attribute is in the `Radio Button` state and whose `checkedness` is true. Otherwise, let it be null.
2. If `element` is null, return the empty string.
3. If `element` is an element with no `value` attribute, return the string "`on`".
4. Otherwise, return the value of `element`'s `value` attribute.

On setting, the `value` IDL attribute must do the following steps:

1. If the new value is the string "`on`", let `element` be the first element in `tree_order` represented by the `RadioNodeList` object that is an `input` element whose `type` attribute is in the `Radio Button` state and whose `value` content attribute is either absent, or present and equal to the new value, if any. If no such element exists, then instead let `element` be null. Otherwise: let `element` be the first element in `tree_order` represented by the `RadioNodeList` object that is an `input` element whose `type` attribute is in the `Radio Button` state and whose `value` content attribute is present and equal to the new value, if any. If no such element exists, then instead let `element` be null.
2. If `element` is not null, then set its `checkedness` to true.

2.7.2.3 The `HTMLOptionsCollection` interface

MDN

[HTMLOptionsCollection](#)

Support in all current engines.

Firefox?+Safari?+Chrome?+Yes

Opera?+Edge?Yes

Edge (Legacy)?12?+Internet Explorer?Yes

Firefox?+Android?+Safari?+iOS?+Chrome?+Android?+WebView?+Android?+Yes?+Samsung?+Internet?+Yes?+Opera?+Android?+Yes

```
IDL([Exposed=Window])
interface HTMLOptionsCollection : HTMLCollection {
  // inherits item(), namedItem()
  readonly attribute long length; // shadows inherited length
  [Calleable] setter void add(unsigned long index, HTMLOptionElement? option);
  [Calleable] void add(HTMLOptionElement or HTMLOptGroupElement element, optional (HTMLElement or long)? before = null);
  [Calleable] void remove(long index);
  attribute long selectedIndex;
}
```

For web developers (non-normative)

`collection.length [= value]`

Returns the number of elements in the collection.

When set to a smaller number, truncates the number of `option` elements in the corresponding container.

When set to a greater number, adds new blank `option` elements to that container.

`element = collection.item(index)`

`element = collection[index]`

Returns the item with index `index` from the collection. The items are sorted in `tree_order`.

`collection[index] = element`

When `index` is a greater number than the number of items in the collection, adds new blank `option` elements in the corresponding container.

When set to null, removes the item at index `index` from the collection.

When set to an `option` element, adds or replaces it at index `index` from the collection.

`element = collection.namedItem(name)`

`element = collection[name]`

Returns the item with `ID` or `name` from the collection.

If there are multiple matching items, then the first is returned.

`collection.appendChild(element [, before])`

Inserts `element` before the node given by `before`.

The `before` argument can be a number, in which case `element` is inserted before the item with that number, or an element from the collection, in which case `element` is inserted before that element.

If `before` is omitted, null, or a number out of range, then `element` will be added at the end of the list.

This method will throw a "`HIERARCHY_REQUEST_ERR`" `DOMException` if `element` is an ancestor of the element into which it is to be inserted.

`collection.remove(index)`

Removes the item with index `index` from the collection.

`collection.selectedIndex [= value]`

Returns the index of the first selected item, if any, or -1 if there is no selected item.

Can be set, to change the selection.

The object's `supported_property_indices` are as defined for `HTMLOptionsCollection` objects.

On getting, the `length` attribute must return the number of nodes `represented by the collection`.

On setting, the behavior depends on whether the new value is equal to, greater than, or less than the number of nodes `represented by the collection` at that time. If the number is the same, then setting the attribute must do nothing. If the new value is greater, then `n` new `option` elements with no attributes and no child nodes must be appended to the `select` element on which the `HTMLOptionsCollection` is rooted, where `n` is the difference between the two numbers (new value minus old value). Mutation events must be fired as if a `DocumentFragment` containing the new `option` elements had been inserted. If the new value is lower, then the last `n` nodes in the collection must be removed from their parent nodes, where `n` is the difference between the two numbers (old value minus new value).

Note

Setting `length` never removes or adds any `option` elements, and never adds new children to existing `option` elements (though it can remove children from them).

The `supported_property_names` consist of the non-empty values of all the `ID` and `name` attributes of all the elements `represented by the collection`, in `tree_order`, ignoring later duplicates, with the `ID` of an element preceding its `name` if it contributes both, they differ from each other, and neither is the duplicate of an earlier entry.

When the user agent is to `get the value of a new indexed property` or `set the value of an existing indexed property` for a given property index `index` to a new value `value`, it must run the following algorithm:

- If `value` is null, invoke the steps for the `remove` method with `index` as the argument, and return.
- Let `length` be the number of nodes `represented by the collection`.
- Let `n` be `index` minus `length`.
- If `n` is greater than zero, then `append` a `DocumentFragment` consisting of `n-1` new `option` elements with no attributes and no child nodes to the `select` element on which the `HTMLOptionsCollection` is rooted.
- If `n` is greater than or equal to zero, `append` `value` to the `select` element. Otherwise, `replace` the `index` element in the collection by `value`.

The `addElement(element, before)` method must act according to the following algorithm:

- If `element` is an ancestor of the `select` element on which the `HTMLOptionsCollection` is rooted, then throw a "`HIERARCHY_REQUEST_ERR`" `DOMException`.
- If `before` is an element, but that element isn't a descendant of the `select` element on which the `HTMLOptionsCollection` is rooted, then throw a "`NOT_FOUND_ERR`" `DOMException`.
- If `element` and `before` are the same element, then return.
- If `before` is a node, then let `reference` be that node. Otherwise, if `before` is an integer, and there is a `before` node in the collection, let `reference` be that node. Otherwise, let `reference` be null.
- If `reference` is not null, let `parent` be the parent node of `reference`. Otherwise, let `parent` be the `select` element on which the `HTMLOptionsCollection` is rooted.
- `Pre-inject` element into `parent` node before `reference`.

The `remove(index)` method must act according to the following algorithm:

- If the number of nodes `represented by the collection` is zero, return.
- If `index` is not a number greater than or equal to 0 and less than the number of nodes `represented by the collection`, return.
- Let `element` be the `index` element in the collection.
- Remove `element` from its parent node.

The `selectedIndex` IDL attribute must act like the identically named attribute on the `select` element on which the `HTMLOptionsCollection` is rooted

2.7.3 The `DOMStringList` interface

DOM

`DOMStringList`

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firfox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `DOMStringList` interface is a non-fashionable retro way of representing a list of strings.

```
IDL([Exposed=Window])
interface DOMStringList {
  readonly attribute unsigned long length;
  [Calleable] getter DOMString? item(unsigned long index);
  [Calleable] boolean contains(DOMString string);
}
```

⚠ Warning!

New APIs must use `sequence<DOMString>` or equivalent rather than `DOMStringList`.

For web developers (non-normative)

`strings.length`

Returns the number of strings in `strings`.

`strings[index]`

`strings.item(index)`

Returns the string with index `index` from `strings`.

`strings.contains(string)`

Returns true if `string` contains `string`, and false otherwise.

Each `DOMStringList` object has an associated `list`.

The `supported_property_indices` for a `DOMStringList` object are the numbers zero to the associated list's `size` minus one. If its associated list is `empty`, it has no `supported_property_indices`.

The `length` attribute's getter must return this `DOMStringList` object's associated list's `size`.

The `item(index)` method, when invoked, must return the `index` item in this `DOMStringList` object's associated list, or null if `index` plus one is greater than this `DOMStringList` object's associated list's `size`.

The `contains(string)` method, when invoked, must return true if this `DOMStringList` object's associated list `contains` `string`, and false otherwise.

2.8 Safe passing of structured data

This section uses the terminology and typographic conventions from the JavaScript specification. [\[JAVASCRIPT\]](#)

2.8.1 Serializable objects

`Serializable objects` support being serialized, and later deserialized, in a way that is independent of any given [JavaScript Realm](#). This allows them to be stored on disk and later restored, or cloned across `agent` and even `agent_cluster` boundaries.

Not all objects are `Serializable objects`, and not all aspects of objects that are `Serializable objects` are necessarily preserved when they are serialized.

`Platform objects` can be `Serializable objects` if their `primary_interface` is decorated with the `(Serializable)` IDL `extended_attribute`. Such interfaces must also define the following algorithms:

A set of steps that serializes the data in *value* into fields of *serialized*. The resulting data serialized into *serialized* must be independent of any [JavaScript Realm](#).

These steps may throw an exception if serialization is not possible.

These steps may perform a [sub-serialization](#) to serialize nested data structures. They should not call [StructuredSerialize](#) directly, as doing so will omit the important *memory* argument.

The introduction of these steps should omit mention of the *forStorage* argument if it is not relevant to the algorithm.

[deserialization steps](#), taking a [Record](#) *serialized* and a [platform object](#) *value*

A set of steps that deserializes the data in *serialized*, using it to set up *value* as appropriate. *value* will be a newly-created instance of the [platform object](#) type in question, with none of its internal data set up; setting that up is the job of these steps.

These steps may throw an exception if deserialization is not possible.

These steps may perform a [sub-deserialization](#) to deserialize nested data structures. They should not call [StructuredDeserializing](#) directly, as doing so will omit the important *targetRealm* and *memory* arguments.

It is up to the definition of individual platform objects to determine what data is serialized and deserialized by these steps. Typically the steps are very symmetric.

The [Serializable](#) extended attribute must take no arguments, and must only appear on an interface. It must not appear more than once on an interface.

For a given [platform object](#), only the object's [primary interface](#) is considered during the (de)serialization process. Thus, if inheritance is involved in defining the interface, each [Serializable](#)-annotated interface in the inheritance chain needs to define standalone [serialization steps](#) and [deserialization steps](#), including taking into account any important data that might come from inherited interfaces.

Example

Let's say we were defining a platform object [Person](#), which had associated with it two pieces of associated data:

- a name value, which is a string;
- a best friend value, which is either another [Person](#) instance or null

We could then define [Person](#) instances to be [serializable objects](#) by annotating the [Person](#) interface with the [Serializable](#) extended attribute, and defining the following accompanying algorithms:

[serialization steps](#)

1. Set *serialized*.[[Name]] to *value*'s associated name value.
2. Let *serializedBestFriend* be the [sub-serialization](#) of *value*'s associated best friend value.
3. Set *serialized*.[[BestFriend]] to *serializedBestFriend*.

[deserialization steps](#)

1. Set *value*'s associated name value to *serialized*.[[Name]].
2. Let *deserializedBestFriend* be the [sub-deserialization](#) of *serialized*.[[BestFriend]].
3. Set *value*'s associated best friend value to *deserializedBestFriend*.

Objects defined in the JavaScript specification are handled by the [StructuredSerialize](#) abstract operation directly.

Note
Originally, this specification defined the concept of "cloneable objects", which could be cloned from one [JavaScript Realm](#) to another. However, to better specify the behavior of certain more complex situations, the model was updated to make the serialization and deserialization explicit.

2.8.2 Transferable objects

[MDN](#)

Transferable

Support in all current engines.

Firefox+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer 10+

Firefox Android 4+ Safari iOS Yes Chrome Android Yes Web View Android Yes Samsung Internet Yes Opera Android Yes

[Transferable objects](#) support being transferred across [agents](#). Transferring is effectively recreating the object while sharing a reference to the underlying data and then detaching the object being transferred. This is useful to transfer ownership of expensive resources. Not all objects are [transferable objects](#) and not all aspects of objects that are [transferable objects](#) are necessarily preserved when transferred.

Note

Transferring is an irreversible and non-idempotent operation. Once an object has been transferred, it cannot be transferred, or indeed used, again.

[Platform objects](#) can be [transferable objects](#) if their [primary interface](#) is decorated with the [{Transferable}](#) IDL [extended attribute](#). Such interfaces must also define the following algorithms:

[transfer steps](#), taking a [platform object](#) *value* and a [Record](#) *dataHolder*

A set of steps that transfers the data in *value* into fields of *dataHolder*. The resulting data held in *dataHolder* must be independent of any [JavaScript Realm](#).

These steps may throw an exception if transferal is not possible.

[transfer-receiving steps](#), taking a [Record](#) *dataHolder* and a [platform object](#) *value*

A set of steps that receives the data in *dataHolder*, using it to set up value as appropriate. *value* will be a newly-created instance of the [platform object](#) type in question, with none of its internal data set up; setting that up is the job of these steps.

These steps may throw an exception if it is not possible to receive the transfer.

It is up to the definition of individual platform objects to determine what data is transferred by these steps. Typically the steps are very symmetric.

The [Serializable](#) extended attribute must take no arguments, and must only appear on an interface. It must not appear more than once on an interface.

For a given [platform object](#), only the object's [primary interface](#) is considered during the transferring process. Thus, if inheritance is involved in defining the interface, each [Serializable](#)-annotated interface in the inheritance chain needs to define standalone [transfer steps](#) and [transfer-receiving steps](#), including taking into account any important data that might come from inherited interfaces.

[Platform objects](#) that are [transferable objects](#) have a [\[\[Detached\]\]](#) internal slot. This is used to ensure that once a platform object has been transferred, it cannot be transferred again.

Objects defined in the JavaScript specification are handled by the [StructuredSerializeWithTransfer](#) abstract operation directly.

2.8.3 StructuredSerializeInternal (*value*, *forStorage* | , *memory*)

The [StructuredSerializeInternal](#) abstract operation takes as input a JavaScript value *value* and serializes it to a [Realm](#)-independent form, represented here as a [Record](#). This serialized form has all the information necessary to later deserialize into a new JavaScript value in a different Realm.

This process can throw an exception, for example when trying to serialize un-serializable objects.

1. If *memory* was not supplied, let *memory* be an empty [map](#).

Note

The purpose of the *memory* map is to avoid serializing objects twice. This ends up preserving cycles and the identity of duplicate objects in graphs.

2. If *memory*[*value*] exists, then return *memory*[*value*].

3. Let *deep* be false.

4. If [Type](#)(*value*) is Undefined, Null, Boolean, Number, BigInt, or String, then return { [[Type]]: "primitive", [[Value]]: *value* }.

5. If [Type](#)(*value*) is Symbol, then throw a ["SerializationError"](#) [DOMException](#).

6. Let *serialized* be an uninitialized value.

7. If *value* has a [\[\[BooleanData\]\]](#) internal slot, then set *serialized* to { [[Type]]: "Boolean", [\[\[BooleanData\]\]](#): *value*[[BooleanData]] }.

8. Otherwise, if *value* has a [\[\[NumberData\]\]](#) internal slot, then set *serialized* to { [[Type]]: "Number", [\[\[NumberData\]\]](#): *value*[[NumberData]] }.

9. Otherwise, if *value* has a [\[\[BigIntData\]\]](#) internal slot, then set *serialized* to { [[Type]]: "BigInt", [\[\[BigIntData\]\]](#): *value*[[BigIntData]] }.

10. Otherwise, if *value* has a [\[\[StringData\]\]](#) internal slot, then set *serialized* to { [[Type]]: "String", [\[\[StringData\]\]](#): *value*[[StringData]] }.

11. Otherwise, if *value* has a [\[\[DateValue\]\]](#) internal slot, then set *serialized* to { [[Type]]: "Date", [\[\[DateValue\]\]](#): *value*[[DateValue]] }.

12. Otherwise, if *value* has a [\[\[RegExpMatcher\]\]](#) internal slot, then set *serialized* to { [[Type]]: "RegExp", [\[\[RegExMatcher\]\]](#): *value*[[RegExMatcher]], [\[\[OriginalSource\]\]](#): *value*[[OriginalSource]], [\[\[OriginalFlags\]\]](#): *value*[[OriginalFlags]] }.

13. Otherwise, if *value* has an [\[\[ArrayBufferData\]\]](#) internal slot, then:

1. Let *size* be *value*[[ArrayBufferByteLength]].

2. If ! [IsSharedArrayBuffer](#)(*value*) is true, then:

1. If *forStorage* is true, then throw a ["SerializationError"](#) [DOMException](#).

2. Set *serialized* to { [[Type]]: "SharedArrayBuffer", [\[\[ArrayBufferData\]\]](#): *value*[[ArrayBufferData]], [\[\[ArrayBufferByteLength\]\]](#): *size*, [\[\[AgentCluster\]\]](#): the [current Realm Record](#)'s corresponding [agent cluster](#) }.

3. Otherwise:

1. If ! [IsDetachableBuffer](#)(*value*) is true, then throw a ["SerializationError"](#) [DOMException](#).

2. Let *dataCopy* be ? [CreateByteDataBlock](#)(*size*).

Note
This can throw a [RangeError](#) exception upon allocation failure.

3. Perform ? [CopyDataBlockByRef](#)(*dataCopy*, 0, *value*[[ArrayBufferData]], 0, *size*).

4. Set *serialized* to { [[Type]]: "ArrayBuffer", [\[\[ArrayBufferData\]\]](#): *dataCopy*, [\[\[ArrayBufferByteLength\]\]](#): *size* }.

14. Otherwise, if *value* has a [\[\[ViewedArrayBuffer\]\]](#) internal slot, then:

1. Let *buffer* be the value of *value*'s [\[\[ViewedArrayBuffer\]\]](#) internal slot.

2. Let *bufferSerialized* be ? [StructuredSerializeInternal](#)(*buffer*, *forStorage*, *memory*).

3. Assert: *bufferSerialized*[[Type]] is "ArrayBuffer".

4. If *value* has a [\[\[DataView \]\]](#) internal slot, then set *serialized* to { [[Type]]: "ArrayBufferView", [\[\[Constructor\]\]](#): ["DataView"](#), [\[\[ArrayBufferSerialized\]\]](#): *bufferSerialized*, [\[\[ByteLength\]\]](#): *value*[[ByteLength]], [\[\[ByteOffset\]\]](#): *value*[[ByteOffset]] }.

5. Otherwise:

1. Assert: *value* has a [\[\[TypedArrayName\]\]](#) internal slot.

2. Set *serialized* to { [[Type]]: "ArrayBufferView", [\[\[Constructor\]\]](#): *value*[[TypedArrayName]], [\[\[ArrayBufferSerialized\]\]](#): *bufferSerialized*, [\[\[ByteLength\]\]](#): *value*[[ByteLength]], [\[\[ByteOffset\]\]](#): *value*[[ByteOffset]], [\[\[ArrayLength\]\]](#): *value*[[ArrayLength]] }.

15. Otherwise, if *value* has a [\[\[MapData\]\]](#) internal slot, then:

2. Set `deep` to true.
16. Otherwise, if `value` has a `[[SetData]]` internal slot, then:
 1. Set `serialized` to `{ [[Type]]: "Set", [[SetData]]: a new empty List }`.
 2. Set `deep` to true.
17. Otherwise, if `value` has an `[[ErrorData]]` internal slot and `value` is not a `platform object`, then:
 1. Let `name` be `? Getvalue, "name"`.
 2. If `name` is not one of "Error", "EvalError", "RangeError", "ReferenceError", "SyntaxError", "TypeError", or "URIError", then set `name` to "Error".
 3. Let `valueMessageDesc` be `? value.[[GetOwnProperty]]("message")`.
 4. Let `message` be undefined if `!IsDataDescriptor(valueMessageDesc)` is false, and `? ToString(valueMessageDesc.[[Value]])` otherwise.
 5. Set `serialized` to `{ [[Type]]: "Error", [[Name]]: name, [[Message]]: message }`.
 6. User agents should attach a serialized representation of any interesting accompanying data which are not yet specified, notably the `stack` property, to `serialized`.

Note
See the `Error Stacks` proposal for in-progress work on specifying this data. [\[JSERRORSTACKS\]](#)

18. Otherwise, if `value` is an Array exotic object, then:
 1. Let `valueLenDescriptor` be `? OrdinaryGetOwnProperty(value, "length")`.
 2. Let `valueLen` be `valueLenDescriptor.[[Value]]`.
 3. Set `serialized` to `{ [[Type]]: "Array", [[Length]]: valueLen, [[Properties]]: a new empty List }`.
 4. Set `deep` to true.

19. Otherwise, if `value` is a `platform object` that is a `serializable object`:
 1. If `value` has a `[[D�achell]]` internal slot whose value is true, then throw a `"DataCloneError"` `DOMException`.
 2. Let `typeString` be the identifier of the `primary interface` of `value`.
 3. Set `serialized` to `{ [[Type]]: typeString }`.
 4. Set `deep` to true.
20. Otherwise, if `value` is a `platform object`, then throw a `"DataCloneError"` `DOMException`.
21. Otherwise, if `!IsCallable(value)` is true, then throw a `"DataCloneError"` `DOMException`.
22. Otherwise, if `value` has any internal slot other than `[[Prototype]]` or `[[Extensible]]`, then throw a `"DataCloneError"` `DOMException`.

Example
For instance, a `[[PromiseState]]` or `[[WeakMapData]]` internal slot.

23. Otherwise, if `value` is an exotic object, then throw a `"DataCloneError"` `DOMException`.

Example
For instance, a proxy object.

24. Otherwise:
 1. Set `serialized` to `{ [[Type]]: "Object", [[Properties]]: a new empty List }`.
 2. Set `deep` to true.

25. `Set memory[value] to serialized`.

26. If `deep` is true, then:
 1. If `value` has a `[[MapData]]` internal slot, then:
 1. Let `copiedList` be a new empty List.
 2. `For each Record { [[Key]], [[Value]] } entry of value.[[MapData]]:`
 1. Let `copiedEntry` be a new `Record` `{ [[Key]], [[Value]] }`.
 2. If `copiedEntry.[[Key]]` is not the special value `empty`, `append copiedEntry to copiedList`.
 3. `For each Record { [[Key]], [[Value]] } entry of copiedList:`
 1. Let `serializedKey` be `? StructuredSerializeInternal(entry.[[Key]], forStorage, memory)`.
 2. Let `serializedValue` be `? StructuredSerializeInternal(entry.[[Value]], forStorage, memory)`.
 3. `Append { [[Key]]: serializedKey, [[Value]]: serializedValue } to serialized.[[MapData]]`.
 2. Otherwise, if `value` has a `[[SetData]]` internal slot, then:
 1. Let `copiedList` be a new empty List.
 2. `For each entry of value.[[SetData]]:`
 1. If `entry` is not the special value `empty`, `append entry to copiedList`.
 3. `For each entry of copiedList:`
 1. Let `serializedEntry` be `? StructuredSerializeInternal(entry, forStorage, memory)`.
 2. `Append serializedEntry to serialized.[[SetData]]`.

3. Otherwise, if `value` is a `platform object` that is a `serializable object`, then perform the `serialization steps` for `value`'s `primary interface`, given `value`, `serialized`, and `forStorage`.

The `serialization steps` need to perform a `sub-serialization`. This is an operation which takes as input a `value subValue`, and returns `StructuredSerializeInternal(subValue, forStorage, memory)`. (In other words, a `sub-serialization` is a specialization of `StructuredSerializeInternal` to be consistent within this invocation.)

4. Otherwise:
 1. Let `enumerableKeys` be a new empty List.
 2. For each key in `value.[[OwnPropertyKeys]]`:
 1. If `Type(key)` is String, then:
 1. Let `valueDesc` be `? value.[[GetOwnProperty]](key)`.
 2. If `valueDesc.[[Enumerable]]` is true, then `append key to enumerableKeys`.
 3. For each key in `enumerableKeys`:
 1. If `? HasOwnProperty(value, key)` is true, then:
 1. Let `inputValue` be `? value.[[Get]](key, value)`.
 2. Let `outputValue` be `? StructuredSerializeInternal(inputValue, forStorage, memory)`.
 3. `Append { [[Key]]: key, [[Value]]: outputValue } to serialized.[[Properties]]`.

Note
The key collection performed above is very similar to the JavaScript specification's `EnumerableOwnProperty` operation, but crucially it uses the deterministic ordering provided by the `[[OwnPropertyKeys]]` internal method, instead of reordering the keys in an unspecified manner as `EnumerableOwnProperty` does. [\[JAVASCRIPT\]](#)

27. Return `serialized`.

Example

It's important to realize that the `Records` produced by `StructuredSerializeInternal` might contain "pointers" to other records that create circular references. For example, when we pass the following JavaScript object into `StructuredSerializeInternal`:

```
const o = {};
o.myself = o;
```

it produces the following result:

```
{
  [[Type]]: "Object",
  [[Properties]]: [
    {
      [[Key]]: "myself",
      [[Value]]: <a pointer to this whole structure>
    }
  ]
}
```

2.8.4 `StructuredSerialize (value)`

1. Return `? StructuredSerializeInternal(value, false)`.

2.8.5 `StructuredSerializeForStorage (value)`

1. Return `? StructuredSerializeInternal(value, true)`.

2.8.6 `StructuredDeserialize (serialized, targetRealm | , memory)`

The `StructuredDeserialize` abstract operation takes as input a `Record` `serialized`, which was previously produced by `StructuredSerialize` or `StructuredSerializeForStorage`, and deserializes it into a new JavaScript value, created in `targetRealm`.

This process can throw an exception, for example when trying to allocate memory for the new objects (especially `ArrayBuffer` objects).

1. If `memory` was not supplied, let `memory` be an empty map.

Note
The purpose of the `memory` map is to avoid deserializing objects twice. This ends up preserving cycles and the identity of duplicate objects in graphs.

2. If `memory[serialized]` exists, then return `memory[serialized]`.

3. Let `deep` be false.

4. Let `value` be an uninitialized value.

It's important to realize that the `Records` produced by `StructuredDeserialize` might contain "pointers" to other records that create circular references. For example, when we pass the following JavaScript object into `StructuredDeserialize`:

```
const o = {};
o.myself = o;
```

it produces the following result:

```
{
  [[Type]]: "Object",
  [[Properties]]: [
    {
      [[Key]]: "myself",
      [[Value]]: <a pointer to this whole structure>
    }
  ]
}
```

6. Otherwise, if `serialized.[[Type]]` is "Boolean", then set `value` to a new Boolean object in `targetRealm` whose `[[BooleanData]]` internal slot value is `serialized.[[BooleanData]]`.

7. Otherwise, if `serialized.[[Type]]` is "Number", then set `value` to a new Number object in `targetRealm` whose `[[NumberData]]` internal slot value is `serialized.[[NumberData]]`.

8. Otherwise, if `serialized.[[Type]]` is "BigInt", then set `value` to a new BigInt object in `targetRealm` whose `[[BigIntData]]` internal slot value is `serialized.[[BigIntData]]`.

9. Otherwise, if `serialized.[[Type]]` is "String", then set `value` to a new String object in `targetRealm` whose `[[StringData]]` internal slot value is `serialized.[[StringData]]`.

10. Otherwise, if `serialized.[[Type]]` is "Date", then set `value` to a new Date object in `targetRealm` whose `[[DateValue]]` internal slot value is `serialized.[[DateValue]]`.

11. Otherwise, if `serialized.[[Type]]` is "RegExp", then set `value` to a new RegExp object in `targetRealm` whose `[[RegExpMatcher]]` internal slot value is `serialized.[[RegExpMatcher]]`, whose `[[OriginalSource]]` internal slot value is `serialized.[[OriginalSource]]`, and whose `[[OriginalFlags]]` internal slot value is `serialized.[[OriginalFlags]]`.

12. Otherwise, if `serialized.[[Type]]` is "SharedArrayBuffer", then:

1. If `targetRealm`'s corresponding `agentCluster` is not `null`, then throw a `"DataCloneError"` `DOMException`.
2. Otherwise, set `value` to a new SharedArrayBuffer object in `targetRealm` whose `[[ArrayBufferData]]` internal slot value is `serialized.[[ArrayBufferData]]` and whose `[[ArrayBufferByteLength]]` internal slot value is `serialized.[[ArrayBufferByteLength]]`.

13. Otherwise, if `serialized.[[Type]]` is "ArrayBuffer", then set `value` to a new ArrayBuffer object in `targetRealm` whose `[[ArrayBufferData]]` internal slot value is `serialized.[[ArrayBufferData]]`, and whose `[[ArrayBufferByteLength]]` internal slot value is `serialized.[[ArrayBufferByteLength]]`.

If this throws an exception, catch it, and then throw a `"DataCloneError"` `DOMException`.

Note
This step might throw an exception if there is not enough memory available to create such an ArrayBuffer object.

14. Otherwise, if `serialized.[[Type]]` is "ArrayBufferView", then:

1. Let `deserializedArrayBuffer` be `? StructuredDeserialize(serialized.[[ArrayBufferSerialized]], targetRealm, memory)`.
2. If `serialized.[[Constructor]]` is "DataView", then set `value` to a new DataView object in `targetRealm` whose `[[ViewedArrayBuffer]]` internal slot value is `deserialized.[[ArrayBuffer]]`, whose `[[ByteLength]]` internal slot value is `serialized.[[ByteLength]]`, and whose `[[ByteOffset]]` internal slot value is `serialized.[[ByteOffset]]`.
3. Otherwise, set `value` to a new typed array object in `targetRealm`, using the constructor given by `serialized.[[Constructor]]`, whose `[[ViewedArrayBuffer]]` internal slot value is `deserialized.[[ArrayBuffer]]`, whose `[[TypedArrayName]]` internal slot value is `serialized.[[Constructor]]`, whose `[[ByteLength]]` internal slot value is `serialized.[[ByteLength]]`, whose `[[ByteOffset]]` internal slot value is `serialized.[[ByteOffset]]`, and whose `[[ArrayLength]]` internal slot value is `serialized.[[ArrayLength]]`.

15. Otherwise, if `serialized.[[Type]]` is "Map", then:

1. Set `value` to a new Map object in `targetRealm` whose `[[MapData]]` internal slot value is a new empty `List`.
2. Set `deep` to true.

16. Otherwise, if `serialized.[[Type]]` is "Set", then:

1. Set `value` to a new Set object in `targetRealm` whose `[[SetData]]` internal slot value is a new empty `List`.
2. Set `deep` to true.

17. Otherwise, if `serialized.[[Type]]` is "Array", then:

1. Let `outputProto` be `targetRealm.[[Intrinsics]].[[%ArrayPrototype%]]`.
2. Set `value` to `! ArrayCreate(serialized.[[length]], outputProto)`.
3. Set `deep` to true.

18. Otherwise, if `serialized.[[Type]]` is "Object", then:

1. Set `value` to a new Object in `targetRealm`.
2. Set `deep` to true.

19. Otherwise, if `serialized.[[Type]]` is "Error", then:

1. Let `prototype` be `%ErrorPrototype%`.
2. If `serialized.[[Name]]` is "EvalError", then set `prototype` to `%EvalErrorPrototype%`.
3. If `serialized.[[Name]]` is "RangeError", then set `prototype` to `%RangeErrorPrototype%`.
4. If `serialized.[[Name]]` is "ReferenceError", then set `prototype` to `%ReferenceErrorPrototype%`.
5. If `serialized.[[Name]]` is "SyntaxError", then set `prototype` to `%SyntaxErrorPrototype%`.
6. If `serialized.[[Name]]` is "TypeError", then set `prototype` to `%TypeErrorPrototype%`.
7. If `serialized.[[Name]]` is "URIError", then set `prototype` to `%URIErrorPrototype%`.
8. Let `message` be `serialized.[[Message]]`.
9. Set `value` to `! ObjectCreate(prototype, {[[ErrorData]]: message})`.

10. If `message` is undefined, then perform a `OrdinaryDefineOwnProperty(value, "message", messageDesc)`.

11. Any interesting accompanying data attached to `serialized` should be deserialized and attached to `value`.

20. Otherwise:

1. Let `interfaceName` be `serialized.[[Type]]`.
2. If the interface identified by `interfaceName` is not `exposed` in `targetRealm`, then throw a `"DataCloneError"` `DOMException`.
3. Set `value` to a new instance of the interface identified by `interfaceName`, created in `targetRealm`.
4. Set `deep` to true.

21. `Set memory[serialized] to value`.

22. If `deep` is true, then:

1. If `serialized.[[Type]]` is "Map", then:
 1. `For each Record` { [[Key]], [[Value]] } entry of `serialized.[[MapData]]`:
 2. Let `deserializedKey` be `? StructuredDeserialize(entry.[[Key]], targetRealm, memory)`.
 3. Let `deserializedValue` be `? StructuredDeserialize(entry.[[Value]], targetRealm, memory)`.
 4. `Append` { [[Key]], `deserializedKey`, [[Value]], `deserializedValue` } to `value.[[MapData]]`.
2. Otherwise, if `serialized.[[Type]]` is "Set", then:
 1. `For each` entry of `serialized.[[SetData]]`:
 2. Let `deserializedEntry` be `? StructuredDeserialize(entry, targetRealm, memory)`.
 3. `Append` `deserializedEntry` to `value.[[SetData]]`.
3. Otherwise, if `serialized.[[Type]]` is "Array" or "Object", then:
 1. `For each Record` { [[Key]], [[Value]] } entry of `serialized.[[Properties]]`:
 1. Let `deserializedValue` be `? StructuredDeserialize(entry.[[Value]], targetRealm, memory)`.
 2. Let `result` be `! CreateDataProperty(value, entry.[[Key]], deserializedValue)`.
 3. Assert: `result` is true.
 4. Otherwise:
 1. Perform the appropriate `deserialization steps` for the interface identified by `serialized.[[Type]]`, given `serialized` and `value`.

The `deserialization steps` may need to perform a `sub-deserialization`. This is an operation which takes as input a previously-serialized `Record` `subSerialized`, and returns `StructuredDeserialize(subSerialized, targetRealm, memory)`. (In other words, a `sub-deserialization` is a specialization of `StructuredDeserialize` to be consistent within this invocation.)

23. Return `value`.

2.8.7 `StructuredSerializeWithTransfer` (`value, transferList`)

1. Let `memory` be an empty `map`.

Note
In addition to how it is used normally by `StructuredSerializeInternal`, in this algorithm `memory` is also used to ensure that `StructuredSerializeInternal` ignores items in `transferList`, and let us do our own handling instead.

2. `For each` `transferable` of `transferList`:

1. If `transferable` has neither an `[[ArrayBufferData]]` internal slot nor a `[[Detached]]` internal slot, then throw a `"DataCloneError"` `DOMException`.
2. If `transferable` has an `[[ArrayBufferData]]` internal slot and ! `IsSharedArrayBuffer(transferable)` is true, then throw a `"DataCloneError"` `DOMException`.
3. If `memory[transferable]` exists, then throw a `"DataCloneError"` `DOMException`.
4. `Set memory[transferable]` to `! [[Type]]`: an uninitialized value .

Note
`transferable` is not transferred yet as transferring has side effects and `StructuredSerializeInternal` needs to be able to throw first.

3. Let `serialized` be `? StructuredSerializeInternal(value, false, memory)`.

4. Let `transferDataHolders` be a new empty `List`.

5. `For each` `transferable` of `transferList`:

1. If `transferable` has an `[[ArrayBufferData]]` internal slot and ! `IsDetachedBuffer(transferable)` is true, then throw a `"DataCloneError"` `DOMException`.
2. If `transferable` has a `[[Detached]]` internal slot and `transferable.[[Detached]]` is true, then throw a `"DataCloneError"` `DOMException`.
3. Let `dataHolder` be `memory[transferable]`.
4. If `transferable` has an `[[ArrayBufferData]]` internal slot, then:
 1. Set `dataHolder.[[Type]]` to "ArrayBuffer".
 2. Set `dataHolder.[[ArrayBufferData]]` to `transferable.[[ArrayBufferData]]`.
 3. Set `dataHolder.[[ArrayBufferByteLength]]` to `transferable.[[ArrayBufferByteLength]]`.

```

boolean queryCommandState(DOMString commandId);
boolean queryCommandEnabled(DOMString commandId);
DOMString queryCommandValue(DOMString commandId);

// special event handler ID attributes that only apply to Document objects
[ElementThis] attribute EventHandler onreadystatechange;
// also has obsolete members
};

Document includes GlobalEventHandlers;
Document includes DocumentAndElementEventHandlers;

```

The `Document` has an `HTTPS state` (an `HTTPS state value`), initially `"none"`, which represents the security properties of the network channel used to deliver the `Document`'s data.

The `Document` has a `referrer policy` (a `referrer policy`), initially the empty string, which represents the default `referrer policy` used by `fetches` initiated by the `Document`.

The `Document` has a `CSP list`, which is a `CSP list` containing all of the `Content Security Policy` objects active for the document. The list is empty unless otherwise specified.

The `Document` has a `feature policy`, which is a `feature policy`, which is initially empty.

The `Document` has a `module map`, which is a `module map`, initially empty.

3.1.2 The `DocumentOrShadowRoot` interface

DOM defines the `DocumentOrShadowRoot` mixin, which this specification extends.

```

IDPartial interface mixin DocumentOrShadowRoot {
  readonly attribute Element? activeElement;
};

```

3.1.3 Resource metadata management

For web developers (non-normative)

`document.referrer`

MDN

`Document.referrer`

Support in all current engines.

Firefox 1+ Safari 1+ Chrome 1+

Opera 3+ Edge 79+

Edge (Legacy) 12+ Internet Explorer 4+

Firefox Android 4+ Safari iOS 1+ Chrome Android 18+ WebView Android 1+ Samsung Internet 1.0+ Opera Android 10.1+

Returns the `URL` of the `Document` from which the user navigated to this one, unless it was blocked or there was no such document, in which case it returns the empty string.

The `preferrer` link type can be used to block the referrer.

The `referrer` attribute must return `the document's referrer`.

For web developers (non-normative)

`document.cookie = value`

Returns the HTTP cookies that apply to the `Document`. If there are no cookies or cookies can't be applied to this resource, the empty string will be returned.

Can be set, to add a new cookie to the element's set of HTTP cookies.

If the contents are `sandboxed into a unique origin` (e.g. in an `iframe` with the `sandbox` attribute), a `"SecurityError" DOMException` will be thrown on getting and setting.

The `cookie` attribute represents the cookies of the resource identified by the document's `URL`.

A `Document` object that falls into one of the following conditions is a `cookie-aware Document object`:

- A `Document` object whose `browsing context` is null.
- A `Document` whose `URL`'s `scheme` is not a `network scheme`.

On getting, if the document is a `cookie-aware Document object`, then the user agent must return the empty string. Otherwise, if the `Document`'s `origin` is an `opaque origin`, the user agent must throw a `"SecurityError" DOMException`. Otherwise, the user agent must return the `cookie-string` for the document's `URL` for a "non-HTTP" API, decoded using `UTF-8 decode without BOM (COOKIES)`.

On setting, if the document is a `cookie-aware Document object`, then the user agent must do nothing. Otherwise, if the `Document`'s `origin` is an `opaque origin`, the user agent must throw a `"SecurityError" DOMException`. Otherwise, the user agent must act as it would when `receiving a set-cookie-string` for the document's `URL` via a "non-HTTP" API, consisting of the new value `encoded at UTF-8 (COOKIE) (ENCODING)`.

Note

Since the `cookie` attribute is accessible across frames, the path restrictions on cookies are only a tool to help manage which cookies are sent to which parts of the site, and are not in any way a security feature.

⚠️ Warning!
The `cookie` attribute's getter and setter synchronously access shared state. Since there is no locking mechanism, other browsing contexts in a multiprocess user agent can modify cookies while scripts are running. A site could, for instance, try to read a cookie, increment its value, then write it back out, using the new value of the cookie as a unique identifier for the session; if the site does this twice in two different browser windows at the same time, it might end up using the same "unique" identifier for both sessions, with potentially disastrous effects.

For web developers (non-normative)

`document.lastModified`

Returns the date of the last modification to the document, as reported by the server, in the form `"yy/yy/yy yy:mm:ss"`, in the user's local time zone.

If the last modification date is not known, the current time is returned instead.

MDN

`Document.lastModified`

Support in all current engines.

Firefox Yes Safari Yes Chrome 1+

Opera Yes Edge 79+

Edge (Legacy) 12+ Internet Explorer?

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `lastModified` attribute, on getting, must return the date and time of the `Document`'s source file's last modification, in the user's local time zone, in the following format:

1. The month component of the date.
2. A U+002F SOLIDUS character (/).
3. The year component of the date.
4. A U+002F SOLIDUS character (/).
5. The year component of the date.
6. A U+0020 SPACE character.
7. The hour component of the time.
8. A U+003A COLON character (:).
9. The minute component of the time.
10. A U+003A COLON character (:).
11. The seconds component of the time.

All the numeric components above, other than the year, must be given as two `ASCII digits` representing the number in base ten, zero-padded if necessary. The year must be given as the shortest possible string of four or more `ASCII digits` representing the number in base ten, zero-padded if necessary.

The `Document`'s source file's last modification date and time must be derived from relevant features of the networking protocols used, e.g. from the value of the HTTP `"Last-Modified"` header of the document, or from metadata in the file system for local files. If the last modification date and time are not known, the attribute must return the current date and time in the above format.

For web developers (non-normative)

`document.readyState`

Returns `"loading"` while the `Document` is loading, `"interactive"` once it is finished parsing but still loading subresources, and `"complete"` once it has loaded.

The `readystatechange` event fires on the `Document` object when this value changes.

The `DOMContentLoaded` event fires after the transition to `"interactive"` but before the transition to `"complete"`, at the point where all subresources apart from `script` elements have loaded.

MDN

`Document.readyState`

Support in all current engines.

Firefox 4+ Safari 1+ Chrome 1+

Opera 11+ Edge 79+

Edge (Legacy) 12+ Internet Explorer 9+

Firefox Android 4+ Safari iOS 1+ Chrome Android 18+ WebView Android 1+ Samsung Internet 1.0+ Opera Android 11+

Each document has a `current document readiness`. When a `Document` object is created, it must have its `current document readiness` set to the string `"loading"` if the document is associated with an `HTML parser`, an `XML parser`, or an `XSLT processor`, and to the string `"complete"` otherwise. Various algorithms during page loading affect this value. When the value is set, the user agent must fire an event named `readystatechange` at the `Document` object.

A `Document` is said to have an `active parser` if it is associated with an `HTML parser` or an `XML parser` that has not yet been `stopped` or `aborted`.

The `readyState` IDL attribute must, on getting, return the `current document readiness`.

3.1.4 DOM tree accessors

The `html` element of a document is its `document element`, if it's an `html` element, and null otherwise.

For web developers (non-normative)

`document.html`

Returns `the html element`.

MDN**Document.head**

Support in all current engines.

Firefox4+Safari5+Chrome4+

Opera11+Edge79+

Edge (Legacy)12+Internet Explorer9+

Firefox, Android4+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

The `head` attribute, on getting, must return `the head element` of the document (a `head` element or null).**Support:** document.headChrome for Android 8.1+Chrome 4+iOS Safari 4.0+Safari 5.1+Firefox 4+Samsung Internet 4+Edge 12+UC Browser for Android 12.12+IE 9+Opera 11+Opera Mini all+Firefox for Android 68+Source: caniuse.com**For web developers (non-normative)**`document.title [= value]`Returns the document's title, as given by `the title element` for HTML and as given by the `SVG title` element for SVG.

Can be set, to update the document's title. If there is no appropriate element to update, the new value is ignored.

The `title` element of a document is the first `title` element in the document (in `tree_order`), if there is one, or null otherwise.**MDN****Document.title**

Support in all current engines.

FirefoxYesSafariYesChrome1+

OperaYesEdge79+

Edge (Legacy)12+Internet ExplorerYes

Firefox, AndroidYesSafari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

The `title` attribute must, on getting, run the following algorithm:

1. If the `document_element` is an `SVG title` element, then let `value` be the `child_text_content` of the first `SVG title` element that is a child of the `document_element`.
2. Otherwise, let `value` be the `child_text_content` of `the title element`, or the empty string if `the title element` is null.
3. `Strip and collapse ASCII whitespace` in `value`.
4. Return `value`.

On setting, the steps corresponding to the first matching condition in the following list must be run:

If the `document_element` is an `SVG title` element

1. If there is an `SVG title` element that is a child of the `document_element`, let `element` be the first such element.
2. Otherwise:
 1. Let `element` be the result of `creating an element` given the `document_element's node_document`, `title`, and the `SVG namespace`.
 2. Insert `element` as the `first child` of the `document_element`.
 3. `String replace all` with the given value within `element`.

If the `document_element` is in the `HTML namespace`

1. If `the title element` is null and `the head element` is null, then return.
2. If `the title element` is non-null, let `element` be `the title element`.
3. Otherwise:
 1. Let `element` be the result of `creating an element` given the `document_element's node_document`, `title`, and the `HTML namespace`.
 2. `Append element` to `the head element`.
4. `String replace all` with the given value within `element`.

Otherwise

Do nothing.

For web developers (non-normative)`document.body [= value]`Returns `the body element`.Can be set, to replace `the body element`.If the new value is not a `body` or `frameset` element, this will throw a `"hierarchyRequestError"` `DOMException`.The `body` element of a document is the first of `the html element's` children that is either a `body` element or a `frameset` element, or null if there is no such element.**MDN****Document.body**

Support in all current engines.

Firefox2+Safari4+Chrome1+

Opera9.6+Edge79+

Edge (Legacy)12+Internet Explorer6+

Firefox, Android4+Safari iOSYesChrome Android18+WebView Android37+Samsung Internet1.0+Opera Android10.1+

The `body` attribute, on getting, must return `the body element` of the document (either a `body` element, a `frameset` element, or null). On setting, the following algorithm must be run:

1. If the new value is not a `body` or `frameset` element, then throw a `"hierarchyRequestError"` `DOMException`.
2. Otherwise, if the new value is the same as `the body element`, return.
3. Otherwise, if `the body element` is not null, then `replace the body element` with the new value within `the body element's` parent and return.
4. Otherwise, if there is no `document_element`, throw a `"hierarchyRequestError"` `DOMException`.
5. Otherwise, `the body element` is null, but there's a `document_element`. `Append` the new value to `the document_element`.

NoteThe value returned by the `body` getter is not always the one passed to the setter.**Example**In this example, the setter successfully inserts a `body` element (though this is non-conforming since SVG does not allow a `body` as child of `SVG title`). However the getter will return null because the document element is not `html`.

```
<svg xmlns="http://www.w3.org/2000/svg">
<title>My Title</title>
<document>body = document.createElementNS("http://www.w3.org/1999/xhtml", "body");
console.assert(document.body === null);
</script>
</svg>
```

For web developers (non-normative)`document.images`Returns an `HTMLCollection` of the `img` elements in the `document`.`document.links`Returns an `HTMLCollection` of the `a` elements in the `document`.`document.forms`Returns an `HTMLCollection` of the `form` elements in the `document`.`document.scripts`Returns an `HTMLCollection` of the `script` elements in the `document`.**MDN****Document.images**

The `currentScript` attribute, on getting, must return the value to which it was most recently set. When the `document` is created, the `currentScript` must be initialized to null.

...

Support: document.currentScript Chrome for Android 81+ Chrome 29+ iOS Safari 8+ Firefox 4+ Samsung Internet 4+ Edge 12+ UC Browser for Android 12.12+ IE None Opera 16+ Opera Mini None Firefox for Android 68+

Source: caniuse.com

Note

This API has fallen out of favor in the implementer and standards community, as it globally exposes `script` or `SVG_script` elements. As such, it is not available in newer contexts, such as when running `module_scripts` or when running scripts in a `shadow_tree`. We are looking into creating a new solution for identifying the running script in such contexts, which does not make it globally available; see issue #1013.

The `document` interface **supports named properties**. The `supported_property_names` of a `document` object `document` at any moment consist of the following, in `tree_order` according to the element that contributed them, ignoring later duplicates, and with values from `id` attributes coming before values from `name` attributes when the same element contributes both:

- the value of the `name` content attribute for all `exposed_iframe`, `img`, and `exposed_iframe` elements that have a non-empty `name` content attribute and are `in a document tree` with `document` as their `root`;
- the value of the `id` content attribute for all `exposed_iframe` elements that have a non-empty `id` content attribute and are `in a document tree` with `document` as their `root`; and
- the value of the `id` content attribute for all `img` elements that have both a non-empty `id` content attribute and a non-empty `name` content attribute, and are `in a document tree` with `document` as their `root`.

To determine the value of a named property name for a `document`, the user agent must return the value obtained using the following steps:

1. Let elements be the list of `named_elements` with the name name that are `in a document tree` with the `Document` as their `root`.

Note

There will be at least one such element, by definition.

2. If elements has only one element, and that element is an `iframe` element, and that `iframe` element's `nested_browsing_context` is not null, then return the `WindowProxy` object of the element's `nested_browsing_context`.

3. Otherwise, if elements has only one element, return that element.

4. Otherwise return an `HTMLCollection` rooted at the `document` node, whose filter matches only `named_elements` with the name name.

Named elements with the name name, for the purposes of the above algorithm, are those that are either:

- `Exposed_iframe`, `img`, `iframe`, and `exposed_iframe` elements that have a `name` content attribute whose value is `name`, or
- `Exposed_iframe` elements that have an `id` content attribute whose value is `name`, and that have a non-empty `name` content attribute present also.

An `embed` or `object` element is said to be `exposed` if it has no `exposed_object` ancestor, and, for `object` elements, is additionally either not showing its `fallback_content` or has no `object` or `embed` descendants.

Note

The `id` attribute on the `document` interface is defined along with the `name` content attribute.

See [Document](#)

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

3.2.1 Semantics

Elements, attributes, and attribute values in HTML are defined (by this specification) to have certain meanings (semantics). For example, the `ol` element represents an ordered list, and the `lang` attribute represents the language of the content.

These definitions allow HTML processors, such as Web browsers or search engines, to present and use documents and applications in a wide variety of contexts that the author might not have considered.

Example

As a simple example, consider a Web page written by an author who only considered desktop computer Web browsers:

```
<!DOCTYPE HTML>
<html lang="en">
<head>
<title>My Page</title>
</head>
<body>
  <h1>Welcome to my page!</h1>
  <p>I like cars and lorries and have a big Jeep!</p>
  <h2>Where I live</h2>
  <p>I live in a small hut on a mountain!</p>
</body>
</html>
```

Because HTML conveys *meaning*, rather than presentation, the same page can also be used by a small browser on a mobile phone, without any change to the page. Instead of headings being in large letters as on the desktop, for example, the browser on the mobile phone might use the same size text for the whole page, but with the headings in bold.

But it goes further than just differences in screen size: the same page could equally be used by a blind user using a browser based around speech synthesis, which instead of displaying the page on a screen, reads the page to the user, e.g. using headphones. Instead of large text for the headings, the speech browser might use a different volume or a slower voice.

That's not all, either. Since the browsers know which parts of the page are the headings, they can create a document outline that the user can use to quickly navigate around the document, using keys for "jump to next heading" or "jump to previous heading". Such features are especially common with speech browsers, where users would otherwise find quickly navigating a page quite difficult.

Even beyond browsers, software can make use of this information. Search engines can use the headings to more effectively index a page, or to provide quick links to subsections of the page from their results. Tools can use the headings to create a table of contents (that is in fact how this very specification's table of contents is generated).

This example has focused on headings, but the same principle applies to all of the semantics in HTML.

Authors must not use elements, attributes, or attribute values for purposes other than their appropriate intended semantic purpose, as doing so prevents software from correctly processing the page.

Example

For example, the following snippet, intended to represent the heading of a corporate site, is non-conforming because the second line is not intended to be a heading of a subsection, but merely a subheading or subtitle (a subordinate heading for the same section).

```
<body>
<h1>ACME Corporation</h1>
<h2>The leaders in arbitrary fast delivery since 1920</h2>
...
The <h2> element is intended for these kinds of situations:
```

```
<body>
<hgroup>
  <h1>ACME Corporation</h1>
  <h2>The leaders in arbitrary fast delivery since 1920</h2>
</hgroup>
...

```

Example

The document in this next example is similarly non-conforming, despite being syntactically correct, because the data placed in the cells is clearly not tabular data, and the `tbl_struct` element mis-used:

```
<!DOCTYPE HTML>
<html lang="en-GB">
<head> <title> Demonstration </title> </head>
<body>
<tbl_struct>
<ttr> <td> My favourite animal is the cat. </td> </tr>
<ttr>
<td> <a href="https://example.org/~ernest/"><code>Ernest</code></a>, in an essay from 1992 </td>
</tr>
</tbl_struct>
</table>
</body>
</html>
```

This would make software that relies on these semantics fail: for example, a speech browser that allowed a blind user to navigate tables in the document would report the quote above as a table, confusing the user; similarly, a tool that extracted titles of works from pages would extract "Ernest" as the title of a work, even though it's actually a person's name, not a title.

A corrected version of this document might be:

```
<!DOCTYPE HTML>
<html lang="en-GB">
<head> <title> Demonstration </title> </head>
<body>
<blockquote>
  <p> My favorite animal is the cat. </p>
</blockquote>
<p> <a href="https://example.org/~ernest/"><code>Ernest</code></a>, in an essay from 1992 </p>
</body>
</html>
```

Authors must not use elements, attributes, or attribute values that are not permitted by this specification or [other applicable specifications](#), as doing so makes it significantly harder for the language to be extended in the future.

Example

In the next example, there is a non-conforming attribute value ("carpet") and a non-conforming attribute ("texture"), which is not permitted by this specification:

```
<label>Carpet: <input type="carpet" name="c" texture="deep pile"></label>
Here would be an alternative and correct way to mark this up:
<label>Carpet: <input type="text" class="carpet" name="c" data-texture="deep pile"></label>
```

DOM nodes whose `node_document's` `browsing context` is null are exempt from all document conformance requirements other than the [HTML syntax](#) requirements and [XML syntax](#) requirements.

Example

In particular, the `template` element's `template_contents's` `node_document's` `browsing context` is null. For example, the `content_model` requirements and attribute value microsyntax requirements do not apply to a `template` element's `template_contents`. In this example an `img` element has attribute values that would be invalid outside a `template` element.

```
<template>
<article>

</article>
</template>
```

However, if the above markup were to omit the `</h1>` end tag, that would be a violation of the [HTML syntax](#), and would thus be flagged as an error by conformance checkers.

Through scripting and using other mechanisms, the values of attributes, text, and indeed the entire structure of the document may change dynamically while a user agent is processing it. The semantics of a document at an instant in time are those represented by the state of the document at that instant in time, and the semantics of a document can therefore change over time. User agents must update their presentation of the document as this occurs.

Example

HTML has a `progress` element that describes a progress bar. If its "value" attribute is dynamically updated by a script, the UA would update the rendering to show the progress changing.

3.2.2 Elements in the DOM

The nodes representing [HTML elements](#) in the DOM must implement, and expose to scripts, the interfaces listed for them in the relevant sections of this specification. This includes [HTML elements](#) in [XML documents](#), even when those documents are in another context (e.g. inside an XSLT transform).

Elements in the DOM represent things; that is, they have intrinsic *meaning*, also known as semantics.

Example

For example, an `ol` element represents an ordered list.

Elements can be [referenced](#) (referred to) in some way, either explicitly or implicitly. One way that an element in the DOM can be explicitly referenced is by giving an `id` attribute to the element, and then creating a [hyperlink](#) with that `id` attribute's value as the `fragment` for the [hyperlink's](#) `first` attribute value. Hyperlinks are not necessary for a reference, however; any manner of referring to the element in question will suffice.

Consider the following `figure` element, which is given an `id` attribute:

```
<figure id="module-script-graph">
<img alt="Module script graph showing module A, which depends on modules C and D." data-bbox="100px 100px 300px 200px"/>
<caption>Figure 27: a simple module graph</caption>
</figure>
```

A [hyperlink-based reference](#) could be created using the `a` element, like so:

```
As we can see in <a href="#module-script-graph">Figure 27</a>, ...
```

However, there are many other ways of [referencing](#) the `figure` element, such as:

- As depicted in the figure of modules A, B, C, and D..."
- In Figure 27..." (without a hyperlink)
- "From the contents of the 'simple module graph' figure..."
- "In the figure below..." (but [this is discouraged](#))

The basic interface, from which all the [HTML elements](#)' interfaces inherit, and which must be used by elements that have no additional requirements, is the [HTMLElement](#) interface.

  [CRActions] attribute [TreatNullAs=EmptyString] DOMString innerText;
  ElementInternals attachInternals();
}

HTMLElement includes GlobalEventHandlers;
HTMLElement includes DocumentAndElementEventHandlers;
HTMLElement includes DocumentEventHandlers;
HTMLElement includes HTMLFormControlsElement;

[Exposed=Window]
interface HTMLUnknownElement : HTMLElement {
  // Note: intentionally no [HTMLConstructor];
}

```

The `HTMLElement` interface holds methods and attributes related to a number of disparate features, and the members of this interface are therefore described in various different sections of this specification.

The `element interface` for an element with name `name` in the `HTML namespace` is determined as follows:

1. If `name` is `applet`, `basefont`, `blink`, `isindex`, `keygen`, `multicell`, `nextid`, or `spacer`, then return `HTMLUnknownElement`.
2. If `name` is `acronym`, `basefont`, `big`, `center`, `hr`, `noembed`, `noframes`, `plaintext`, `rb`, `rt`, `strike`, or `tt`, then return `HTMLElement`.
3. If `name` is `listing` or `img`, then return `HTMLPreElement`.
4. Otherwise, if this specification defines an interface appropriate for the `element type` corresponding to the local name `name`, then return that interface.
5. If `other applicable specifications` define an appropriate interface for `name`, then return the interface they define.
6. If `name` is a `valid custom element name`, then return `HTMLElement`.
7. Return `HTMLUnknownElement`.

Note

The use of `HTMLElement` instead of `HTMLUnknownElement` in the case of `valid custom element names` is done to ensure that any potential future `upgrades` only cause a linear transition of the element's prototype chain, from `HTMLElement` to a subclass, instead of a lateral one, from `HTMLElement` to an unrelated subclass.

Features shared between HTML and SVG elements use the `HTMLOrSVGElement` interface mixin. [SVG]

```
IDLInterface mixin HTMLOrSVGElement {
  [SameObject] readonly attribute DOMStringMap dataset;
  attribute DOMString group; // intentionally no [CRActions];
  [CRActions] attribute long tabIndex;
  [CRActions] attribute long offsetIndex;
  void focus(optional FocusOptions options = ());
  void blur();
}
```

3.2.3 HTML element constructors

To support the `custom elements` feature, all HTML elements have special constructor behavior. This is indicated via the `[HTMLConstructor]` IDL `extended attribute`. It indicates that the interface object for the given interface will have a specific behavior when called, as defined in detail below.

The `[HTMLConstructor]` extended attribute must take no arguments, and must only appear on `constructor operations`. It must appear only once on a constructor operation, and the interface must contain only the single, annotated constructor operation, and no others. The annotated constructor operation must be declared to take no arguments.

Interfaces declared with constructor operations that are annotated with the `[HTMLConstructor]` extended attribute have the following `overridden constructor steps`:

1. Let `registry` be the `current global object's` `customElementRegistry` object.
2. If `NewTarget` is equal to the `active function object`, then throw a `TypeError`.

Example

This can occur when a custom element is defined using an `element interface` as its constructor:

```
customElements.define("bad-1", HTMLButtonElement);
new HTMLButtonElement(); // (1)
document.createElement("bad-1"); // (2)
```

In this case, during the execution of `HTMLButtonElement` (either explicitly, as in (1), or implicitly, as in (2)), both the `active function object` and `NewTarget` are `HTMLButtonElement`. If this check was not present, it would be possible to create an instance of `HTMLButtonElement` whose local name was `bad-1`.

3. Let `definition` be the entry in `registry` with `constructor` equal to `NewTarget`. If there is no such definition, then throw a `TypeError`.

Note

Since there can be no entry in `registry` with a `constructor` of undefined, this step also prevents HTML element constructors from being called as functions (since in that case `NewTarget` will be undefined).

4. Let `value` be null.

5. If `definition's local name` is equal to `definition's name` (i.e., `definition` is for an `autonomous custom element`), then:

1. If the `active function object` is not `HTMLElement`, then throw a `TypeError`.

Example

This can occur when a custom element is defined to not extend any local names, but inherits from a non-`HTMLElement` class:

```
customElements.define("bad-2", class Bad2 extends HTMLParagraphElement {});
```

In this case, during the (implicit) `super()` call that occurs when constructing an instance of `Bad2`, the `active function object` is `HTMLParagraphElement`, not `HTMLElement`.

6. Otherwise (i.e., if `definition` is for a `customized built-in element`):

1. Let `valid local names` be the list of local names for elements defined in this specification or in `other applicable specifications` that use the `active function object` as their `element interface`.
2. If `valid local names` does not contain `definition's local name`, then throw a `TypeError`.

Example

This can occur when a custom element is defined to extend a given local name but inherits from the wrong class:

```
customElements.define("bad-3", class Bad3 extends HTMLQuoteElement {}, { extends: "p" });
```

In this case, during the (implicit) `super()` call that occurs when constructing an instance of `Bad3`, `valid local names` is the list containing `p` and `blockquote`, but `definition's local name` is `p`, which is not in that list.

3. Set `value` to `definition's name`.

7. If `definition's construction stack` is empty, then:

1. Let `element` be the result of `internally creating a new object implementing the interface` to which the `active function object` corresponds, given the `current Realm Record` and `NewTarget`.

2. Set `element's node document` to the `current global object's associated Document`.

3. Set `element's namespace` to the `HTML namespace`.

4. Set `element's namespace prefix` to null.

5. Set `element's local name` to `definition's local name`.

6. Set `element's custom element state` to "custom".

7. Set `element's custom element definition` to `definition`.

8. Set `element's __value` to `value`.

9. Return `element`.

Note

This occurs when author script constructs a new custom element directly, e.g. via `new MyCustomElement()`.

8. Let `prototype` be `Get(NewTarget, "prototype")`. Rethrow any exceptions.

9. If `Type(prototype)` is not `Object`, then:

1. Let `realm` be `GetFunctionRealm(NewTarget)`.

2. Set `prototype` to the `interface prototype object` of `realm` whose interface is the same as the interface of the `active function object`.

The realm of the `active function object` might not be `realm`, so we are using the more general concept of "the same interface" across realms; we are not looking for equality of `interface objects`. This fallback behavior, including using the realm of `NewTarget` and looking up the appropriate prototype there, is designed to match analogous behavior for the JavaScript built-in and Web IDL's `internally create a new object implementing the interface` algorithm.

10. Let `element` be the last entry in `definition's construction stack`.

11. If `element` is an `already constructed marker`, then throw an `"InvalidStateError"` `DOMException`.

Example

This can occur when the author code inside the `custom element constructor non-conformantly` creates another instance of the class being constructed, before calling `super()`:

```
let doSillyThing = false;
class DontDoThis extends HTMLElement {
  constructor() {
    if (doSillyThing) {
```

- style
 - template
 - title

Elements from other namespaces whose semantics are primarily metadata-related (e.g. RDF) are also [metadata content](#).

Example

Thus, in the XML serialization, one can use RDF, like this:

This isn't possible in the HTML serialization, however.

3.2.5.2.2 Flow content

Most elements that are used in the body of documents and applications are categorized as *flow content*.

3.2.5.2.3 Sectioning content

Sectioning content is content that defines the scope of [headings](#) and [footers](#).

- article
 - aside
 - nav
 - section

Each [sectioning content](#) element potentially has a heading and an [outline](#). See the section on [headings and sections](#) for further details.

Note

There are also certain elements that are [sectioning roots](#). These are distinct from [sectioning content](#), but they can also have an [outline](#).

3.2.5.24 Heading content

Heading content defines the header of a section (whether explicitly marked up using `<sectioning-content>` elements, or implied by the heading content itself).

- h1
 - h2
 - h3
 - h4
 - h5
 - h6
 - hgroup

3.2.5.2.5 Phrasing content

Phrasing content is the text of the document, as well as elements that mark up that text at the intra-paragraph level. Runs of *phrasing content* form *paragraphs*.

- [a](#)
 - abbr
 - area (if it is a descendant of a map element)
 - audio
 - b
 - bdi
 - bdo
 - br
 - button
 - canvas
 - cite
 - code
 - data

wbr
video
webgl
and
any custom elements

Not

Note Most elements that are categorized as phrasing content can only contain elements that are themselves categorized as phrasing content, not any flow content.

Text, in the context of content models, means either nothing, or [Text nodes](#). [Text](#) is sometimes used as a content model on its own, but it is also [phrasing content](#), and can be [inter-element whitespace](#) (if the [Text](#) nodes are empty or contain just [ASCII whitespace](#)).

`text` nodes and attribute values must consist of [scalar values](#), excluding [noncharacters](#), and [controls](#) other than [ASCII whitespace](#). This specification includes extra constraints on the exact value of `text` nodes and attribute values depending on their precise context.

3.2.5.2.6 Embedded content

Embedded content is content that imports another resource into the document, or content from another vocabulary that is inserted into the document.

- audio
- canvas
- embed
- iframe
- img
- MathML mat
- object
- picture
- SVG sv
- video

Elements that are from namespaces other than the [HTML namespace](#) and that convey content but not metadata, are [embedded content](#) for the purposes of the content models defined in this specification. (For example, MathML, or SVG.)

Some embedded content elements can have *fallback content*: content that is to be used when the external resource cannot be used (e.g. because it is of an unsupported format). The element definitions state what the fallback is, if any.

3.2.5.2.7 Interactive content

Interactive content is content that is specifically intended for user interaction.

- [\(if the `href` attribute is present\)](#)
 - `audio` (if the `controls` attribute is present)
 - `button`
 - `details`
 - `embed`
 - `iframe`
 - `img` (if the `usemap` attribute is present)
 - `input` (if the `type` attribute is *not* in the `Hidden` state)
 - `object` (if the `usemap` attribute is present)
 - `select`
 - `textarea`
 - `video` (if the `controls` attribute is present)

The `tabindex` attribute can also make any element into interactive content.

3.2.5.2.8 Palpable content

As a general rule, elements whose content model allows any [flow content](#) or [phrasing content](#) should have at least one node in its [contents](#) that is [palpable content](#) and that does not have the [hidden](#) attribute specified.

Note The following table summarizes the key parameters used in the model.

Palpable content makes an element non-empty by providing either some descendant non-empty `text`, or else something users can hear (`audio` elements) or view (`video` or `img` or `canvas` elements) or otherwise interact with (for example, interactive form controls).

This requirement is not a hard requirement, however, as there are many cases where an element can be empty legitimately, for example when it is

Conformance checkers are encouraged to pro-

The following elements are palpable content:

- `a`
- `abbr`
- `address`
- `article`
- `aside`
- `details` (if the `controls` attribute is present)
- `b`
- `bdi`
- `bdo`
- `blockquote`
- `button`
- `div`
- `em`
- `h1`
- `h2`
- `h3`
- `h4`
- `h5`
- `h6`
- `header`
- `hgroup`
- `img`
- `input`
- `label`
- `main`
- `map`
- `math`
- `MathML math` (if the element's children include at least one `math` element)
- `meta`
- `nav`
- `object`
- `output` (if the element's children include at least one `input` element)
- `p`
- `pre`
- `progress`
- `q`
- `span`
- `section`
- `select`
- `small`
- `span`

- [itemref](#)
- [itemtype](#)
- [interact](#)
- [lang](#)
- [nonce](#)
- [spellcheck](#)
- [style](#)
- [translate](#)
- [title](#)
- [translate](#)

These attributes are only defined by this specification as attributes for [HTML elements](#). When this specification refers to elements having these attributes, elements from namespaces that are not defined as having these attributes must not be considered as being elements with these attributes.

[Example](#)

For example, in the following XML fragment, the “`bogus`” element does not have a `dir` attribute as defined in this specification, despite having an attribute with the literal name “`dir`”. Thus, [the directionality](#) of the inner-most `span` element is ‘`rtl`’, inherited from the `dir` element indirectly through the “`bogus`” element.

```
<div xmlns="http://www.w3.org/1999/xhtml" dir="rtl">
  <bogus xmlns="https://example.net/ns" dir="ltr">
    <span>
      </span>
    </bogus>
</div>
```

DOM standard defines the user agent requirements for the `class`, `id`, and `slot` attributes for any element in any namespace. [\[DOM\]](#)

The `class` and `id` attributes may be specified on all [HTML elements](#).

When specified on [HTML elements](#), the `class` attribute must have a value that is a set of space-separated tokens representing the various classes that the element belongs to.

Note

Assigning classes to an element affects class matching in selectors in CSS, the `getElementsByClassName()` method in the DOM, and other such features.

There are no additional restrictions on the tokens authors can use in the `class` attribute, but authors are encouraged to use values that describe the nature of the content, rather than values that describe the desired presentation of the content.

When specified on [HTML elements](#), the `id` attribute value must be unique amongst all the IDs in the element's tree and must contain at least one character. The value must not contain any ASCII whitespace.

Note

The `id` attribute specifies its element's [unique identifier \(ID\)](#).

There are no other restrictions on what form an ID can take; in particular, IDs can consist of just digits, start with a digit, start with an underscore, consist of just punctuation, etc.

An element's [unique identifier](#) can be used for a variety of purposes, most notably as a way to link to specific parts of a document using `fragments`, as a way to target an element when scripting, and as a way to style a specific element from CSS.

Identifiers are opaque strings. Particular meanings should not be derived from the value of the `id` attribute.

There are no conformance requirements for the `slot` attribute specific to [HTML elements](#).

Note

The `slot` attribute is used to [assign a slot](#) to an element: an element with a `slot` attribute is assigned to the `slot` created by the `slot` element whose `name` attribute's value matches that `slot` attribute's value — but only if that `slot` element finds itself in the [shadow tree](#) whose `root`'s `host` has the corresponding `slot` attribute value.

To enable assistive technology products to expose a more fine-grained interface than is otherwise possible with HTML elements and attributes, a set of [annotations for assistive technology products](#) can be specified (the ARIA `role` and `aria-` attributes). [\[ARIA\]](#)

The following `event handler content attributes` may be specified on any [HTML element](#):

- [onabort](#)
- [onauxclick](#)
- [onblur*](#)
- [oncancel](#)
- [oncancelablechange](#)
- [onchange](#)
- [oncancelablechange](#)
- [onclose](#)
- [oncontextmenu](#)

- [onemptied](#)
- [onended](#)
- [onerror*](#)
- [onfocus*](#)
- [onformdata](#)
- [oninput](#)
- [oninvalid](#)
- [onkeydown](#)
- [onkeydown](#)
- [onkeypress](#)
- [onload*](#)
- [onloadeddata](#)
- [onloadedmetadata](#)
- [onloadstart](#)
- [onmousedown](#)
- [onmousemove](#)
- [onmousemove](#)
- [onmouseleave](#)
- [onmouseenter](#)
- [onmouseout](#)
- [onmouseover](#)
- [onprogress](#)
- [onratechange](#)
- [onseek](#)
- [onseeks](#)*
- [onscroll*](#)
- [onsecuritypolicyviolation](#)
- [onseeked](#)
- [onstop](#)
- [onselect](#)
- [onslotchange](#)
- [onstalled](#)
- [onsubmit](#)
- [ontransitionend](#)
- [ontimeupdate](#)
- [onvolumechange](#)
- [onwriting](#)
- [onwheel](#)

Note

The attributes marked with an asterisk have a different meaning when specified on `body` elements as those elements expose `event handlers` of the `Window` object with the same names.

Note

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

[Custom data attributes](#) (e.g. `data-foldername` or `data-msgid`) can be specified on any [HTML element](#), to store custom data, state, annotations, and similar, specific to the page.

In [HTML documents](#), elements in the [HTML namespace](#) may have an `xmna` attribute specified, if, and only if, it has the exact value "<http://www.w3.org/1999/xhtml>". This does not apply to [XML documents](#).

Note
In [HTML](#), the `xmna` attribute has absolutely no effect. It is basically a talisman. It is allowed merely to make migration to and from XML mildly easier. When parsed by an [HTML parser](#), the attribute ends up in no namespace, not the "<http://www.w3.org/2000/xmlns/>" namespace like namespace declaration attributes in XML do.

Note
In [XML](#), an `xmna` attribute is part of the namespace declaration mechanism, and an element cannot actually have an `xmna` attribute in no namespace specified.

[XML](#) also allows the use of the `xmna` attribute in the [XML namespace](#) on any element in an [XML document](#). This attribute has no effect on [HTML elements](#), as the default behavior in HTML is to preserve whitespace. [\[XML\]](#)

Note
There is no way to serialize the `xmna` attribute on [HTML elements](#) in the `text/html` syntax.

3.2.6.1 The `title` attribute

MDN

[Global_attributes/title](#)

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `title` attribute represents advisory information for the element, such as would be appropriate for a tooltip. On a link, this could be the title or a description of the target resource; on an image, it could be the image credit or a description of the image; on a paragraph, it could be a footnote or commentary on the text; on a citation, it could be further information about the source; on [interactive content](#), it could be a label for, or instructions for, use of the element; and so forth. The value is text.

Note
Relying on the `title` attribute is currently discouraged as many user agents do not expose the attribute in an accessible manner as required by this specification (e.g., requiring a pointing device such as a mouse to cause a tooltip to appear, which excludes keyboard-only users and touch-only users, such as anyone with a modern phone or tablet).

If this attribute is omitted from an element, then it implies that the `title` attribute of the nearest ancestor [HTML element](#) with a `title` attribute set is also relevant to this element. Setting the attribute overrides this, explicitly stating that the advisory information of any ancestors is not relevant to this element. Setting the attribute to the empty string indicates that the element has no advisory information.

If the `title` attribute's value contains U+000A LINE FEED (LF) characters, the content is split into multiple lines. Each U+000A LINE FEED (LF) character represents a line break.

Example

Citation is advised with respect to the use of newlines in `title` attributes.

For instance, the following snippet actually defines an abbreviation's expansion with a *line break in it*:

```
empty logs show that there was some interest in <abbr title="Hypertext  
Transport Protocol">HTTP</abbr> today.</p>
```

Some elements, such as `link`, `img`, and `input`, define additional semantics for the `title` attribute beyond the semantics described above.

The [advisory information](#) of an element is the value that the following algorithm returns, with the algorithm being aborted once a value is returned. When the algorithm returns the empty string, then there is no advisory information.

1. If the element has a `title` attribute, then return its value.

2. If the element has a parent element, then return the parent element's [advisory information](#).

3. Return the empty string.

User agents should inform the user when elements have [advisory information](#), otherwise the information would not be discoverable.

MDN

[HTML Element/title](#)

The `title` IDL attribute must [reflect](#) the `title` content attribute.

3.2.6.2 The `lang` and `xml:lang` attributes

MDN

[Global_attributes/lang](#)

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `lang` attribute (in no namespace) specifies the primary language for the element's contents and for any of the element's attributes that contain text. Its value must be a valid BCP 47 language tag, or the empty string. Setting the attribute to the empty string indicates that the primary language is unknown. [\[BCP47\]](#)

The `lang` attribute in the [XML namespace](#) is defined in XML. [\[XML\]](#)

If these attributes are omitted from an element, then the language of this element is the same as the language of its parent element, if any.

The `lang` attribute in no namespace may be used on any [HTML element](#).

The `lang` attribute in the [XML namespace](#) may be used on [HTML elements](#) in [XML documents](#), as well as elements in other namespaces if the relevant specifications allow it (in particular, MathML and SVG allow [raw attributes in the XML namespace](#) to be specified on their elements). If both the `lang` attribute in no namespace and the `lang` attribute in the [XML namespace](#) are specified on the same element, they must have exactly the same value when compared in an ASCII case-insensitive manner.

Authors must not use the `lang` attribute on [HTML elements](#) in [HTML documents](#). To ease migration to and from XML, authors may specify an attribute in no namespace with no prefix and with the literal localname "`xmnl:lang`" on [HTML elements](#) in [HTML documents](#), but such attributes must only be specified if a `lang` attribute in no namespace is also specified, and both attributes must have the same value when compared in an ASCII case-insensitive manner.

Note

The attribute in no namespace with no prefix and with the literal localname "`xmnl:lang`" has no effect on language processing.

To determine the [language](#) of a node, user agents must look at the nearest ancestor element (including the element itself if the node is an element) that has a [lang attribute in the XML namespace](#) set or is an [HTML element](#) and has a `lang` in no namespace attribute set. That attribute specifies the language of the node (regardless of its value).

If both the `lang` attribute in no namespace and the [lang attribute in the XML namespace](#) are set on an element, user agents must use the [lang attribute in the XML namespace](#), and the `lang` attribute in no namespace must be [ignored](#) for the purposes of determining the element's language.

If node's [inclusive ancestors](#) do not have either attribute set, but there is a [pragma-set-default language](#) set, then that is the language of the node. If there is no [pragma-set-default language](#) set, then language information from a higher-level protocol (such as HTTP), if any, must be used as the final fallback language instead. In the absence of any such language information, and in cases where the higher-level protocol reports multiple languages, the language of the node is unknown, and the corresponding language tag is the empty string.

If the resulting value is not a recognized language tag, then it must be treated as an unknown language tag, distinct from all other languages. For the purposes of round-tripping or communicating with other services that expect language tags, user agents should pass unknown language tags through unmodified, and tagged as being BCP 47 language tags, so that subsequent services do not interpret the data as another type of language description. [\[BCP47\]](#)

Example

Thus, for instance, an element with `lang="xyzzy"` would be matched by the selector `:lang(xyzzy)` (e.g. in CSS), but it would not be matched by `:lang(abode)`, even though both are equally invalid. Similarly, if a Web browser and screen reader working in unison communicated about the language of the element, the browser would tell the screen reader that the language was "xyzzy", even if it knew it was invalid, just in case the screen reader actually supported a language with that tag after all. Even if the screen reader supported both BCP 47 and another syntax for encoding language names, and in that other syntax the string "xyzzy" was a way to denote the Belarusian language, it would be *incorrect* for the screen reader to then start treating text as Belarusian, because "xyzzy" is not how Belarusian is described in BCP 47 codes (BCP 47 uses the code "be" for Belarusian).

If the resulting value is the empty string, then it must be interpreted as meaning that the language of the node is explicitly unknown.

User agents may use the element's language to determine proper processing or rendering (e.g. in the selection of appropriate fonts or pronunciations, for dictionary selection, or for the user interfaces of form controls such as date pickers).

The `lang` IDL attribute must [reflect](#) the `lang` content attribute in no namespace.

3.2.6.3 The `translate` attribute

MDN

[Global_attributes/translate](#)

Firefox No Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) No Internet Explorer No

Firefox Android No Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `translate` attribute is an [enumerated attribute](#) that is used to specify whether an element's attribute values and the values of its `text` node children are to be translated when the page is localized, or whether to leave them unchanged.

The attribute's keywords are the `yes`, `no`, and `auto`. The `empty` string and the `yes` keyword map to the `no` state. In addition, there is a `third` state, the `inherit` state, which is the `missing_value.default` and the `invalid_value.default`.

Each element (even non-HTML elements) has a [translation mode](#), which is in either the [translate-enabled state](#) or the [no-translate state](#). If an [HTML element](#)'s `translate` attribute is in the `yes` state, then the element's `translation mode` is in the [translate-enabled state](#); otherwise, if the element's `translate` attribute is in the `no` state, then the element's `translation mode` is in the [no-translate state](#). Otherwise, either the element's `translate` attribute is in the `inherit` state, or the element is not an [HTML element](#) and thus does not have a `translate` attribute; in either case, the element's `translation mode` is in the same state as its parent element's, if any, or in the [translate-enabled state](#), if the element is a [document element](#).

When an element is in the [translate-enabled state](#), the element's `translatable attributes` and the values of its `text` node children are to be translated when the page is localized.

When an element is in the [no-translate state](#), the element's `attribute values` and the values of its `text` node children are to be left-as-is when the page is localized, e.g. because the element contains a person's name or a name of a computer program.

The following attributes are [translatable attributes](#):

- `area` on `img` elements
- `alt` on `area`, `img`, and `input` elements
- `content` on `meta` elements, if the `name` attribute specifies a metadata name whose value is known to be translatable
- `download` on `a` and `area` elements
- `label` on `button`, `input`, and `track` elements
- `lang` on [HTML elements](#); must be "translated" to match the language used in the translation

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

- `srcdoc` on `iframe` elements must be parsed and recursively processed
- `content` on `HTML` elements must be parsed and recursively processed (e.g. for the values of `content` properties)
- `title` on all `HTML` elements
- `value` on `input` elements with a `type` attribute in the `Button` state or the `Reset Button` state

Other specifications may define other attributes that are also [translatable attributes](#). For example, `ARIA` would define the `aria-label` attribute as translatable.

The `translate` IDL attribute must, on getting, return true if the element's `translation mode` is `translate-enabled`, and false otherwise. On setting, it must set the content attribute's value to "`yes`" if the new value is true, and set the content attribute's value to "`no`" otherwise.

Example

In this example, everything in the document is to be translated when the page is localized, except the sample keyboard input and sample program output:

```
<!DOCTYPE HTML>
<html lang="en"><!-- default on the document element is translate="yes" -->
<head>
<title>The Bee Game</title><!-- implied translate="yes" inherited from ancestors -->
</head>
<body>
<p>The Bee Game is a text adventure game in English.</p>
<p>When the game launches, the first thing you should do is type "y" to catch a bunch of honey!</p>
<p><code>translate="no">Yum yum! That was some good honey!</code></p>
</body>
</html>
```

3.2.6.4 The `dir` attribute

MDN

[Global_attributes/dir](#)

Support in all current engines.

FirefoxYes SafariYes ChromeAndroidYes WebViewAndroidYes Samsung InternetYes OperaYes

OperaYes EdgeYes

Edge (Legacy)No Internet ExplorerNo

Firefox AndroidYes Safari iOSYes Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidYes

The `dir` attribute specifies the element's text directionality. The attribute is an [enumerated attribute](#) with the following keywords and states:

The `ltr` keyword, which maps to the `ltr` state

Indicates that the contents of the element are explicitly directionally isolated left-to-right text.

The `rtl` keyword, which maps to the `rtl` state

Indicates that the contents of the element are explicitly directionally isolated right-to-left text.

The `auto` keyword, which maps to the `auto` state

Indicates that the contents of the element are explicitly directionally isolated text, but that the direction is to be determined programmatically using the contents of the element (as described below).

Note
The heuristic used by this state is very crude (it just looks at the first character with a strong directionality, in a manner analogous to the Paragraph Level determination in the bidirectional algorithm). Authors are urged to only use this value as a last resort when the direction of the text is truly unknown and no better server-side heuristic can be applied.

Note
For `textarea` and `pre` elements, the heuristic is applied on a per-paragraph level.

The attribute has no [invalid value default](#) and no [missing value default](#).

The [directionality](#) of an element (any element, not just an `HTML element`) is either '`ltr`' or '`rtl`', and is determined as per the first appropriate set of steps from the following list:

If the element's `dir` attribute is in the `lr` state

If the element is a `document element` and the `dir` attribute is not in a defined state (i.e. it is not present or has an invalid value)

If the element is an `input` element whose `type` attribute is in the `Text`, `Search`, `Telephone`, or `URL` state, and the `dir` attribute is in the `auto` state

If the element is a `textarea` element and the `dir` attribute is in the `auto` state

If the element's `value` contains a character of bidirectional character type AL or R, and there is no character of bidirectional character type L anywhere before it in the element's `value`, then the [directionality](#) of the element is '`rl`'. (BIDI)
Otherwise, if the element's `value` is not the empty string, or if the element is a `document element`, the [directionality](#) of the element is '`lr`'.

Otherwise, the [directionality](#) of the element is the same as the element's parent element's [directionality](#).

If the element's `dir` attribute is in the `auto` state

If the element is a `td` element and the `dir` attribute is not in a defined state (i.e. it is not present or has an invalid value)

Find the first character in `tree_order` that matches the following criteria:

- The character is from a `Text` node that is a descendant of the element whose [directionality](#) is being determined.
- The character is of bidirectional character type L, AL, or R. (BIDI)
- The character is not in a `Text` node that has an ancestor element that is a descendant of the element whose [directionality](#) is being determined and that is either:
 - A `td` element.
 - A `tbody` element.
 - A `table` element.
 - A `tr` element.
 - A `textarea` element.
 - An element with a `dir` attribute in a defined state.

If such a character is found and it is of bidirectional character type AL or R, the [directionality](#) of the element is '`rl`'.

If such a character is found and it is of bidirectional character type L, the [directionality](#) of the element is '`lr`'.

Otherwise, if the element is a `document element`, the [directionality](#) of the element is '`lr`'.

Otherwise, the [directionality](#) of the element is the same as the element's parent element's [directionality](#).

If the element has a parent element and the `dir` attribute is not in a defined state (i.e. it is not present or has an invalid value)

The [directionality](#) of the element is the same as the element's parent element's [directionality](#).

Note
Since the `dir` attribute is only defined for `HTML elements`, it cannot be present on elements from other namespaces. Thus, elements from other namespaces always just inherit their [directionality](#) from their parent element, or, if they don't have one, default to '`lr`'.

Note
This attribute [has rendering requirements involving the bidirectional algorithm](#).

The [directionality](#) of an attribute of an `HTML element`, which is used when the text of that attribute is to be included in the rendering in some manner, is determined as per the first appropriate set of steps from the following list:

If the attribute is a `directionality-capable attribute` and the element's `dir` attribute is in the `auto` state

Find the first character (in logical order) of the attribute's value that is of bidirectional character type L, AL, or R. (BIDI)

If such a character is found and it is of bidirectional character type AL or R, the [directionality of the attribute](#) is '`rl`'.

Otherwise, the [directionality of the attribute](#) is '`lr`'.

Otherwise, the [directionality of the attribute](#) is the same as the `element's directionality`.

The following attributes are [directionality-capable attributes](#):

- `alt` on `img` elements
- `alt` on `area`, `img`, and `input` elements
- `content` on `meta` elements, if the `name` attribute specifies a metadata name whose value is primarily intended to be human-readable rather than machine-readable
- `label` on `checkbox`, `radio`, and `track` elements
- `placeholder` on `input` and `textarea` elements
- `title` on all `HTML elements`

For web developers (non-normative)

`document.dir = value`

Returns the `html element`'s `dir` attribute's value, if any.

Can be set, to either '`ltr`', '`rtl`', or '`auto`' to replace the `html element`'s `dir` attribute's value.

If there is no `html element`, returns the empty string and ignores new values.

MDN

[HTML Element/dir](#)

Support in all current engines.

Firefox1+ Safari6+ Chrome1+

OperaYes Edge79+

Edge (Legacy)12+ Internet Explorer?

Firefox Android4+ Safari iOSYes Chrome Android18+ WebViewAndroid4.4+ Samsung Internet1.0+ Opera AndroidYes

The `dir` IDL attribute on an element must [reflect](#) the `dir` content attribute of that element, limited to only known values.

MDN

Support in all current engines.

FirefoxYesSafariYesChrome45+

OperaYesEdge79+

Edge (Legacy)12+Internet ExplorerYes

Firefox AndroidYes Safari iOSYes Chrome Android45+WebView Android45+Samsung Internet5.0+Opera AndroidYes

The `dir` IDL attribute on `Document` objects must reflect the `dir` content attribute of the `html` element, if any, limited to only known values. If there is no such element, then the attribute must return the empty string and do nothing on setting.

Note

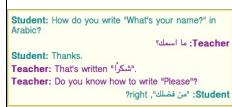

Authors are strongly encouraged to use the `dir` attribute to indicate text direction rather than using CSS, since that way their documents will continue to render correctly even in the absence of CSS (e.g. as interpreted by search engines).

Example

This markup fragment is of an IM conversation.

```
<rp dir=auto class="u1"><b>Student</b></rp></b> How do you write "What's your name?" in Arabic?</p>
<rp dir=auto class="u2"><b>Teacher</b></rp></b> <span dir="rtl">شما اسمك؟</span></p>
<rp dir=auto class="u1"><b>Student</b></rp></b> Thank you!</p>
<rp dir=auto class="u2"><b>Teacher</b></rp></b> You wrote it correctly!<span dir="rtl">كتبتها بشكل صحيح</span>.</p>
<rp dir=auto class="u1"><b>Student</b></rp></b> Do you know how to write "Please"?</p>
<rp dir=auto class="u2"><b>Teacher</b></rp></b> <span dir="rtl">الرجاء</span>, right?</p>
```

Given a suitable style sheet and the default alignment styles for the `p` element, namely to align the text to the `start` edge of the paragraph, the resulting rendering could be as follows:

As noted earlier, the `auto` value is not a panacea. The final paragraph in this example is misinterpreted as being right-to-left text, since it begins with an Arabic character, which causes the "right?" to be to the left of the Arabic text.

3.2.6.5 The `style` attribute

MDN

Global_attributes/style

Support in all current engines.

FirefoxYesSafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet ExplorerYes

Firefox AndroidYes Safari iOSYes Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidYes

All `HTML_element`s may have the `style` content attribute set. This is a `style attribute` as defined by [CSS Style Attributes](#). [\[CSSATTR\]](#)

In user agents that support CSS, the attribute's value must be parsed when the attribute is added or has its value changed, according to the rules given for `style attributes`. [\[CSSATTR\]](#)

However, if the `Should element's inline behavior be blocked by Content Security Policy?` algorithm returns "blocked" when executed upon the attribute's `element.style attribute`, and the attribute's value, then the style rules defined in the attribute's value must not be applied to the `element`. [\[CSP\]](#)

Documents that use `style` attributes on any of their elements must still be comprehensible and usable if those attributes were removed.

Note

In particular, using the `style` attribute to hide and show content, or to convey meaning that is otherwise not included in the document, is non-conforming. (To hide and show content, use the `hidden` attribute.)

For web developers (non-normative)

element.style

Returns a `CSSStyleDeclaration` object for the element's `style` attribute.

The `style` IDL attribute is defined in [CSS Object Model \(CSSOM\)](#). [\[CSSOM\]](#)

Example

In the following example, the words that refer to colors are marked up using the `span` element and the `style` attribute to make those words show up in the relevant colors in visual media.

```
<p>My sweat suit is <span style="color: green; background: transparent; opacity: 0.5;>green</span> and my eyes are <span style="color: blue; background: transparent; opacity: 0.5;>blue</span>.</p>
```

3.2.6.6 Embedding custom non-visible data with the `data-*` attributes

MDN

Global_attributes/data*

Support in all current engines.

FirefoxYesSafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet ExplorerYes

Firefox AndroidYes Safari iOSYes Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidYes

A `custom data attribute` is an attribute in no namespace whose name starts with the string "data-", has at least one character after the hyphen, is [XML-compatible](#), and contains no [ASCII upper alphas](#).

Note

All attribute names on `HTML_element`s in `HTML_document`s get ASCII-lowercased automatically, so the restriction on ASCII uppercase letters doesn't affect such documents.

`Custom data attributes` are intended to store custom data, state, annotations, and similar, private to the page or application, for which there are no more appropriate attributes or elements.

These attributes are not intended for use by software that is not known to the administrators of the site that uses the attributes. For generic extensions that are to be used by multiple independent tools, either this specification should be extended to provide the feature explicitly, or a technology like [microdata](#) should be used (with a standardized vocabulary).

Example

For instance, a site about music could annotate list items representing tracks in an album with custom data attributes containing the length of each track. This information could then be used by the site itself to allow the user to sort the list by track length, or to filter the list for tracks of certain lengths.

```
<ol>
  <li data-length="2m11s">Beyond The Sea</li>
  ...
</ol>
```

It would be inappropriate, however, for the user to use generic software not associated with that music site to search for tracks of a certain length by looking at this data.

This is because these attributes are intended for use by the site's own scripts, and are not a generic extension mechanism for publicly-visible metadata.

Example

Similarly, a page author could write markup that provides information for a translation tool that they are intending to use:

```
<p>The third <span data-mytrans-de="Aproschn">claim</span> covers the case of <span
translate="no">HTML</span> markup.</p>
```

In this example, the `data-mytrans-de` attribute gives specific text for the MyTrans product to use when translating the phrase "claim" to German. However, the standard `translate` attribute is used to tell it that in all languages, "HTML" is to remain unchanged. When a standard attribute is available, there is no need for a `custom data attribute` to be used.

Example

In this example, custom data attributes are used to store the result of a feature detection for `PaymentRequest`, which could be used in CSS to style a checkout page differently.

```
<script>
  if (document.PaymentRequest) {
    document.documentElement.dataset.hasPaymentRequest = '';
  }
</script>
```

Here, the `data-has-payment-request` attribute is effectively being used as a `boolean attribute`; it is enough to check the presence of the attribute. However, if the author so wishes, it could later be populated with some value, maybe to indicate limited functionality of the feature.

Every `HTML_element` may have any number of `custom data attributes` specified, with any value.

Authors should carefully design such extensions so that when the attributes are ignored and any associated CSS dropped, the page is still usable.

User agents must not derive any implementation behavior from these attributes or values. Specifications intended for user agents must not define these attributes to have any meaningful values.

JavaScript libraries may use the `custom data attributes`, as they are considered to be part of the page on which they are used. Authors of libraries that are reused by many authors are encouraged to include their name in the attribute names, to reduce the risk of clashes. Where it makes sense, library authors are also encouraged to make the exact name used in the attribute names customizable, so that libraries whose authors unknowingly picked the same name can be used on the same page, and so that multiple versions of a particular library can be used on the same page even when those versions are not mutually compatible.

Example

For example, a library called "DoQuery" could use attribute names like `data-doquery-range`, and a library called "jIo" could use attributes names like `data-jio-range`. The jIo library could also provide an API to set which prefix to use (e.g. `jIo.setDataPrefix('j2')`), making the attributes have names like `data-j2-range`.

For web developers (non-normative)

element.dataset

Returns a `DOMStringMap` object for the element's `data-*` attributes.

Hyphenated names become camel-cased. For example, `data-foo-bar=""` becomes `element.dataset.fooBar`.

MDN

HTML_OperationElement/dataset

Support in all current engines.

Firefox6+Safari5.1+Chrome8+

Opera41+Edge79+

Edge (Legacy)17+Internet ExplorerNo

Firefox Android51+Safari iOS10+Chrome Android55+WebView Android55+Samsung Internet6.0+Opera Android41+

The `dataset` IDL attribute provides convenient accessors for all the `data-` attributes on an element. On getting, the `dataset` IDL attribute must return a `DOMStringMap` whose associated element is this element.

The `DOMStringMap` interface is used for the `dataset` attribute. Each `DOMStringMap` has an *associated element*.

MDN

[DOMStringMap](#)

Support in all current engines.

Firefox6+SafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)8+Internet Explorer?

Firefox AndroidYesSafari iOSSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

```
IID([ReparseWindows,
OverrideBuiltins])
interface DOMStringMap {
  DOMString get(string name);
  ([CReactions] setter void DOMString name, DOMString value);
  ([CReactions] deleter void DOMString name);
}
```

To get a `DOMStringMap`'s name-value pairs, run the following algorithm:

- Let `list` be an empty list of name-value pairs.
- For each content attribute on the `DOMStringMap`'s *associated element* whose first five characters are the string "data-" and whose remaining characters (if any) do not include any [ASCII upper alpha](#), in the order that those attributes are listed in the element's *attribute list*, add a name-value pair to `list` whose name is the attribute's name with the first five characters removed and whose value is the attribute's value.
- For each name in `list`, for each U+002D HYPHEN-MINUS character (-) in the name that is followed by an [ASCII lower alpha](#), remove the U+002D HYPHEN-MINUS character (-) and replace the character that followed it by the same character [converted to ASCII uppercase](#).
- Return `list`.

The [supported property names](#) on a `DOMStringMap` object at any instant are the names of each pair returned from [getting the DOMStringMap's name-value pairs](#) at that instant, in the order returned.

To determine the value of a named property name for a `DOMStringMap`, return the value component of the name-value pair whose name component is `name` in the list returned from [getting the DOMStringMap's name-value pairs](#).

To set the value of a new named property or get the value of an existing named property for a `DOMStringMap`, given a property name `name` and a new value `value`, run the following steps:

- If `name` contains a U+002D HYPHEN-MINUS character (-) followed by an [ASCII lower alpha](#), then throw a [SyntaxError](#) `DOMException`.
- For each [ASCII upper alpha](#) in `name`, insert a U+002D HYPHEN-MINUS character (-) before the character and replace the character with the same character [converted to ASCII lowercase](#).
- Insert the string `data-` at the front of `name`.
- If `name` does not match the XML [Name production](#), throw an [invalidCharacterError](#) `DOMException`.
- Set an attribute value for the `DOMStringMap`'s *associated element* using `name` and `value`.

To delete an existing named property `name` for a `DOMStringMap`, run the following steps:

- For each [ASCII upper alpha](#) in `name`, insert a U+002D HYPHEN-MINUS character (-) before the character and replace the character with the same character [converted to ASCII lowercase](#).
- Insert the string `data-` at the front of `name`.
- Remove an attribute by `name` given name and the `DOMStringMap`'s *associated element*.

Note

This algorithm will only get invoked by [Web IDL](#) for names that are given by the earlier algorithm for [getting the DOMStringMap's name-value pairs](#) ([WEBIDL](#)).

Example

If a Web page wanted an element to represent a space ship, e.g. as part of a game, it would have to use the `class` attribute along with `data-` attributes:

```
<div class="spaceship" data-ship-id="92432" data-ship-hp="100" data-ship-dmg="10" data-ship-x="50" data-ship-y="80">
<button class="fire" onclick="spaceShips[this.parentNode.dataset.shipId].fire()>
  Fire
</button>
</div>
```

Notice how the hyphenated attribute name becomes camel-cased in the API.

Example

Given the following fragment and elements with similar constructions:

```

```

One could imagine a function `splashDamage()` that takes some arguments, the first of which is the element to process:

```
function splashDamage(node, x, y, damage) {
  if (node.classList.contains('tower')) { // checking the 'class' attribute
    node.dataset.x = x; // reading the 'data-x' attribute
    node.dataset.y = y; // reading the 'data-y' attribute
    var hp = parseInt(node.dataset.hp); // reading the 'data-hp' attribute
    hp -= damage;
    if (hp <= 0) {
      hp = 0;
      node.dataset.ai = 'dead'; // setting the 'data-ai' attribute
      node.dataset.ability = ''; // removing the 'data-ability' attribute
    }
    node.dataset.hp = hp; // setting the 'data-hp' attribute
  }
}
```

3.2.7 The `innerText` IDL attribute

[...]

[HTML Element/innerText](#)

Support in all current engines.

Firefox45+Safari3+Chrome1+

Opera9.6+Edge79+

Edge (Legacy)12+Internet Explorer5.5+

Firefox Android5+Safari iOSS4+Chrome Android18+WebView Android4.4+Samsung Internet1.0+Opera Android0.1+

[For web developers \(non-normative\)](#)

`element : innerText [= value]`

Returns the element's text content "as rendered".

Can be set, to replace the element's children with the given value, but with line breaks converted to [text](#) elements.

On getting, the `innerText` attribute must follow these steps:

- If this element is not [being rendered](#), or if the user agent is a non-CSS user agent, then return this element's [descendant text content](#).

Note
This step can produce surprising results, as when the `innerText` attribute is accessed on an element not [being rendered](#), its text contents are returned, but when accessed on an element that is [being rendered](#), all of its children that are not [being rendered](#) have their text contents ignored.

- Let `results` be a new empty `list`.

- For each child node `node` of this element:

- Let `current` be the `list` resulting in running the `inner text collection steps` with `node`. Each item in `results` will either be a [JavaScript string](#) or a positive integer (a *required line break count*).

Note
Intuitively, a *required line break count* item means that a certain number of line breaks appear at that point, but they can be collapsed with the line breaks induced by adjacent *required line break count* items, reminiscent to CSS margin-collapsing.

- For each item `item` in `current`, append `item` to `results`.

- Remove any items from `results` that are the empty string.

- Remove any runs of consecutive *required line break count* items at the start or end of `results`.

- Replace each remaining run of consecutive *required line break count* items with a string consisting of as many U+000A LINE FEED (LF) characters as the maximum of the values in the *required line break count* items.

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

7. Return the concatenation of the string items in *results*.

The *inner text collection steps*, given a *node node*, are as follows:

1. Let *items* be the result of running the *inner text collection steps* with each child node of *node* in *tree_order*, and then concatenating the results to a single *list*.

2. If *node's computed value of 'visibility'* is not 'visible', then return *items*.

3. If *node* is not *being rendered*, then return *items*. For the purpose of this step, the following elements must act as described if the *computed value* of the *display* property is not 'none':

- *select* elements have an associated non-replaced inline *CSS box* whose child boxes include only those of *optgroup* and *option* element child nodes;
- *optgroup* elements have an associated non-replaced block-level *CSS box* whose child boxes include only those of *option* element child nodes; and
- *option* element have an associated non-replaced block-level *CSS box* whose child boxes are as normal for non-replaced block-level *CSS boxes*.

Note

items can be non-empty due to *display:contents*.

4. If *node* is a *text node*, then for each CSS text box produced by *node*, in content order, compute the text of the box after application of the CSS '*white-space*' processing rules and '*text-transform*' rules, set *items* to the *list* of the resulting strings, and return *items*. The CSS '*white-space*' processing rules are slightly modified: collapsible spaces at the end of lines are always collapsed, but they are only removed if the line is the last line of the block, or it ends with a *br* element. Soft hyphens should be preserved. [*CSSText*]

5. If *node* is a *br* element, then *append* a string containing a single U+000A LINE FEED (LF) character to *items*.

6. If *node's computed value of 'display'* is 'table-cell', and *node's CSS box* is not the last *table-cell* box of its enclosing *table-row* box, then *append* a string containing a single U+0009 CHARACTER TABULATION (tab) character to *items*.

7. If *node's computed value of 'display'* is 'table-row', and *node's CSS box* is not the last *table-row* box of the nearest ancestor *table* box, then *append* a string containing a single U+000A LINE FEED (LF) character to *items*.

8. If *node* is a *g* element, then *append* 2 (a required line break count) at the beginning and end of *items*.

9. If *node's used value of 'display'* is 'block-level' or 'table-caption', then *append* 1 (a required line break count) at the beginning and end of *items*. [*CSSDISPLAY*]

Note

Floating and absolutely-positioned elements fall into this category.

10. Return *items*.

Note

Note that descendant nodes of most replaced elements (e.g., *textarea*, *input*, and *video* — but not *button*) are not rendered by CSS, strictly speaking, and therefore have no *CSS boxes* for the purposes of this algorithm.

This algorithm is amenable to being generalized to work on *ranges*. Then we can use it as the basis for *Selection*'s stringifier and maybe expose it directly on *ranges*. See [Bugzilla bug 10583](#).

On setting, the *innerHTML* attribute must follow these steps:

1. Let *document* be this element's *node document*.
2. Let *fragment* be a new *DocumentFragment* object whose *node document* is *document*.

3. Let *input* be the given value.

4. Let *position* be a pointer into *input*, initially pointing at the start of the string.

5. Let *text* be the empty string.

6. While *position* is not past the end of *input*:

1. Collect a sequence of code points that are not U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters from *input* given *position*. Set *text* to the collected characters.

2. If *text* is not the empty string, then *append* a new *text* node whose *data* is *text* and *node document* is *document* to *fragment*.

3. While *position* is not past the end of *input*, and the character at *position* is either a U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) character:

1. If the character at *position* is a U+000D CARRIAGE RETURN (CR) character and the next character is a U+000A LINE FEED (LF) character, then advance *position* to the next character in *input*.

2. Advance *position* to the next character in *input*.

3. *Append* the result of creating an element given *document*, *px*, and the *HTML namespace* to *fragment*.

7. Replace all *with* *fragment* within this element.

3.2.8 Requirements relating to the bidirectional algorithm

3.2.8.1 Authoring conformance criteria for bidirectional-algorithm-formating characters

Text content in *HTML elements* with *text* nodes in their *contents*, and text in attributes of *HTML elements* that allow free-form text, may contain characters in the ranges U+202A to U+202E and U+2066 to U+2069 (the bidirectional-algorithm-formating characters). [*BIDI*]

Note

Authors are encouraged to use the *dir* attribute, the *bdo* element, and the *rtl* element, rather than maintaining the bidirectional-algorithm-formating characters manually. The bidirectional-algorithm-formating characters interact poorly with CSS. [*CSSGC*]

3.2.8.2 User agent conformance criteria

User agents must implement the Unicode bidirectional algorithm to determine the proper ordering of characters when rendering documents and parts of documents. [*BIDI*]

The mapping of HTML to the Unicode bidirectional algorithm must be done in one of three ways. Either the user agent must implement CSS, including in particular the CSS '*unicode-bidi*', '*direction*', and '*content*' properties, and must have, in its user agent style sheet, the rules using those properties given in this specification's *rendering* section, or, alternatively, the user agent must act as if it implemented just the aforementioned properties and had a user agent style sheet that included all the aforementioned rules, but without letting style sheets specified in documents override them, or, alternatively, the user agent must implement another styling language with equivalent semantics. [*CSSGC*]

The following elements and attributes have requirements defined by the *rendering* section that, due to the requirements in this section, are requirements on all user agents (not just those that support the suggested default rendering):

- *dir* attribute
- *bdi* element
- *bdo* element
- *dc* element
- *pre* element
- *textarea* element
- *u* element

3.2.9 Requirements related to ARIA and to platform accessibility APIs

User agent requirements for implementing Accessibility API semantics on *HTML elements* are defined in *HTML Accessibility API Mappings*: [*HTMLAAM*]

Conformance checker requirements for checking use of ARIA *role* and *aria-** attributes on *HTML elements* are defined in *ARIA in HTML*: [*ARIAHTML*]

Contexts in which this element can be used:

As document's *document element*.
Wherever a subdocument fragment is allowed in a compound document.

Content model:

A *start element* followed by a *body* element.

Tag omission in *text/html*:

An *html* element's *start tag* can be omitted if the first thing inside the *html* element is not a *comment*.

An *html* element's *end tag* can be omitted if the *html* element is not immediately followed by a *comment*.

Content attributes:

lang — *Application cache manifest*

Accessibility considerations:

For authors.

For implementers.

DOM interface:

```
IDL Exports<#> interface [HTMLConstructor] HTMLDocument {
  // ...
  // also has obsolete members
}
```

The *html* element represents the root of an HTML document.

Authors are encouraged to specify a *lang* attribute on the root *html* element, giving the document's language. This aids speech synthesis tools to determine what pronunciations to use, translation tools to determine what rules to use, and so forth.

The *manifest* attribute gives the address of the document's *application cache manifest*, if there is one. If the attribute is present, the attribute's value must be a *valid non-empty URL potentially surrounded by spaces*.

The *manifest* attribute is part of the legacy "*offline Web applications*" feature, which is in the process of being removed from the Web platform. (This is a long process that takes many years.) Using the *manifest* attribute at this time is highly discouraged. Use service workers instead. [*SW*]

The *manifest* attribute only *has an effect* during the early stages of document load. Changing the attribute dynamically thus has no effect (and thus, no DOM API is provided for this attribute).

Note

For the purposes of *application cache selection*, later *meta* elements cannot affect the *parsing of URLs* in *manifest* attributes, as the attributes are processed before those elements are seen.

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

The `window.applicationCache` IDL attribute provides scripted access to the offline [application cache](#) mechanism.

Example

```
<!DOCTYPE html>
<html lang="en">
<head>
<title>Swapping Songs</title>
</head>
<body>
<h1>Swapping Songs</h1>
<p>Tonight I swapped some of the songs I wrote with some friends, who  
wrote some of the songs they wrote. I love sharing my music.</p>
</body>
</html>
```

4.2 Document metadata

4.2.1 The `head` element

Contexts in which this element can be used:

As the first element in an `html` element.

Content model:

If the document is [an HTML document](#) or if title information is available from a higher-level protocol: Zero or more elements of [metadata content](#), of which no more than one is a `title` element and no more than one is a `base` element.

Otherwise: One or more elements of [metadata content](#), of which exactly one is a `title` element and no more than one is a `base` element.

[Tag omission in text/html:](#)

A `head` element's `start tag` can be omitted if the element is empty, or if the first thing inside the `head` element is an element.

A `head` element's `end tag` can be omitted if the `head` element is not immediately followed by [ASCII whitespace](#) or a `comment`.

Content attributes:

[Global attributes](#)

Accessories considerations:

For authors

For implementers

DOM interface:

```
IDL[Exposed=Window]
interface HTMLHeadElement : HTMLElement {
  [HTMLConstructor] constructor();
};
```

The `head` element [represents](#) a collection of metadata for the [document](#).

Example

The collection of metadata in a `head` element can be large or small. Here is an example of a very short one:

```
<!DOCTYPE html>
<html lang=en>
<head>
<title>A document with a short head</title>
</head>
<body>
<...

```

Here is an example of a longer one:

```
<!DOCTYPE HTML>
<html>
<head>
<meta charset="UTF-8">
<link href="https://www.example.com/">
<title>An application with a long head</title>
<link rel="stylesheet" href="definite.css">
<script src="big.js" href="big.css" title="Big Text">
<script src="support.js"></script>
<meta name="APPLICATION-NAME" content="Long headed application">
</head>
<body>
<...

```

Note

The `title` element is a required child in most situations, but when a higher-level protocol provides title information, e.g. in the Subject line of an e-mail when HTML is used as an e-mail authoring format, the `title` element can be omitted.

4.2.2 The `title` element

Categories:

Metadata content

Contexts in which this element can be used:

In a `head` element containing no other `title` elements.

Content model:

Text that is not [inter-element whitespace](#).

[Tag omission in text/html:](#)

Neither tag ismissible.

Content attributes:

[Global attributes](#)

Accessories considerations:

For authors

For implementers

DOM interface:

```
IDL[Exposed=Window]
interface HTMLTitleElement : HTMLElement {
  [HTMLConstructor] constructor();
  [CSSReactions] attribute DOMString text;
};
```

The `title` element [represents](#) the document's title or name. Authors should use titles that identify their documents even when they are used out of context, for example in a user's history or bookmarks, or in search results. The document's title is often different from its first heading, since the first heading does not have to stand alone when taken out of context.

There must be no more than one `title` element per document.

Note

If it's reasonable for the [document](#) to have no title, then the `title` element is probably not required. See the `head` element's content model for a description of when the element is required.

For web developers (non-normative)

`title : text [= value]`

Returns the [child text content](#) of the element.

Can be set, to replace the element's children with the given value.

The `text` attribute's getter must return this `title` element's [child text content](#).

The `text` attribute's setter must [string.replace_all](#) with the given value within this `title` element.

Example

```
<title>Introduction to The Mating Rituals of Bees</title>
<h1>Introduction</h1>
<p>This companion guide to the highly successful
<code>Introduction to Medieval Bee-Keeping</code> book is...
The next page might be a part of the same site. Note how the title describes the subject matter unambiguously, while the first heading assumes the reader knows what the context is and therefore won't wonder if the dances are Salsa or Waltz:
<title>Dances used during bee mating rituals</title>
<h1>The Dances</h1>
```

The string to use as the document's title is given by the `document.title` IDL attribute.

User agents should use the document's title when referring to the document in their user interface. When the contents of a `title` element are used in this way, the directionality of that `title` element should be used to set the directionality of the document's title in the user interface.

4.2.3 The `base` element

[Categories:](#)

[Metadata content](#)

[Contexts in which this element can be used:](#)

In a `head` element containing no other `base` elements.

[Content model:](#)

Nothing

[Tag omission in text/html:](#)

No omission

[Content attributes:](#)

[Global attributes](#)

`base` — Document base URL

`target` — Default browsing context for hyperlink navigation and form submission

[Accessibility considerations:](#)

For authors

For implementers

[DOM interface:](#)

```
IDL [Exposed=Window]
interface HTMLBaseElement : HTMLElement {
  [HTMLConstructor] constructor();
  [XMLHttpRequests] attribute USVString href;
  [XMLHttpRequests] attribute USVString target;
};
```

The `base` element allows authors to specify the [document base URL](#) for the purposes of [parsing URLs](#), and the name of the default [browsing context](#) for the purposes of [following hyperlinks](#). The element does not [represent](#) any content beyond this information.

There must be no more than one `base` element per document.

A `base` element must have either an `href` attribute, a `target` attribute, or both.

The `href` content attribute, if specified, must contain a [valid URL potentially surrounded by spaces](#).

A `base` element, if it has an `href` attribute, must come before any other elements in the tree that have attributes defined as taking [URLs](#), except the `script` element (its `manifest` attribute isn't affected by `base` elements).

[Note](#)

If there are multiple `base` elements with `href` attributes, all but the first are ignored.

The `target` attribute, if specified, must contain a [valid browsing context name or keyword](#), which specifies which [browsing context](#) is to be used as the default when [hyperlinks](#) and [forms](#) in the [document](#) cause [navigation](#).

A `base` element, if it has a `target` attribute, must come before any elements in the tree that represent [hyperlinks](#).

[Note](#)

If there are multiple `base` elements with `target` attributes, all but the first are ignored.

To get an element's `target`, given an `a`, `area`, or `form` element `element`, run these steps:

1. If `element` has a `target` attribute, then return that attribute's value.
2. If `element`'s `nodeDocument` contains a `base` element with a `target` attribute, then return the value of the `target` attribute of the first such `base` element.
3. Return the empty string.

A `base` element that is the first `base` element with an `href` content attribute [in a document tree](#) has a [frozen base URL](#). The [frozen base URL](#) must be [immediately set](#) for an element whenever any of the following situations occur:

- The `base` element becomes the first `base` element in `treeOrder` with an `href` content attribute in its `nodeDocument`.
- The `base` element is the first `base` element in `treeOrder` with an `href` content attribute in its `nodeDocument`, and its `href` content attribute is changed.

To set the [frozen base URL](#) for an element:

1. Let `document` be `element.nodeDocument`.
2. Let `urlRecord` be the result of [parsing](#) the value of `element.href` content attribute with `document's fallback base URL`, and `document's character encoding`. (Thus, the `base` element isn't affected by itself.)
3. Set `element's frozen base URL` to `document's fallback base URL`, if `urlRecord` is failure or running `Is base allowed for Document?` on the `resulting URL record` and `document` returns "blocked", and to `urlRecord` otherwise.

The `href` IDL attribute, on getting, must return the result of running the following algorithm:

1. Let `document` be `element.nodeDocument`.
2. Let `url` be the value of the `href` attribute of this element, if it has one, and the empty string otherwise.
3. Let `urlRecord` be the result of [parsing](#) `url` with `document's fallback base URL`, and `document's character encoding`. (Thus, the `base` element isn't affected by other `base` elements or itself.)
4. If `urlRecord` is failure, return `url`.
5. Return the [serialization](#) of `urlRecord`.

The `href` IDL attribute, on setting, must set the `href` content attribute to the given new value.

The `target` IDL attribute must [reflect](#) the content attribute of the same name.

[Example](#)

In this example, a `base` element is used to set the [document base URL](#):

```
<!DOCTYPE html>
<html lang="en">
  <head>
    <title>This is an example for the <code>base</code> element</title>
    <base href="https://www.example.com/index.html">
  </head>
  <body>
    <p>Visit the <a href="archives.html">archives</a>.</p>
  </body>
</html>
```

The link in the above example would be a link to "<https://www.example.com/news/archives.html>".

If the element is allowed in the body: **flow content**.
 If the element is allowed in the body: **phrasing content**.
Content in which this element can be used:
 Where **metadata content** is expected.
 In a **noscript** element that is a child of a **head** element.
 If the element is allowed in the body: where **phrasing content** is expected.
Content attributes:
Global attributes:
href — Address of the **link**
crossorigin — How the element handles crossorigin requests
rel — Relationship between the document containing the **hyperlink** and the destination resource
media — Applicable media
integrity — Integrity metadata used in **Subresource Integrity** checks [SRI]
target — Link target of the linked resource
size — Hint for the type of the referenced resource
referrerpolicy — Referrer policy for **fetches** initiated by the element
sizes — Sizes of the icons (for **rel="icon"**)
imageSize — Images to use in different situations (e.g., high-resolution displays, small monitors, etc.)
imageSizeList — Image sizes for different print layouts
color — Potential **color** for a preloaded request (for **rel="prefetch"** and **rel="modulepreload"**)
 Also, the **title** attribute has **special semantics** on this element: Title of the link: [CSS style sheet set name](#).

Accessibility considerations:**For authors:****For implementers:****DOM interface:**

```
IDL(Exposed=Window)
interface HTMLLinkElement : HTMLElement {
  [HTMLConstructor] constructor();
  [CRACTIONS] attribute USVString href;
  [CRACTIONS] attribute DOMString crossorigin;
  [CRACTIONS] attribute DOMString rel; // default ""
  [SameOrigin] attribute DOMString href; // readonly attribute
  [SameOrigin] attribute DOMString hrefLang;
  [CRACTIONS] attribute DOMString integrity;
  [CRACTIONS] attribute DOMString media;
  [SameOrigin] attribute DOMString sizes;
  [CRACTIONS] attribute USVString imageSize;
  [CRACTIONS] attribute DOMString title;
  [CRACTIONS] attribute DOMString referrerPolicy;
} // also has obsolete members
}
HTMLLinkElement includes Integrity;
```

The **link** element allows authors to link their document to other resources.

The destination of the link(s) is given by the **href** attribute, which must be present and must contain a [valid non-empty URL, potentially surrounded by spaces](#). If the **href** attribute is absent, then the element does not define a link.

The **crossorigin** attribute is a [CORS settings attribute](#). It is intended for use with [external resource links](#).

MDN[HTML Link Element](#)

Support in all current engines.

FirefoxYes SafariYes ChromeYes

OperaYes EdgeYes

Edge (Legacy)12+ Internet ExplorerYes

Firefox AndroidYes Safari iOSYes Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidYes

The types of link indicated (the relationships) are given by the value of the **rel** attribute, which, if present, must have a value that is a [unordered set of unique space-separated tokens](#). The [allowed keywords and their meanings](#) are defined in a later section. If the **rel** attribute is absent, has no keywords, or if none of the keywords used are allowed according to the definitions in this specification, then the element does not create any links.

rel's supported tokens are the keywords defined in [HTML link types](#) which are applied to elements, impact the processing model, and are supported by the user agent. The possible **supported tokens** are **alternate**, **dns-prefetch**, **icon**, **modulepreload**, **next**, **pingback**, **preconnect**, **prefetch**, **preload**, **prerender**, **search**, and **stylesheet**; **rel's unsupported tokens** must only include the tokens from this list that the user agent implements the processing model for.

Note

Theoretically a user agent could support the processing model for the **canonical** keyword — if it were a search engine that executed JavaScript. But in practice that's quite unlikely. So in most cases, **canonical** ought not be included in **rel's supported tokens**.

A **link** element must have either a **rel** attribute or an **itemprop** attribute, but not both.

If a **link** element has an **itemprop** attribute, or has a **rel** attribute that contains only keywords that are **body-only**, then the element is said to be *allowed in the body*. This means that the element can be used where **phrasing content** is expected.

Note

If the **rel** attribute is used, the element can only sometimes be used in the **body** of the page. When used with the **itemprop** attribute, the element can be used both in the **head** element and in the **body** of the page, subject to the constraints of the microdata model.

Two categories of links can be created using the **link** element: [links to external resources](#) and [hyperlinks](#). The **link types** section defines whether a particular link type is an external resource or a hyperlink. One **link** element can create multiple links (of which some might be [external resource links](#) and some might be [hyperlinks](#)); exactly which and how many links are created depends on the keywords given in the **rel** attribute. User agents must process the links on a per-link basis, not a per-element basis.

Note

Each link created for a **link** element is handled separately. For instance, if there are two **link** elements with **rel="stylesheet"**, they each count as a separate external resource, and each is affected by its own attributes independently. Similarly, if a single **link** element has a **rel** attribute with the value **next stylesheet**, it creates both a [hyperlink](#) (for the **next** keyword) and an [external resource link](#) (for the **stylesheet** keyword), and they are affected by other attributes (such as **media** or **title**) differently.

Example

For example, the following **link** element creates two [hyperlinks](#) (to the same page):

```
<link rel="author license" href="#about">
```

The two links created by this element are one whose semantic is that the target page has information about the current page's author, and one whose semantic is that the target page has information regarding the license under which the current page is provided.

Note

[Hyperlinks](#) created with the **link** element and its **rel** attribute apply to the whole document. This contrasts with the **rel** attribute of **a** and **area** elements, which indicates the type of a link whose context is given by the link's location within the document.

The exact behavior for [links to external resources](#) depends on the exact relationship, as defined for the relevant [link type](#).

The **media** attribute says which media the resource applies to. The value must be a [valid media query list](#).

The **integrity** attribute represents the [integrity metadata](#) for requests which this element is responsible for. The value is text. The attribute must only be specified on **link** elements that have a **rel** attribute that contains the **stylesheet**, **preload**, or **modulepreload** keyword. [SRI]

The **hrefLang** attribute on the **link** element has the same semantics as the [hreflang attribute on the a element](#).

The **type** attribute gives the [MIME type](#) of the linked resource. It is purely advisory. The value must be a [valid MIME type string](#).

For [external resource links](#), the **type** attribute is used as a hint to user agents so that they can avoid fetching resources they do not support.

The **referrerpolicy** attribute is a [referrer policy attribute](#). It is intended for use with [external resource links](#), where it helps set the [referrer policy](#) used when [fetching and processing the linked resource](#) [REFERRERPOLICY].

The **title** attribute gives the title of the link. With one exception, it is purely advisory. The value is text. The exception is for style sheet links that are [in a document tree](#), for which the **title** attribute defines [CSS style sheet sets](#).

Note

The **title** attribute on **link** elements differs from the global **title** attribute of most other elements in that a link without a title does not inherit the title of the parent element: it merely has no title.

The **imageIcon** attribute may be present, and is a [great attribute](#).

The **imageIcon** and **href** attributes (if **width** descriptor is not used) together contribute the **image sources** to the **source set**.

If the **imageIcon** attribute is present and has any **image candidate strings** using a **width descriptor**, the **imageSizes** attribute must also be present, and is a **sizes** attribute. The **imageSizes** attribute contributes the **source size** to the **source set**.

The **sizes** attribute gives the sizes of icons for visual media. Its value, if present, is merely advisory. User agents may use the value to decide which icon(s) to use if multiple icons are available. If specified, the attribute must have a value that is an [unordered set of unique space-separated tokens](#) which are [ASCII case-insensitive](#). Each value must be either an [ASCII case-insensitive](#) match for the string "**any**", or a value that consists of two [valid non-negative integers](#) that do not have a leading U+0030 DIGIT ZERO character and that are separated by a single U+0078 LATIN SMALL LETTER X or U+0058 LATIN CAPITAL LETTER X character. The attribute must not be specified on **link** elements that do not have a **rel** attribute that specifies the **icon** keyword or the **apple-touch-icon** keyword.

Note

The **apple-touch-icon** keyword is a registered [extension to the predefined set of link types](#), but user agents are not required to support it in any way.

The **as** attribute specifies the [potential destination](#) for a preloaded request for the resource given by the **href** attribute. It is an [enumerated attribute](#). Each [potential destination](#) is a keyword for this attribute, mapping to a state of the same name. The attribute must be specified on **link** elements that have a **rel** attribute that contains the **preload** keyword. It may be specified on **link** elements that have a **rel** attribute that contains the **modulepreload** keyword; in such cases it must have a value which is a [script-like destination](#). For other **link** elements, it must not be specified.

The processing model for how the **as** attribute is used is given in an individual link type's [fetch and process the linked resource](#) algorithm.

Note

The attribute does not have a [missing value default](#) or [invalid value default](#), meaning that invalid or missing values for the attribute map to no state. This is accounted for in the processing model. For [prefetch](#) links, both conditions are an error; for [modulepreload](#) links, a missing value will be treated as "script".

The **color** attribute is used with the [mask-icon](#) link type. The attribute must not be specified on **link** elements that do not have a **rel** attribute that contains the **mask-icon** keyword. The value must be a string that matches the CSS **color** production, defining a suggested color that user agents can use to customize the display of the icon that the user sees when they view your site.

Note

This specification does not have any user agent requirements for the **color** attribute.

Note

The **mask-icon** keyword is a registered [extension to the predefined set of link types](#), but user agents are not required to support it in any way.

The IDL attributes **href**, **hrefLang**, **integrity**, **media**, **rel**, **sizes**, and **type** each must [reflect](#) the respective content attributes of the same name.

The **IDL** attributes **href**, **hrefLang**, **integrity**, **media**, **rel**, **sizes**, and **type** each must [reflect](#) the respective content attributes of the same name.

Note

There is no reflecting IDL attribute for the **color** attribute, but this might be added later.

The **IDL** attribute must [reflect](#) the **as** content attribute, [limited to only known values](#).

The **crossorigin** IDL attribute must [reflect](#) the **crossorigin** content attribute, [limited to only known values](#).

The **referrerpolicy** IDL attribute must [reflect](#) the **referrerpolicy** content attribute, [limited to only known values](#).

The **imageSrcset** IDL attribute must [reflect](#) the **imageSrcset** content attribute.

The **imageSizes** IDL attribute must [reflect](#) the **imageSizes** content attribute.

[HTML Link Element \(rel=list\)](#)

Support in all current engines.

Firefox30+SafariYesChrome54+

OperaYesEdge79+

Edge (Legacy)17+Internet Explorer?

Firefox Android30+Safari iOSYesChrome Android54+WebView Android54+Samsung Internet6.0+Opera AndroidYes

The `rel=list` IDL attribute must [reflect](#) the `rel` content attribute.

4.2.4.1 Processing the `media` attribute

If the link is a [hyperlink](#) then the `media` attribute is purely advisory, and describes for which media the document in question was designed.

However, if the link is an [external resource link](#), then the `media` attribute is prescriptive. The user agent must apply the external resource when the `media` attribute's value [matches the environment](#) and the other relevant conditions apply, and must not apply it otherwise.

The default, if the `media` attribute is omitted, is "all", meaning that by default links apply to all media.

Note

The external resource might have further restrictions defined within that limit its applicability. For example, a CSS style sheet might have some `media` blocks. This specification does not override such further restrictions or requirements.

4.2.4.2 Processing the `type` attribute

If the `type` attribute is present, then the user agent must assume that the resource is of the given type (even if that is not a [valid MIME-type string](#), e.g. the empty string). If the attribute is omitted, but the [external resource link](#) type has a default type defined, then the user agent must assume that the resource is of that type. If the UA does not support the given `MIME-type` for the given link relationship, then the UA should not [fetch and process the linked resource](#); if the UA does support the given `MIME-type` for the given link relationship, then the UA should fetch and process the [linked resource](#) at the appropriate time as specified for the [external resource link](#)'s particular type. If the attribute is omitted, and the [external resource link](#) type does not have a default type defined, but the user agent would [fetch and process the linked resource](#) if the type was known and supported, then the user agent should [fetch and process the linked resource](#) under the assumption that it will be supported.

User agents must not consider the `type` attribute authoritative — upon fetching the resource, user agents must not use the `type` attribute to determine its actual type. Only the actual type (as defined in the next paragraph) is used to determine whether to [apply](#) the resource, not the aforementioned assumed type.

If the [external resource link](#) type defines rules for processing the resource's [Content-Type metadata](#), then those rules apply. Otherwise, if the resource is expected to be an image, user agents may apply the [image sniffing rules](#), with the `official type` being the type determined from the resource's [Content-Type metadata](#), and use the resulting [computed type of the resource](#) as it was the actual type. Otherwise, if neither of these conditions apply or if the user agent opts not to apply the image sniffing rules, then the user agent must use the resource's [Content-Type metadata](#) to determine the type of the resource. If there is no type metadata, but the [external resource link](#) type has a default type defined, then the user agent must assume that the resource is of that type.

Note

The `stylesheet` link type defines rules for processing the resource's [Content-Type metadata](#).

Once the user agent has established the type of the resource, the user agent must apply the resource if it is of a supported type and the other relevant conditions apply, and must ignore the resource otherwise.

Example

If a document contains style sheet links labeled as follows:

```
<link rel="stylesheet" href="#" type="text/plain">
<link rel="stylesheet" href="#" type="text/css">
<link rel="stylesheet" href="#" type="text/less">
```

...then a compliant UA that supported only CSS style sheets would fetch the B and C files, and skip the A file (since `text/plain` is not the `MIME-type` for CSS style sheets).

For files B and C, it would then check the actual types returned by the server. For those that are sent as `text/css`, it would apply the styles, but for those labeled as `text/plain` or any other type, it would not.

If one of the two files was returned without a [Content-Type](#) metadata, or with a syntactically incorrect type like `Content-Type: "null"`, then the default type for `stylesheet` links would kick in. Since that default type is `text/css`, the style sheet *would* nonetheless be applied.

4.2.4.3 Fetching and processing a resource from a `link` element

All [external resource links](#) have a [fetch and process the linked resource](#) algorithm, which takes a `link` element `el`. They also have [linked resource fetch setup steps](#) which take a `link` element `el` and `request`. Individual link types may provide their own [fetch and process the linked resource](#) algorithm, but unless explicitly stated, they use the [default fetch and process the linked resource](#) algorithm. Similarly, individual link types may provide their own [linked resource fetch setup steps](#), but unless explicitly stated, these steps just return true.

The [default fetch and process the linked resource](#), given a `link` element `el`, is as follows:

1. If `el's href` attribute's value is the empty string, then return.
2. Parse the `URL` given by `el's href` attribute, relative to `el's node document`. If that fails, then return. Otherwise, let `url` be the [resulting URL record](#).
3. Let `corsAttributeState` be the current state of the `el's crossorigin` content attribute.
4. Let `request` be the result of [creating a potential-CORS request](#) given `url`, the empty string, and `corsAttributeState`.
5. Set `request's synchronous flag`.
6. Set `request's client` to `el's node document's relevant settings object`.
7. Set `request's cryptographic nonce metadata` to the current value of `el's [[CryptographicNonce]]` internal slot.
8. Set `request's integrity metadata` to the current value of `el's integrity` content attribute.
9. Set `request's referer policy` to the current state of the `el's referrerPolicy` attribute.
10. Run the [linked resource fetch setup steps](#), given `el` and `request`. If the result is false, then return.

11. Run the following steps [in parallel](#):

1. Let `response` be the result of [fetching request](#).
2. Let `success` be true.
3. If `response` is a [network error](#) or its `status` is not an `ok status`, set `success` to false.

Note

Note that content-specific errors, e.g., CSS parse errors or PNG decoding errors, do not affect `success`.

4. If `success` is true, wait for the `link resource's critical subresources` to finish loading.

The specification that defines a link type's `critical subresources` (e.g., CSS) is expected to describe how these subresources are fetched and processed. However, since this is not currently explicit, this specification describes waiting for a `link resource's critical subresources` to be fetched and processed, with the expectation that this will be done correctly.

5. Queue an element task on the [networking task source](#) given `el` to [process the linked resource](#) given `el`, `success`, and `response`.

User agents may opt to only try to [fetch and process](#) such resources when they are needed, instead of proactively fetching all the [external resources](#) that are not applied.

Similar to the [fetch and process the linked resource](#) algorithm, all [external resource links](#) have a [process the linked resource](#) algorithm which takes a `link` element `el`, boolean `success`, and `response response`. Unless an individual link type provides its own [process the linked resource](#) algorithm, the [default process the linked resource](#) algorithm, given a `link` element `el`, and boolean `success` (ignoring `response`) is used:

1. If `success` is true, fire an event named `load` at `el`.
2. Otherwise, fire an event named `error` at `el`.

Unless otherwise specified for a given `rel` keyword, the element must [delay the load event](#) of the element's `node document` until all the attempts to [fetch and process the linked resource](#) and its `critical subresources` are complete. (Resources that the user agent has not yet attempted to fetch and process, e.g., because it is waiting for the resource to be needed, do not [delay the load event](#).)

4.2.4.4 Processing `link` headers

HTTP `link` headers, if supported, must be assumed to come before any links in the document, in the order that they were given in the HTTP message. These headers are to be processed according to the rules given in the relevant specifications. [\[HTTP\]](#) [\[WEBLINK\]](#)

Note

Registration of relation types in HTTP `link` headers is distinct from [HTML link types](#), and thus their semantics can be different from same-named HTML types.

The processing of `link` headers, in particular their influence on a [Document's script-blocking style sheet counter](#), is not defined. See [issue #4224](#) for discussion on integrating this into the spec.

4.2.4.5 Providing users with a means to follow hyperlinks created using the `link` element

Interactive user agents may provide users with a means to [follow the hyperlinks](#) created using the `link` element, somewhere within their user interface. The exact interface is not defined by this specification, but it could include the following information (obtained from the element's attributes, again as defined below), in some form or another (possibly simplified), for each `hyperlink` created with each `link` element in the document:

- The URL of this document and the resource (given by the `rel` attribute)
- The title of the resource (given by the `title` attribute)
- The address of the resource (given by the `href` attribute)
- The language of the resource (given by the `lang` attribute)
- The optimum media for the resource (given by the `media` attribute)

User agents could also include other information, such as the type of the resource (as given by the `type` attribute).

The [activation behavior](#) of `link` elements that create [hyperlinks](#) is to [follow the hyperlink](#) created by the `link` element.

4.2.5 The `meta` element

[MDN](#)

[Element/meta](#)

Support in all current engines.

Firefox1+SafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet ExplorerYes

Firefox Android4+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

[Category:](#)

[Metadata content](#)

If the `name` attribute is present: [flow content](#).

If the `content` attribute is present: [parsing content](#).

If the `http-equiv` attribute is present but not in the `encoding-declaration-state` in a `head` element.
 If the `name` attribute is present but not in the `encoding-declaration-state` in a `meta` element that is a child of a `head` element.
 If the `name` attribute is present: where `metadata-content` is expected.
 If the `name` attribute is present: where `phrasing-content` is expected.

Context model:**Nothing****Taxonomy in `text/html`:****No end tag****Content attributes:****Global attributes:**`name` — Metadata name`http-equiv` — Pragma directive`content` — Value of the element`charset` — Character encoding declaration**Accessibility considerations:****For authors****For implementers****DOM interface:**

```
IDL Exports<#> void httpEquiv(DOMString value);
IDL Exports<#> void name(DOMString value);
IDL Exports<#> void content(DOMString value);
IDL Exports<#> void charset(DOMString value);
// also has obsolete members
```

The `meta` element **represents** various kinds of metadata that cannot be expressed using the `title`, `base`, `link`, `style`, and `script` elements.

The `meta` element can represent document-level metadata with the `name` attribute, pragma directives with the `http-equiv` attribute, and the file's character encoding declaration when an HTML document is serialized to string form (e.g. for transmission over the network or for disk storage) with the `charset` attribute.

Exactly one of the `name`, `http-equiv`, `charset`, and `content` attributes must be specified.

If either `name`, `http-equiv`, or `content` is specified, then the `content` attribute must also be specified. Otherwise, it must be omitted.

The `charset` attribute specifies the character encoding used by the document. This is a character encoding declaration. If the attribute is present, its value must be an ASCII case-insensitive match for the string "utf-8".

Note

The `charset` attribute on the `meta` element has no effect in XML documents, but is allowed in XML documents in order to facilitate migration to and from XML.

There must not be more than one `meta` element with a `charset` attribute per document.

The `content` attribute gives the value of the document metadata or pragma directive when the element is used for those purposes. The allowed values depend on the exact context, as described in subsequent sections of this specification.

If a `meta` element has a `name` attribute, it sets document metadata. Document metadata is expressed in terms of name-value pairs, the `name` attribute on the `meta` element giving the name, and the `content` attribute on the same element giving the value. The name specifies what aspect of metadata is being set; valid names and the meaning of their values are described in the following sections. If a `meta` element has no `content` attribute, then the value part of the metadata name-value pair is the empty string.

The `name` and `content` IDL attributes must `reflect` the respective content attributes of the same name. The IDL attribute `http-equiv` must `reflect` the content attribute `http-equiv`.

4.2.5.1 Standard metadata name**MDN****Element/meta/name**

Support in all current engines.

Firefox 1+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox, Android 4+ Safari iOS Yes Chrome Android Yes Web View Android Yes Samsung Internet Yes Opera Android Yes

This specification defines a few names for the `name` attribute of the `meta` element.

Names are case-insensitive, and must be compared in an ASCII case-insensitive manner.

application-name

The value must be a short free-form string giving the name of the Web application that the page represents. If the page is not a Web application, the `application-name` metadata name must not be used. Translations of the Web application's name may be given, using the `lang` attribute to specify the language of each name.

There must not be more than one `meta` element with a given `language` and where the `name` attribute value is an ASCII case-insensitive match for `application-name` per document.

User agents may use the application name in UI in preference to the page's `title`, since the title might include status messages and the like relevant to the status of the page at a particular moment in time instead of just being the name of the application.

To find the application name to use given an ordered list of languages (e.g. British English, American English, and English), user agents must run the following steps:

1. Let `languages` be the list of languages.
2. Let `default-language` be the `language` of the `document-element`, if any, and if that language is not unknown.
3. If there is a `default-language`, and if it is not the same language as any of the languages in `languages`, append it to `languages`.
4. Let `winning-language` be the first language in `languages` for which there is a `meta` element in the `document` where the `name` attribute value is an ASCII case-insensitive match for `application-name` and whose `language` is the language in question.
- If none of the languages have such a `meta` element, then return; there's no given application name.
5. Return the value of the `content` attribute of the first `meta` element in the `document` in `tree-order` where the `name` attribute value is an ASCII case-insensitive match for `application-name` and whose `language` is `winning-language`.

Note

This algorithm would be used by a browser when it needs a name for the page, for instance, to label a bookmark. The languages it would provide to the algorithm would be the user's preferred languages.

author

The value must be a free-form string giving the name of one of the page's authors.

descriptionThe value must be a free-form string that describes the page. The value must be appropriate for use in a directory of pages, e.g. in a search engine. There must not be more than one `meta` element where the `name` attribute value is an ASCII case-insensitive match for `description` per document.**generator**

The value must be a free-form string that identifies one of the software packages used to generate the document. This value must not be used on pages whose markup is not generated by software, e.g. pages whose markup was written by a user in a text editor.

Example

Here is what a tool called "Frontweaver" could include in its output, in the page's `head` element, to identify itself as the tool used to generate the page:

```
<meta name="generator" content="Frontweaver 8.2">
```

keywordsThe value must be a `set of comma-separated tokens`, each of which is a keyword relevant to the page.**Example**

This page about typefaces on British motorways uses a `meta` element to specify some keywords that users might use to look for the page:

```
<!DOCTYPE HTML>
<html lang="en-GB">
<head>
<title>Typefaces on UK motorways</title>
<meta name="Keywords" content="british,type,face,font,fonts,highway,highways">
</head>
<body>
</body>
```

Note
Many search engines do not consider such keywords, because this feature has historically been used unreliable and even misleadingly as a way to spam search engine results in a way that is not helpful for users.

To obtain the list of keywords that the author has specified as applicable to the page, the user agent must run the following steps:

1. Let `keywords` be an empty list.
2. For each `meta` element with a `name` attribute and a `content` attribute and where the `name` attribute value is an ASCII case-insensitive match for `keywords`.
 1. Split the value of the element's `content` attribute on commas.
 2. Add the resulting tokens, if any, to `keywords`.
3. Remove any duplicates from `keywords`.
4. Return `keywords`. This is the list of keywords that the author has specified as applicable to the page.

User agents should not use this information when there is insufficient confidence in the reliability of the value.

Example

For instance, it would be reasonable for a content management system to use the keyword information of pages within the system to populate the index of a site-specific search engine, but a large-scale content aggregator that used this information would likely find that certain users would try to game its ranking mechanism through the use of inappropriate keywords.

referrerThe value must be a `referrer-policy`, which defines the default `referrer-policy` for the `document`. [REFERRERPOLICY]

If any `meta` elements are inserted into the `document` or removed from the `document`, or existing `meta` elements have their `name` or `content` attributes changed, user agents must run the following algorithm:

1. Let `candidate-elements` be the list of all `meta` elements that meet the following criteria, in `tree-order`:
 - o The element is in a `document`.
 - o The element has a `name` attribute, whose value is an ASCII case-insensitive match for `referrer`.
 - o The element has a `name` attribute, whose value is not the empty string.
 - o The element is a child of the `head` element of the document.
2. For each `element` in `candidate-elements`:
 1. Let `value` be the value of `element`'s `content` attribute, converted to ASCII lowercase.
 2. If `value` is one of the values given in the first column of the following table, then set `value` to the value given in the second column:

Legacy value	Referrer policy
<code>no-referrer</code>	<code>no-referrer</code>
<code>no-referrer-when-downgrade</code>	<code>no-referrer-when-downgrade</code>
<code>no-store</code>	<code>no-store</code>
<code>strict-origin</code>	<code>strict-origin</code>
<code>strict-origin-when-downgrade</code>	<code>strict-origin-when-downgrade</code>
<code>same-origin</code>	<code>same-origin</code>
<code>unsafe-url</code>	<code>unsafe-url</code>

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Legacy value	Referrer policy
default	<code>no-referrer-when-downgrade</code>
always	<code>unsafe-url</code>
origin-when-crossorigin	<code>origin-when-cross-origin</code>

3. If value is a [referrer policy](#), then set element's [node document's referrer policy](#) to policy.

Note
The fact that these steps are applied for each element enables deployment of fallback values for older user agents. [REFERRERPOLICY]

[theme-color](#)

AMDN

[Element/meta/name/theme-color](#)

Support in one engine only.

[FirefoxNoSafariNoChrome](#) 73+

[OperaNoEdge](#) 79+

[Edge \(Legacy\)NoInternet ExplorerNo](#)

[Firefox AndroidNoSafari iOSNoChrome Android80+WebView AndroidNoSamsung Internet6.2+Opera AndroidNo](#)

The value must be a string that matches the CSS `color` production, defining a suggested color that user agents should use to customize the display of the page or of the surrounding user interface. For example, a browser might color the page's title bar with the specified value, or use it as a color highlight in a tab bar or task switcher.

There must not be more than one [meta](#) element with its `name` attribute value set to an [ASCII case-insensitive](#) match for `theme-color` per document.

Example

This standard itself uses "WHATWG green" as its theme color:

```
<!DOCTYPE HTML>
<title>HTML Standard</title>
<meta name="theme-color" content="#337700">
...
```

To obtain a page's theme color, user agents must run the following steps:

1. Let *candidate elements* be the list of all [meta](#) elements that meet the following criteria, in [tree order](#):

- The element is in a [document tree](#).
- The element has a `name` attribute, whose value is an [ASCII case-insensitive](#) match for `theme-color`.
- The element has a `content` attribute.

2. For each element in *candidate elements*:

1. Let *value* be the result of [striping leading and trailing ASCII whitespace](#) from the value of *element's content* attribute.
2. Let *color* be the result of [parsing value](#).
3. If *color* is not failure, then return *color*.

3. Return nothing (the page has no theme color).

If any [meta](#) elements are [inserted into the document](#) or [removed from the document](#), or existing [meta](#) elements have their `name` or `content` attributes changed, user agents must re-run the above algorithm and apply the result to any affected UI.

When using the theme color in UI, user agents may adjust it in implementation-specific ways to make it more suitable for the UI in question. For example, if a user agent intends to use the theme color as a background and display white text over it, it might use a darker variant of the theme color in that part of the UI, to ensure adequate contrast.

4.2.5.2 Other metadata names

Anyone can create and use their own [extensions to the predefined set of metadata names](#). There is no requirement to register such extensions.

However, a new metadata name should not be created in any of the following cases:

- If either the name is a [URL](#), or the value of its accompanying `content` attribute is a [URL](#); in those cases, registering it as an [extension to the predefined set of link types](#) is encouraged (rather than creating a new metadata name).
- If the name is for something expected to have processing requirements in user agents; in that case it ought to be standardized.

Also, before creating and using a new metadata name, consulting the [WHATWG Wiki MetaExtensions page](#) is encouraged — to avoid choosing a metadata name that's already in use, and to avoid duplicating the purpose of any metadata names that are already in use, and to avoid new standardized names clashing with your chosen name. [WHATWGWiki]

Anyone is free to edit the WHATWG Wiki MetaExtensions page at any time to add a metadata name. New metadata names can be specified with the following information:

Keyword

The actual name being defined. The name should not be confusingly similar to any other defined name (e.g. differing only in case).

Brief description

A short non-normative description of what the metadata name's meaning is, including the format the value is required to be in.

Specification

A link to a more detailed description of the metadata name's semantics and requirements. It could be another page on the Wiki, or a link to an external page.

Synonyms

A list of other names that have exactly the same processing requirements. Authors should not use the names defined to be synonyms (they are only intended to allow user agents to support legacy content). Anyone may remove synonyms that are not used in practice; only names that need to be processed as synonyms for compatibility with legacy content are to be registered in this way.

Status

One of the following:

Proposed

The name has not received wide peer review and approval. Someone has proposed it and is, or soon will be, using it.

Ratified

The name has received wide peer review and approval. It has a specification that unambiguously defines how to handle pages that use the name, including when they use it in incorrect ways.

Discontinued

The metadata name has received wide peer review and it has been found wanting. Existing pages are using this metadata name, but new pages should avoid it. The "brief description" and "specification" entries will give details of what authors should use instead, if anything.

If a metadata name is found to be redundant with existing values, it should be removed and listed as a synonym for the existing value.

If a metadata name is added in the "proposed" state for a period of a month or more without being used or specified, then it may be removed from the WHATWG Wiki MetaExtensions page.

If a metadata name is added with the "proposed" status and found to be redundant with existing values, it should be removed and listed as a synonym for the existing value. If a metadata name is added with the "proposed" status and found to be harmful, then it should be changed to "discontinued" status.

Anyone can change the status at any time, but should only do so in accordance with the definitions above.

4.2.5.3 Pragma directives

When the `http-equiv` attribute is specified on a [meta](#) element, the element is a pragma directive.

The `http-equiv` attribute is an [enumerated attribute](#). The following table lists the keywords defined for this attribute. The states given in the first cell of the rows with keywords map to the states to which those keywords map. Some of the keywords are non-conforming, as noted in the last column.

State	Keyword	Notes
Content-Language	<code>content-language</code>	Non-conforming
Encoding declaration	<code>content-type</code>	
Default style	<code>default-style</code>	
Refresh	<code>refresh</code>	
Set-Cookie	<code>set-cookie</code>	Non-conforming
X-UA-Compatible	<code>x-ua-compatible</code>	
Content security policy	<code>content-security-policy</code>	

When a [meta](#) element is [inserted into the document](#), if its `http-equiv` attribute is present and represents one of the above states, then the user agent must run the algorithm appropriate for that state, as described in the following list:

[Content language state \(`http-equiv="content-language"`\)](#)

Note

This feature is non-conforming. Authors are encouraged to use the `lang` attribute instead.

This pragma sets the [pragma-set-default-language](#). Until such a pragma is successfully processed, there is no [pragma-set-default-language](#).

1. If the [meta](#) element has no `content` attribute, then return.

2. If the element's `content` attribute contains a U+002C COMMA character (,) then return.

3. Let *input* be the value of the element's `content` attribute.

4. Let *position* point at the first character of *input*.

5. Skip ASCII whitespace within *input* given *position*.

6. Collect a sequence of code points that are not [ASCII whitespace](#) from *input* given *position*.

7. Let *candidate* be the string that resulted from the previous step.

8. If *candidate* is the empty string, return.

9. Set the `pragma-set-default-language` to *candidate*.

Note

If the value consists of multiple space-separated tokens, tokens after the first are ignored.

[Content declaration state \(`http-equiv="content-type"`\)](#)

The `Encoding declaration` state is just an alternative form of setting the `charset` attribute: it is a [character encoding declaration](#). This state's user agent requirements are all handled by the parsing section of the specification.

For [meta](#) elements with an `http-equiv` attribute in the `Encoding declaration state`, the `content` attribute must have a value that is an [ASCII case-insensitive](#) match for a string that consists of: the literal string "`text/html;`", optionally followed by any number of [ASCII whitespace](#), followed by the literal string "`charset=ut8-s`".

A document must not contain both a [meta](#) element with an `http-equiv` attribute in the `Encoding declaration state` and a [meta](#) element with the `charset` attribute present.

Default style state (`http-equiv="default-style"`)
REFRESH

Alternative style sheets

Support in one engine only.

Firefox?Safari?Chrome?

Opera?Yes?Edge?

Edge (Legacy)?Internet Explorer?

Firefox?Android?Safari?iOS?Chrome?Android?WebView?Android?Samsung Internet?Opera?Android?

This pragma sets the `name` of the default [CSS style sheet set](#).

1. If the `meta` element has no `content` attribute, or if that attribute's value is the empty string, then return.

2. Change the preferred CSS style sheet set name with the name being the value of the element's `content` attribute. [\[CSSOM\]](#)

Refresh state (`http-equiv="refresh"`)

This pragma acts as timed redirect.

A `Document` object has an associated *will declaratively refresh* (a boolean). It is initially false.

1. If the `meta` element has no `content` attribute, or if that attribute's value is the empty string, then return.

2. Let `input` be the value of the element's `content` attribute.

3. Run the [shared declarative refresh steps](#) with the `meta` element's `node.document`, `input`, and the `meta` element.

The shared declarative refresh steps, given a `Document` object `document`, string `input`, and optionally a `meta` element `meta`, are as follows:

1. If `document's "will declaratively refresh"` is true, then return.

2. Let `position` point at the first `code point` of `input`.

3. [Skip ASCII whitespace](#) within `input` given `position`.

4. Let `time` be 0.

5. [Collect a sequence of code points](#) that are [ASCII digits](#) from `input` given `position`, and let the result be `timeString`.

6. If `timeString` is the empty string, then:

1. If the `code point` in `input` pointed to by `position` is not U+002E (.), then return.

7. Otherwise, set `time` to the result of parsing `timeString` using the [rules for parsing non-negative integers](#).

8. [Collect a sequence of code points](#) that are [ASCII digits](#) and U+002E FULL STOP characters (.) from `input` given `position`. Ignore any collected characters.

9. Let `urlRecord` be `document's URL`.

10. If `position` is not past the end of `input`, then:

1. If the `code point` in `input` pointed to by `position` is not U+003B (;), U+002C (,), or [ASCII whitespace](#), then return.

2. [Skip ASCII whitespace](#) within `input` given `position`.

3. If the `code point` in `input` pointed to by `position` is U+003B (;) or U+002C (,), then advance `position` to the next `code point`.

4. [Skip ASCII whitespace](#) within `input` given `position`.

11. If `position` is not past the end of `input`, then:

1. Let `uriString` be the substring of `input` from the `code point` at `position` to the end of the string.

2. If the `code point` in `input` pointed to by `position` is U+0055 (U) or U+0075 (u), then advance `position` to the next `code point`. Otherwise, jump to the step labeled *skip quotes*.

3. If the `code point` in `input` pointed to by `position` is U+0052 (R) or U+0072 (r), then advance `position` to the next `code point`. Otherwise, jump to the step labeled *parse*.

4. If the `code point` in `input` pointed to by `position` is U+004C (L) or U+006C (l), then advance `position` to the next `code point`. Otherwise, jump to the step labeled *parse*.

5. [Skip ASCII whitespace](#) within `input` given `position`.

6. If the `code point` in `input` pointed to by `position` is U+003D (=), then advance `position` to the next `code point`. Otherwise, jump to the step labeled *parse*.

7. [Skip ASCII whitespace](#) within `input` given `position`.

8. *Skip quotes*: If the `code point` in `input` pointed to by `position` is U+0027 (') or U+0022 ("'), then let `quote` be that `code point`, and advance `position` to the next `code point`. Otherwise, let `quote` be the empty string.

9. Set `uriString` to the substring of `input` from the `code point` at `position` to the end of the string.

10. If `quote` is not the empty string, and there is a `code point` in `uriString` equal to `quote`, then truncate `uriString` at that `code point`, so that it and all subsequent `code points` are removed.

11. *Parse*: Parse `uriString` relative to `document`. If that fails, return. Otherwise, set `urlRecord` to the [resulting URL record](#).

12. Set `document's "will declaratively refresh"` to true.

13. Perform one or more of the following steps:

- After the refresh has come due (as defined below), if the user has not canceled the redirect and, if `meta` is given, `document's active sandboxing flag set` does not have the [sandboxed automatic features browsing context flag](#) set, then [navigate document's browsing context to urlRecord](#), with [replacement enabled](#), and with `document's browsing context as the source browsing context`.

For the purposes of the previous paragraph, a refresh is said to have come due as soon as the *later* of the following two conditions occurs:

- At least `time` seconds have elapsed since `document's completely loaded`, adjusted to take into account user or user agent preferences.

- If `meta` is given, at least `time` seconds have elapsed since `meta was inserted into the document's document`, adjusted to take into account user or user agent preferences.

Note

It is important to use `document here`, and not `meta's node.document`, as that might have changed between the initial set of steps and the refresh coming due and `meta` is not always given (in case of the HTTP '`refresh`' header).

- Provide the user with an interface that, when selected, [navigates a browsing context to urlRecord](#), with `document's browsing context as the source browsing context`.

- Do nothing.

In addition, the user agent may, as with anything, inform the user of any and all aspects of its operation, including the state of any timers, the destinations of any timed redirects, and so forth.

For `meta` elements with `http-equiv` attribute in the [Refresh state](#), the `content` attribute must have a value consisting either of:

- just a [valid non-negative integer](#), or
- a [valid non-negative integer](#), followed by a U+003B SEMICOLON (;), followed by one or more [ASCII whitespace](#), followed by a substring that is an [ASCII case-insensitive](#) match for the string "`URL`", followed by a U+003D EQUALS SIGN character (=), followed by a [valid URL string](#) that does not start with a literal U+0027 APOSTROPHE ('') or U+0022 QUOTATION MARK ("") character.

In the former case, the integer represents a number of seconds before the page is to be reloaded; in the latter case the integer represents a number of seconds before the page is to be replaced by the page at the given [URL](#).

Example

A news organization's front page could include the following markup in the page's `head` element, to ensure that the page automatically reloads from the server every five minutes:

```
<meta http-equiv="Refresh" content="300">
```

Example

A sequence of pages could be used as an automated slide show by making each page refresh to the next page in the sequence, using markup such as the following:

```
<meta http-equiv="Refresh" content="20; URL=page4.html">
```

SetCookie state (`http-equiv="set-cookie"`)

This pragma is non-conforming and has no effect.

User agents are required to ignore this pragma.

X-UA-Compatible state (`http-equiv="x-ua-compatible"`)

In practice, this pragma encourages Internet Explorer to more closely follow the specifications.

For `meta` elements with an `http-equiv` attribute in the [X-UA-Compatible state](#), the `content` attribute must have a value that is an [ASCII case-insensitive](#) match for the string "`IE=<version>`".

User agents are required to ignore this pragma.

Content security policy state (`http-equiv="Content-Security-Policy"`)

This pragma enforces a Content Security Policy on a `Document`. [\[CSP\]](#)

1. If the `meta` element is not a child of a `head` element, return.
2. If the `meta` element has no `content` attribute, or if that attribute's value is the empty string, then return.
3. Let `policy` be the result of executing Content Security Policy's [parse a serialized Content Security Policy](#) algorithm on the `meta` element's `content` attribute's value, with a source of "meta", and a disposition of "enforce".
4. Remove all occurrences of the `report-uri`, `frame-ancestors`, and `sandbox` directives from `policy`.
5. Enforce the policy `policy`.

For `meta` elements with an `http-equiv` attribute in the [Content security policy state](#), the `content` attribute must have a value consisting of a [valid Content Security Policy](#), but must not contain any `report-uri`, `frame-ancestors`, or `sandbox` directives. The Content Security Policy given in the `content` attribute will be enforced upon the current document. [\[CSP\]](#)

Example

A page might choose to mitigate the risk of cross-site scripting attacks by preventing the execution of inline JavaScript, as well as blocking all plugin content, using a policy such as the following:

```
<meta http-equiv="Content-Security-Policy" content="script-src 'self'; object-src 'none'">
```

There must not be more than one `meta` element with any particular state in the document at a time.

4.2.5.4 Specifying the document's character encoding

A character encoding declaration is a mechanism by which the `character encoding` used to store or transmit a document is specified.

The Encoding standard requires use of the [UTF-8 character encoding](#) and requires use of the "`x-x-`" [encoding label](#) to identify it. Those requirements necessitate that the document's `character encoding declaration`, if it exists, specifies an `encoding label` using an [ASCII case-insensitive](#) match for "`utf-8`". Regardless of whether a `character encoding declaration` is present or not, the actual `character encoding` used to encode the document must be [UTF-8 \[ENCODING\]](#).

The following restrictions also apply:

- The character encoding declaration must be serialized without the use of [character references](#) or character escapes of any kind.
- The element containing the character encoding declaration must be serialized completely within the first 1024 bytes of the document.

In addition, due to a number of restrictions on [meta](#) elements, there can only be one [meta](#)-based character encoding declaration per document.

If an [HTML](#) document does not start with a BOM, and its [encoding](#) is not explicitly given by [Content-Type](#) metadata, and the document is not [an iframe's doc](#), then the encoding must be specified using a [meta](#) element with a [charset](#) attribute or a [meta](#) element with an [http-equiv](#) attribute in the [Encoding declaration state](#).

Note

A character encoding declaration is required (either in the [Content-Type](#) metadata or explicitly in the file) even when all characters are in the ASCII range, because a character encoding is needed to process non-ASCII characters entered by the user in forms, in URLs generated by scripts, and so forth.

Using non-UTF-8 encodings can have unexpected results on form submission and URL encodings, which use the [document's character encoding](#) by default.

If the document is [an iframe's doc](#), the document must not have a [character encoding declaration](#). (In this case, the source is already decoded, since it is part of the document that contained the [iframe](#).)

In XML, the XML declaration should be used for inline character encoding information, if necessary.

Example

In HTML, to declare that the character encoding is [UTF-8](#), the author could include the following markup near the top of the document (in the [head](#) element):

```
<meta charset="utf-8">
```

In XML, the XML declaration would be used instead, at the very top of the markup:

```
<?xml version="1.0" encoding="utf-8"?>
```

4.2.6 The `style` element

Metadata content

Contexts in which this element can be used:

Where [metadata content](#) is expected.

In a [script](#) element that is a child of a [head](#) element.

Content model:

Text that gives a [conformant style sheet](#).

Tag omission in `text/html`:

Another tag is omitted.

Content attributes:

[Global attributes](#)

[media](#) – Applicable media

Also, the [title](#) attribute has [special semantics](#) on this element: [CSS style sheet set name](#).

Accessibility considerations:

For authors:

For implementers:

DOM interface:

```
IDL(Exposed=Windows)
interface HTMLStyleElement : HTMLElement {
  [DOMConstructor] constructor();
  [CSSReactions] attribute DOMString media;
  // also has obsolete members
};
```

[HTMLStyleElement](#) includes [LinkStyle](#)

The [style](#) element allows authors to embed CSS style sheets in their documents. The [style](#) element is one of several inputs to the styling processing model. The element does not [represent](#) content for the user.

MDN

[HTML: StyleElement: media](#)

Support in all current engines.

FirefoxYesSafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet ExplorerYes

Firefox AndroidYes Safari iOSYes Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidYes

The [media](#) attribute says which media the styles apply to. The value must be a [valid media query list](#). The user agent must apply the styles when the [media](#) attribute's value [matches the environment](#) and the other relevant conditions apply, and must not apply them otherwise.

Note

The styles might be further limited in scope, e.g. in CSS with the use of [@media](#) blocks. This specification does not override such further restrictions or requirements.

The default, if the [media](#) attribute is omitted, is "`all`", meaning that by default styles apply to all media.

MDN

[Alternative style sheets](#)

Support in one engine only.

Firefox3+Safari?Chrome?

OperaYesEdge?

Edge (Legacy)?Internet Explorer?

Firefox Android4+Safari iOS?Chrome Android?WebView Android?Samsung Internet?Opera Android?

The [title](#) attribute on [style](#) elements defines [CSS style sheet sets](#). If the [style](#) element has no [title](#) attribute, then it has no title; the [title](#) attribute of ancestors does not apply to the [style](#) element. If the [style](#) element is not [in a document tree](#), then the [title](#) attribute is ignored. [\[CSSOM\]](#)

Note

The [title](#) attribute on [style](#) elements, like the [title](#) attribute on [link](#) elements, differs from the global [title](#) attribute in that a [style](#) block without a title does not inherit the title of the parent element: it merely has no title.

The [child text content](#) of a [style](#) element must be that of a [conformant style sheet](#).

The user agent must run the [update a style block](#) algorithm whenever one of the following conditions occur:

- The element is popped off the [stack of open elements](#) of an [HTML parser](#) or [XML parser](#).
- The element is not on the [stack of open elements](#) of an [HTML parser](#) or [XML parser](#), and it [becomes connected](#) or [disconnected](#).
- The element's [children changed](#) runs.

The update a style block algorithm is as follows:

1. Let element be the [style](#) element.
2. If element has an [associated CSS style sheet](#), [remove the CSS style sheet](#) in question.
3. If element's [root](#) is neither a [shadow root](#) nor a [document](#), then return.
4. If element's [type](#) attribute is present and its value is neither the empty string nor an [ASCII case-insensitive](#) match for "`text/css`", then return.

Note
In particular, a `type` value with parameters, such as "`*text/css; charset=utf-8`", will cause this algorithm to return early.

5. If the [Should element's inline behavior be blocked by Content Security Policy?](#) algorithm returns "Blocked" when executed upon the [style](#) element, "`style`", and the [style](#) element's [child text content](#), then return. [\[CSP\]](#)

6. Create a [CSS style sheet](#) with the following properties:

types

`text/css`

owner node

element

media

The [media](#) attribute of [element](#).

Note

This is a reference to the (possibly absent at this time) attribute, rather than a copy of the attribute's current value. [CSSOM](#) defines what happens when the attribute is dynamically set, changed, or removed.

title

Note
 Again, this is a reference to the attribute.

alternate flag

Unset.

origin-clean flag

Set.

location
parent CSS style sheet
owner CSS rule

null

disabled flag

Left at its default value.

CSS rules

Left uninitialized.

This doesn't seem right. Presumably we should be using the element's `childTextContent`? Tracked as [issue #2997](#).

Once the attempts to obtain the style sheet's `critical subresources`, if any, are complete, or, if the style sheet has no `critical subresources`, once the style sheet has been parsed and processed, the user agent must run these steps:

1. Let `element` be the `style` element associated with the style sheet in question.

2. Let success be true.

3. If the attempts to obtain any of the style sheet's `critical subresources` failed for any reason (e.g., DNS error, HTTP 404 response, a connection being prematurely closed, unsupported Content-Type), set success to false.

Note

Note that content-specific errors, e.g., CSS parse errors or PNG decoding errors, do not affect success.

4. Queue an element task on the `networkingTaskSource` given `element` and the following steps:

1. If success is true, fire an event named `load` at `element`.

2. Otherwise, fire an event named `error` at `element`.

3. If `element` contributes a script-blocking style sheet:

1. Assert: `element's node document's script-blocking style sheet counter` is greater than 0.

2. Decrement `element's node document's script-blocking style sheet counter` by 1.

The element must `delay the load event` of the element's `node document` until all the attempts to obtain the style sheet's `critical subresources`, if any, are complete.

Note

This specification does not specify a style system, but CSS is expected to be supported by most Web browsers. [\[CSS\]](#)

The `media` IDL attribute must `reflect` the content attribute of the same name.

The `playstyle` interface is also implemented by this element. [\[CSSOM\]](#)

Example

The following document has its stress emphasis styled as bright red text rather than italics text, while leaving titles of works and Latin words in their default italics. It shows how using appropriate elements enables easier restyling of documents.

```
<!DOCTYPE html>
<html lang="en-US">
<title>My favorite book</title>
<body>
  <body> ( color: black; background: white; )
  em { font-style: normal; color: red; }
</head>
<body>
  <p><em>My favorite</em> book of all time has <em>got</em> to be
  <em>Cat's Life</em>. It is a book by F. Rahmel that talks
  about the <i lang="la">Pellis Catus</i> in modern human society.</p>
</body>
</html>
```

4.2.7 Interactions of styling and scripting

If the style sheet referenced no other resources (e.g., it was an internal style sheet given by a `style` element with no `@import` rules), then the style rules must be `immediately` made available to script; otherwise, the style rules must only be made available to script once the `event loop` reaches its `update the rendering` step.

An element `e` in the context of a `document` of an [HTML parser](#) or [XML parser](#) contributes a script-blocking style sheet if all of the following conditions are true:

- `e` was created by that `document`'s parser.
- `e` is either a `style` element or a `link` element that was an [external resource link that contributes to the styling processing model](#) when the `e` was created by the parser.
- If the `e` is a `link` element, its `media` attribute's value matches the environment.
- `e`'s style sheet was enabled when the element was created by the parser.
- The last time the `event loop` reached step 1, `e's top` was that `document`.
- The user agent hasn't given up on loading that particular style sheet yet. A user agent may give up on loading a style sheet at any time.

Note

Giving up on a style sheet before the style sheet loads, if the style sheet eventually does still load, means that the script might end up operating with incorrect information. For example, if a style sheet sets the color of an element to green, but a script that inspects the resulting style is executed before the sheet is loaded, the script will find that the element is black (or whatever the default color is), and might thus make poor choices (e.g., deciding to use black as the color elsewhere on the page, instead of green). Implementers have to balance the likelihood of a script using incorrect information with the performance impact of doing nothing while waiting for a slow network request to finish.

It is expected that counterparts to the above rules also apply to `XML-stylesheet`? Pls and HTTP `"link"` headers. However, this has not yet been thoroughly investigated.

A `Document` has a `script-blocking style sheet counter`, which is a number, initially 0.

A `Document` has a style sheet that is blocking scripts if its `script-blocking style sheet counter` is greater than 0, or if that `Document` has a non-null `browsing context` whose `container document` is non-null and has a `script-blocking style sheet counter` greater than 0.

A `Document` has no style sheet that is blocking scripts if it does not `have a style sheet that is blocking scripts` as defined in the previous paragraph.

[For authors](#)
[For implementors](#)
[DOM interface](#)

```
IDL Exposed=Window
interface HTMLBodyElement : HTMLElement {
  [HTMLConstructor] constructor();
  // also has obsolete members
};

HTMLBodyElement includes WindowEventHandlers;
```

The `body` element represents the contents of the document.

In conforming documents, there is only one `body` element. The `document.body` IDL attribute provides scripts with easy access to a document's `body` element.

Note
 Some DOM operations (for example, parts of the `drag and drop` model) are defined in terms of "[the body element](#)". This refers to a particular element in the DOM, as per the definition of the term, and not any arbitrary `body` element.

The `body` element exposes as `event handler content attributes` a number of their `event handlers` of the `Window` object. It also mirrors their `event handler IDL attributes`.

The `event handlers` of the `Window` object named by the `user-agent-reflecting body element event handler set`, exposed on the `body` element, replace the generic `event handlers` with the same names normally supported by [HTML elements](#).

Example
 Thus, for example, a bubbling `error` event dispatched on a child of the `body element` of a `document` would first trigger the `error event handler content attributes` of that element, then that of the root `traj` element, and only then would it trigger the `error event handler content attribute` on the `body` element. This is because the event would bubble from the target, to the `body`, to the `html`, to the `document`, to the `Window`, and the `event handler` on the `body` is watching the `Window` not the `body`. A regular event listener attached to the `body` using `addEventListner()`, however, would be run when the event bubbled through the `body` and not when it reaches the `Window` object.

Example

This page updates an indicator to show whether or not the user is online:

```
<!DOCTYPE HTML>
<html lang="en">
<title>Online or offline?</title>
<script>
function update(online) {
  document.getElementById('status').textContent =
  online ? 'Online' : 'Offline';
}
</script>
</head>
<body ononline="update(true)"
      onoffline="update(false)">
<p>You are:<span id="status">(Unknown)</span></p>
</body>
</html>
```

Neither tag is omitted.

Content attributes:

`itemprop`

Accessibility considerations:

For authors

For implementors

DOM interface

Uses `HTMLElement`.

The `article` element represents a complete, or self-contained, composition in a document, page, application, or site and that is, in principle, independently distributable or reusable, e.g. in syndication. This could be a forum post, a magazine or newspaper article, a blog entry, a user-submitted comment, an interactive widget or gadget, or any other independent item of content.

When `article` elements are nested, the inner `article` elements represent articles that are in principle related to the contents of the outer article. For instance, a blog entry on a site that accepts user-submitted comments could represent the comments as `article` elements nested within the `article` element for the blog entry.

Author information associated with an `article` element (q.v. the `address` element) does not apply to nested `article` elements.

Note

When used specifically with content to be redistributed in syndication, the `article` element is similar in purpose to the `entry` element in Atom. [\[ATOM\]](#)

Note

The schema.org microdata vocabulary can be used to provide the publication date for an `article` element, using one of the CreativeWork subtypes.

When the main content of the page (i.e. excluding footers, headers, navigation blocks, and sidebars) is all one single self-contained composition, that content may be marked with an `article`, but it is technically redundant in that case (since it's self-evident that the page is a single composition, as it is a single document).

Example

This example shows a blog post using the `article` element, with some schema.org annotations:

```
<article itemscope itemtype="http://schema.org/BlogPosting">
<h1 itemprop="headline">The Very First Rule of Lite</h1>
<p itemprop="datePublished" datetime="2009-10-09T03:00:00-07:00">3 days ago</p>
<header>
<img itemprop="url" href="commented" alt="commented icon" />
<p>It's there's a microphone anywhere near you, assume it's hot and sending whatever you're saying to the world. Seriously.</p>
</header>
<footnote>
<img itemprop="url" href="#" alt="comment icon" />
<p>It's there's a microphone anywhere near you, assume it's hot and sending whatever you're saying to the world. Seriously.</p>
</footnote>
<section>
<h2>Comments</h2>
<ul>
<li itemscope itemtype="http://schema.org/UserComment" id="c1">
<img itemprop="comment" href="#" alt="comment icon" />
<link itemprop="url" href="#" alt="comment url" />
<p>Created by: <span itemprop="creator" itemscope itemtype="http://schema.org/Person">
<span>George Washington</span>
</span></p>
<img itemprop="commentTime" datetime="2009-10-10T15:15:00-07:00" alt="comment time" />
</li>
<li>
<p>You know, especially when talking about your lobbyist friends!</p>
</li>
<li itemscope itemtype="http://schema.org/UserComment" id="c2">
<img itemprop="comment" href="#" alt="comment icon" />
<link itemprop="url" href="#" alt="comment url" />
<p>Poster by: <span itemprop="creator" itemscope itemtype="http://schema.org/Person">
<span>George Hammond</span>
</span></p>
<img itemprop="commentTime" datetime="2009-10-10T15:15:00-07:00" alt="comment time" />
<img alt="comment reply icon" />
<p>Hey, you have the same first name as me.</p>
</li>
</ul>
</section>
</article>
```

Notice the use of `footer` to give the information for each comment (such as who wrote it and when): the `footer` element can appear at the start of its section when appropriate, such as in this case. (Using `header` in this case wouldn't be wrong either; it's mostly a matter of authoring preference.)

Example

In this example, `article` elements are used to host widgets on a portal page. The widgets are implemented as [customized built-in elements](#) in order to get specific styling and scripted behavior.

```
<!DOCTYPE HTML>
<html lang="en">
<title>A Portal</title>
<script src="scripts/widgets.js">
</script>
<article is="stock-widget">
<div>Stocks</div>
<table>
<thead> <tr> <th> Stock </th> <th> Value </th> <th> Delta </th> </tr>
</thead> <tbody> <tr> <td> Stock A </td> <td> $100.00 </td> <td> +10.00 </td> </tr>
<tr> <td> Stock B </td> <td> $200.00 </td> <td> -20.00 </td> </tr>
<tr> <td> Stock C </td> <td> $300.00 </td> <td> +30.00 </td> </tr>
</tbody> </table>
<input type="button" value="Refresh" onclick="this.parentElement.refresh()"/>
</article>
<article is="news-widget">
<h2>News</h2>
<template>
<li>
<img alt="image" />
<strong> <a href="#">Headline</a> </strong>
</li>
</template>
<input type="button" value="Refresh" onclick="this.parentElement.refresh()"/>
</article>
```

4.3.3 The `section` element

Flow content

Tag omission in text/html:

Neither tag is omissionable.

Content attributes:

Global attributes

Accessibility considerations:

For authors

For implementers

DOM interface

Uses `HTMLElement`.The `<section>` element represents a generic section of a document or application. A section, in this context, is a thematic grouping of content, typically with a heading.Example

Examples of sections would be chapters, the various tabbed pages in a tabbed dialog box, or the numbered sections of a thesis. A Web site's home page could be split into sections for an introduction, news items, and contact information.

NoteAuthors are encouraged to use the `<article>` element instead of the `<section>` element when it would make sense to syndicate the contents of the element.NoteThe `<section>` element is not a generic container element. When an element is needed only for styling purposes or as a convenience for scripting, authors are encouraged to use the `<div>` element instead. A general rule is that the `<section>` element is appropriate only if the element's contents would be listed explicitly in the document's outline.Example

In the following example, we see an article (part of a larger Web page) about apples, containing two short sections.

```
<article>
  <hgroup>
    <h1>Apples</h1>
    <h2>Tasty, delicious fruit!</h2>
  </hgroup>
  <p>Apple is the pomaceous fruit of the apple tree.</p>
  <section>
    <h3>Red Delicious</h3>
    <p>Red Delicious apples are the most common found in many supermarkets.</p>
  </section>
  <h3>Granny Smith</h3>
  <p>These juicy, green apples make a great filling for pies and crisps.</p>
</section>
</article>
```

Notice how the use of `<section>` means that the author can use `h1` elements throughout, without having to worry about whether a particular section is at the top level, the second level, the third level, and so on.Example

Here is a graduation programme with two sections, one for the list of people graduating, and one for the description of the ceremony. (The markup in this example features an uncommon style sometimes used to minimize the amount of inter-element whitespace.)

```
<!DOCTYPE html>
<html lang="en">
  <head>
    <title>Graduation Ceremony Summer 2022</title>
  </head>
  <body>
    <h1>Graduation</h1>
    <h2>Ceremony</h2>
    <h3>Opening Procession</h3>
    <p>>Speech by Validatororian</p>
    <p>>Speech by Class President</p>
    <p>>Presentation of Diplomas</p>
    <p>>Closing Speech by Headmaster</p>
  </section>
  <section>
    <h3>Graduates</h3>
    <ul>
      <li>Molly Carpenter</li>
      <li>Anastasia Lucido</li>
      <li>Emanuele McCoy</li>
      <li>Garrison Murphy</li>
      <li>Thomas Raith</li>
      <li>Susan Rodriguez</li>
    </ul>
  </section>
</body>
</html>
```

Example

In this example, a book author has marked up some sections as chapters and some as appendices, and uses CSS to style the headers in these two classes of section differently.

```
<style>
  section { border: double medium margin; 2em; }
  section.chapter h1 { font: 2em Roboto, Helvetica Neue, sans-serif; }
  section.appendix h1 { font: small-caps 2em Roboto, Helvetica Neue, sans-serif; }
</style>
<header>
  <h1>Book</h1>
  <h2>A sample with not much content</h2>
</header>
<div>Published by Dummy Publicorp Ltd.</div>
<header>
  <h1>First Chapter</h1>
  <p>This is the first of my chapters. It doesn't say much.</p>
  <p>It has two paragraphs!</p>
</header>
<section class="chapter">
  <h2>Second Chapter</h2>
  <p>Bla bla bla, bla bla bla, Boon.</p>
</section>
<section class="chapter">
  <h2>Chapter Three: A Further Example</h2>
  <p>It's not like a battle between brightness and earthtones would go on</p>
  <p>It might ruin my story.</p>
</section>
<section class="appendix">
  <h2>Appendix A: Overview of Examples</h2>
  <p>Theoretical demonstrations.</p>
</section>
<section class="appendix">
  <h2>Appendix B: Writing Remarks</h2>
  <p>Hopefully this long example shows that you <em>can</em> style sections, so long as they are used to indicate actual sections.</p>
</section>
```

4.3.4 The `nav` elementMDNElement/nav

Support in all current engines.

Firefox4+Safari5+Chrome5+

Opera11.1+Edge79+

Contexts in which this element can be used:Where flow content is expected.Content model:

Flow content

Tag omission in text/html:

Neither tag is omissionable.

Content attributes:

Global attributes

Accessibility considerations:

For authors

For implementers

DOM interface

Uses `HTMLElement`.The `<nav>` element is a section of a page that links to other pages or parts within the page, a section with no intrinsic value.

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Note
Not all groups of links on a page need to be in a `<nav>` element — the element is primarily intended for sections that consist of major navigation blocks. In particular, it is common for footers to have a short list of links to various pages of a site, such as the terms of service, the home page, and a copyright page. The `<meta>` element alone is sufficient for such cases; while a `<nav>` element can be used in such cases, it is usually unnecessary.

Note
User agents (such as screen readers) that are targeted at users who can benefit from navigation information being omitted in the initial rendering, or who can benefit from navigation information being immediately available, can use this element as a way to determine what content on the page to initially skip or provide on request (or both).

Example

In the following example, there are two `<nav>` elements, one for primary navigation around the site, and one for secondary navigation around the page itself.

```
<body>
<h1>The Wild Center Of Exampland</h1>
<nav>
  <ul>
    <li><a href="#">Home</a></li>
    <li><a href="#">Events</a></li>
    ...more...
  </ul>
</nav>
<article>
  <h2>Sheep in Exampland</h2>
  <p>Written by A. N. Other.</p>
  </header>
  <ul>
    <li><a href="#public">Public demonstrations</a></li>
    <li><a href="#destroy">Demolitions</a></li>
    ...more...
  </ul>
</div>
<div id="public">
  <h1>Public demonstrations</h1>
  <p>...more...</p>
  <section id="destroy">
    <h1>Demolitions</h1>
    <p>...more...</p>
  </section>
  ...more...
</div>
<footnote>
  <a href="#">Edit</a> | <a href="#">Delete</a> | <a href="#">Rename</a></p>
</footnote>
</article>
<p><small>© copyright 1998 Exampland Emperor</small></p>
</body>
```

Example

In the following example, the page has several places where links are present, but only one of those places is considered a navigation section.

```
<body itemscope itemtype="http://schema.org/Blog">
<header>
  <h1>Wake up sheep!</h1>
  <p><a href="#">About Us</a> | <a href="#">Contact Us</a> | <a href="#">Blog</a> | <a href="#">Forums</a></p>
  <p>Last Modified: <span itemtype="dateModified">2009-04-01</span></p>
<nav>
  <h1>Navigation</h1>
  <ul>
    <li><a href="#">Index of all articles</a></li>
    <li><a href="#">Today.html</a>>Things sheep need to wake up for today</li>
    <li><a href="#">Successful.html</a>>Sheep we have managed to wake</li>
  </ul>
</nav>
<main>
  <article itemscope="BlogPost" itemtype="http://schema.org/BlogPosting">
    <header>
      <h1>My day at the Beach</h1>
    <div itemprop="articleBody">
      <p>Today I went to the beach and had a lot of fun.</p>
      <p>More content...</p>
    </div>
    <footer>
      <time itemprop="datePublished" datetime="2009-10-10">Thursday</time></p>
    </article>
    <article>
      <h2>Blog posts...</h2>
    </article>
    <div>
      <p>Copyright ©<br/>
        <span itemprop="copyrightYear">2010</span><br/>
        <span itemprop="copyrightHolder">The Example Company</span></p>
    </div>
    <nav>
      <ul>
        <li><a href="#">About.html</a> | <a href="#">Privacy Policy</a> | <a href="#">Contact Us</a></li>
      </ul>
    </nav>
  </main>
</body>
```

You can also see microdata annotations in the above example that use the schema.org vocabulary to provide the publication date and other metadata about the blog post.

Example

A `<nav>` element doesn't have to contain a list, it can contain other kinds of content as well. In this navigation block, links are provided in prose:

```
<nav>
  <h1>Navigation</h1>
  <p>You are on my home page. To the south lies <a href="#">Blog</a> my  

  <a href="#">About</a> page. You can hear the sounds of battle can be heard. To the west  

  you can see a large mountain, upon which many <a href="#">sheep</a> are grazing.  

  If you look closely, you can spy a little figure who appears to be me, desperately  

  scribbling a <a href="#">thesis</a>. </p>
  <p>To the north is a small opening in the mountain wall. This opening is labeled <a href="https://games.example.com/">Games</a>. Another more  

  boring-looking exit is labeled <a href="#">Logout</a>. </p>
  <p>To the east lies a dark and dank <a href="#">about</a> contacts  

  page</a>. Cobwebs cover its disused entrance, and at one point you  

  see a rat run quickly out of the page.</p>
</nav>
```

Example

In this example, `<nav>` is used in an e-mail application, to let the user switch folders:

```
<nav>
  <input type="button" value="Compose" onclick="compose()"/></p>
  <nav>
    <h1>Folders</h1>
    <ul>
      <li><a href="#">inbox</a> onclick="return openFolder(this.href)">Inbox</li>
      <li><a href="#">spam</a> onclick="return openFolder(this.href)">Spam</li>
      <li><a href="#">drafts</a> onclick="return openFolder(this.href)">Drafts</li>
      <li><a href="#">trash</a> onclick="return openFolder(this.href)">Trash</li>
      <li><a href="#">customers</a> onclick="return openFolder(this.href)">Customers</li>
    </ul>
  </nav>
```

4.3.5 The `<aside>` element

MDN

Element/aside

Where `flow content` is expected.

Content model:

Flow content

Tag omission in `text/html`:

Neither tag is omission.

Content attributes:

Global attributes

Accessibility considerations:

None

For implementers

DOM interface

Uses `HTMLElement`.

The `<aside>` element represents a section of a page that consists of content that is tangentially related to the content around the `<aside>` element, and which could be considered separate from that content. Such sections are often represented as sidebars in printed typography.

The element can be used for typographical effects like pull quotes or sidebars, for advertising, for groups of `<nav>` elements, and for other content that is considered separate from the main content of the page.

Note

It's not appropriate to use the `<aside>` element just for parentheticals, since those are part of the main flow of the document.

Example

The following example shows how an `<aside>` is used to mark up background material on Switzerland in a much longer news story on Europe.

```
<aside>
  <h2>Switzerland</h2>
  <p>Switzerland, a land-locked country in the middle of geographic Europe, has not joined the geopolitical European Union, though it is a party to a number of European treaties.</p>
</aside>
```

Example

The following example shows how an `<aside>` is used to mark up a callout in a license article.

```
...
<p>He later joined a large company, continuing on the same work, but I'm not sure what he does there. He still does not at work. But I'm paid to do my hobby, so I never know what to answer. Some people wonder what they would do if they didn't have to work, but I know what I would do, because I'm unemployed for a year, and I figured that time doing exactly what I do now.</p>
</aside>
<p>People ask me what I do for fun when I'm not at work. But I'm paid to do my hobby, so I never know what to answer. </p>
</div>
<p>Of course his work – or should that be hobby? – isn't his only passion. He also enjoys other pleasures.</p>
...

```

Example

The following extract shows how `aside` can be used for blogrolls and other side content on a blog:

```
<body>
<aside>
  <h1>My wonderful blog</h1>
  <p>My tagline</p>
</aside>
<!-- This aside contains two sections that are tangentially related
    to the page, namely, links to other blogs, and links to blog posts
    from this blog -->
<h2>My blogroll</h2>
<ul>
  <a href="https://blog.example.com/">Example Blog</a>
</ul>
</nav>
<h2>Archives</h2>
<ol reversed>
  <a href="/last-post">My last post</a>
  <a href="/first-post">My first post</a>
</ol>
</nav>
<aside>
  <!-- This aside is tangentially related to the page also, it
      contains twitter messages from the blog author -->
  <blockquote cite="https://twitter.example.net/t31351234">
    I'm on vacation, writing my blog.
  </blockquote>
  <blockquote cite="https://twitter.example.net/t31219752">
    I'm going to go on vacation soon.
  </blockquote>
</aside>
<article>
  <!-- This is a blog post -->
  <h1>My last post</h1>
  <p>This is my last post.</p>
  <footnote>
    <a href="/last-post" rel="bookmark">Permalink</a>
  </footnote>
</article>
<article>
  <!-- This is also a blog post -->
  <h1>My first post</h1>
  <p>This is my first post.</p>
  <!-- This aside is about the blog post, since it's inside the
      <article> element, it would be wrong, for instance, to put the
      aside inside the article, as the aside would then be specifically
      related to the page as a whole -->
  <h2>Posting</h2>
  <p>I was thinking about it, I wanted to say something about
      posting. Posting is fun!</p>
  <footnote>
    <a href="/first-post" rel="bookmark">Permalink</a>
  </footnote>
</article>
<nav>
  <a href="/archives">Archives</a> -
  <a href="/about">About me</a> -
  <a href="/copyright">Copyright</a>
</nav>
</footnote>
</body>
```

Categories:

Flow content

Header content

Phrasing content

Content in which this element can be used:

As a child of an `article` element.

As a child of an `aside` element.

Phrasing content**Tag content in text/html:**

Neither tag is omission.

Content attributes:[Global attributes](#)**Accessibility considerations:**[For authors](#)[For implementers](#)[DOM interface](#)

```
IDLExposed=Window
interface HTMLReadingElement : HTMLElement {
  [HTMLConstructor] constructor();
  // also has obsolete members
}
```

These elements **represent** headings for their sections.The semantics and meaning of these elements are defined in the section on [headings and sections](#).These elements have a *rank* given by the number in their name. The `h1` element is said to have the highest rank, the `h6` element has the lowest rank, and two elements with the same name have equal rank.**Example**

As far as their respective document outlines (their heading and section structures) are concerned, these two snippets are semantically equivalent:

```
<body>
<h1>Let's call it a drawing surface</h1>
<h2>Drawing Inc</h2>
<h3>Simple shapes</h3>
<h3>Canvas coordinates</h3>
<h2>Canvas</h2>
</body>

<body>
<h1>Let's call it a drawing surface</h1>
<section>
<h2>Drawing Inc</h2>
<section>
<h3>Simple shapes</h3>
</section>
<h3>Canvas coordinates</h3>
</section>
<h2>Canvas</h2>
<h1>Paths</h1>
</section>
</body>
```

Authors might prefer the former style for its terseness, or the latter style for its convenience in the face of heavy editing; which is best is purely an issue of preferred authoring style.

The two styles can be combined, for compatibility with legacy tools while still future-proofing for when that compatibility is no longer needed. This third snippet again has the same outline as the previous two:

```
<body>
<h1>Let's call it a drawing surface</h1>
<section>
<h2>Drawing Inc</h2>
<section>
<h3>Simple shapes</h3>
</section>
<h3>Canvas coordinates</h3>
</section>
<h2>Canvas coordinates diagram</h2>
<h3>Canvas</h3>
<h1>Paths</h1>
</section>
</body>
```

Categories:[Flow content](#)[Heading content](#)[Phrasing content](#)**Contexts in which this element can be used:**Where [flow content](#) is expected.**Content model:**One or more `h1`, `h2`, `h3`, `h4`, `h5`, `h6` elements, optionally intermixed with [script-supporting elements](#).**Tag omission in text/html:**

Neither tag is omission.

Content attributes:[Global attributes](#)**Accessibility considerations:**[For authors](#)[For implementers](#)[DOM interface](#)[Uses `content`](#).The `hgroup` element **represents** the heading of a section, which consists of all the `h1`-`h6` element children of the `hgroup` element. The element is used to group a set of `h1`-`h6` elements when the heading has multiple levels, such as subheadings, alternative titles, or taglines.The *rank* of an `hgroup` element is the rank of the highest-ranked `h1`-`h6` element descendant of the `hgroup` element, if there are any such elements, or otherwise the same as for an `h1` element (the highest rank). Other `h1`-`h6` elements of [heading content](#) in the `hgroup` element indicate subheadings or subtitles or (secondary) alternative titles.The section on [headings and sections](#) defines how `hgroup` elements are assigned to individual sections.**Example**

Here are some examples of valid headings.

```
<hgroup>
<h1>The reality dysfunction</h1>
<h2>Space is not the only void</h2>
</hgroup>

<hgroup>
<h1>Dr. Strangelove</h1>
<h2>How I Learned to Stop Worrying and Love the Bomb</h2>
</hgroup>
```

The point of using `hgroup` in these examples is to prevent the `h2` element (which acts as a secondary title) from creating a separate section of its own in any [outline](#) and to instead cause the contents of the `h2` to be shown in rendered output from the [outline](#) algorithm in some way to indicate that it is not the title of a separate section but instead just a secondary title in a group of titles.

How a user agent exposes such multi-level headings in user interfaces (e.g. in tables of contents or search results) is left open to implementers, as it is a user interface issue. The first example above could be rendered as:

The reality dysfunction: Space is not the only void

Alternatively, it could look like this:

The reality dysfunction (Space is not the only void)

In interfaces where a title can be rendered on multiple lines, it could be rendered as follows, maybe with the first line in a bigger font size:

The reality dysfunction

Space is not the only void

ExampleThe following two examples show ways in which two `h1` headings could be used within an `hgroup` element to group the US and UK names for the same movie.

```
<hgroup>
<h1>The Avengers</h1>
<h1>Avengers Assemble</h1>
</hgroup>

<hgroup>
<h1>Avengers Assemble</h1>
<h1>The Avengers</h1>
</hgroup>
```

The first example above shows how the movie names might be grouped in a publication in the US, with the US name *The Avengers* as the (primary) title, and the UK name *Avengers Assemble* as the (secondary) alternative title.In both cases it is important to note the use of the `hgroup` element to group the two titles indicates that the titles are not equivalent; instead the first `h1` gives the (primary) title while the second gives the (secondary) alternative title. Even though both the title and alternative title are marked up with `h1` elements, in a rendered view of output from the [outline](#) algorithm, the second `h1` in the `hgroup` will be shown in some way that clearly indicates it is secondary; for example:

In a US publication:

The Avengers (Avengers Assemble)

In a UK publication:

Avengers Assemble (The Avengers)

ExampleIn the following example, an `hgroup` element is used to mark up a two-level heading in a wizard-style dialog box:

```
<dialog onclose="walletSetup.continue(this.returnValue)">
<hgroup>
<h1>Wallet Setup</h1>
<h2>Configure your Wallet funding source</h2>
<p>Your Wallet can be used to buy wands at the merchant in town, to buy potions from travelling salesmen you may find in the dungeons, and to pay for mercenaries.</p>
</hgroup>

```

```
<fieldset oninput="this.getElementsByTagName('input')[0].checked = true">
<legend><label><input type="radio" name="cavayan-type" value="c"> Credit Card </label></legend>
<p><label>Name on card: <input name="cc1" type="text" value="John Doe" placeholder="John Doe"></label>
<input type="text" value="3331 1019 9999 0016" placeholder="3331 1019 9999 0016"></p>
<p><label>Expiry Date: <input name="cc2" type="month" autocomplete="section-cc cc-exp" placeholder="2020-02"></label>
<input type="text" value="2020-02" placeholder="2020-02"></p>
<p><label>Security Code: <input name="cc3" type="text" value="123" placeholder="123" autocomplete="section-cc cc-csc" placeholder="123"></label>
<input type="text" value="123" placeholder="123"></p>
<input type="submit" value="Back" type="button" />
<input type="submit" value="Next" type="button" />
</form>
</dialog>
```

4.3.8 The `header` element

[MDN](#)

Element header

Support in all current engines.

Firefox 4+ Safari 5+ Chrome 5+

Opera 11.1+ Edge 79+

Edge (Legacy) 12+ Internet Explorer 9+

Firefox Android 4+ Safari iOS 4.2+ Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android 11.1+

Categories:
[Flow content](#)
[Listed content](#)

Content in which this element can be used:

Where `flow content` is expected.

Content model:

`Flow content`, but with no `header` or `footer` element descendants.

`Text` or `comment` (text/html)

Neither tag is permissible.

Content attributes:

[Global attributes](#)

Accessibility considerations:

If the nearest ancestor `sectioning content` or `sectioning root` element is the `body` element: for authors; for implementers.

Otherwise: for authors; for implementers.

DOM interface:

Uses [HTMLElement](#).

The `header` element represents a group of introductory or navigational aids.

Note

A `header` element is intended to usually contain the section's heading (an `h1`-`h6` element or an `hgroup` element), but this is not required. The `header` element can also be used to wrap a section's table of contents, a search form, or any relevant logos.

Example

Here are some sample headers. This first one is for a game:

```
<header>
<p>Welcome to...</p>
<h1>Voidwars!</h1>
</header>

The following snippet shows how the element can be used to mark up a specification's header:
```

`<header>`

`<hgroup>`

`<h2>Fullscreen API</h2>`

`<h3>Living Standard – Last Updated 19 October 2015</h3>`

`</hgroup>`

`<dd>Participate</dd>`

`<dd>GitHub whatwg/fullscreen</dd>`

`<dd>GitHub whatwg/fullscreen/commits</dd>`

`</dd></dd>`

Note
The `header` element is not `sectioning content`; it doesn't introduce a new section.

Example

In this example, the page has a page heading given by the `h1` element, and two subsections whose headings are given by `h2` elements. The content after the `header` element is still part of the last subsection started in the `header` element, because the `header` element doesn't take part in the `outline` algorithm.

`<body>`

`<h1>Little Green Guys With Guns</h1>`

`<nav>`

``

`Games`

`Forum`

`Download`

``

`<h2>Important News</h2> <-- this starts a second subsection -->`

`<!-- this is part of the subsection entitled "Important News" -->`

`<!-- play oddball games and need to update your client. -->`

`<h2>Games</h2> <-- this starts a third subsection -->`

`</h2>`

`You have three active games:`

`<!-- this is still part of the subsection entitled "Games" -->`

`<..>`

4.3.9 The `footer` element

[MDN](#)

Element footer

Support in all current engines.

Firefox 4+ Safari 5+ Chrome 5+

Opera 11.1+ Edge 79+

Edge (Legacy) 12+ Internet Explorer 9+

Firefox Android 4+ Safari iOS 4.2+ Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android 11.1+

Categories:
[Flow content](#)
[Listed content](#)

Content in which this element can be used:

Where `flow content` is expected.

Content model:

`Flow content`, but with no `header` or `footer` element descendants.

`Text` or `comment` (text/html)

Neither tag is permissible.

Content attributes:

[Global attributes](#)

Accessibility considerations:

If the nearest ancestor `sectioning content` or `sectioning root` element is the `body` element: for authors; for implementers.

Otherwise: for authors; for implementers.

DOM interface:

Uses [HTMLElement](#).

The `footer` element represents a footer for its nearest ancestor `sectioning content` or `sectioning root` element. A footer typically contains information about its section such as who wrote it, links to related documents, copyright data, and the like.

When the `footer` element contains entire sections, they represent appendices, indexes, long colophons, verbose license agreements, and other such content.

Note

Contact information for the author or editor of a section belongs in an `address` element, possibly itself inside a `footer`. Bylines and other information that could be suitable for both a `header` or a `footer` can be placed in either (or neither). The primary purpose of these elements is merely to help the author write self-explanatory markup that is easy to maintain and style; they are not intended to impose specific structures on authors.

Footers don't necessarily have to appear at the end of a section, though they usually do.

When the nearest ancestor `sectioning content` or `sectioning root` element is the `body` element, then it applies to the whole page.

Note

The `footer` element is not `sectioning content`; it doesn't introduce a new section.

Example

Here is a page with two footers, one at the top and one at the bottom, with the same content:

`<body>`

`<header>Back to index..</header>`

`<h1>The ipsum of all lorem</h1>`

`<h2>The ipsum of all lorem</h2>`

`<p>A dolor sit amet, consectetur adipisicing elit, sed do eiusmod`

`tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim`

`veniam, nostrud exercitation ullamco laboris nisi ut aliquip ex ea`

`commodo consequat. Duis aute irure dolor in reprehenderit in`

`voluptate velit esse cillum dolore eu fugiat nulla`

`pariatur. Excepteur sint occaecat cupidatat non proident, sunt in`

`culpa qui officia deserunt mollit anim id est laborum.</p>`

`<footer>Back to index..</footer>`

`</body>`

Here is an example which shows the `footer` element being used both for a site-wide footer and for a section footer.

```

4.3.10 The `address` element**MDN****Element/Address**

Support in all current engines.

Firefox+|Safari+|ChromeYes

OperaYes|EdgeYes

Edge (Legacy)12+|Internet ExplorerYes

Firefox|Android+|Safari|iOS|S|Chrome|AndroidYes|WebView|AndroidYes|Samsung|InternetYes|Opera|AndroidYes

Categories:

[Flat content](#)

[Parsable content](#)

Contexts in which this element can be used:

Where [flow content](#) is expected.

Content model:

Text content, but with no [heading content](#) descendants, no [sectioning content](#) descendants, and no [header](#), [footer](#), or [address](#) element descendants.

[Tag omission in text/html:](#)

Neither tag is omissionable.

Content attributes:

[Global attributes](#)

Accessibility considerations:

[For users](#)

[For implementers](#)

DOM interface:

Uses [HTMLElement](#).

The `address` element [represents](#) the contact information for its nearest [article](#) or [body](#) element ancestor. If that is [the body element](#), then the contact information applies to the document as a whole.

Example

For example, a page at the W3C Web site related to HTML might include the following contact information:

```
<ADDRESS>
<A href="mailto:...@people.raggett.org">Dave Raggett</A>
<A href="mailto:...@people.arnaudu.org">Arnaud Le Hors</A>
contact persons for the <A href="#activity">W3C HTML Activity</A>
</ADDRESS>
```

The `address` element must not be used to represent arbitrary addresses (e.g. postal addresses), unless those addresses are in fact the relevant contact information. (The `a` element is the appropriate element for marking up postal addresses in general.)

The `address` element must not contain information other than contact information.

Example

For example, the following is non-conforming use of the `address` element:

```
<ADDRESS>Last Modified: 1999/12/24 23:37:50</ADDRESS>
```

Typically, the `address` element would be included along with other information in a `footer` element.

The contact information for a `node` is a collection of `address` elements defined by the first applicable entry from the following list:

If `node` is an `article` element

If `node` is a `body` element

The contact information consists of all the `address` elements that have `node` as an ancestor and do not have another `body` or `article` element ancestor that is a descendant of `node`.

If `node` has an ancestor element that is an `article` element

If `node` has an ancestor element that is a `body` element

The contact information of `node` is the same as the contact information of the nearest `article` or `body` element ancestor, whichever is nearest.

If `node`'s `node document` has a `body` element

The contact information of `node` is the same as the contact information of [the body element](#) of the `document`.

Otherwise

There is no contact information for `node`.

User agents may expose the contact information of a node to the user, or use it for other purposes, such as indexing sections based on the sections' contact information.

Example

In this example the footer contains contact information and a copyright notice.

```

  <A href="mailto:j@example.com">John Smith</A>
<A href="http://example.com">Example Corp</A>
<P><small>© copyright 2008 Example Corp.</small></P>
</FOOTER>
```

4.3.11 Headings and sections

The `h1`-`h6` elements and the `hgroup` element are headings.

The first element of `heading content` in an element of `sectioning content` represents the heading for that section. Subsequent headings of equal or higher `rank` start new (implied) sections, headings of lower `rank` start implied subsections that are part of the previous one. In both cases, the element [represents](#) the heading of the implied section.

Certain elements are said to be `sectioning roots`, including `blockquote` and `td` elements. These elements can have their own outlines, but the sections and headings inside these elements do not contribute to the outlines of their ancestors.

- `blockquote`
- `body`
- `details`
- `dialog`
- `fieldset`
- `figure`
- `td`

`Sectioning content` elements are always considered subsections of their nearest ancestor `sectioning root` or their nearest ancestor element of `sectioning content`, whichever is nearest, regardless of what implied sections other headings may have created.

Example

For the following fragment:

```
<BODY>
<H1>Food</H1>
<H2>Drinks</H2>
<BLOCKQUOTE>
<H3>Bla</H3>
<H4>Bla</H4>
</BLOCKQUOTE>
```

```
<section>
  <h3>The Grunt</h3>
</section>
<p>Grunt</p>
</body>
```

...the structure would be:

1. Foo (heading of explicit `body` section, containing the "Grunt" paragraph)
2. Bar (heading starting implied section, containing a block quote and the "Bar" paragraph)
3. Quux (heading starting implied section with no content other than the heading itself)
4. Thud (heading of explicit `section` section)

Notice how the `section` ends the earlier implicit section so that a later paragraph ("Grunt") is back at the top level.

Sections may contain headings of any `rank`, but authors are strongly encouraged to either use only `h1` elements, or to use elements of the appropriate `rank` for the section's nesting level.

Authors are also encouraged to explicitly wrap sections in elements of `sectioning content`, instead of relying on the implicit sections generated by having multiple headings in one element of `sectioning content`.

Example

For example, the following is correct:

```
<body>
  <h1>Apples</h1>
  <p>Apples are fruit.</p>
  <section>
    <h2>Taste</h2>
    <p>Apples taste lovely.</p>
    <h3>Sweet</h3>
    <p>Red apples are sweeter than green ones.</p>
    <h3>Color</h3>
    <p>Apples come in various colors.</p>
  </section>
</body>
```

However, the same document would be more clearly expressed as:

```
<body>
  <h1>Apples</h1>
  <p>Apples are fruit.</p>
  <section>
    <h2>Taste</h2>
    <p>Apples taste lovely.</p>
    <section>
      <h3>Sweet</h3>
      <p>Red apples are sweeter than green ones.</p>
    </section>
    <h2>Color</h2>
    <p>Apples come in various colors.</p>
  </section>
</body>
```

Both of the documents above are semantically identical and would produce the same outline in compliant user agents.

This third example is also semantically identical, and might be easier to maintain (e.g. if sections are often moved around in editing):

```
<body>
  <h1>Apples</h1>
  <p>Apples are fruit.</p>
  <section>
    <h2>Taste</h2>
    <p>Apples taste lovely.</p>
    <section>
      <h3>Sweet</h3>
      <p>Red apples are sweeter than green ones.</p>
    </section>
    <h2>Color</h2>
    <p>Apples come in various colors.</p>
  </section>
</body>
```

This final example would need explicit style rules to be rendered well in legacy browsers. Legacy browsers without CSS support would render all the headings as top-level headings.

4.3.1.1 Creating an outline

This section defines an algorithm for creating an outline for a `sectioning content` element or a `sectioning root` element. It is defined in terms of a walk over the nodes of a DOM tree, in `tree_order`, with each node being visited when it is *entered* and when it is *exited* during the walk.

The `outline` for a `sectioning content` element or a `sectioning root` element consists of a list of one or more potentially nested `sections`. The element for which an `outline` is created is said to be the *outline's owner*.

A `section` is a container that corresponds to some nodes in the original DOM tree. Each section can have one heading associated with it, and can contain any number of further nested sections. The algorithm for the outline also associates each node in the DOM tree with a particular section and potentially a heading. (The sections in the outline aren't `section` elements, though some may correspond to such elements — they are merely conceptual sections.)

Example

The following markup fragment:

```
<body>
  <hgroup id="document-title">
    <h1>HTML</h1>
    <h2>Living Standard – Last Updated 12 August 2016</h2>
  </hgroup>
  <p>Some intro to the document.</p>
  <h2>Table of contents</h2>
  <h3>First section</h3>
  <p>Some intro to the first section.</p>
</body>
```

...results in the following outline being created for the `body` node (and thus the entire document):

1. Section created for `body` node.

Associated with heading `<hgroup id="document-title">...</hgroup>` consisting of primary heading `<h1>HTML</h1>` and secondary heading `<h2>Living Standard – Last Updated 12 August 2016</h2>`.

Also associated with the paragraph `<p>Some intro to the document.</p>` (though it likely would not be shown in a rendered view of the outline).

Nested sections:

1. Section implied for first `h2` element.

Associated with heading `<h2>Table of contents</h2>`.

Also associated with the ordered list `<ol id="toc">...` (though it likely would not be shown in a rendered view of the outline).

No nested sections.

2. Section implied for second `h2` element.

Associated with heading `<h2>First section</h2>`.

Also associated with the paragraph `<p>Some intro to the first section.</p>` (though it likely would not be shown in a rendered view of the outline).

No nested sections.

The following image shows what a rendered view of the outline might look like.

The algorithm that must be followed during a walk of a DOM subtree rooted at a `sectioning content` element or a `sectioning root` element to determine that element's `outline` is as follows:

1. Let `current outline target` be null. (It holds the element whose `outline` is being created.)
2. Let `current section` be null. (It holds a pointer to a `section`, so that elements in the DOM can all be associated with a section.)
3. Create a stack to hold elements, which is used to handle nesting. Initialize this stack to empty.
4. Walk over the DOM in `tree_order`, starting with the `sectioning content` element or `sectioning root` element at the root of the subtree for which an outline is to be created, and trigger the first relevant step below for each element as the walk enters and exits it.

When exiting an element, if that element is the element at the top of the stack

Note
The element being exited is a `heading content` element or an element with a `hidden` attribute.

Pop that element from the stack.

If the top of the stack is a `heading content` element or an element with a `hidden` attribute

Do nothing.

When entering an element with a `hidden` attribute

Push the element being entered onto the stack. (This causes the algorithm to skip that element and any descendants of the element.)

When entering a `sectioning content` element

Run these steps:

1. If `current outline target` is not null, then:
 1. If the `current section` has no heading, create an implied heading and let that be the heading for the `current section`.
 2. Push `current outline target` onto the stack.
2. Let `current outline target` be the element that is being entered.
3. Let `current section` be a newly created `section` for the `current outline target` element.
4. Associate `current outline target` with `current section`.
5. Let there be a new `outline` for the new `current outline target`, initialized with just the new `current section` as the only `section` in the outline.

When exiting a `sectioning content` element, if the stack is not empty

Run these steps:

1. If the *current section* has no heading, create an implied heading and let that be the heading for the *current section*.
2. Pop the top element from the stack, and let the *current outline target* be that element.
3. Let *current section* be the last section in the *outline* of the *current outline target* element.
4. Append the *outline* of the *sectioning content* element being exited to the *current section*. (This does not change which section is the last section in the *outline*.)

When entering a *sectioning root* element

Run these steps:

1. If *current outline target* is not null, push *current outline target* onto the stack.
2. Let *current outline target* be the element that is being entered.
3. Let *current outline target's parent section* be *current section*.
4. Let *current section* be a newly created *section* for the *current outline target* element.
5. Let there be a new *outline* for the new *current outline target*, initialized with just the new *current section* as the only *section* in the *outline*.

When exiting a *sectioning root* element, if the stack is not empty

Run these steps:

1. If the *current section* has no heading, create an implied heading and let that be the heading for the *current section*.
2. Let *current section* be *current outline target's parent section*.
3. Pop the top element from the stack, and let the *current outline target* be that element.

When exiting a *sectioning content* element or a *sectioning root* element (when the stack is empty)

Note

The *current outline target* is the element being exited, and it is the *sectioning content* element or a *sectioning root* element at the root of the subtree for which an outline is being generated.

If the *current section* has no heading, create an implied heading and let that be the heading for the *current section*.

Skip to the next step in the overall set of steps. (The walk is over.)

When entering a *heading content* element

If the *current section* has no heading, let the element being entered be the heading for the *current section*.

Note

If the element being entered is an *hgroup* element, that *hgroup* as a whole is a *multi-level heading* for the *current section*, with the highest-pinned *h1-h6* descendant of the *hgroup* providing the primary heading for the *current section*, and with other *h1-h6* descendants of the *hgroup* providing secondary headings for the *current section*.

Otherwise, if the element being entered has a *rank* equal to or higher than the heading of the last section of the *outline* of the *current outline target*, or if the heading of the last section of the *outline* of the *current outline target* is an implied heading, then create a new *section* and append it to the *outline* of the *current outline target* element, so that the new section is the new last section of that outline. Let *current section* be that new section. Let the element being entered be the new heading for the *current section*.

Otherwise, run these substeps:

1. Let *candidate section* be *current section*.
2. **Heading loop:** If the element being entered has a *rank* lower than the *rank* of the heading of the *candidate section*, then create a new *section*, and append it to *candidate section*. (This does not change which section is the last section in the *outline*.) Let *current section* be this new section. Let the element being entered be the new heading for the *current section*. Abort these substeps.
3. Let *new candidate section* be the *section* that contains *candidate section* in the *outline* of *current outline target*.
4. Let *candidate section* be *new candidate section*.
5. Return to the step labeled *heading loop*.

Push the element being entered onto the stack. (This causes the algorithm to skip any descendants of the element.)

Note

Recall that *h1* has the highest rank, and *h6* has the lowest rank.

Otherwise

Do nothing.

In addition, whenever the walk exits a node, after doing the steps above, if the node is not associated with a *section* yet, associate the node with the *section current section*.

5. Associate all non-element nodes that are in the subtree for which an outline is being created with the *section* with which their parent element is associated.

6. Associate all nodes in the subtree with the heading of the *section* with which they are associated, if any.

The tree of sections created by the algorithm above, or a proper subset thereof, must be used when generating document outlines, for example when generating tables of contents.

The outline created for the *body element* of a *Document* is the *outline* of the entire document.

When creating an interactive table of contents, entries should jump the user to the relevant *sectioning content* element, if the *section* was created for a real element in the original document, or to the relevant *heading content* element, if the *section* in the tree was generated for a heading in the above process.

Note

Selecting the first *section* of the document therefore always takes the user to the top of the document, regardless of where the first heading in the *body* is to be found.

The *outline depth* of a *heading content* element associated with a *section* section is the number of *sections* that are ancestors of *section* in the outermost *outline* that *section* finds itself in when the *outline*s of its *Document*'s elements are created, plus 1. The *outline depth* of a *heading content* element not associated with a *section* is 1.

User agents should provide default headings for sections that do not have explicit section headings.

Example

Consider the following snippet:

```
<body>
<div>
<p><a href="/">Home</a></p>
<ul>
<li>Hello world.</li>
<li><a href="#">Cat is cute.</a></li>
</ul>
</div>
</body>
```

Although it contains no headings, this snippet has three sections: a document (the *body*) with two subsections (a *div* and an *ul*). A user agent could present the outline as follows:

1. Untitled document
2. Navigation
3. Sidebar

These default headings ("Untitled document", "Navigation", "Sidebar") are not specified by this specification, and might vary with the user's language, the page's language, the user's preferences, the user agent implementer's preferences, etc.

Note

The following JavaScript function shows how the tree walk could be implemented. The *root* argument is the root of the tree to walk (either a *sectioning content* element or a *sectioning root* element), and the *enter* and *exit* arguments are callbacks that are called with the nodes as they are entered and exited. [JAVASCRIPT]

```
function (root, enter, exit) {
  var node = root;
  start: while (node) {
    if (node.firstChild) {
      node = node.firstChild;
      continue start;
    }
    while (node) {
      exit(node);
      if (node == root) {
        continue start;
      } else if (node.nextSibling) {
        node = node.nextSibling;
        continue start;
      } else {
        node = node.parentNode;
      }
    }
  }
}
```

4.3.11.2 Sample outlines

This section is non-normative.

Example

The following document shows a straight-forward application of the [outline](#) algorithm. First, here is the document, which is a book with very short chapters and subsections:

```
<!DOCTYPE HTML>
<html lang="en">
<title>My Tax Book (all in one page)</title>
<h1>Earning money</h1>
<p>Earning money is good.</p>
<h2>Spending money</h2>
<p>To earn money you typically need a job.</p>
<h3>Buying things</h3>
<p>Buying things is mainly used for.</p>
<h3>Cheap things</h3>
<p>The most expensive thing is often not the most cost-effective.</p>
<h3>Investing money</h3>
<p>You can lend your money to other people.</p>
<h3>Losing money</h3>
<p>If you spend money or invest money, sooner or later you will lose money.</p>
<h3>Poor judgement</h3>
<p>Usually if you lose money it's because you made a mistake.</p>
```

This book would form the following outline:

1. The Tax Book
 1. Earning money
 1. Getting a job
 2. Spending money
 1. Cheap things
 2. Expensive things
 3. Investing money
 4. Losing money
 1. Poor judgement

Notice that the [title](#) element does not participate in the outline.

Example

Here is a similar document, but this time using [section](#) elements to get the same effect:

```
<!DOCTYPE HTML>
<html lang="en">
<title>My Tax Book (all in one page)</title>
<h1>Earning money</h1>
<section>
<p>Earning money is good.</p>
</section>
<h2>Buying a job</h2>
<p>To earn money you typically need a job.</p>
</section>
<h3>Buying things</h3>
<p>Buying cheap things is what money is mainly used for.</p>
</section>
<h3>Expensive things</h3>
<p>The most expensive thing is often not the most cost-effective either.</p>
</section>
<h3>Investing money</h3>
<p>You can lend your money to other people.</p>
</section>
<h3>Losing money</h3>
<p>If you spend money or invest money, sooner or later you will lose money.</p>
<h3>Poor judgement</h3>
<p>Usually if you lose money it's because you made a mistake.</p>
```

This book would form the same outline:

1. The Tax Book
 1. Earning money
 1. Getting a job
 2. Spending money
 1. Cheap things
 2. Expensive things
 3. Investing money
 4. Losing money
 1. Poor judgement

Example

A document can contain multiple top-level headings:

```
<!DOCTYPE HTML>
<html lang="en">
<title>Alphabetical Fruit</title>
<h1>Apples</h1>
<p>Apples</p>
<h1>Bananas</h1>
<p>Bananas</p>
<h1>Bibbles</h1>
<p>Bibbles</p>
<h1>Starfruit</h1>
<p>Starfruit</p>
```

This would form the following simple outline consisting of three top-level sections:

1. Apples
2. Bananas
3. Carambola

Effectively, the [body](#) element is split into three.

Example

Mixing both the [h1-hn](#) model and the [section/h1](#) model can lead to some unintuitive results.

Consider for example the following, which is just the previous example but with the contents of the (implied) [body](#) wrapped in a [section](#):

```
<!DOCTYPE HTML>
<html lang="en">
<title>Alphabetical Fruit</title>
<section>
<h1>Apples</h1>
<p>Apples</p>
<h1>Bananas</h1>
<p>Bananas</p>
<h1>Bibbles</h1>
<p>Bibbles</p>
<h1>Starfruit</h1>
<p>Starfruit</p>
```

The resulting outline would be:

1. *(untitled page)*
 1. Apples
 2. Bananas
 3. Carambola

This result is described as *unintuitive* because it results in three subsections even though there's only one [section](#) element. Effectively, the [section](#) is split into three, just like the implied [body](#) element in the previous example.

(In this example, "*(untitled page)*" is the implied heading for the [body](#) element, since it has no explicit heading.)

Example

Headings never rise above other sections. Thus, in the following example, the first [h1](#) does not actually describe the page header; it describes the header for the second half of the page:

```
<!DOCTYPE HTML>
<html lang="en">
<title>Heathers On The Site of Encyclopedic Knowledge</title>
<section>
<h1>A plea from our caretakers</h1>
<p>Please, we beg of you, send help! We're stuck in the server room!</p>
<h2>A plea</h2>
<h3>A plea from our caretakers</h3>
<p>Apidinal growths.</p>
```

The resulting outline would be:

1. *(untitled page)*
 1. A plea from our caretakers
 2. Feathers

Example

Thus, when an [article](#) element starts with a [nav](#) block and only later has its heading, the result is that the [nav](#) block is not part of the same section as the rest of the [article](#) in the outline. For instance, take this document:

```
<!DOCTYPE HTML>
<html lang="en">
<title>We're adopting a child! – Ray's blog</title>
<h1>Ray's blog</h1>
<nav>
<ul>
<li><a href="#">Yesterday</a>
<li><a href="#">Last week</a>
<li><a href="#">Last month</a>
<li><a href="#">We're adopting a child!</a>
</ul>
</nav>
<article>
<h2>Today, Janine and I have signed the papers to become the proud parents of baby Diane! We've been looking forward to this day for weeks.</h2>
</article>
</html>
```

The resulting outline would be:

1. Ray's blog
 1. Untitled article
 1. Untitled navigation section

Also worthy of note in this example is that the `hgroup` element has no effect whatsoever on the document outline.

Example

The `hgroup` element can be used for subheadings. For example:

```
<!DOCTYPE HTML>
<html lang="en">
<title>My Day</title>
<head>
<group>
<h1>The morning</h1>
<h2>06:00 to 12:00</h2>
</group>
<p>We sleep.</p>
<group>
<h1>The afternoon</h1>
<h2>12:00 to 18:00</h2>
</group>
<p>We study.</p>
<group>
<h2>Additional Commentary</h2>
<h3>Because not all this is necessarily true</h3>
<h3>Ok it's almost certainly not true</h3>
</group>
<p>We probably play, rather than study.</p>
<group>
<h1>The evening</h1>
<h2>18:00 to 00:00</h2>
</group>
<p>We play.</p>
<group>
<h1>The night</h1>
<h2>00:00 to 06:00</h2>
</group>
<p>We play some more.</p>
</html>
```

The resulting outline would be:

1. The morning 06:00 to 12:00
2. The afternoon 12:00 to 18:00
 1. Additional Commentary Because not all this is necessarily true Ok it's almost certainly not true
3. The evening 18:00 to 00:00
4. The night 00:00 to 06:00

Exactly how this is represented by user agents, as most interface issues, is left as a matter of implementation preference, but the key part is that the `hgroup`'s descendant `h1-h6` elements are what form the element's heading. Thus, the following would be equally valid:

1. The morning — 06:00 to 12:00
2. The afternoon — 12:00 to 18:00
 1. Additional Commentary — Because not all this is necessarily true — Ok it's almost certainly not true
3. The evening — 18:00 to 00:00
4. The night — 00:00 to 06:00

But so would the following:

1. The morning
2. The afternoon
 1. Additional Commentary
3. The evening
4. The night

The following would also be valid, though maybe less practical in most contexts:

1. The morning

06:00 to 12:00
2. The afternoon

12:00 to 18:00

 1. Additional Commentary

Because not all this is necessarily true

Ok it's almost certainly not true
3. The evening

18:00 to 00:00
4. The night

00:00 to 06:00

4.3.11.3 Exposing outlines to users

User agents are encouraged to expose page outlines to users to aid in navigation. This is especially true for non-visual media, e.g. screen readers.

However, to mitigate the difficulties that arise from authors misusing `sectioning content`, user agents are also encouraged to offer a mode that navigates the page using `heading content` alone.

Example

For instance, a user agent could map the arrow keys as follows:

```
Shift+ Left Go to previous section, including subsections of previous sections
Shift+ Right Go to next section, including subsections of the current section
Shift+ Up Go to parent section of the current section
Shift+ Down Go to next section, skipping subsections of the current section
```

Plus in addition, the user agent could map the `j` and `k` keys to navigating to the previous or next element of `heading content`, regardless of the section's outline depth and ignoring sections with no headings.

4.3.12 Usage summary

This section is non-normative.

Element

The contents of the document.

Example

```
<!DOCTYPE HTML>
<html lang="en">
<head> <title>Steve Hill's Home Page</title> </head>
<body> <p>Hard Trance is My Life.</p>
</body>
```

Purpose

Example

A complete, or self-contained, composition in a document, page, application, or site and that is, in principle, independently distributable or reusable, e.g. in syndication. This could be a forum post, a magazine or newspaper article, a blog entry, a user-submitted comment, an interactive widget or gadget, or any other independent item of content.

Example

```
<article>

<p>My favo Masif Tee so far!</p>
<footer>Posted 2 days ago</footer>
</article>
```

Example

```
<article>

<p>2nd Birthday Masif Saturday!!</p>
<footer>Posted 3 weeks ago</footer>
</article>
```

A generic section of a document or application. A section, in this context, is a thematic grouping of content, typically with a heading.

Example

```
<h1>Biography</h1>
<section>
<h2>Facts</h2>
<p>150+ shows, 14+ countries</p>
</section>
<section>
<h2>2010/2011 figures per year</h2>
<p>150+ shows, 8+ countries</p>
</section>
```

Example

A section of a page that links to other pages or to parts within the page: a section with navigation links.

Example

```
<nav>
<p><a href="#">Home</a>
<a href="#">About</a>
<a href="#">Discog</a>
</nav>
```

A section of a page that consists of content that is tangentially related to the content around the `aside` element, and which could be considered separate from that content. Such sections are often represented as sidebars in printed typography.

Example

```
<h1>Music</h1>
<p>As any burnd can tell you, the event has a lot of trance.</p>
<code>buy</code> buy the music is played at our <a href="buy.html">playlist page</a></code>
<p>This year we played a kind of trance that originated in Belgium, Germany, and the Netherlands in the mid 90s.</p>
```

A section heading.

Example

```
<h2>Main Stage</h2>
<p>If you want to play on a stage, you should bring one.</p>
<h2>M&P</h2>
<p>M&P players up to 90dB are welcome.</p>
```

The heading of a section, which consists of all the `h1-h6` element children of the `hgroup` element. The element is used to group a set of `h1-h6` elements when the heading has multiple levels, such as subheadings, alternative titles, or taglines.

Example

```
<hgroup>
<h1>Reading Music</h1>
<h2>The Guide To Music On The Plays</h2>
</hgroup>
```

```
<li>faster-than-light travel, and
</li>
<p>and is further discussed below.</p>
```

Authors wishing to conveniently style such "logical" paragraphs consisting of multiple "structural" paragraphs can use the `div` element instead of the `p` element.

Example

Thus for instance the above example could become the following:

```
<div>For instance, this fantastic sentence has bullet points relating to
<ul>
<li>Wizards,
<li>faster-than-light travel, and
<li>telepathy,
</ul>
and is further discussed below.</div>
```

This example still has five structural paragraphs, but now the author can style just the `div` instead of having to consider each part of the example separately.

4.4.2 The `hr` element

MDN

Element ---

Categories:

[Flow content](#)

[Contexts in which this element can be used:](#)

Where [flow-content](#) is expected.

Content model:

[Nothing](#)

[Tag omission in text/html:](#)

[End tag](#)

Content attributes:

[Global attributes](#)

Accessibility considerations:

[For authors](#)

[For implementers](#)

DOM interface:

```
IDL Exports<#>interface [HTMLHRElement] {
  constructor();
  // also has obsolete members
};
```

The `hr` element represents a [paragraph](#)-level thematic break, e.g. a scene change in a story, or a transition to another topic within a section of a reference book.

Example

The following fictional extract from a project manual shows two sections that use the `hr` element to separate topics within the section.

```
<div>
<h2>Communication</h2>
<p>There are various methods of communication. This section covers a few of the important ones used by the project.</p>
<p>Communication stones seem to come in pairs and have mysterious properties:</p>
<ul>
<li>They can transfer thoughts in two directions once activated if used alone.</li>
<li>If placed next to another device, they can transfer one's consciousness to another body.</li>
<li>If both stones are used with another device, the consciousness switch bodies.</li>
</ul>
<p>Radios use the electromagnetic spectrum in the meter range and longer.</p>
<p>Signal flares use the electromagnetic spectrum in the nanometer range.</p>
</div>
<div>
<h2>Food</h2>
<p>Food at the project is rationed:</p>
<table>
<tr>
<td>potatoes</td>
<td>two per day</td>
<td>soup</td>
<td>one bowl per day</td>
</tr>
</table>
<p>Cooking is done by the chefs on a set rotation.</p>
</div>
```

There is no need for an `hr` element between the sections themselves, since the `section` elements and the `h2` elements imply thematic changes themselves.

Note

The `hr` element does not affect the document's [outline](#).

4.4.3 The `pre` element

[Flow content](#)

[Table content](#)

[Contexts in which this element can be used:](#)

Where [flow-content](#) is expected.

Content model:

[Prasing content](#)

[Tag omission in text/html:](#)

Neither tag is omission.

[Global attributes](#)

[For authors](#)
[For implementers](#)
[DOM interface](#)

```
IDL Exposed=Window
interface HTMLPreElement : HTMLElement {
  [HTMLConstructor] constructor();
  // also has obsolete members
};
```

The `pre` element **represents** a block of preformatted text, in which structure is represented by typographic conventions rather than by elements.

Note
In the [HTML syntax](#), a leading newline character immediately following the `pre` element start tag is stripped.

Some examples of cases where the `pre` element could be used:

- Including an e-mail, with paragraphs indicated by blank lines, lists indicated by lines prefixed with a bullet, and so on.
- Including fragments of computer code, with structure indicated according to the conventions of that language.
- Displaying ASCII art.

Note
Authors are encouraged to consider how preformatted text will be experienced when the formatting is lost, as will be the case for users of speech synthesizers, braille displays, and the like. For cases like ASCII art, it is likely that an alternative presentation, such as a textual description, would be more universally accessible to the readers of the document.

To represent a block of computer code, the `pre` element can be used with a `code` element; to represent a block of computer output the `pre` element can be used with a `sample` element. Similarly, the `phb` element can be used within a `pre` element to indicate text that the user is to enter.

Note
This element **has rendering requirements involving the bidirectional algorithm**.

Example

In the following snippet, a sample of computer code is presented.

```
<p>This is the <code>Panel</code> constructor:</p>
<pre><code>function Panel(element, canClose, closeHandler) {
  this.element = element;
  this.canClose = canClose;
  this.closeHandler = function () { if (closeHandler) closeHandler(); }
}</code></pre>
```

Example

In the following snippet, `amp` and `xmp` elements are mixed in the contents of a `pre` element to show a session of Zork I.

```
<pre><amp>You are in an open field west of a big white house with a boarded front door.
There is a small mailbox here.
</amp> <xmp>Open mailbox</xmp>
<xmp>Opening the mailbox reveals:
A leaflet.
</xmp></pre>
```

Example

The following shows a contemporary poem that uses the `pre` element to preserve its unusual formatting, which forms an intrinsic part of the poem itself.

```
<p>> maxing
it is with a heart
      heavy
that i admit loss of a feline
      so loved
a friend lost to the
      unknown
          (night)
-cdr 11dec07</pre>
```

4.4.4 The `blockquote` element

Phrasing content

Contexts in which this element can be used:

Where `flow content` is expected.

Content model

Flow content

Text content in `text/html`:

Neither tag is omissionable.

Content attributes

Global attributes

`cite` – Link to the source of the quotation or more information about the edit

Accessibility considerations:

For authors

For implementers

DOM interface

```
IDL Exposed=Window
interface HTMLQuoteElement : HTMLElement {
  [HTMLConstructor] constructor();
  // also has obsolete members
};

[HTMLReactions] attribute USVString cite;
```

Note
The `HTMLQuoteElement` interface is also used by the `cite` element.

The `blockquote` element **represents** a section that is quoted from another source.

Content inside a `blockquote` must be quoted from another source, whose address, if it has one, may be cited in the `cite` attribute.

If the `cite` attribute is present, it must be a [valid URL potentially surrounded by spaces](#). To obtain the corresponding citation link, the value of the attribute must be [parsed](#) relative to the element's `node.document`. User agents may allow users to follow such citation links, but they are primarily intended for private use (e.g., by server-side scripts collecting statistics about a site's use of quotations), not for readers.

The content of a `blockquote` may be abbreviated or may have context added in the conventional manner for the text's language.

Example

For example, here the attribution is given in a paragraph after the quote:

```
<blockquote>
<p>[Jane] then said she liked [...] fish.</p>
</blockquote>
```

Attribution for the quotation, if any, must be placed outside the `blockquote` element.

Example

For example, here the attribution is given in a paragraph after the quote:

```
<blockquote>
<p>I don't contend that we are both atheists. I just believe in one fewer god than you do. When you understand why you dismiss all the other possible gods, you will understand why I dismiss yours.</p>
</blockquote>
<p>— Stephen Roberts</p>
```

The other examples below show other ways of showing attribution.

The `cite` IDL attribute must [reflect](#) the element's `cite` content attribute.

Example

Here a `blockquote` element is used in conjunction with a `figure` element and its `figcaption` to clearly relate a quote to its attribution (which is not part of the quote and therefore doesn't belong inside the `blockquote` itself):

```
<figure>
<blockquote>
  <p>Truth may be purring. It may take some work to grapple with. It may be counterintuitive. It may contradict deeply held prejudices. It may not be consonant with what we desperately want to believe. We have a method, and that method helps us to reach not absolute truth, only asymptotic approaches to the truth – never there, just closer and closer, and possibilities. Cleverly designed experiments are the key.</p>
</blockquote>
<img alt="Cartoon of a cat with a speech bubble." data-bbox="100px 100px 200px 200px"/>

```

The following markup shows a list where the order matters, and where the `ul` element is therefore appropriate. Compare this list to the equivalent list in the `ol` section to see an example of the same items using the `ul` element.

```
<p>I have lived in the following countries (given in the order of when I first lived there):</p>
<ul>
<li>Norway</li>
<li>Switzerland</li>
<li>United Kingdom</li>
<li>United States</li>
<li>Norway</li>
</ul>
```

Note how changing the order of the list changes the meaning of the document. In the following example, changing the relative order of the first two items has changed the birthplace of the author:

```
<p>I have lived in the following countries (given in the order of when I first lived there):</p>
<ol>
<li>United Kingdom</li>
<li>Switzerland</li>
<li>United States</li>
<li>Norway</li>
</ol>
```

4.4.6 The `ul` element

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

Categories:

[Flow content](#)
If the element's children include at least one `li` element: [Parsable content](#).
Contexts in which this element can be used:
[Where flow content is expected](#).

Content model:

Zero or more `li` and [script-supporting](#) elements.
[Tag omission in text/html](#): Neither tag is omitted.

Content attributes:

[Global attributes](#)

Accessibility considerations:

For authors
For implementers

DOM interface:

```
IDL[Exposed=Window]
interface HTMUListElement : HTMLElement {
  [HTMLConstructor] constructor();
  // also has obsolete members
};
```

The `ul` element [represents](#) a list of items, where the order of the items is not important — that is, where changing the order would not materially change the meaning of the document.

The items of the list are the `li` element child nodes of the `ul` element.

Example

The following markup shows a list where the order does not matter, and where the `ul` element is therefore appropriate. Compare this list to the equivalent list in the `ol` section to see an example of the same items using the `ul` element.

```
<p>I have lived in the following countries:</p>
<ul>
<li>Norway</li>
<li>Switzerland</li>
<li>United Kingdom</li>
<li>United States</li>
</ul>
```

Note that changing the order of the list does not change the meaning of the document. The items in the snippet above are given in alphabetical order, but in the snippet below they are given in order of the size of their current account balance in 2007, without changing the meaning of the document whatsoever:

```
<p>I have lived in the following countries:</p>
<ul>
<li>Switzerland</li>
<li>Norway</li>
<li>United Kingdom</li>
<li>United States</li>
</ul>
```

4.4.7 The `menu` element

Content model:

Zero or more `li` and [script-supporting](#) elements.
[Tag omission in text/html](#): Neither tag is omitted.

Content attributes:

[Global attributes](#)

Accessibility considerations:

For authors
For implementers

DOM interface:

```
IDL[Exposed=Window]
interface HTTMMenusElement : HTMLElement {
  [HTMLConstructor] constructor();
  // also has obsolete members
};
```

The `menu` element [represents](#) a toolbar consisting of its contents, in the form of an unordered list of items (represented by `li` elements), each of which represents a command that the user can perform or activate.

Note

The `menu` element is simply a semantic alternative to `ul` to express an unordered list of commands (a "toolbar").

Example

In this example, a text-editing application uses a `menu` element to provide a series of editing commands:

```
<menu>
<li><button onclick="copy()"></button></li>
<li><button onclick="cut()"></button></li>
<li><button onclick="paste()"></button></li>
</menu>
```

Note that the styling to make this look like a conventional toolbar menu is up to the application.

4.4.8 The `li` element

MDN

Content: child [this element can be used](#):Inside [a elements](#).Inside [li elements](#).Inside [ul elements](#).**Content model:**

Flow content.

Tag omission:An [li](#) element's [end tag](#) can be omitted if the [li](#) element is immediately followed by another [li](#) element or if there is no more content in the parent element.**Content attributes:**

Global attributes

If the element is not a child of an [ul](#) or [menu](#) element: [value](#) — [Ordinal value](#) of the list item**Accessibility considerations:**

For authors

For implementors

DOM interface:

```
IDL(Exposed=Window)
interface HTMLLIElement : HTMLElement {
  [HTMLConstructor] constructor();
  [REactions] attribute long value;
  // also has obsolete members
};
```

The [li](#) element [represents](#) a list item. If its parent element is an [ul](#), [ol](#), or [menu](#) element, then the element is an item of the parent element's list, as defined for those elements. Otherwise, the list item has no defined list-related relationship to any other [li](#) element.The [value](#) attribute, if present, must be a [valid integer](#). It is used to determine the [ordinal value](#) of the list item, when the [li](#)'s [list owner](#) is an [ul](#) element.Any element whose [computed value of display](#) is 'list-item' has a [list owner](#), which is determined as follows:

1. If the element is not [being rendered](#), return null; the element has no [list owner](#).
2. Let [ancestor](#) be the element's parent.

3. If the element has an [ul](#), [ol](#), or [menu](#) ancestor, set [ancestor](#) to the closest such ancestor element.4. Return the closest inclusive ancestor of [ancestor](#) that produces a [CSS box](#).**Note**Such an element will always exist, as at the very least the [document element](#) will always produce a [CSS box](#).To determine the [ordinal value](#) of each element owned by a given [list owner](#) [owner](#), perform the following steps:

1. Let [i](#) be 1.
2. If [owner](#) is an [ul](#) element, let [numbering](#) be [owner's starting value](#). Otherwise, let [numbering](#) be 1.
3. [Loop](#): If [i](#) is greater than the number of [list items](#) [owner owns](#), then return; all of [owner's owned list items](#) have been assigned [ordinal values](#).
4. Let [item](#) be the [i](#)th of [owner's owned list items](#), in [tree order](#).
5. If [item](#) is an [li](#) element that has a [value](#) attribute, then:
 1. Let [parsed](#) be the result of [parsing the value of the attribute as an integer](#).
 2. If [parsed](#) is not an error, then set [numbering](#) to [parsed](#).
6. The [ordinal value](#) of [item](#) is [numbering](#).
7. If [owner](#) is an [ul](#) element, and [owner](#) has a [reversed](#) attribute, decrement [numbering](#) by 1; otherwise, increment [numbering](#) by 1.
8. Increment [i](#) by 1.
9. Go to the step labeled [loop](#).

The [value](#) IDL attribute must [reflect](#) the value of the [value](#) content attribute.**Example**The element's [value](#) IDL attribute does not directly correspond to its [ordinal value](#); it simply [reflects](#) the content attribute. For example, given this list:

```
<ol>
  <li>Item 1
  <li value="3">Item 3
  <li>Item 4
</ol>
```

The [ordinal values](#) are 1, 3, and 4, whereas the [value](#) IDL attributes return 0, 3, 0 on getting.**Example**The following example, the top ten movies are listed (in reverse order). Note the way the list is given a title by using a [figure](#) element and its [figcaption](#) element.

```
<figure>
<figcaption>the top 10 movies of all time</figcaption>
<ol reversed>
  <li value="10"><cite>Josie and the Pussycats</cite>, 2001</li>
  <li value="9"><cite lang="zh-hant">黑寡妇，女魔萬惡</cite>, 1998</li>
  <li value="8"><cite>Toy Story</cite>, 1995</li>
  <li value="7"><cite>Monsters, Inc.</cite>, 2001</li>
  <li value="6"><cite>Toy Story 2</cite>, 1999</li>
  <li value="5"><cite>Finding Nemo</cite>, 2003</li>
  <li value="4"><cite>The Incredibles</cite>, 2004</li>
  <li value="3"><cite>Ratatouille</cite>, 2007</li>
</ol>
</figure>
```

The markup could also be written as follows, using the [reversed](#) attribute on the [ol](#) element:

```
<figure>
<figcaption>the top 10 movies of all time</figcaption>
<ol reversed>
  <li><cite>Josie and the Pussycats</cite>, 2001</li>
  <li><cite lang="zh-hant">黑寡妇，女魔萬惡</cite>, 1998</li>
  <li><cite>Toy Story</cite>, 1995</li>
  <li><cite>Monsters, Inc.</cite>, 2001</li>
  <li><cite>Toy Story 2</cite>, 1999</li>
  <li><cite>Finding Nemo</cite>, 2003</li>
  <li><cite>The Incredibles</cite>, 2004</li>
  <li><cite>Ratatouille</cite>, 2007</li>
</ol>
</figure>
```

NoteWhile it is conforming to include heading elements (e.g. [h1](#)) inside [li](#) elements, it likely does not convey the semantics that the author intended. A heading starts a new section, so a heading in a list implicitly splits the list into spanning multiple sections.**4.4.9 The [ol](#) element****MDN****Element**

Flow content.

If the element's children include at least one name-value group: [Parsable content](#).**Content in which this element can be used:**Where [flow content](#) is expected.**Content model:**

Or one or more `dt` elements, optionally intermixed with [script-supporting elements](#).

Tag omission in text/html:

Neither tag is omission.

Content attributes:

[Global attributes](#)

Accessibility considerations:

[For authors](#)

[For无障碍](#)

[DOM interface](#)

```
IDL Exports=Window
interface HTMLListElement : HTMLElement
  [HTMLConstructor] constructor();
  // also has obsolete members
}
```

The `dt` element represents an association list consisting of zero or more name-value groups (a description list). A name-value group consists of one or more names (`dt` elements, possibly as children of a `div` element child) followed by one or more values (`dd` elements, possibly as children of a `div` element child), ignoring any nodes other than `dt` and `dd` element children, and `dt` and `dd` elements that are children of `div` element children. Within a single `dt` element, there should not be more than one `dt` element for each name.

Name-value groups may be terms and definitions, metadata topics and values, questions and answers, or any other groups of name-value data.

The values within a group are alternatives; multiple paragraphs forming part of the same value must all be given within the same `dd` element.

The order of the list of groups, and of the names and values within each group, may be significant.

In order to annotate groups with [microdata](#) attributes, or other [global attributes](#) that apply to whole groups, or just for styling purposes, each group in a `dt` element can be wrapped in a `div` element. This does not change the semantics of the `dt` element.

The name-value groups of a `dt` element *d* are determined using the following algorithm. A name-value group has a name (a list of `dt` elements, initially empty) and a value (a list of `dd` elements, initially empty).

1. Let *groups* be an empty list of name-value groups.
2. Let *current* be a new name-value group.
3. Let *seenDd* be false.
4. Let *child* be *d*'s [first child](#).
5. Let *grandchild* be null.
6. While *child* is not null:

1. If *child* is a `div` element, then:

1. Let *grandchild* be *child*'s [first child](#).
2. While *grandchild* is not null:

1. [Process dt or dd](#) for *grandchild*.

2. Set *grandchild* to *grandchild*'s [next sibling](#).

2. Otherwise, [process dt or dd](#) for *child*.

3. Set *child* to *child*'s [next sibling](#).

7. If *current* is not empty, then append *current* to *groups*.

8. Return *groups*.

To [process dt or dd](#) for a node *node* means to follow these steps:

1. Let *groups*, *current*, and *seenDd* be the same variables as those of the same name in the algorithm that invoked these steps.

2. If *node* is a `dt` element, then:

1. If *seenDd* is true, then append *current* to *groups*, set *current* to a new name-value group, and set *seenDd* to false.
2. Append *node* to *current*'s name.

3. Otherwise, if *node* is a `dd` element, then append *node* to *current*'s value and set *seenDd* to true.

Note

When a name-value group has an empty list as name or value, it is often due to accidentally using `dt` elements in the place of `dt` elements and vice versa. Conformance checkers can spot such mistakes and might be able to advise authors how to correctly use the markup.

Example

In the following example, one entry ("Authors") is linked to two values ("John" and "Luke").

```
<dt>
<dd> Authors
<dd> John
<dd> Luke
<dd> Editor
<dd> Frank
</dd>
```

Example

In the following example, one definition is linked to two terms.

```
<dt>
<dt lang="en-US"><dfn><color></dfn></dt>
<dt lang="en-GB"><dfn><colour></dfn></dt>
<dd> The <code>color</code> CSS property derives from the ability of the eye to distinguish three differently filtered analyses of a view. </dd>
</dd>
```

Example

The following example illustrates the use of the `dt` element to mark up metadata of sorts. At the end of the example, one group has two metadata labels ("Authors" and "Editors") and two values ("Robert Rothman" and "Daniel Jackson"). This example also uses the `div` element around the groups of `dt` and `dd` element, to aid with styling.

```
<dt>
<dt>
<dt> Last modified: 2004-12-23T23:33Z </dt>
<div>
<dt> Recommended update interval </dt>
<dt> 80s </dt>
</div>
<dt> Authors </dt>
<dt> Editors </dt>
<dd> Robert Rothman </dd>
<dd> Daniel Jackson </dd>
</div>
</div>
```

Example

The following example shows the `dt` element used to give a set of instructions. The order of the instructions here is important (in the other examples, the order of the blocks was not important).

```
<p>Determine the victory points as follows (use the first matching rule):</p>
<dt>
<dt> If you have exactly five gold coins </dt>
<dt> You get five victory points </dt>
<dt> If you have one or more gold coins, and you have one or more silver coins </dt>
<dt> You get two victory points </dt>
<dt> If you have one or more silver coins </dt>
<dt> You get one victory point </dt>
<dt> You get no victory points </dt>
</dt>
```

Example

The following snippet shows a `dt` element being used as a glossary. Note the use of `dt` to indicate the word being defined.

```
<dt>
<dt> department </dt>
<dd> An execution context grouping one or more threads with one or more COM objects. </dd>
<dt> flat </dt>
<dd> n. </dd>
<dt> home </dt>
<dd> n. </dd>
<dt> user </dt>
<dd> The user's login directory. </dd>
</dt>
```

Example

This example uses [microdata](#) attributes in a `dt` element, together with the `div` element, to annotate the ice cream desserts at a French restaurant.

```
<div itemscope itemtype="http://schema.org/Product">
<dt itemprop="name">Café ou Chocolat Liégeois</dt>
<dt itemscope itemtype="http://schema.org/Offer">
<span itemprop="price">3,50</span>
<span itemprop="priceCurrency" value="EUR">€</span>
<dt itemscope itemtype="http://schema.org/Description">
  2 boules Café ou Chocolat, 1 boule Vanille, sauce café ou chocolat, chantilly
</dt>
```

```
<div itemscope itemtype="http://schema.org/Product">
<dt itemprop="name">Crème brûlée</dt>
<dt itemscope itemtype="http://schema.org/Offer">
<span itemprop="price">3,50</span>
<span itemprop="priceCurrency" value="EUR">€</span>
<dt itemscope itemtype="http://schema.org/Description">
  1 boule Crème brûlée, 1 boule Vanille, 1 boule Caramel, chantilly
</dt>
```

Without the `div` element the markup would need to use the `itemref` attribute to link the data in the `dd` elements with the item, as follows.

```
<dt itemscope itemtype="http://schema.org/Product" itemref="1-offer 1-description">
<span itemprop="name">Café ou Chocolat Liégeois</span>
<dd id="1-offer" itemscope itemtype="http://schema.org/Offer" itemref="1-description">
<span itemprop="price">3,50</span>
<span itemprop="priceCurrency" value="EUR">€</span>
<dt itemscope itemtype="http://schema.org/Description" itemref="1-description">
  2 boules Café ou Chocolat, 1 boule Vanille, sauce café ou chocolat, chantilly
</dt>
```

```
<dt itemscope itemtype="http://schema.org/Product" itemref="2-offer 2-description">
<span itemprop="name">Crème brûlée</span>
<dd id="2-offer" itemscope itemtype="http://schema.org/Offer" itemref="2-description">
<span itemprop="price">3,50</span>
<span itemprop="priceCurrency" value="EUR">€</span>
<dt itemscope itemtype="http://schema.org/Description" itemref="2-description">
  1 boule Crème brûlée, 1 boule Vanille, 1 boule Caramel, chantilly
</dt>
```

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

Contexts in which this element can be used:

Before `dd` or `dt` elements inside `dl` elements.

Before `dt` or `dd` elements inside `ul` elements that are children of a `dt` element.

Content model:

Flow content, but with no `header`, `footer`, `sectioning content`, or `heading content` descendants.

Tag omission in text/html:

The `dt` element's `end tag` can be omitted if the `dt` element is immediately followed by another `dt` element or a `dd` element.

Content attributes:

[Global attributes](#)

Accessibility considerations:

For authors

For implementors

DOM interface:

Uses [HTMLElement](#).

The `dt` element **represents** the term, or name, part of a term-description group in a description list (`dl` element).

Note

The `dt` element itself, when used in a `dl` element, does not indicate that its contents are a term being defined, but this can be indicated using the `def` element.

Example

This example shows a list of frequently asked questions (a FAQ) marked up using the `dt` element for questions and the `dd` element for answers.

```
<article>
  <h2>FAQ</h2>
  <dl>
    <dt>What do we want?</dt>
    <dd>Our data.</dd>
    <dt>Who do we want it?</dt>
    <dd>Our data.</dd>
    <dt>Where is it?</dt>
    <dd>We are not sure.</dd>
  </dl>
</article>
```

Flow content

Flow content node

Phrasing content

Contexts in which this element can be used:

Where `flow content` is expected.

Content model:

The `figure` element followed by `flow content`.

Or, `flow content` followed by one `figcaption` element.

Or, `flow content`.

Tag omission in text/html:

Neither tag is omitable.

Content attributes:

[Global attributes](#)

Accessibility considerations:

For authors

For implementors

DOM interface:

Uses [HTMLFigureElement](#).

The `figure` element **represents** some `flow content`, optionally with a caption, that is self-contained (like a complete sentence) and is typically [referenced](#) as a single unit from the main flow of the document.

Note
 "Self-contained" in this context does not necessarily mean independent. For example, each sentence in a paragraph is self-contained; an image that is part of a sentence would be inappropriate for `figure`, but an entire sentence made of images would be fitting.

The element can thus be used to annotate illustrations, diagrams, photos, code listings, etc.

Note

When a `figure` is referred to from the main content of the document by identifying it by its caption (e.g., by figure number), it enables such content to be easily moved away from that primary content, e.g., to the side of the page, to dedicated pages, or to an appendix, without affecting the flow of the document.

If a `figure` element is [referenced](#) by its relative position, e.g., "in the photograph above" or "as the next figure shows", then moving the figure would disrupt the page's meaning. Authors are encouraged to consider using labels to refer to figures, rather than using such relative references, so that the page can easily be restyled without affecting the page's meaning.

The first `figcaption` element child of the element, if any, represents the caption of the `figure` element's content's. If there is no child `figcaption` element, then there is no caption.

A `figure` element's contents are part of the surrounding flow. If the purpose of the page is to display the figure, for example a photograph on an image sharing site, the `figure` and `figcaption` elements can be used to explicitly provide a caption for that figure. For content that is only tangentially related, or that serves a separate purpose than the surrounding flow, the `aside` element should be used (and can itself wrap a `figure`). For example, a pull quote that repeats content from an `article` would be more appropriate in an `aside` than in a `figure`, because it isn't part of the content, it's a repetition of the content for the purposes of enticing readers or highlighting key topics.

Example

This example shows the `figure` element to mark up a code listing.

```
<pre><a href="#14">listing 4</a> we see the primary core interface
```

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

```
<figcaption>Listing 4. The primary core interface API declaration.</figcaption>
<pre><code>interface PrimaryCore {
  boolean verifyDataLine();
  void writeDataInSequence(byte[] data);
  void init();
}</code></pre>
<p>The API is designed to use UTF-8.</p>
```

Example

Here we see a `figure` element to mark up a photo that is the main content of the page (as in a gallery).

```
<!DOCTYPE HTML>
<html lang="en">
<title>bubbles at work - My Gallery</title>
<img alt="A man in his office chair, works on his latest project intently."/>
<caption>bubbles at work</caption>
</figure>
<a href="19414.html">Prev</a> ~ <a href="19416.html">Next</a></nav>
```

`Figure`

In this example, we see an image that is *not* a figure, as well as an image and a video that are. The first image is literally part of the example's second sentence, so it's not a self-contained unit, and thus `figure` would be inappropriate.

`Figure`

`This case centered on some sort of "intellectual property" infringement related to a comic (see Exhibit A). The suit started after a trailer ending with these words:`

`Figure`

`...was aired. A lawyer, armed with a Bigger Notebook, launched a preemptive strike using snowballs. A complete copy of the trailer is online with Exhibit B.`

`Figure`

`<caption>Exhibit A. The alleged <code>rough copy</code> comic.</caption>`

`Figure`

`<caption>Exhibit B. The <code>rough copy</code> trailer.</caption>`

`Figure`

`The case was resolved out of court.`

Example

Here, a part of a poem is marked up using `figure`.

```
<figure>
<p>Two billing, and the silvy coves<br>
Bills and gills in the wave,<br>
All silvy were the horogaves,<br>
And the moon rats outgrabe.</p>
<caption><code>Jabberwocky</code> (first verse). Lewis Carroll, 1832-98</caption>
</figure>
```

Example

In this example, which could be part of a much larger work discussing a castle, nested `figure` elements are used to provide both a group caption and individual captions for each figure in the group:

```
<figure>
<caption>The castle through the ages: 1423, 1858, and 1999 respectively.</caption>
<img alt="Etching, Anonymous, ca. 1423."/>
<caption>Etching, Anonymous, ca. 1423.</caption>
<img alt="Oil-based paint on canvas, Maria Toulis, 1858."/>
<caption>Oil-based paint on canvas. Maria Toulis, 1858.</caption>
<img alt="Film photograph, Peter Jankle, 1999."/>
<caption>Film photograph. Peter Jankle, 1999.</caption>
<img alt="The castle lies in ruins, the original tower all that remains in one piece."/>
</figure>
```

Example

The previous example could also be more succinctly written as follows (using `title` attributes in place of the nested `figure/figcaption` pairs):

```
<img alt="Etching, Anonymous, ca. 1423." title="Etching, Anonymous, ca. 1423."/>
<img alt="Oil-based paint on canvas, Maria Toulis, 1858." title="Oil-based paint on canvas. Maria Toulis, 1858."/>
<img alt="Film photograph, Peter Jankle, 1999." title="Film photograph. Peter Jankle, 1999."/>
<caption>The castle through the ages: 1423, 1858, and 1999 respectively.</caption>
</figure>
```

Example

The figure is sometimes [referenced](#) only implicitly from the content:

```
<article>
<h1>Fiscal negotiations stumble in Congress as deadline nears</h1>
<img alt="obama-reid.jpg" title="Barack Obama and Harry Reid sit together smiling in the Oval Office."/>
<caption>Barack Obama and Harry Reid. White House press photograph.</caption>
<p>Negotiations in Congress to end the fiscal impasse sputtered on Tuesday, leaving both chambers grasping for a way to reopen the government and raise the country's borrowing authority with a Thursday deadline drawing near.</p>
</article>
```

4.4.13 The `figcaption` element

MDN

Categories:

Flow content.

Portable content.

Contexts in which this element can be used:

Where `flow content` is expected, but only if it is a [hierarchically correct `main` element](#).

Content model:

Flow content.

[Content attributes:](#)
[Global attributes:](#)
[Accessibility considerations:](#)
 For authors:
 For implementers:
[DOM interface:](#)
 Uses [HTMLElement](#).

The `main` element [represents](#) the dominant contents of the document.

A document must not have more than one `main` element that does not have the `hidden` attribute specified.

A [hierarchically correct](#) `main` element is one whose ancestor elements are limited to `html`, `body`, `div`, `form` without an [accessible name](#), and [autonomous custom elements](#). Each `main` element must be a [hierarchically correct](#) `main` element.

Example

In this example, the author has used a presentation where each component of the page is rendered in a box. To wrap the main content of the page (as opposed to the header, the footer, the navigation bar, and a sidebar), the `main` element is used.

```
<!DOCTYPE html>
<html lang="en">
<title>RG System 17</title>
<head>
  <header>nav, aside, main, footer { margin: 0.5em; border: thin solid black; padding: 0 0 0.25em 0.333; background: #FFF; color: black; box-shadow: 0 0 0 1px black; }</header>
  <main><h1>System Eighteen</h1></main>
  <nav>
    <a href="#">/18/</a>- System 17</a>
    <a href="#">/19/<a href="http://www.w3.org/2011/html/logo.html">W3C</a>
  </nav>
  <p>This system has no HP mechanic, so there's no healing.</p>
  <aside>
    <h2>Character creation</h2>
    <p>Attributes (magic, strength, agility) are purchased at the cost of one point per level.</p>
    <script>function roll() {
      let sum = 0;
      for (let i = 0; i < 3; i++) {
        sum += Math.floor(Math.random() * 6 + 1);
      }
      return sum;
    }
    </script>
    <p>Each encounter, roll the dice for all your skills. If you roll more than the opponent, you win.</p>
  </aside>
  <footer>
    <small>Copyright © 2013</small>
  </footer>
</body>
```

In the following example, multiple `main` elements are used and script is used to make navigation work without a server roundtrip and to set the `hidden` attribute on those that are not current:

```
<!DOCTYPE html>
<html lang="en">
<head>
  <meta charset="UTF-8">
  <title>...</title>
  <link rel="stylesheet" href="spa.css">
  <script>document.addEventListener("DOMContentLoaded", () => {
    const links = document.querySelectorAll("a");
    links.forEach(link => link.addEventListener("click", event => {
      const href = event.target.getAttribute("href");
      if (href === "/about") {
        document.querySelector("#main").hidden = true;
        document.querySelector("#about").hidden = false;
        document.querySelector("#about h1").style.color = "red";
      } else if (href === "/contact") {
        document.querySelector("#main").hidden = true;
        document.querySelector("#contact").hidden = false;
        document.querySelector("#contact h1").style.color = "blue";
      }
    }));
  });
</head>
<body>
  <main hidden="hidden">
    <h1>Home</h1>
  </main>
  <main hidden="hidden">
    <h1>About</h1>
  </main>
  <main hidden="hidden">
    <h1>Contact</h1>
  </main>
  <script>Made with ❤ by <a href="https://example.com">Example 🎨</a>.</script>
</body>
```

4.4.15 The `div` element

Firefox Android+ Safari iOS+ Chrome Android+ WebView Android+ Yes Samsung Internet+ Yes Opera+ Android+ Yes

[Categories:](#)

[Flow content](#)

[Parsable content](#)

[Contexts in which this element can be used:](#)

As a child of a `div` element.

[Content model:](#)

If the element is a child of a `div` element: one or more `div` elements followed by one or more `div` elements, optionally intermixed with [script-supporting elements](#).

If the element is not a child of a `div` element: [flow content](#).

[Tag omission in text/html:](#)

Neither tag ismissible.

[Content attributes:](#)

[Global attributes](#)

[Accessibility considerations:](#)

For authors:

For implementers:

[DOM interface:](#)

```
IDL Exports=Hidden
interface RTCMediaElement : HTMLElement {
  [HTMLConstructor] constructor();
  // also has obsolete members
};
```

The `div` element has no special meaning at all. It [represents](#) its children. It can be used with the `class`, `lang`, and `title` attributes to mark up semantics common to a group of consecutive elements. It can also be used in a `div` element, wrapping groups of `div` and `div` elements.

[Note](#)

Authors are strongly encouraged to view the `div` element as an element of last resort, for when no other element is suitable. Use of more appropriate elements instead of the `div` element leads to better accessibility for readers and easier maintainability for authors.

Example

For example, a blog post would be marked up using `article`, a chapter using `section`, a page's navigation aids using `nav`, and a group of form controls using `fieldset`.

On the other hand, `div` elements can be useful for stylistic purposes or to wrap multiple paragraphs within a section that are all to be annotated in a similar way. In the following example, we see `div` elements used as a way to set the language of two paragraphs at once, instead of setting the language on the two paragraph elements separately:

```
<article lang="en-US">
  <div>I'm back from my cat's absence and my cat's behavior hasn't changed much since her absence, except that she plays her new physique to the neighbours regularly, in an attempt to get them to notice her again.</div>
  <div lang="en-GB">
    <p>My other cat, coloured black and white, is a sweetie. He followed us to the park today, walking down the pavement with us. Yesterday he apparently visited our neighbours. I wonder if he recognises that their first floor is a mirror, though it's dark.</p>
    <p>I just noticed that in the second paragraph I used British English. But I'm supposed to write in American English. So I shouldn't say "pavement" or "flat" or "colour"!</p>
  </div>
  <p>I should say "sidewalk" and "apartment" and "color"!</p>
</article>
```

4.5 Text-level semantics

4.5.1 The `a` element

[DOM](#)

Support in all current engines.

Firefox1+SafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet ExplorerYes

Firefox Android4+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

Categories:[Flow content](#)[Phrasing content](#)If the element has an `href` attribute: [Interactive content](#)[Parsable content](#)[Contexts in which this element can be used:](#)Where [phrasing content](#) is expected.[Content model](#):Phrasing content, but there must be no [interactive content](#) or `a` element descendants.[Tag omission in text/html:](#)

Neither tag ismissible.

[Content attributes:](#)[Global attributes](#)`href` — Address of the [hyperlink](#)`target` — [Navigation context for hyperlink navigation](#)`download` — Whether to download the resource instead of navigating to it, and its file name if so`ping` — [URLs](#) to ping`rel` — Relationship between the location of the document containing the [hyperlink](#) and the destination resource`noopener` — [Opening of the linked resource](#)`noopener` — Hint for the user of the referenced resource`referrerpolicy` — [Referrer policy](#) for `fetch` initiated by the element[Accessibility considerations:](#)If the element has an `href` attribute: [for authors](#) [for implementors](#).Otherwise: [for authors](#) [for implementors](#).[DOM interface:](#)

```
IDL Exports<HTMLAnchorElement>
interface HTMLAnchorElement : HTMLElement {
  [HTMLConstructor] constructor();
  [HTMLAttributes] attribute DOMString target;
  [HTMLAttributes] attribute DOMString download;
  [HTMLAttributes] attribute USVString ping;
  [HTMLAttributes] attribute DOMString rel;
  [SameOrigin] attribute DOMString referrer;
  [CRAactions] attribute DOMString hreflang;
  [CRAactions] attribute DOMString href;
  [CRAactions] attribute DOMString text;
  [CRAactions] attribute DOMString referrerPolicy;
  // also has obsolete members
};

HTMLAnchorElement includes HTMLHyperlinkElementUtils;
```

If the `a` element has an `href` attribute, then it [represents](#) a [hyperlink](#) (a hypertext anchor) labeled by its contents.If the `a` element has no `href` attribute, then the element [represents](#) a placeholder for where a link might otherwise have been placed, if it had been relevant, consisting of just the element's contents.The `target`, `download`, `ping`, `rel`, `hreflang`, `type`, and `referrerpolicy` attributes must be omitted if the `href` attribute is not present.If the `referrerpolicy` attribute is specified on an `a` element, then the `href` attribute must also be specified.**Example**If a site uses a consistent navigation toolbar on every page, then the link that would normally link to the page itself could be marked up using an `a` element:

```
<nav>
<ul>
  <li><a href="#">Home</a></li>
  <li><a href="#">Newspaper</a></li>
  <li><a href="#">Examples</a></li>
  <li><a href="#">Legal</a></li>
</ul>
</nav>
```

The `target`, `target`, `download`, `ping`, and `referrerpolicy` attributes affect what happens when users [follow hyperlinks](#) or [download hyperlinks](#) created using the `a` element. The `rel`, `text`, and `type` attributes may be used to indicate to the user the likely nature of the target resource before the user follows the link.The [activation behavior](#) of `a` elements that create [hyperlinks](#) is to run the following steps:

- If the target of the `click` event is an `img` element with an `ismap` attribute specified, then server-side image map processing must be performed, as follows:
 - Let `x` and `y` be zero.
 - If the `click` event was a real pointing-device-triggered `click` event on the `img` element, then set `x` to the distance in [CSS pixels](#) from the left edge of the image to the location of the click, and set `y` to the distance in [CSS pixels](#) from the top edge of the image to the location of the click.
 - If `x` is negative, set `x` to zero.
 - If `y` is negative, set `y` to zero.
 - Let `hyperlink suffix` be a U+033F QUESTION MARK character, the value of `x` expressed as a base-ten integer using [ASCII digits](#), a U+002C COMMA character (,), and the value of `y` expressed as a base-ten integer using [ASCII digits](#).

- Follow the [hyperlink](#) or [download the hyperlink](#) created by the `a` element, as determined by the `download` attribute and any expressed user preference, passing `hyperlink suffix`, if the steps above defined it.

[For web developers \(non-normative\)](#)[#a](#)Same as `textContent`.**MDN**[HTML Anchor Element \(rel\)](#)

Support for all current engines.

Firefox1+SafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet ExplorerYes

Firefox, Android4+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

The IDL attributes `download`, `ping`, `target`, `rel`, `hreflang`, and `type`, must [reflect](#) the respective content attributes of the same name.**MDN**[HTML Anchor Element \(relList\)](#)

Support for all current engines.

Firefox1+SafariYesChrome65+

OperaYesEdge79+

Edge (Legacy)18+Internet ExplorerYes

Firefox, Android4+Safari iOSYesChrome Android65+WebView Android65+Samsung Internet9.0+Opera AndroidYes

The `IDL attribute relList must reflect the rel content attribute.`The `text` attribute's getter must return this element's [descendant text content](#).The `text` attribute's setter must `stringReplaceAll` with the given value within this element.**Example**The `a` element may be wrapped around entire paragraphs, lists, tables, and so forth, even entire sections, so long as there is no interactive content within (e.g. buttons or other links). This example shows how this can be used to make an entire advertising block into a link:

```
<div class="advertising">
<div>Advertising</div>
<a href="http://ad.example.com/?adid=192&pubid=1422">
<section>
<h1>Wellblomatic 9000!</h1>
<p>Get the most out of your Wellblom!<br/>
<p>Only $9.99 plus shipping and handling.</p>
</section>
</a>
<a href="https://ad.example.com/?adid=375&pubid=1422">
<section>
<h1>Wellblom Browser</h1>
<p>Web browsing at the speed of light.</p>
<p>No other browser goes faster!</p>
</section>
</a>
</div>
```

4.5.2 The `area` element**MDN**[Element area](#)

Palpable content
 Contexts in which this element can be used:
 Where `phrasing-content` is expected.
Content model:
 Phrasing content
Tag omission in text/html:
 Neither tag is ommissible.
Content attributes:
 Global attributes
Accessibility considerations:
 For authors
 For implementers
DOM interface:
 Uses `HTMLElement`.

The `u` element **represents** stress emphasis of its contents.

The level of stress that a particular piece of content has is given by its number of ancestor `u` elements.

The placement of stress emphasis changes the meaning of the sentence. The element thus forms an integral part of the content. The precise way in which stress is used in this way depends on the language.

Example

These examples show how changing the stress emphasis changes the meaning. First, a general statement of fact, with no stress:

```
<p>Cats are cute animals.</p>
```

By emphasizing the first word, the statement implies that the kind of animal under discussion is in question (maybe someone is asserting that dogs are cute):

```
<p><em>Cats</em> are cute animals.</p>
```

Moving the stress to the verb, one highlights that the truth of the entire sentence is in question (maybe someone is saying cats are not cute):

```
<p>Cats <em>are</em> cute animals.</p>
```

By moving it to the adjective, the exact nature of the cats is reasserted (maybe someone suggested cats were *mean* animals):

```
<p>Cats are <em>are</em> cute animals.</p>
```

Similarly, if someone asserted that cats were vegetables, someone correcting this might emphasize the last word:

```
<p>Cats are cute <em>animals</em>.</p>
```

By emphasizing the entire sentence, it becomes clear that the speaker is fighting hard to get the point across. This kind of stress emphasis also typically affects the punctuation, hence the exclamation mark here.

```
<p><em>Cats are cute animals!</em></p>
```

Annoy mixed with emphasizing the cuteness could lead to markup such as:

```
<p><em><em>Cats are <em>cute</em> animals!</em></em></p>
```

Note

The `u` element isn't a generic "italics" element. Sometimes, text is intended to stand out from the rest of the paragraph, as if it was in a different mood or voice. For this, the `u` element is more appropriate.

The `u` element also isn't intended to convey importance; for that purpose, the `strong` element is more appropriate.

4.5.3 The `strong` element

MDN

[Element/strong](#)

Support in all current engines.

Content model:

Phrasing content
 Tag omission in text/html:
 Neither tag is ommissible.

Content attributes:

Global attributes
 For authors
 For implementers

DOM interface:

Uses `HTMLElement`.

The `strong` element **represents** strong importance, seriousness, or urgency for its contents.

Importance: the `strong` element can be used in a heading, caption, or paragraph to distinguish the part that really matters from other parts that might be more detailed, more jovial, or merely boilerplate. (This is distinct from marking up subheadings, for which the `strong` element is appropriate.)

Example

For example, the first word of the previous paragraph is marked up with `strong` to distinguish it from the more detailed text in the rest of the paragraph.

Seriousness: the `strong` element can be used to mark up a warning or caution notice.

Urgency: the `strong` element can be used to denote contents that the user needs to see sooner than other parts of the document.

The relative level of importance of a piece of content is given by its number of ancestor `strong` elements; each `strong` element increases the importance of its contents.

Changing the importance of a piece of text with the `strong` element does not change the meaning of the sentence.

Example

Here, the word "chapter" and the actual chapter number are mere boilerplate, and the actual name of the chapter is marked up with `strong`:

```
<h1>Chapter 1: <strong>The Praxis</strong></h1>
```

In the following example, the name of the diagram in the caption is marked up with `strong`, to distinguish it from boilerplate text (before) and the description (after):

```
<figcaption>Figure 1. <strong>Ant colony dynamics</strong>. The ants in this colony are affected by the heat source (upper left) and the food source (lower right).</figcaption>
```

In this example, the heading is really "Flowers, Bees, and Honey", but the author has added a light-hearted addition to the heading. The `strong` element is thus used to mark up the first part to distinguish it from the latter part.

```
<h1><strong>Flowers, Bees, and Honey</strong> and other things I don't understand</h1>
```

Example

Here is an example of a warning notice in a game, with the various parts marked up according to how important they are:

```
<p><strong>Warning:</strong> This dungeon is dangerous.
```

```
<strong>Avoid the ducks.</strong> Don't touch any gold you find.
```

```
<strong>Don't touch the lava!</strong> The lava is very hot,
```

```
they are explosive and <strong>will</strong> destroy anything within
```

```
ten meters.</strong></p>
```

The author has also marked up the warning text itself as `strong`.

Example

In this example, the `strong` element is used to denote the part of the text that the user is intended to read first.

```
<p>Welcome to Remy, the reminder system.</p>
```

```
<p>Your tasks for today:</p>
```

```
<ul><li><strong>Turn off the oven.</strong></li>
```

```
<li><strong>Put out the trash.</strong></li>
```

```
<li><strong>Do the laundry.</strong></li>
```

Example

4.5.4 The `small` element

MDN

[Element/small](#)

Support in all current engines.

Firefox1+SafariYesChromeYes

OperaYesEdgeYes

 Where `phrasing-content` is expected.

Content model:

Phrasing content
 Tag omission in text/html:
 Neither tag is ommissible.

Content attributes:

Global attributes
 For authors
 For implementers

The `small` element represents side comments such as small print.

Note

Small print typically features disclaimers, caveats, legal restrictions, or copyrights. Small print is also sometimes used for attribution, or for satisfying licensing requirements.

Note

The `small` element does not "de-emphasize" or lower the importance of text emphasized by the `em` element or marked as important with the `strong` element. To mark text as not emphasized or important, simply do not mark it up with the `em` or `strong` elements respectively.

The `small` element should not be used for extended spans of text, such as multiple paragraphs, lists, or sections of text. It is only intended for short runs of text. The text of a page listing terms of use, for instance, would not be a suitable candidate for the `small` element: in such a case, the text is not a side comment, it is the main content of the page.

The `small` element must not be used for subheadings; for that purpose, use the `hgroup` element.

Example

In this example, the `small` element is used to indicate that value-added tax is not included in a price of a hotel room:

```
<code>
<div>
  <dt>Single room</dt>
  <dd>199 € <small>breakfast included, VAT not included</small>
<dt>Double room</dt>
  <dd>299 € <small>breakfast included, VAT not included</small>
</div>
</code>
```

Example

In this second example, the `small` element is used for a side comment in an article.

```
<p>Example Corp today announced record profits for the second quarter <small>(Full Disclosure: Foo News is a subsidiary of Example Corp)</small>, leading to speculation about a third quarter merger with Demo Group.</p>
```

This is distinct from a sidebar, which might be multiple paragraphs long and is removed from the main flow of text. In the following example, we see a sidebar from the same article. This sidebar also has small print, indicating the source of the information in the sidebar.

```
<aside>
  <p>Example Corp</p>
  <p><small>This company mostly creates small software and Web sites.</small></p>
  <p><small>Example Corp company mission is "To provide entertainment and news on a sample basis".</small><br/>
  <small>Information obtained from a home page at <a href="http://www.example.com/about.html">example.com</a> home page.</small></p>
</aside>
```

Example

In this last example, the `small` element is marked as being *important* small print.

```
<p><strong><small>Continued use of this service will result in a kiss.</small></strong></p>
```

4.5.5 The `a` element

Neither tag is omissionable.

Content attributes:

Global attributes

Accessibility considerations:

For authors

For implementers

DOM interface:

Uses `HTMLAnchorElement`.

The `a` element represents contents that are no longer accurate or no longer relevant.

Note

The `a` element is not appropriate when indicating document edits; to mark a span of text as having been removed from a document, use the `del` element.

Example

In this example a recommended retail price has been marked as no longer relevant as the product in question has a new sale price.

```
<p>Buy our Iced Tea and Lemonade!</p>
<p><del>Recommended retail price: $3.99 per bottle!</del></p>
<p><strong>Now selling for just $2.99 a bottle!</strong></p>
```

4.5.6 The `cite` element

MDN

Element's

Support in all current engines.

Firefox 1+ Safari Yes Chrome Yes

Categories:

Flow content

Phrasing content

Palatable content

Contexts in which this element can be used:

Where phrasing content is expected.

Content model:

Phrasing content

Tag omission in text/html:

Neither tag is omissionable.

Content attributes:

Global attributes

Accessibility considerations:

For authors

For implementers

DOM interface:

Uses `HTMLCiteElement`.

The `cite` element represents the title of a work (e.g. a book, a paper, an essay, a poem, a score, a song, a script, a film, a TV show, a game, a sculpture, a painting, a theatre production, a play, an opera, a musical, an exhibition, a legal case report, a computer program, etc). This can be a work that is being quoted or referenced in detail (i.e. a citation), or it can just be a work that is mentioned in passing.

A person's name is not the title of a work — even if people call that person a piece of work — and the element must therefore not be used to mark up people's names. (In some cases, the `a` element might be appropriate for names; e.g. in a gossip article where the names of famous people are keywords rendered with a different style to draw attention to them. In other cases, if an element is *really* needed, the `span` element can be used.)

Example

This next example shows a typical use of the `cite` element:

```
<p>My favorite book is <code><code>The Reality Dysfunction</code></code> by Peter F. Hamilton. My favorite comic is <code><code>Pearls Before Swine</code></code> by Jeff Parker and Ted Mills. My favorite movie is <code><code>Jaws</code></code> by the Cannibalistic Amity Sextet.</p>
```

Example

This is correct usage:

```
<p>According to the Wikipedia article <code><code>HTML</code></code>, as it stood in mid-February 2008, leaving attribute values unquoted is unsafe. This is obviously an over-simplification.</p>
```

The following, however, is incorrect usage, as the `cite` element here is containing far more than the title of the work:

```
<p>So doing a copy-and-paste example of the above usage is unsafe. According to the Wikipedia article on HTML<code><code>HTML</code></code>, as it stood in mid-February 2008, leaving attribute values unquoted is unsafe. This is obviously an over-simplification.</p>
```

Example

The `cite` element is obviously a key part of any citation in a bibliography, but it is only used to mark the title:

```
<p><code><code>Universal Declaration of Human Rights</code></code>, United Nations, December 1948. Adopted by General Assembly resolution 217 A (III).</p>
```

Note

A citation is not a quote (for which the `a` element is appropriate).

Example

This is incorrect usage, because `value` is not for quotes:

Example

In this example, notice again how each annotation corresponds to a single base character. In this example, each compound word (jukugo) corresponds to a single `<ruby>` element. The rendering here is expected to be that each annotation is placed over (or next to, in vertical text) the corresponding base character, with the annotations not overlapping any of the adjacent characters.

```
<ruby>鬼</rt>き</rt>門</rt>もん</rt></ruby>の<ruby>方</rt>ほう</rt><rb>ほ</rb></ruby>を<ruby>鬼</rt>き</rt>門</rt>もん</rt></ruby>する
  ↳ ほ ほん ほん ほん ほん
  鬼門の方角を 篤 祀る
```

Jukugo-ruby

This is semantically identical to the previous case (each individual ideographic character in the base compound word has its reading given in an annotation in hiragana or katakana characters), but the rendering is the more complicated Jukugo Ruby rendering.

Example

This is the same example as above for mono-ruby for compound words. The different rendering is expected to be achieved using different styling (e.g. in CSS), and is not shown here.

```
<ruby>鬼</rt>き</rt>門</rt>もん</rt></ruby>の<ruby>方</rt>ほう</rt><rb>ほ</rb></ruby>を<ruby>鬼</rt>き</rt>門</rt>もん</rt></ruby>する
```

Note

For more details on [Jukugo Ruby rendering](#), see Appendix F in the [Requirements for Japanese Text Layout \[JLREQ\]](#).

Group ruby for describing meanings

The annotation describes the meaning of the base text, rather than (or in addition to) the pronunciation. As such, both the base text and the annotation can be multiple characters long.

Example

```
<ruby>BASE</rt>annotation</ruby>
```

Example

Here a compound ideographic word has its corresponding katakana given as an annotation.

```
<ruby>境界面</rt>インターフェース</ruby>
  ↳ インターフェース
  境界面
```

Example

Here a compound ideographic word has its translation in English provided as an annotation.

```
<ruby lang="ja">編集者</rt>lang="en">editor</ruby>
  ↳ 编集者
  编辑者
```

Group ruby for Jukugi readings

A phonetic reading that corresponds to multiple base characters, because a one-to-one mapping would be difficult. (In English, the words "Colonel" and "Lieutenant" are examples of words where a direct mapping of pronunciation to individual letters is, in some dialects, rather unclear.)

Example

In this example, the name of a species of flowers has a phonetic reading provided using group ruby:

```
<ruby>紫陽花</rt>あじきゅう</ruby>
  ↳ あじきゅう
  紫陽花
```

Text with both phonetic and semantic annotations (double-sided ruby)

Sometimes, ruby styles described above are combined.

If this results in two annotations covering the same single base segment, then the annotations can just be placed back to back.

Example

```
<ruby>BASE</rt>annotation 1</rt>annotation 2</ruby>
```

Example

```
<ruby><rt>a</rt><rb>A</rb><rt>a</rt><rb>A</rb><rt>b</rt><rb>B</rb><rt>b</rt><rb>B</rb></ruby>
```

Example

In this contrived example, some symbols are given names in English and French.

```
<ruby>
  ▲ <rt> Heart <rt> large=fr <rb> Coeur </rb>
  ▲ <rt> Shamrock <rt> lang=fr <rb> Trèfle </rb>
  * <rt> Star <rt> lang=fr <rb> Etoile </rb>
</ruby>
```

In more complication situations such as following examples, a nested `<ruby>` element is used to give the inner annotations, and then that whole `<ruby>` is then given an annotation at the "outer" level.

Example

```
<ruby><ruby>B</rt>a</rt><rb>A</rb><rt>n</rt><rb>B</rb><rt>n</rt></ruby><rb>Annotation</rb></ruby>
```

Example

Here both a phonetic reading and the meaning are given in ruby annotations. The annotation on the nested `<ruby>` element gives a mono-ruby phonetic annotation for each base character, while the annotation in the `<rb>` element that is a child of the outer `<ruby>` element gives the meaning using hiragana.

```
<ruby><ruby>東</rt>とう</rt><rb>東</rb><rt>なん</rt><rb>東</rb><rt>の方向
  ↳ とう
  東の方向
```

Example

This is the same example, but the meaning is given in English instead of Japanese:

```
<ruby><ruby>東</rt>とう</rt><rb>東</rb><rt lang=en>Southeast</rt></ruby><rb>の方向
  ↳ とう
  東南の方向
```

Writing a `<ruby>` element that does not have a `<rb>` element ancestor, content is segmented and segments are placed into three categories: base text segments, annotation segments, and ignored segments. Ignored segments do not form part of the document's semantics (they consist of some [inter-element whitespace](#) and `<hr>` elements, the latter of which are used for legacy user agents that do not support ruby at all). Base text segments can overlap (with a limit of two segments overlapping any one position in the DOM, and with any segment having an earlier start point than an overlapping segment also having an equal or later end point, and any segment have a later end point than an overlapping segment also having an equal or earlier start point). Annotation segments correspond to `<rb>` elements. Each annotation segment can be associated with a base text segment, and each base text segment can have annotation segments associated with it. (In a conforming document, each base text segment is associated with at least one annotation segment, and each annotation segment is associated with one base text segment.) A `<rb>` element represents the union of the segments of base text it contains, along with the mapping from those base text segments to annotation segments. Segments are described in terms of DOM ranges; annotation segment ranges always consist of exactly one element. [\[DOM\]](#)

At any particular time, the segmentation and categorization of content of a `<ruby>` element is the result that would be obtained from running the following algorithm:

1. Let `base text segments` be an empty list of base text segments, each potentially with a list of base text subsegments.
2. Let `annotation segments` be an empty list of annotation segments, each potentially being associated with a base text segment or subsegment.
3. Let `root` be the `<ruby>` element for which the algorithm is being run.
4. If `root` has a `<rb>` element ancestor, then jump to the step labeled `end`.
5. Let `current parent` be `root`.
6. Let `index` be 0.
7. Let `start index` be null.
8. Let `parent start index` be null.
9. Let `current base text` be null.
10. **Start mode:** If `index` is equal to or greater than the number of child nodes in `current parent`, then jump to the step labeled `end mode`.
11. If the `index` node in `current parent` is an `<hr>` or `<rb>` element, jump to the step labeled `annotation mode`.
12. Set `start index` to the value of `index`.
13. **Base mode:** If the `index` node in `current parent` is a `<rb>` element, and if `current parent` is the same element as `root`, then `push a ruby level` and then jump to the step labeled `start mode`.
14. If the `index` node in `current parent` is an `<hr>` or `<rb>` element, then `set the current base text` and then jump to the step labeled `annotation mode`.
15. Increment `index` by one.
16. **Base mode post-increment:** If `index` is equal to or greater than the number of child nodes in `current parent`, then jump to the step labeled `end mode`.
17. Jump back to the step labeled `base mode`.
18. **Annotation mode:** If the `index` node in `current parent` is an `<hr>` element, then `push a ruby annotation` and jump to the step labeled `annotation mode increment`.
19. If the `index` node in `current parent` is an `<hr>` element, jump to the step labeled `annotation mode increment`.
20. If the `index` node in `current parent` is not a `<text>` node, or is a `<text>` node that is not `inter-element whitespace`, then jump to the step labeled `base mode`.
21. **Annotation mode increment:** Let `lookahead index` be `index` plus one.
22. **Annotation mode white-space skipper:** If `lookahead index` is equal to the number of child nodes in `current parent` then jump to the step labeled `end mode`.
23. If the `lookahead index` node in `current parent` is an `<hr>` element or an `<rb>` element, then set `index` to `lookahead index` and jump to the step labeled `annotation mode`.
24. If the `lookahead index` node in `current parent` is not a `<text>` node, or is a `<text>` node that is not `inter-element whitespace`, then jump to the step labeled `base mode` (without further incrementing `index`, so the `inter-element whitespace` seen so far becomes part of the next base text segment).
25. Increment `lookahead index` by one.
26. Jump to the step labeled `annotation mode white-space skipper`.
27. **End mode:** If `current parent` is not the same element as `root`, then `pop a ruby level` and jump to the step labeled `base mode post-increment`.
28. **End:** Return `base text segments` and `annotation segments`. Any content of the `<ruby>` element not described by segments in either of those lists is implicitly in an `ignored segment`.

When the steps above say to `set the current base text`, it means to run the following steps at that point in the algorithm:

2. Let *new text segment* be a base text segment described by the range *annotation range*.

3. Add *new text segment* to *base text segments*.

4. Let *current base text* be *new text segment*.

5. Let *start index* be null.

When the steps above say to *push a ruby level*, it means to run the following steps at that point in the algorithm:

1. Let *current parent* be the *indepth node* in *current parent*.

2. Let *index* be 0.

3. Set *saved start index* to the value of *start index*.

4. Let *start index* be null.

When the steps above say to *pop a ruby level*, it means to run the following steps at that point in the algorithm:

1. Let *index* be the position of *current parent* in *root*.

2. Let *current parent* be *root*.

3. Increment *index* by 1.

4. Set *start index* to the value of *saved start index*.

5. Let *saved start index* be null.

When the steps above say to *push a ruby annotation*, it means to run the following steps at that point in the algorithm:

1. Let *r* be the *rt* element that is the *indepth node* of *current parent*.

2. Let *annotation range* be a DOM range whose *start* is the *boundary point* (*current parent*, *index*) and whose *end* is the *boundary point* (*current parent*, *index* plus one) (i.e. that contains only *r*).

3. Let *new annotation segment* be an annotation segment described by the range *annotation range*.

4. If *current base text* is not null, associate *new annotation segment* with *current base text*.

5. Add *new annotation segment* to *annotation segments*.

Example

In this example, each ideograph in the Japanese text 漢字 is annotated with its reading in hiragana.

```
<ruby>漢<rt>かん</rt>字<rt>じ</rt></ruby>
```

This might be rendered as:

かん
... 漢字 ...

Example

In this example, each ideograph in the traditional Chinese text 漢字 is annotated with its bopomofo reading.

```
<ruby>漢<rt>ㄏㄢˋ</rt>字<rt>ㄐㄧˋ</rt></ruby>
```

This might be rendered as:

ㄏㄢˋ
... 漢字 ...

Example

In this example, each ideograph in the simplified Chinese text 汉字 is annotated with its pinyin reading.

```
<ruby>汉<rt>han</rt>字<rt>zhi</rt></ruby>...
```

This might be rendered as:

hàn
... 汉字 ...

Example

In this more contrived example, the acronym "HTML" has four annotations: one for the whole acronym, briefly describing what it is, one for the letters "HT" expanding them to "Hypertext", one for the letter "M" expanding it to "Markup", and one for the letter "L" expanding it to "Language".

```
<ruby>HTML<rt>HyperText</rt><rt>Markup</rt><rt>Language</rt></ruby>...<br><!-- An abstract language for describing documents and applications -->
```

This might be rendered as:

... HTML ...

4.5.11 The *rt* element

DOM

Element API

Support in all current engines.

Firefox 38+ Safari 5+ Chrome 5+

Opera 15+ Edge 79+

Edge (Legacy) No Internet Explorer 5+

Firefox, Android 38+, Safari, iOS Yes, Chrome, Android Yes, WebView, Android Yes, Samsung Internet Yes, Opera, Android 14+

Categories:

None.

Contexts in which this element can be used:

As a child of a *ruby* element.

Content model:

Phrasing content

Tag omission in text/html:

An *rt* element's *end tag* can be omitted if the *rt* element is immediately followed by an *rt* or *rp* element, or if there is no more content in the parent element.

Content attributes:

Global attributes

Accessories and considerations:

For authors

For implementers

DOM interface:

Uses [HTMLElement](#).

The *rt* element marks the ruby text component of a ruby annotation. When it is the child of a *ruby* element, it doesn't *represent* anything itself, but the *ruby* element uses it as part of determining what it *represents*.

An *rt* element that is not a child of a *ruby* element *represents* the same thing as its children.

4.5.12 The *rp* element

DOM

Element API

Support in all current engines.

Firefox 38+ Safari 5+ Chrome 5+

Opera 15+ Edge 79+

Edge (Legacy) No Internet Explorer 5+

Firefox, Android 38+, Safari, iOS Yes, Chrome, Android Yes, WebView, Android Yes, Samsung Internet Yes, Opera, Android 14+

Categories:

None.

Contexts in which this element can be used:

As a child of a *ruby* element, either immediately before or immediately after an *rt* element.

Content model:

Text

Tag omission in text/html:

An *rp* element's *end tag* can be omitted if the *rp* element is immediately followed by an *rt* or *rt* element, or if there is no more content in the parent element.

Content attributes:

Global attributes

Accessories and considerations:

For authors

For implementers

DOM interface:

Uses [HTMLElement](#).

The *rp* element can be used to provide parentheses or other content around a ruby text component of a ruby annotation, to be shown by user agents that don't support ruby annotations.

An *rp* element that is a child of a *ruby* element *represents* nothing. An *rp* element whose parent element is not a *ruby* element *represents* its children.

Example

The example above, in which each ideograph in the text 漢字 is annotated with its phonetic reading, could be expanded to use *rp* so that in legacy user agents the readings are in parentheses:

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

```
<ruby>漢</rp> </rp><rt>かん</rt></rp> </rp>字</rp> </rp><rt>字</rt></rp> </rp></ruby>
...

```

In conforming user agents the rendering would be as above, but in user agents that do not support ruby, the rendering would be:

... 漢（かん）字（字）...

Example

When there are multiple annotations for a segment, `rt` elements can also be placed between the annotations. Here is another copy of an earlier contrived example showing some symbols with names given in English and French, but this time with `rt` elements as well:

```
<ruby>
  <rp>*</rp><rt>Heart</rt><rp>, </rp><rt>langfr-Cuir</rt><rp>.</rp>
  <rp>♣</rp><rt>Shamrock</rt><rp>, </rp><rt>langfr-Tréfle</rt><rp>.</rp>
  <rp>♦</rp><rt>Star</rt><rp>, </rp><rt>langfr-Etoile</rt><rp>.</rp>
</ruby>
```

This would make the example render as follows in non-ruby-capable user agents:

*; Heart, Cuir, ♣; Shamrock, Tréfle, ♦; Star, Etoile.

4.5.13 The `data` element

[MDN](#)

Element

Firefox22+SafariNoChrome62+

Categories:

Flow content

Phrasing content

Palpable content

Contexts in which this element can be used:

Where phrasing content is expected.

Content model:

Phrasing content

Tag omission in `text/html`:

Neither tag is omitable.

Content attributes:

Global attributes

`value` — Machine-readable value

Accessibility considerations:

For authors

For implementers

DOM interface:

```
IDL[Exposed=Window]
interface HTMLDataElement : HTMLElement {
  [HTMLConstructor] constructor();
  [CSSReactions] attribute DOMString value;
};
```

The `data` element represents its contents, along with a machine-readable form of those contents in the `value` attribute.

The `value` attribute must be present. Its value must be a representation of the element's contents in a machine-readable format.

Note

When the value is date- or time-related, the more specific `time` element can be used instead.

The element can be used for several purposes.

When combined with microformats or the `microdata attributes` defined in this specification, the element serves to provide both a machine-readable value for the purposes of data processors, and a human-readable value for the purposes of rendering in a Web browser. In this case, the format to be used in the `value` attribute is determined by the microformats or microdata vocabulary in use.

The element can also, however, be used in conjunction with scripts in the page, for when a script has a literal value to store alongside a human-readable value. In such cases, the format to be used depends only on the needs of the script. (The `data-n` attributes can also be useful in such situations.)

[MDN](#)

HTML DataElementValue

Firefox22+SafariNoChrome62+

Opera49+Edge79+

Edge (Legacy) Internet ExplorerNo

Firefox Android22+Safari iOSNoChrome Android62+WebView Android62+Samsung Internet8.0+Opera Android46+

The `value` IDL attribute must `reflect` the `content` attribute of the same name.

Example

Here, a short table has its numeric values encoded using the `data` element so that the table sorting JavaScript library can provide a sorting mechanism on each column despite the numbers being presented in textual form in one column and in a decomposed form in another.

```
<script src="sortable.js"></script>
<table border="1">
  <thead> <tr> <th> Game </th> Corporations </th> Map Size
  </thead>
  <tbody>
    <tr> <td> 1830 </td> <td> data value="8">Eight</td> <td> <data value="93">19+74 hexes (93 total)</data>
    <tr> <td> 1856 </td> <td> data value="11">Eleven</td> <td> <data value="99">12+87 hexes (99 total)</data>
    <tr> <td> 1870 </td> <td> data value="10">Ten</td> <td> <data value="149">4+145 hexes (149 total)</data>
  </tbody>
</table>
```

4.5.14 The `time` element

Categories:

Flow content

Phrasing content

Palpable content

Contexts in which this element can be used:

Where phrasing content is expected.

Content model:

If the element has a `data-time` attribute: Phrasing content.

Otherwise: Text, but must match requirements described in prose below.

Tag omission in `text/html`:

Neither tag is omitable.

Content attributes:

Global attributes

`value` — Machine-readable value

Accessibility considerations:

For authors

For implementers

DOM interface:

```
IDL[Exposed=Window]
interface HTMLTimeElement : HTMLElement {
  [HTMLConstructor] constructor();
  [CSSReactions] attribute DOMString value;
  [CSSReactions] attribute DOMString dataTime;
};
```

The `time` element represents its contents, along with a machine-readable form of those contents in the `data-time` attribute. The kind of content is limited to various kinds of dates, times, time-zone offsets, and durations, as described below.

The `data-time` attribute may be present. If present, its value must be a representation of the element's contents in a machine-readable format.

A `time` element that does not have a `data-time` content attribute must not have any element descendants.

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

7. If [parsing a global date and time string](#) from the element's `datetime` value returns a [global date and time](#), that is the machine-readable equivalent; return.
8. If [parsing a week string](#) from the element's `datetime` value returns a [week](#), that is the machine-readable equivalent; return.
9. If the element's `datetime` value consists of only [ASCII digits](#), at least one of which is not U+0030 DIGIT ZERO (0), then the machine-readable equivalent is the base-ten interpretation of those digits, representing a year; return.
10. If [parsing a duration string](#) from the element's `datetime` value returns a [duration](#), that is the machine-readable equivalent; return.
11. There is no machine-readable equivalent.

Note

The algorithms referenced above are intended to be designed such that for any arbitrary string *s*, only one of the algorithms returns a value. A more efficient approach might be to create a single algorithm that parses all these data types in one pass; developing such an algorithm is left as an exercise to the reader.

MDN[HTML.TimeElement/dateTime](#)

Support in all current engines.

Firefox22+Safari10+Chrome62+

Opera49+Edge79+

Edge (Legacy)14+Internet ExplorerNo

Firefox, Android22+Safari iOS10+Chrome Android62+WebView Android62+Samsung Internet8.0+Opera Android46+

The `dateTime` IDL attribute must [reflect](#) the element's `datetime` content attribute.

Example

The `time` element can be used to encode dates, for example in microformats. The following shows a hypothetical way of encoding an event using a variant on hCalendar that uses the `time` element:

```
<div class="vevent">
<div class="url" href="http://www.web2con.com/"><a href="http://www.web2con.com/"></a>
<div class="summary">Web 2.0 Conference</div>
<time class="start" datetime="2005-10-05">October 5</time>
<time class="end" datetime="2005-10-07">7</time>
<div class="location">Argent Hotel, San Francisco, CA</span>
</div>
```

Example

Here, a fictional microdata vocabulary based on the Atom vocabulary is used with the `time` element to mark up a blog post's publication date.

```
<article itemscope itemtype="https://a.example.org/rfc2878">
<h1 itemprop="title">Big tasks</h1>
<footer>Published <time itemprop="published" datetime="2009-08-23">two days ago</time>.</footer>
<p>I wrote a blog post about how I went nut and bought a bike for my kid.</p>
</article>
```

Example

In this example, another article's publication date is marked up using `time`, this time using the schema.org microdata vocabulary:

```
<article itemscope itemtype="http://schema.org/BlogPosting">
<h1 itemprop="headline">Small Tasks</h1>
<div>Published <time itemprop="datePublished" datetime="2009-08-30">yesterday</time>.</div>
<p>I wrote a blog post about how I went nut and bought a bike for my kid.</p>
</article>
```

Example

In the following snippet, the `time` element is used to encode a date in the ISO8601 format, for later processing by a script:

```
<p>Our first date was <time datetime="2006-09-23">a Saturday</time>.</p>
```

In this second snippet, the value includes a time:

```
<p>We stopped talking at <time datetime="2006-09-24T05:00-07:00">5am the next morning</time>.</p>
```

A script loaded by the page (and thus privy to the page's internal convention of marking up dates and times using the `time` element) could scan through the page and look at all the `time` elements therein to create an index of dates and times.

Example

For example, this element conveys the string "Friday" with the additional semantic that the 18th of November 2011 is the meaning that corresponds to "Friday":

```
<day> is <time datetime="2011-11-18">Friday</time>.
```

Example

In this example, a specific time in the Pacific Standard Time timezone is specified:

```
<your next meeting is at <time datetime="2011-11-18T15:00-08:00">3pm</time>.
```

4.5.15 The `code` element**MDN**[Element/code](#)

Tag omission in text/html:

The `code` tag is omitted.

Content attributes:

[Global attributes](#)

Accessibility considerations:

[For authors](#)

[For implementers](#)

[DOM interface](#)

[User agent](#)

The `code` element represents a fragment of computer code. This could be an XML element name, a file name, a computer program, or any other string that a computer would recognize.

There is no formal way to indicate the language of computer code being marked up. Authors who wish to mark `code` elements with the language used, e.g. so that syntax highlighting scripts can use the right rules, can use the `class` attribute, e.g. by adding a class prefix with "`language-`" to the element.

Example

The following example shows how the element can be used in a paragraph to mark up element names and computer code, including punctuation.

```
<p>The <code><code></code></code> element represents a fragment of computer
code.</p>
<p>When you call the <code>.activate()</code> method on the
<code>robot.html</code> object, the eye blinks.</p>
<p>The <code>w</code> below uses the <code><code>w</code></code></code> keyword to indicate
the end of a statement block. It is paired with an <code>w</code><code>w</code>
keyword, which is followed by the <code></code></code> punctuation character
(full stop) to indicate the end of the program.</p>
```

Example

The following example shows how a block of code could be marked up using the `pre` and `code` elements.

```
<pre><code class="language-pascal">var i: Integer;
begin
  i := 1;
end.</code></pre>
```

A class is used in that example to indicate the language used.

Note

See the `pre` element for more details.

4.5.16 The `var` element**MDN**[Element/var](#)

Phrasing content
Text omission in text/html:
Neither tag is omissionable.
Content attributes
Global attributes
Accessibility considerations:
The sub element: For authors ; For implementers .
The sup element: For authors ; For implementers .
DOM interface:
Uses HTMLSubElement .

The [sub](#) element represents a superscript and the [sup](#) element represents a subscript.

These elements must be used only to mark up typographical conventions with specific meanings, not for typographical presentation for presentation's sake. For example, it would be inappropriate for the [sub](#) and [sup](#) elements to be used in the name of the LaTeX document preparation system. In general, authors should use these elements only if the absence of those elements would change the meaning of the content.

In certain languages, superscripts are part of the typographical conventions for some abbreviations.

Example
<pre>Their names are
<sup>elle</sup></br> Gwenoline and
<sup>ea</sup>
 Denis.</p></pre>

The [sub](#) element can be used inside a [var](#) element, for variables that have subscripts.

Example
<pre><p>The coordinates of the <var>i</var>th point is <var>x</var><sub>i</sub><var>y</var><sub>i</sub><var>z</var>. For example, the 10th point has coordinate <var>x</var><sub>10</sub><var>y</var><sub>10</sub><var>z</var>.1.</p></pre>

Mathematical expressions often use subscripts and superscripts. Authors are encouraged to use MathML for marking up mathematics, but authors may opt to use [sub](#) and [sup](#) if detailed mathematical markup is not desired. [\[MATHML\]](#)

Example
<pre><var>x</var><sub>n</sub><var>m</var><sub>k</sub><var>l</var>><sup>2</sup> f(<var>x</var>, <var>n</var>) = log(<sub>k</sub><sub>n</sub><sub>m</sub><sub>l</sub><var>x</var><sup>k</sup><sup>n</sup><sup>m</sup><sup>l</sup>)</pre>

4.5.20 The [i](#) element

DOM

Element

Support in all current engines.

Firefox 1+ Safari Yes Chrome 1+

Opera Yes Edge 79+

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

Categories:

Parsable content
Contexts in which this element can be used:
Where phrasing-content is expected.
Content model:
Phrasing content
Text omission in text/html:
Neither tag is omissionable.
Content attributes
Global attributes
Accessibility considerations:
For authors.
For implementers.
DOM interface:
Uses HTMLIElement .

The [i](#) element represents a span of text in an alternate voice or mood, or otherwise offset from the normal prose in a manner indicating a different quality of text, such as a taxonomic designation, a technical term, an idiomatic phrase from another language, transliteration, a thought, or a ship name in Western texts.

Terms in languages different from the main text should be annotated with [lang](#) attributes (or, in XML, [lang](#) attributes in the XML namespace).

Example
<pre><p>The examples below show uses of the <i> element: <p><code><i>The <code><class="taxon">#Falis silvestris catus</i> is cute.</code></p> <p>The term <code><i>prose content</i></code> is defined above.</p> <p>There is a certain <code><i>#ne sais quoi</i></code> in the air.</p></pre>

In the following example, a dream sequence is marked up using [i](#) elements.

<pre><p>Raymond tried to sleep.</p> <p>One night the ship sailed away on Thursday</i>, he had a dream about a girl including a beautiful princess called Care. He watched her, day and night, hoping she would notice him, but she never did.</i></p> <p>Finally one night he picked up the courage to speak with her.</i></p> <p>Raymond woke with a start as the fire alarm rang out.</p></pre>

Authors can use the [class](#) attribute on the [i](#) element to identify why the element is being used, so that if the style of a particular use (e.g. dream sequences as opposed to taxonomic terms) is to be changed at a later date, the author doesn't have to go through the entire document (or series of related documents) annotating each use.

Authors are encouraged to consider whether other elements might be more applicable than the [i](#) element, for instance the [u](#) element for marking up stress emphasis, or the [u2044](#) element to mark up the defining instance of a term.

Note

Style sheets can be used to format [i](#) elements, just like any other element can be restyled. Thus, it is not the case that content in [i](#) elements will necessarily be italicized.

4.5.21 The b element
--

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Example

The following example shows a use of the `u` element to highlight key words without marking them up as important:

```
<p>The <b>frobnicator</b> and <b>barbiturator</b> components are fried.</p>
```

Example

In the following example, objects in a text adventure are highlighted as being special by use of the `u` element.

```
<p>You enter a small room. Your <b>sword</b> glows brighter. A <b>rabbit</b> scurries past the corner wall.</p>
```

Example

Another case where the `u` element is appropriate is in marking up the lead (or lead) sentence or paragraph. The following example shows how a BBC article about kittens adopting a rabbit as their own could be marked up:

```
<article>
<h2>Kittens 'adopted' by pet rabbit</h2>
<p><code>class="lead">Six abandoned kittens have found an unexpected new mother figure - a pet rabbit.</code></p>
<p>Veterinary nurse Malvina Humble took the three-week-old kittens to her Abberdeen home.</p>
<...>
```

As with the `u` element, authors can use the `class` attribute on the `u` element to identify why the element is being used, so that if the style of a particular use is to be changed at a later date, the author doesn't have to go through annotating each use.

The `u` element should be used as a last resort when no other element is more appropriate. In particular, headings should use the `h1` to `h6` elements, stress emphasis should use the `strong` element, importance should be denoted with the `strong` element, and text marked or highlighted should use the `mark` element.

Example

The following would be *incorrect* usage:

```
<p><b>WARNING!</b> Do not frob the barbiturator!</p>
```

In the previous example, the correct element to use would have been `strong`, not `u`.

Note

Style sheets can be used to format `u` elements, just like any other element can be restyled. Thus, it is not the case that content in `u` elements will necessarily be bolded.

Neither tag is omission.

Content attributes:

Global attributes

Accessibility considerations:

For authors

For implementers

DOM interface:

Uses `HTMLElement`.

The `u` element represents a span of text with an unarticulated, though explicitly rendered, non-textual annotation, such as labeling the text as being a proper name in Chinese text (a Chinese proper name mark), or labeling the text as being misspelt.

In most cases, another element is likely to be more appropriate: for marking stress emphasis, the `em` element should be used; for marking key words or phrases either the `u` element or the `mark` element should be used, depending on the context; for marking book titles, the `cite` element should be used; for labeling text with explicit textual annotations, the `sub` element should be used; for technical terms, taxonomic designation, transliteration, a thought, or for labeling ship names in Western texts, the `u` element should be used.

Note

The default rendering of the `u` element in visual presentations clashes with the conventional rendering of hyperlinks (underlining). Authors are encouraged to avoid using the `u` element where it could be confused for a hyperlink.

Example

In this example, a `u` element is used to mark a word as misspelt:

```
<p>The <u>sea</u> is full of fish.</p>
```

4.5.23 The `mark` element**MDN****Element`mark`**

Support in all current engines.

For implementers

DOM interface:

Uses `HTMLElement`.

The `mark` element represents a run of text in one document marked or highlighted for `reference` purposes, due to its relevance in another context. When used in a quotation or other block of text referred to from the prose, it indicates a highlight that was not originally present but which has been added to bring the reader's attention to a part of the text that might not have been considered important by the original author when the block was originally written, but which is now under previously unexpected scrutiny. When used in the main prose of a document, it indicates a part of the document that has been highlighted due to its likely relevance to the user's current activity.

Example

This example shows how the `mark` element can be used to bring attention to a particular part of a quotation:

```
<p lang="en-US">Consider the following quote:</p>
<blockquote lang="en-US">
<p>Look around and you will find, no-one's really
mark-blind.</p>
</blockquote>
<p lang="en-US">As we can tell from the <code>lang</code> of the word,
the person writing this quote is clearly not American.</p>
```

If the goal was to mark the element as misspelt, however, the `u` element, possibly with a class, would be more appropriate.)

Example

Another example of the `mark` element is highlighting parts of a document that are matching some search string. If someone looked at a document, and the server knew that the user was searching for the word "kitten", then the server might return the document with one paragraph modified as follows:

```
<p>I also have some <mark>kittens</mark> who are visiting me
these days. They're really cute. I think they like my garden! Maybe I
should adopt a <mark>kitten</mark>.</p>
```

Example

In the following snippet, a paragraph of text refers to a specific part of a code fragment.

```
<p>The highlighted part below is where the error lies:</p>
<pre><code>var i: Integer;
  i := <mark>i.1</mark>;</code></pre>

This is separate from syntax highlighting, for which span is more appropriate. Combining both, one would get:
```

```
<p>The highlighted part below is where the error lies:</p>
<pre><code><span class="keyword">var</span> <span class="operator">:=</span> <span class="identifier">i</span>: <span class="type">Integer</span>;
<span class="keyword">begin</span> <span class="operator">writeln</span>(<span class="identifier">i</span>); <span class="operator">end</span>.</code></pre>
```

Example

This is another example showing the use of `mark` to highlight a part of quoted text that was originally not emphasized. In this example, common typographic conventions have led the author to explicitly style `mark` elements in quotes to render in italics.

```
<pre>
blockquote mark, q mark
  font: inherit; font-style: italic;
  font-variant: none;
  background-color: transparent; color: inherit;
} bubble em {
  font: inherit; font-style: italic;
}
```

Example

In the following example, someone is quoted as saying something which, for effect, is written as one long word. However, to ensure that the text can be wrapped in a readable fashion, the individual words in the quote are separated using a `<wbr>` element.

```
<p>do then she pointed at the tiger and screamed<br><em>she</em><del>she</del><ins>she</ins><wbr>going<wbr>to<wbr>catch<wbr>me!</p>
```

Any content inside `<wbr>` elements must not be considered part of the surrounding text.

```
Example
var wbr = document.createElement("wbr");
wbr.textContent = "this is wrong";
document.body.appendChild(wbr);
```

Note

This element has rendering requirements involving the bidirectional algorithm.

4.5.29 Usage summary

This section is non-normative.

Element	Purpose	Example
<code>a</code>	Hyperlinks	<code>Example</code> Visit my drinks page.
<code>em</code>	Stress emphasis	<code>Example</code> I must say I do lemonade.
<code>strong</code>	Importance	<code>Example</code> This tea is very hot.
<code>small</code>	Side comments	<code>Example</code> These grapes are made into wine. <small>Alcohol is addictive.</small>
<code>b</code>	Inaccurate text	<code>Example</code> Price: \$4.50 £2.00
<code>cite</code>	Titles of works	<code>Example</code> The case <cite>Rugo v. Danielle</cite> is relevant here.
<code>q</code>	Quotations	<code>Example</code> The judge said <q>You can drink water from the fish tank</q> but advised against it.
<code>dfn</code>	Defining instance	<code>Example</code> The term <dfn>organic food</dfn> refers to food produced without synthetic chemicals.
<code>abbr</code>	Abbreviations	<code>Example</code> Organic food in Ireland is certified by the <abbr title="Irish Organic Farmers and Growers Association">IOFGA</abbr>.
<code>ruby</code> , <code>rt</code> , <code>rp</code>	Ruby annotations	<code>Example</code> <ruby> OJ <rp>(رت)<rt>Orange Juice</rt></rp></ruby>
<code>data</code>	Machine-readable equivalent	<code>Example</code> Available starting today! <data value="UPC:022014640201">North Coast Organic Apple Cider</data>
<code>time</code>	Machine-readable equivalent of date- or time-related data	<code>Example</code> Available starting on <time datetime="2011-11-18">November 18th</time>.
<code>code</code>	Computer code	<code>Example</code> The <code>FruitDB</code> program can be used for tracking fruit production.
<code>var</code>	Variables	<code>Example</code> If there are <var>n</var> fruit in the bowl, at least <var>n</var>-2 will be ripe.
<code>anno</code>	Computer output	<code>Example</code> The computer said <samp>Unknown error -3</samp>.
<code>kbd</code>	User input	<code>Example</code> Hit <kbd>P1</kbd> to continue.
<code>sub</code>	Subscripts	<code>Example</code> Water is H ₂ O.
<code>sup</code>	Superscripts	<code>Example</code> The hydrogen in heavy water is usually H ² .
<code>i</code>	Alternative voice	<code>Example</code> Lemonade consists primarily of <i>Citrus limon</i>.
<code>b</code>	Keywords	<code>Example</code> Take a lemon and squeeze it with a juicer.
<code>u</code>	Annotations	<code>Example</code> The mixture of apple juice and <u class="spelling">eldeflower</u> juice is very pleasant.
<code>mark</code>	Highlight	<code>Example</code> Eldeflower cordial, with one <mark>part</mark> cordial to ten <mark>part</mark> water, stands <mark>part</mark> from the rest.
<code>bdi</code>	Text directionality isolation	<code>Example</code> The recommended restaurant is <bdi lang="ar">My Juice Café (At The Beach)</bdi>.
<code>bdo</code>	Text directionality formatting	<code>Example</code> The proposal is to write English, but in reverse order. "Juice" would become "<bdo dir="rtl">Juice</bdo>".
<code>span</code>	Other	<code>Example</code> In French we call it sirop de sureau.
<code>br</code>	Line break	<code>Example</code> Simply Orange Juice Company Orlando, FL 32703 U.S.A.
<code>wbr</code>	Line breaking opportunity	<code>Example</code> www.simply<wbr>orange<wbr>.juice.com

4.6 Links**4.6.1 Introduction**

Links are a conceptual construct, created by `a`, `area`, and `link` elements, that represent a connection between two resources, one of which is the current `document`. There are two kinds of links in HTML:

Links to external resources

These are links to resources that are to be used to augment the current document, generally automatically processed by the user agent. All `external resource links` have a `fetch` and `process the linked resource` algorithm which describes how the resource is obtained.

Hyperlinks

These are links to other resources that are generally exposed to the user by the user agent so that the user can cause the user agent to `navigate` to those resources, e.g. to visit them in a browser or download them.

For `link` elements with an `href` attribute and a `rel` attribute, links must be created for the keywords of the `rel` attribute, as defined for those keywords in the `link types` section.

Similarly, for `a` and `area` elements with an `href` attribute and a `rel` attribute, links must be created for the keywords of the `rel` attribute as defined for those keywords in the `link types` section. Unlike `link` elements, however, `a` and `area` elements with an `href` attribute that either do not have a `rel` attribute, or whose `rel` attribute has no keywords that are defined as specifying `hyperlinks`, must also create a `hyperlink`. This implied hyperlink has no special meaning (it has no `link type`) beyond linking the element's `node document` to the resource given by the element's `href` attribute.

Similarly, for `form` elements with a `rel` attribute, links must be created for the keywords of the `rel` attribute as defined for those keywords in the `link types` section. `form` elements that do not have a `rel` attribute, or whose `rel` attribute has no keywords that are defined as specifying `hyperlinks`, must also create a `hyperlink`.

A `hyperlink` can have one or more `hyperlink annotations` that modify the processing semantics of that hyperlink.

4.6.2 Links created by `a` and `area` elements

The `href` attribute on `a` and `area` elements must have a value that is a `valid URL potentially surrounded by spaces`.

Note

The `href` attribute on `a` and `area` elements is not required; when those elements do not have `href` attributes they do not create hyperlinks.

The `target` attribute, if present, must be a `valid browsing context name or keyword`. It gives the name of the `browsing context` that will be used. User agents use this name when `following hyperlinks`.

When an `a` or `area` element's `activation behavior` is invoked, the user agent may allow the user to indicate a preference regarding whether the hyperlink is to be used for `navigation` or whether the resource it specifies is to be downloaded.

In the absence of a user preference, the default should be navigation if the element has no `download` attribute, and should be to download the specified resource if it does.

Whether determined by the user's preferences or via the presence or absence of the attribute, if the decision is to use the hyperlink for `navigation` then the user agent must `follow the hyperlink`, and if the decision is to use the hyperlink to download a resource, the user agent must `download the hyperlink`. These terms are defined in subsequent sections below.

The `download` attribute, if present, indicates that the author intends the hyperlink to be used for [downloading a resource](#). The attribute may have a value; the value, if any, specifies the default file name that the author recommends for use in labeling the resource in a local file system. There are no restrictions on allowed values, but authors are cautioned that most file systems have limitations with regard to what punctuation is supported in file names, and user agents are likely to adjust file names accordingly.

The `pings` attribute, if present, gives the URLs of the resources that are interested in being notified if the user follows the hyperlink. The value must be a [set of space-separated tokens](#), each of which must be a [valid non-empty URL](#), whose `scheme` is an [HTTP\(S\) scheme](#). The value is used by the user agent for [hyperlink auditing](#).

Support: pingChrome for Android 81+Chrome 15+iOS Safari 5.0+Safari 6+Firefox NoneSamsung Internet 4+Edge 17+UC Brower for Android 12.12+IE NoneOpera 15+Opera Mini NoneFirefox for Android None

Source: [caniuse.com](#)

The `rel` attribute on `a` and `area` elements controls what kinds of links the elements create. The attribute's value must be a [unordered set of unique space-separated tokens](#). The [allowed keywords and their meanings](#) are defined below.

`rel's supported tokens` are the keywords defined in [HTML link types](#) which are allowed on `a` and `area` elements, impact the processing model, and are supported by the user agent. The possible `supported tokens` are `noreferrer`, `noreferrerer`, `noopener`, and `noopener, rel's supported tokens` must only include the tokens from this list that the user agent implements the processing model for.

Other specifications may add [HTML link types](#) as defined in [Other link types](#), with the following additional requirements:

- Such specifications may require that their link types be included in `rel's supported tokens`.
- Such specifications may specify that their link types are `body|cok`.

The `rel` attribute has no default value. If the attribute is omitted or if none of the values in the attribute are recognized by the user agent, then the document has no particular relationship with the destination resource other than there being a hyperlink between the two.

The `hrefLang` attribute on elements that create [hyperlinks](#), if present, gives the language of the linked resource. It is purely advisory. The value must be a valid BCP 47 language tag. [\[BCP47\]](#) User agents must not consider this attribute authoritative — upon fetching the resource, user agents must use only language information associated with the resource to determine its language, not metadata included in the link to the resource.

The `type` attribute, if present, gives the [MIME type](#) of the linked resource. It is purely advisory. The value must be a [valid MIME type string](#). User agents must not consider the `type` attribute authoritative — upon fetching the resource, user agents must not use metadata included in the link to the resource to determine its type.

The `referrerPolicy` attribute is a [referrer policy attribute](#). Its purpose is to set the `referrer policy` used when [following hyperlinks](#). [\[REFERRERPOLICY\]](#)

4.6.3 API for `a` and `area` elements

For web developers (non-normative)
`hyperlink::tostring()`

Returns the hyperlink's URL.

Can be set, to change the URL.

`hyperlink::origin`

Returns the hyperlink's URL's origin.

`hyperlink::protocol`

Return the hyperlink's URL's scheme.

Can be set, to change the URL's scheme.

`hyperlink::username`

Returns the hyperlink's URL's username.

Can be set, to change the URL's username.

`hyperlink::password`

Returns the hyperlink's URL's password.

Can be set, to change the URL's password.

`hyperlink::host`

Returns the hyperlink's URL's host and port (if different from the default port for the scheme).

Can be set, to change the URL's host and port.

`hyperlink::hostname`

Returns the hyperlink's URL's host.

Can be set, to change the URL's host.

`hyperlink::port`

Returns the hyperlink's URL's port.

Can be set, to change the URL's port.

`hyperlink::pathname`

Returns the hyperlink's URL's path.

Can be set, to change the URL's path.

`hyperlink::search`

Returns the hyperlink's URL's query (includes leading "?" if non-empty).

Can be set, to change the URL's query (ignores leading "?").

`hyperlink::hash`

Returns the hyperlink's URL's fragment (includes leading "#" if non-empty).

Can be set, to change the URL's fragment (ignores leading "#").

An element implementing the [HTMLHyperlinkElementUtils](#) mixin has an associated `url` (null or a [URL](#)). It is initially null.

An element implementing the [HTMLHyperlinkElementUtils](#) mixin has an associated `set the url` algorithm, which runs these steps:

1. If this element's `href` content attribute is absent, set this element's `url` to null.
2. Otherwise, parse this element's `href` content attribute value relative to this element's `node document`. If [parsing](#) is successful, set this element's `url` to the result; otherwise, set this element's `url` to null.

When elements implementing the [HTMLHyperlinkElementUtils](#) mixin are created, and whenever those elements have their `href` content attribute set, changed, or removed, the user agent must [set the url](#).

Note

This is only observable for `blob` URLs as [parsing](#) them involves a [Blob URI Store](#) lookup.

An element implementing the [HTMLHyperlinkElementUtils](#) mixin has an associated [retrn initial url](#) algorithm, which runs these steps:

1. If element's `url` is non-null, its `scheme` is "blob", and its `cannot-be-a-base-URL` flag is set, terminate these steps.
2. [Set the url](#).

To [update href](#), set the element's `href` content attribute's value to the element's `url`, [serialized](#).

6. Return `"."`, followed by the strings in `url`'s `path` (including empty strings), separated from each other by `"."`.

The `pathname` attribute's setter must run these steps:

1. [Reinitialize url](#).
2. Let `url` be this element's `url`.
3. If `url` is null or `url`'s `cannot-be-a-base-URL` flag is set, terminate these steps.
4. Set `url`'s `path` to the empty list.
5. [Basic URL parse](#) the given value, with `url` as `url` and `path_start_state` as `state override`.
6. [Update href](#).

MDN

[HTML.HyperlinkElement#url/search](#)

Support in all current engines.

Firefox22+SafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet Explorer5+

Firefox Android22+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

The `search` attribute's getter must run these steps:

1. [Reinitialize url](#).
2. Let `url` be this element's `url`.
3. If `url` is null, or `url`'s `query` is either null or the empty string, return the empty string.
4. Return `"?"`, followed by `url`'s `query`.

The `search` attribute's setter must run these steps:

1. [Reinitialize url](#).
2. Let `url` be this element's `url`.
3. If `url` is null, terminate these steps.
4. If the given value is the empty string, set `url`'s `query` to null.
5. Otherwise:
 1. Let `input` be the given value with a single leading `"?"` removed, if any.
 2. Set `url`'s `query` to the empty string.
 3. [Basic URL parse](#) `input`, with `url` as `url` and `query_state` as `state override`, and this element's `node_document`'s `document`'s `character_encoding` as `encoding override`.
6. [Update href](#).

MDN

[HTML.HyperlinkElement#url/hash](#)

Support in all current engines.

Firefox22+SafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet Explorer5+

Firefox Android22+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

The `hash` attribute's getter must run these steps:

1. [Reinitialize url](#).
2. Let `url` be this element's `url`.
3. If `url` is null, or `url`'s `fragment` is either null or the empty string, return the empty string.

The `hash` attribute's setter must run these steps:

1. [Reinitialize url](#).
2. Let `url` be this element's `url`.
3. If `url` is null, then return.
4. If the given value is the empty string, set `url`'s `fragment` to null.
5. Otherwise:
 1. Let `input` be the given value with a single leading "#" removed, if any.
 2. Set `url`'s `fragment` to the empty string.
 3. [Basic URL parse input](#), with `url` as `url` and `fragment state` as `state override`.
6. [Update href](#).

4.6.4 Following hyperlinks

An element `element` cannot navigate if one of the following is true:

- `element's node document` is not [fully active](#)
- `element` is not an `a` element and is not [connected](#).

Note

This is also used by [form submission](#) for the `form` element. The exception for `a` elements is for compatibility with web content.

To get an element's `noreferrer`, given an `a`, `area`, or `form` element `element` and a string `target`, run these steps:

1. If `element's link types` include the `noreferrer` or `no-referrer` keyword, then return true.
2. If `element's link types` do not include the `opener` keyword and `target` is an [ASCII case-insensitive](#) match for "`_blank`", then return true.
3. Return false.

When a user follows a hyperlink created by an element `subject`, optionally with a `hyperlink suffix`, the user agent must run the following steps:

1. If `subject` [cannot navigate](#), then return.
2. Let `replace` be false.
3. Let `source` be `subject's node document's browsing context`.
4. Let `targetAttributeValue` be the empty string.
5. If `subject` is an `a` or `area` element, then set `targetAttributeValue` to the result of [getting an element's target](#) given `subject`.
6. Let `noreferrer` be the result of [getting an element's noreferrer](#) with `subject` and `targetAttributeValue`.
7. Let `target` and `replace` be the result of applying [the rules for choosing a browsing context](#) given `targetAttributeValue`, `source`, and `noreferrer`.
8. If `target` is null, then return.
9. [Parse the URL](#) given by `subject's href` attribute, relative to `subject's node document`.
10. If that is successful, let `URL` be the [resulting URL string](#).

Otherwise, if [parsing the URL](#) failed, the user agent may report the error to the user in a user-agent-specific manner, may [queue a task](#) to [navigate](#) the target `browsing context` to an error page to report the error, or may ignore the error and do nothing. In any case, the user agent must then return.

11. If there is a `hyperlink suffix`, append it to `URL`.

12. Let `request` be a new `request` whose `url` is `URL` and whose `referrer policy` is the current state of `subject's referrerPolicy` content attribute.

13. If `subject's link types` includes the `no-referrer` keyword, then set `request's referrer` to "no-referrer".

14. [Queue a task](#) to [navigate](#) the target `browsing context` to `request`. If `replace` is true, the navigation must be performed with [replacement enabled](#). The `source browsing context` must be `source`.

The `task source` for the tasks mentioned above is the [DOM manipulation task source](#).

4.6.5 Downloading resources

Support: downloadChrome for Android 8.1+Chrome 14+iOS Safari 13.0+Safari 10.1+Firefox 20+Samsung Internet 4+Edge 13+UC Browser for Android 12.12+IE NoneOpera 15+Opera Mini NonFirefox for Android 68+

Source: caniuse.com

In some cases, resources are intended for later use rather than immediate viewing. To indicate that a resource is intended to be downloaded for use later, rather than immediately used, the `download` attribute can be specified on the `a` or `area` element that creates the [hyperlink](#) to that resource.

The attribute can furthermore be given a value, to specify the file name that user agents are to use when storing the resource in a file system. This value can be overridden by the [Content-Disposition](#) HTTP header's filename parameters. [RFC6266](#)

In cross-origin situations, the `download` attribute has to be combined with the [Content-Disposition](#) HTTP header, specifically with the `attachment` disposition type, to avoid the user being warned of possibly nefarious activity. (This is to protect users from being made to download sensitive personal or confidential information without their full understanding.)

When a user downloads a hyperlink created by an element `subject`, optionally with a `hyperlink suffix`, the user agent must run the following steps:

1. If `subject` [cannot navigate](#), then return.
2. [Parse the URL](#) given by `subject's href` attribute, relative to `subject's node document`.
3. If [parsing the URL](#) fails, the user agent may report the error to the user in a user-agent-specific manner, may [queue a task](#) to [navigate](#) to an error page to report the error, or may ignore the error and do nothing. In either case, the user agent must return.
4. Otherwise, let `URL` be the [resulting URL string](#).
5. If there is a `hyperlink suffix`, append it to `URL`.
6. Run these steps [in parallel](#):
 1. Let `request` be a new `request` whose `url` is `URL`, `client` is `entry settings object`, `initiator` is "download", `destination` is the empty string, and whose `synchronous flag` and `use-URL-credentials flag` are set.
 2. Handle the result of [fetching request as a download](#).

When a user agent is to handle a resource obtained from a fetch as a `download`, act in a user-agent-defined manner to safeguard the user from a potentially hostile download. If the download is not to be aborted, it should provide the user with a way to save the resource for later use, if a resource is successfully obtained; or otherwise should report any problems downloading the file to the user.

If the user agent needs a file name for a resource being handled as a `download`, it should select one using the following algorithm.

⚠Warning!

This algorithm is intended to mitigate security dangers involved in downloading files from untrusted sites, and user agents are strongly urged to follow it.

1. Let `filename` be the void value.
2. If the resource has a [Content-Disposition](#) header, that header specifies the `attachment` disposition type, and the header includes file name information, then let `filename` have the value specified by the header, and jump to the step labeled `sanitize` below. [RFC6266](#)
3. Let `interface origin` be the `origin` of the `Document` in which the `download` or `navigate` action resulting in the download was initiated, or `any`.
4. Let `resource origin` be the `origin` of the URL of the resource being downloaded, unless that URL's `scheme` component is `data`, in which case let `resource origin` be the same as the `interface origin`, if any.
5. If there is no `interface origin`, then let `trusted operation` be true. Otherwise, let `trusted operation` be true if `resource origin` is the `same origin` as `interface origin`, and false otherwise.
6. If `trusted operation` is true and the resource has a [Content-Disposition](#) header and that header includes file name information, then let `filename` have the value specified by the header, and jump to the step labeled `sanitize` below. [RFC6266](#)
7. If the download was not initiated from a [hyperlink](#) created by an `a` or `area` element, or if the element of the [hyperlink](#) from which it was initiated did not have a `download` attribute when the download was initiated, or if there was such an attribute but its value when the download was initiated was the empty string, then jump to the step labeled `no proposed file name`.
8. Let `proposed filename` have the value of the `download` attribute of the element of the [hyperlink](#) that initiated the download at the time the download was initiated.
9. If `trusted operation` is true, let `filename` have the value of `proposed filename`, and jump to the step labeled `sanitize` below.
10. If the resource has a [Content-Disposition](#) header and that header specifies the `attachment` disposition type, let `filename` have the value of `proposed filename`, and jump to the step labeled `sanitize` below. [RFC6266](#)
11. No proposed file name: If `trusted operation` is true, or if the user indicated a preference for having the resource in question downloaded, let `filename` have a value derived from the `URL` of the resource in a user-agent-defined manner, and jump to the step labeled `sanitize` below.
12. Let `filename` be set to the user's preferred file name or to a file name selected by the user agent, and jump to the step labeled `sanitize` below.

⚠Warning!

If the algorithm reaches this step, then a download was begun from a different origin than the resource being downloaded, and the origin did not mark the file as suitable for downloading, and the download was not initiated by the user. This could be because a `download` attribute was used to trigger the download, or because the resource in question is not of a type that the user agent supports.

This could be dangerous, because, for instance, a hostile server could be trying to get a user to unknowingly download private information and then re-upload it to the hostile server, tricking the user into thinking the data is from the hostile server.

Thus, it is in the user's interests that the user be somehow notified that the resource in question comes from quite a different source, and to prevent confusion, any suggested file name from the potentially hostile `interface origin` should be ignored.

13. `Sanitize`: Optionally, allow the user to influence `filename`. For example, a user agent could prompt the user for a file name, potentially providing the value of `filename` as determined above as a default value.

14. Adjust `filename` to be suitable for the local file system.

Example
For example, this could involve removing characters that are not legal in file names, or trimming leading and trailing whitespace.

15. If the platform conventions do not in any way use `extensions` to determine the types of file on the file system, then return `filename` as the file name.

16. Let `claimed type` be the type given by the resource's `Content-Type metadata`, if any is known. Let `named type` be the type given by `filename's extension`, if any is known. For the purposes of this step, `type` is a mapping of a `MIME type` to an `extension`.

17. If `named type` is consistent with the user's preferences (e.g. because the value of `filename` was determined by prompting the user), then return `filename` as the file name.

18. If `claimed type` and `named type` are the same type (i.e. the type given by the resource's `Content-Type metadata` is consistent with the type given by `filename's extension`), then return `filename` as the file name.

19. If the `claimed type` is known, then alter `filename` to add an `extension` corresponding to `claimed type`.

Otherwise, if `named type` is known to be potentially dangerous (e.g. it will be treated by the platform conventions as a native executable, shell script, HTML application, or executable-macro-capable document) then optionally alter `filename` to add a known-safe `extension` (e.g. ".txt").

Note
This last step would make it impossible to download executables, which might not be desirable. As always, implementers are forced to balance security and usability in this matter.

20. Return `filename` as the file name.

For the purposes of this algorithm, a file `extension` consists of any part of the file name that platform conventions dictate will be used for identifying the type of the file. For example, many operating systems use the part of the file name following the last dot (".") in the file name to determine the type of the file, and from that the manner in which the file is to be handled.

EXPAND

User agents should ignore any directory or path information provided by the resource itself, its [URL](#), and any [download](#) attribute, in deciding where to store the resulting file in the user's file system.

4.6.5.1 Hyperlink auditing

If a [hyperlink](#) created by an [a](#) or [area](#) element has a [ping](#) attribute, and the user follows the hyperlink, and the value of the element's [href](#) attribute can be [parsed](#), relative to the element's [node_document](#), without failure, then the user agent must take the [ping](#) attribute's value, [split that string on ASCII whitespace](#), [parse](#) each resulting token relative to the element's [node_document](#), and then run these steps for each resulting [URL](#) record [ping URL](#), ignoring tokens that fail to parse:

- If [ping URL's scheme](#) is not an [\(HTTPS\)scheme](#), then return.
- Optionally, return. (For example, the user agent might wish to ignore any or all ping URLs in accordance with the user's expressed preferences.)
- [Let request](#) be a new [request](#) whose [url](#) is [ping URL](#), [method](#) is [POST](#), [body](#) is [PING](#). [client](#) is the [environment settings object](#) of the [document](#) containing the [hyperlink](#), [destination](#) is the empty string, [credentials mode](#) is ["include"](#), [referrer](#) is ["no-referrer"](#), and whose [use-URL-credentials flag](#) is set.
- [Let target URL](#) be the [resulting URL](#) string obtained from [parsing](#) the value of the element's [href](#) attribute and then:
 - If the [URL](#) of the [document](#) containing the hyperlink being audited and [ping URL](#) have the [same origin](#). If the origins are different, but the [HTTPs state](#) of the [document](#) containing the hyperlink being audited is ["none"](#), [request](#) must include a ["Ping-Pong"](#) header with, as its value, the [URL](#) of the document containing the hyperlink, and a ["Ping-To"](#) HTTP header with, as its value, the [target URL](#).
 - Otherwise [request](#) must include a ["Ping-To"](#) HTTP header with, as its value, [target URL](#).
- [Note](#)
- [request](#) does not include a ["Ping-Pong"](#) header.

5. Fetch request.

This may be done [in parallel](#) with the primary fetch, and is independent of the result of that fetch.

User agents should allow the user to adjust this behavior, for example in conjunction with a setting that disables the sending of HTTP [Referer](#) (sic) headers. Based on the user's preferences, UAs may either [ignore](#) the [ping](#) attribute altogether, or selectively ignore URLs in the list (e.g. ignoring any third-party URLs); this is explicitly accounted for in the steps above.

User agents must ignore any entity bodies returned in the responses. User agents may close the connection prematurely once they start receiving a response body.

When the [ping](#) attribute is present, user agents should clearly indicate to the user that following the hyperlink will also cause secondary requests to be sent in the background, possibly including listing the actual target URLs.

Example

For example, a visual user agent could include the hostnames of the target ping URLs along with the hyperlink's actual URL, in a status bar or tooltip.

Note

The [ping](#) attribute is redundant with pre-existing technologies like HTTP redirects and JavaScript in allowing Web pages to track which off-site links are most popular or allowing advertisers to track click-through rates.

However, the [ping](#) attribute provides these advantages to the user over those alternatives:

- It allows the user to see the final target URL unobscured.
- It allows the UA to inform the user about the out-of-band notifications.
- It allows the user to disable the notifications without losing the underlying link functionality.
- It allows the UA to optimize the use of available network bandwidth so that the target page loads faster.

Thus, while it is possible to track users without this feature, authors are encouraged to use the [ping](#) attribute so that the user agent can make the user experience more transparent.

4.6.6 Link types

MDN

Link types

The following table summarizes the link types that are defined by this specification, by their corresponding keywords. This table is non-normative; the actual definitions for the link types are given in the next few sections.

In this section, the term [referenced document](#) refers to the resource identified by the element representing the link, and the term [current document](#) refers to the resource within which the element representing the link finds itself.

To determine which link types apply to a [link](#), [a](#), [area](#), or [form](#) element, the element's [rel](#) attribute must be [split on ASCII whitespace](#). The resulting tokens are the keywords for the link types that apply to that element.

Except where otherwise specified, a keyword must not be specified more than once per [rel](#) attribute.

Some of the sections that follow the table below list synonyms for certain keywords. The indicated synonyms are to be handled as specified by user agents, but must not be used in documents (for example, the keyword ["copyright"](#)).

Keywords are always [ASCII case-insensitive](#), and must be compared as such.

Example

Thus, [rel="next"](#) is the same as [rel="NEXT"](#).

Keywords that are [body-ok](#) affect whether [link](#) elements are [allowed](#) in the [body](#). The [body-ok](#) keywords defined by this specification are [dns-prefetch](#), [modulepreload](#), [pingback](#), [preconnect](#), [prefetch](#), [preload](#), [prerender](#), and [stylesheet](#). Other specifications can also define [body-ok](#) keywords.

Link type	Effect on...	link	a and area	form	body-ok	Brief description
alternate	Hyperlink				not allowed	Gives alternate representations of the current document.
canonical	Hyperlink				not allowed	Gives the preferred URL for the current document.
author	Hyperlink				not allowed	Gives a link to the author of the current document or article.
bookmark	not allowed	Hyperlink	not allowed			Gives the permalink for the nearest ancestor section.
dns-prefetch	External Resource	not allowed			Yes	Specifies that the user agent should preemptively perform DNS resolution for the target resource's origin .
external	not allowed	Annotation				Indicates that the referenced document is not part of the same site as the current document.
help	Hyperlink					Provides a link to context-sensitive help.
icon	External Resource	not allowed			Yes	Imports an icon to represent the current document.
modulepreload	External Resource	not allowed				Specifies that the user agent must preemptively fetch the module script and store it in the document's module map for later evaluation. Optionally, the module's dependencies can be fetched as well.
license	Hyperlink					Indicates that the main content of the current document is covered by the copyright license described by the referenced document.
next	Hyperlink					Indicates that the current document is a part of a series, and that the next document in the series is the referenced document.
nofollow	not allowed	Annotation				Indicates that the current document's original author or publisher does not endorse the referenced document.
noopener	not allowed	Annotation				Creates a top-level browsing context that is not an auxiliary browsing context if the hyperlink would create either of those to begin with (i.e., has an appropriate target attribute value).
noreferrer	not allowed	Annotation				No Referrer (sic) header will be included. Additionally, has the same effect as noopener .
open	not allowed	Annotation				Creates an auxiliary browsing context if the hyperlink would otherwise create a top-level browsing context that is not an auxiliary browsing context (i.e., has " _blank " as target attribute value).
pingback	External Resource	not allowed			Yes	Gives the address of the pingback server that handles pingbacks to the current document.
preconnect	External Resource	not allowed			Yes	Specifies that the user agent should preemptively connect to the target resource's origin .
prefetch	External Resource	not allowed			Yes	Specifies that the user agent should preemptively fetch and cache the target resource for current navigation according to the potential destination given by the as attribute (and the priority associated with the corresponding destination).
preload	External Resource	not allowed			Yes	Specifies that the user agent must preemptively fetch the target resource and process it in a way that helps deliver a faster response in the future.
prerender	External Resource	not allowed				Indicates that the current document is a part of a series, and that the previous document in the series is the referenced document.
prev	Hyperlink					Gives a link to a resource that can be used to search through the current document and its related pages.
search	Hyperlink				Yes	Imports a style sheet.
stylesheet	External Resource	not allowed				Gives a tag (identified by the given address) that applies to the current document.
tag	not allowed	Hyperlink	not allowed			

4.6.6.1 Link type "alternate"

MDN

Alternative style sheets

Support in one engine only.

Firefox3/Safari?Chrome?

OperaYesEdge?

Edge (Legacy)?Internet Explorer?

Foxfire Android++Safari iOS?Chrome Android?WebView Android?Samsung Internet?Opera Android?

The [alternate](#) keyword may be used with [link](#), [a](#), and [area](#) elements.

The meaning of this keyword depends on the values of the other attributes.

If the element is a [link](#) element and the [rel](#) attribute also contains the keyword [stylesheet](#)

The [alternate](#) keyword modifies the meaning of the [stylesheet](#) keyword in the way described for that keyword. The [alternate](#) keyword does not create a link of its own.

Example

Here, a set of [link](#) elements provide some style sheets:

```
<!-- a persistent style sheet -->
<link rel="stylesheet" href="default.css">

<!-- the preferred alternate style sheet -->
<link rel="stylesheet" href="green.css" title="Green styles">

<!-- some alternate style sheets -->
<link rel="alternate stylesheet" href="optimal.css" title="High contrast">
<link rel="alternate stylesheet" href="bold.css" title="Big font">
<link rel="alternate stylesheet" href="wide.css" title="Wide screen">
```

If the [alternate](#) keyword is used with the [type](#) attribute set to the value [application/rss+xml](#) or the value [application/atom+xml](#)

The keyword creates a [hyperlink](#) referencing a syndication feed (though not necessarily syndicating exactly the same content as the current page).

For the purpose of feed autodiscovery, user agents should consider all [link](#) elements in the document with the [alternate](#) keyword used and with their [type](#) attribute set to the value [application/rss+xml](#) or the value [application/atom+xml](#). If the user agent has the concept of a default syndication feed, the first such element (in [tree_order](#)) should be used as the default.

Example

The following [link](#) elements give syndication feeds for a blog:

```
<link rel="alternate" type="application/atom+xml" href="posts.xml" title="Cool Stuff Blog">
<link rel="alternate" type="application/rss+xml" href="posts.xml?format=atom" title="Cool Stuff Blog: robots category">
<link rel="alternate" type="application/rss+xml" href="comments.xml" title="Cool Stuff Blog: Comments">
```

Such [link](#) elements would be used by agents engaged in feed autodiscovery, with the first being the default (where applicable).

The following example offers various different syndication feeds to the user, using [a](#) elements:

```
<p>You can access the planets database using Atom feeds:</p>
<ul><li><a href="recently-visited-planets.xml" rel="alternate" type="application/atom+xml">Recently Visited Planets</a></li>
<li><a href="known-had-planets.xml" rel="alternate" type="application/atom+xml">Known Bad Planets</a></li>
<li><a href="unexplored-planets.xml" rel="alternate" type="application/atom+xml">Unexplored Planets</a></li>
</ul>
```

These links would not be used in feed autodiscovery.

Otherwise

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

The keyword creates a [hyperlink](#) referencing an alternate representation of the current document.

The nature of the referenced document is given by the `hreflang` and `type` attributes.

If the `alternate` keyword is used with the `hreflang` attribute, and that attribute's value differs from the [document element's language](#), it indicates that the referenced document is a translation.

If the `alternate` keyword is used with the `type` attribute, it indicates that the referenced document is a reformulation of the current document in the specified format.

The `hreflang` and `type` attributes can be combined when specified with the `alternate` keyword.

Example

The following example shows how you can specify versions of the page that use alternative formats, are aimed at other languages, and that are intended for other media:

```
<link rel="alternate href="/en/html" hreflang=en type="text/html" title="English HTML">
<link rel="alternate href="/fr/html" hreflang=fr type="text/html" title="French HTML">
<link rel="alternate href="/en/print/" hreflang=en type="text/html" media="print" title="English HTML (for printing)">
<link rel="alternate href="/an/pdf" hreflang=en type="application/pdf" title="English PDF">
<link rel="alternate href="/fr/pdf" hreflang=fr type="application/pdf" title="French PDF">
```

This relationship is transitive — that is, if a document links to two other documents with the link type "`alternate`", then, in addition to implying that those documents are alternative representations of the first document, it is also implying that those two documents are alternative representations of each other.

4.6.6.2 Link type "author"

The `author` keyword may be used with `link`, `a`, and `area` elements. This keyword creates a [hyperlink](#).

For `a` and `area` elements, the `author` keyword indicates that the referenced document provides further information about the author of the nearest `article` element ancestor of the element defining the hyperlink, if there is one, or of the page as a whole, otherwise.

For `link` elements, the `author` keyword indicates that the referenced document provides further information about the author for the page as a whole.

Note

The "referenced document" can be, and often is, a [mailto](#) URL giving the e-mail address of the author. [MAILTO]

Synonyms: For historical reasons, user agents must also treat `link`, `a`, and `area` elements that have a `rev` attribute with the value "`sada`" as having the `author` keyword specified as a link relationship.

4.6.6.3 Link type "bookmark"

The `bookmark` keyword may be used with `a` and `area` elements. This keyword creates a [hyperlink](#).

The `bookmark` keyword gives a permalink for the nearest ancestor `article` element of the linking element in question, or of the [section the linking element is most closely associated with](#), if there are no ancestor `article` elements.

Example

The following snippet has three permalinks. A user agent could determine which permalink applies to which part of the spec by looking at where the permalinks are given.

```
...
<body>
  <h1>Example of permalinks</h1>
  <div id="a">
    <h2>First example</h2>
    <p><a href="#a" rel="bookmark">This permalink applies to only the content from the first H2 to the second H2</a>. The DIV isn't exactly that section, but it roughly corresponds to it.</p>
  </div>
  <h2>Second example</h2>
  <article id="b">
    <h3>Inner H3</h3> rel="bookmark">This permalink applies to the outer ARTICLE element</a> (which could be, e.g., a blog post).</p>
    <article id="c">
      <h4>Inner H4</h4> rel="bookmark">This permalink applies to the inner ARTICLE element</a> (which could be, e.g., a blog comment).</p>
    </article>
  </article>
</body>
...
```

4.6.6.4 Link type "canonical"

The `canonical` keyword may be used with `link` element. This keyword creates a [hyperlink](#).

The `canonical` keyword indicates that URL given by the `href` attribute is the preferred URL for the current document. That helps search engines reduce duplicate content, as described in more detail in [The Canonical Link Relation](#). [RFC6596]

4.6.6.5 Link type "dns-prefetch"

MDN

Link types/dns-prefetch

Firefox 3+|Safari/Chrome46+

Opera33+|Edge79+

Edge (Legacy) | NoInternet Explorer?

Firefox, Android+| Safari iOS| Chrome Android| Yes| WebView| Android| 6+| Samsung Internet| Yes| Opera Android?

The `dns-prefetch` keyword may be used with `link` elements. This keyword creates an [external resource link](#). This keyword is `body-ok`.

The `dns-prefetch` keyword indicates that preemptively performing DNS resolution for the `origin` of the specified resource is likely to be beneficial, as it is highly likely that the user will require resources located at that `origin`, and the user experience would be improved by preempting the latency costs associated with DNS resolution. User agents must implement the processing model of the `dns-prefetch` keyword described in [Resource Hints](#). [RESOURCETHINTS]

There is no default type for resources given by the `dns-prefetch` keyword.

4.6.6.6 Link type "external"

The `external` keyword may be used with `a`, `area`, and `form` elements. This keyword does not create a [hyperlink](#), but [annotates](#) any other hyperlinks created by the element (the implied hyperlink, if no other keywords create one).

The `external` keyword indicates that the link is leading to a document that is not part of the site that the current document forms a part of.

4.6.6.7 Link type "help"

The `help` keyword may be used with `link`, `a`, `area`, and `form` elements. This keyword creates a [hyperlink](#).

For `a`, `area`, and `form` elements, the `help` keyword indicates that the referenced document provides further help information for the parent of the element defining the hyperlink, and its children.

Example

In the following example, the form control has associated context-sensitive help. The user agent could use this information, for example, displaying the referenced document if the user presses the "Help" or "F1" key.

```
<form><label> Topic: <input name="topic"> <a href="help/topic.html" rel="help">(Help)</a></label></form>
```

For `link` elements, the `help` keyword indicates that the referenced document provides help for the page as a whole.

For `a` and `area` elements, on some browsers, the `help` keyword causes the link to use a different cursor.

4.6.6.8 Link type "icon"

MDN

Support: link-icon-pngChrome for Android 8+|Chrome 4+|iOS Safari None|Safari 3.1+|Firefox 2+|Samsung Internet 4+|Edge 12+|UC Browser for Android 12.12+|IE 11+|Opera 9+|Opera Mini None|Firefox for Android 68+

Source: caniuse.com

The `icon` keyword may be used with `link` elements. This keyword creates an [external resource link](#).

The specified resource is an icon representing the page or site, and should be used by the user agent when representing the page in the user interface.

Icons could be auditory icons, visual icons, or other kinds of icons. If multiple icons are provided, the user agent must select the most appropriate icon according to the `type`, `media`, and `sizes` attributes. If there are multiple equally appropriate icons, user agents must use the last one declared in `tree order` at the time that the user agent collected the list of icons. If the user agent tries to use an icon but that icon is determined, upon closer examination, to in fact be inappropriate (e.g. because it uses an unsupported format), then the user agent must try the next-most-appropriate icon as determined by the attributes.

Note

User agents are not required to update icons when the list of icons changes, but are encouraged to do so.

There is no default type for resources given by the `icon` keyword. However, for the purposes of [determining the type of the resource](#), user agents must expect the resource to be an image.

The `icon` keywords represent icon sizes in raw pixels (as opposed to [CSS pixels](#)).

Note

An icon that is 50 [CSS pixels](#) wide intended for displays with a device pixel density of two device pixels per [CSS pixel](#) (2x, 192dpi) would have a width of 100 raw pixels. This feature does not support indicating that a different resource is to be used for small high-resolution icons vs large low-resolution icons (e.g. 50x50 2x vs 100x100 1x).

To parse and process the attribute's value, the user agent must first [split the attribute's value on ASCII whitespace](#), and must then parse each resulting keyword to determine what it represents.

The `any` keyword represents that the resource contains a scalable icon, e.g. as provided by an SVG image.

Other keywords must be further parsed as follows to determine what they represent:

- If the keyword doesn't contain exactly one U+0070 LATIN SMALL LETTER X or U+0058 LATIN CAPITAL LETTER X character, then this keyword doesn't represent anything. Return for that keyword.
- Let `width string` be the string before the ":" or ";".
- Let `height string` be the string after the ":" or ";".
- If either `width string` or `height string` start with a U+0030 DIGIT ZERO (0) character or contain any characters other than [ASCII digits](#), then this keyword doesn't represent anything. Return for that keyword.
- Apply the [rules for parsing non-negative integers](#) to `width string` to obtain `width`.
- Apply the [rules for parsing non-negative integers](#) to `height string` to obtain `height`.
- The keyword represents that the resource contains a bitmap icon with a width of `width` device pixels and a height of `height` device pixels.

The keywords specified on the `sizes` attribute must not represent icon sizes that are not actually available in the linked resource.

In the absence of a `link` with the `icon` keyword, for `Document` objects whose `URL`'s `scheme` is an [HTTP\(s\) scheme](#), user agents may instead run these steps [in parallel](#):

1. Let `request` be a new `Request` whose `url` is the `URL record` obtained by resolving the `URL "/favicon.ico"` against the `Document` object's `URL client` is the `Document` object's `relevant settings object`, `destination` is "`image`", `synchronous flag` is set, `credentials mode` is "`include`", and whose `use-URL-credentials flag` is set.
2. Let `response` be the result of [fetching request](#).
3. Use `response's unsafe response` as an icon as if it had been declared using the `icon` keyword.

Example

The following snippet shows the top part of an application with several icons.

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

```
html lang="en">
<head>
  <title>lsForums - Inbox</title>
  <link rel="icon" href="index.ico" sizes="16x16" type="image/png">
  <link rel="icon" href="windows.ico" sizes="32x32 48x48" type="image/vnd.microsoft.icon">
  <link rel="icon" href="mac-ico" sizes="128x128 512x512 8192x8192 32768x32768">
  <link rel="icon" href="apple-touch-icon.png" type="image/png">
  <link rel="stylesheet" href="lsforums.css">
  <script></script>
  <meta name="application-name" content="lsForums">
</head>
<body>
```

For historical reasons, the `icon` keyword may be preceded by the keyword "shortcut". If the "shortcut" keyword is present, the `rel` attribute's entire value must be an [ASCII case-insensitive](#) match for the string "shortcut icon" (with a single U+0020 SPACE character between the tokens and no other [ASCII whitespace](#)).

4.6.6.9 Link type "license"

The `license` keyword may be used with `link`, `a`, `area`, and `form` elements. This keyword creates a [hyperlink](#).

The `license` keyword indicates that the referenced document provides the copyright license terms under which the main content of the current document is provided.

This specification does not specify how to distinguish between the main content of a document and content that is not deemed to be part of that main content. The distinction should be made clear to the user.

Example

Consider a photo sharing site. A page on that site might describe and show a photograph, and the page might be marked up as follows:

```
<!DOCTYPE HTML>
<html lang="en">
  <head>
    <title>Example Pictures: Kissat</title>
    <link rel="stylesheet" href="style/default">
  </head>
  <body>
    <h1>Kissat</h1>
    <nav>
      <a href="#">Return to photo index</a>
    </nav>
    
    <div>Caption of the photo of the kiss cat</div>
    <p>Photo of the has six toes!</p>
    <p><img alt="A small thumbnail image of a cat." href="http://www.opensource.org/licenses/mit-license.php">MIT Licensed</a></p>
    <footnote>
      <p><img alt="A small thumbnail image of a cat." href="#">Photo index</a><br/>
      <small>© 2009 Example Pictures. All Rights Reserved.</small></p>
    </footnote>
  </body>
</html>
```

In this case the `license` applies to just the photo (the main content of the document), not the whole document. In particular not the design of the page itself, which is covered by the copyright given at the bottom of the document. This could be made clearer in the styling (e.g. making the license link prominently positioned near the photograph, while having the copyright in light small text at the foot of the page).

Synonyms: For historical reasons, user agents must also treat the keyword "copyright" like the `license` keyword.

4.6.6.10 Link type "modulepreload"

Support: link-rel-modulepreload for Android 81+Chrome 66+iOS Safari NonoSafari NonFirefox NonSamsung Internet 9.2+Edge 79+UC Browser for Android NonIE NonOpera 53+Opera Mini NonFirefox for Android None

Source: [caniuse.com](#)

AMDN

Link_types/modulepreload

Support in one engine only.

Firefox?Safari?Chrome66+

Opera53+Edge79+

Edge (Legacy)NoInternet Explorer?

Firefox?Android?Safari?iOS?Chrome?Android66+WebView?Android66+Samsung Internet9.0+Opera?Android47+

The `modulepreload` keyword may be used with `link` elements. This keyword creates an [external resource link](#). This keyword is [body-only](#).

The `modulepreload` keyword is a specialized alternative to the `preload` keyword, with a processing model geared toward preloading `module scripts`. In particular, it uses the specific fetch behavior for module scripts (including, e.g., a different interpretation of the `crossorigin` attribute), and places the result into the appropriate `module map` for later evaluation. In contrast, a similar [external resource link](#) using the `preload` keyword would place the result in the preload cache, without affecting the document's `module map`.

Additionally, implementations can take advantage of the fact that `module scripts` declare their dependencies in order to fetch the specified module's dependency as well. This is intended as an optimization opportunity, since the user agent knows that, in all likelihood, those dependencies will also be needed later. It will not generally be observable without using technology such as service workers, or monitoring on the server side. Notably, the appropriate `load` or `error` events will occur after the specified module is fetched, and will not wait for any dependencies.

The appropriate times to `fetch` and `process the linked resource` for such a link are:

- When the [external resource link](#) is created on a `link` element that is already [browsing-context connected](#).
- When the `external resource link`'s `link` element becomes [browsing-context connected](#).
- When the `user` attribute of the `link` element of an [external resource link](#) that is already [browsing-context connected](#) is changed.

Note
Unlike some other link relations, changing the relevant attributes (such as `as`, `crossorigin`, and `referrerpolicy`) of such a `link` does not trigger a new fetch. This is because the document's `module map` has already been populated by a previous fetch, and so re-fetching would be pointless.

The `fetch and process the linked resource` algorithm for `modulepreload` links, given a `link` element `el`, is as follows:

1. If the `user` attribute's value is the empty string, then return.
2. Let `destination` be the current state of the `__` attribute (a `destination`), or "script" if it is in no state.
3. If `destination` is not `script-like`, then `queue a task` on the `networking task source` to `fire an event` named `preload` at the `link` element, and return.
4. `Parse the URL` given by the `user` attribute, relative to the element's `node document`. If that fails, then return. Otherwise, let `url` be the `resulting URL record`.
5. Let `settings object` be the `link` element's `node document's relevant settings object`.
6. Let `credentials mode` be the `module script credentials mode` for the `crossorigin` attribute.
7. Let `cryptographic nonce` be the current value of the element's `[!CryptographicNonce]` internal slot.
8. Let `integrity metadata` be the value of the `integrity` attribute, if it is specified, or the empty string otherwise.
9. Let `referrer policy` be the current state of the element's `referrerpolicy` attribute.
10. Let `options` be a `script fetch options` whose `cryptographic nonce` is `cryptographic nonce`, `integrity metadata` is `integrity metadata`, `parser metadata` is "not-parsed-inserted", `credentials mode` is `credentials mode`, and `referrer policy` is `referrer policy`.
11. `Fetch a modulepreload module script` given `url`, `destination`, `settings object`, and `options`. Wait until the algorithm asynchronously completes with `result`.
12. If `result` is null, then `fire an event` named `error` at the `link` element, and return.
13. `Fire an event` named `load` at the `link` element.

Example

The following snippet shows the top part of an application with several modules preloaded:

```
<!DOCTYPE HTML>
<html lang="en">
  <title>IRCCopy</title>
  <link rel="modulepreload" href="app.mjs">
  <link rel="modulepreload" href="helpers.mjs">
  <link rel="modulepreload" href="irc.mjs">
  <link rel="modulepreload" href="fog-machine.mjs">
  <script type="module" src="app.mjs">
  ...
```

Assume that the module graph for the application is as follows:

The module graph is rooted at `app.mjs`, which depends on `irc.mjs` and `fog-machine.mjs`. In turn, `irc.mjs` depends on `helpers.mjs`.

Here we see the application developer has used `modulepreload` all of the modules in their module graph, ensuring that the user agent initiates fetches for them all. Without such preloading, the user agent might need to go through multiple network roundtrips before discovering `helpers.mjs`, if technologies such as HTTP/2 Server Push are not in play. In this way, `modulepreload` elements can be used as a sort of "manifest" of the application's modules.

Example

The following code shows how `modulepreload` links can be used in conjunction with `import()` to ensure network fetching is done ahead of time, so that when `import()` is called, the module is already ready (but not evaluated) in the `module map`:

```
<link rel="modulepreload" href="awesome-viewer.mjs">
<button onclick="import('./awesome-viewer.mjs').then(m => m.view())">
  View awesome thing
</button>
```

4.6.6.11 Link type "nofollow"

The `nofollow` keyword may be used with `a`, `area`, and `form` elements. This keyword does not create a [hyperlink](#), but [annotates](#) any other hyperlinks created by the element (the implied hyperlink, if no other keywords create one).

The `nofollow` keyword indicates that the link is not endorsed by the original author or publisher of the page, or that the link to the referenced document was included primarily because of a commercial relationship between people affiliated with the two pages.

4.6.6.12 Link type "noopener"

User agents must implement the processing model of the `preload` keyword described in [Preload](#), as well as in this specification's `fetch` and `process the linked resource algorithm`. [\(PRELOAD\)](#)

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

The [linked resource fetch setup steps](#) for this type of linked resource, given a [link](#) element *el* and [request](#) request, are:

1. Let *as* be the current state of *el*'s [as](#) attribute.
2. If *as* does not represent a state, return false.
3. Set *request*'s [destination](#) to the result of [translating as](#).
4. If *as* is "image",:
 1. Let [selected source](#) and [selected pixel density](#) be the URL and pixel density that results from [selecting an image source](#) given *el*, respectively.
 2. If [selected source](#) is null, then return.
3. [Parse selected source](#), relative to *el*'s [node document](#). If that fails, then return false. Otherwise, let *url* be the [resulting URL record](#).
4. Set *request*'s [url](#) to *url*.

5. Return true.

4.6.6.19 Link type "preconnect"

[AMDN](#)

[Link types/preconnect](#)

Support in one engine only.

FirefoxNoSafariNoChrome13+

Opera15+Edge79+

Edge (Legacy)NoInternet Explorer11

Firefox AndroidNoSafari iOSNoChrome Android18+WebView Android4.4+Samsung Internet1.5+Opera Android14+

The [preconnect](#) keyword may be used with [link](#) elements. This keyword creates an [external resource link](#). This keyword is [body-ok](#).

The [preconnect](#) keyword indicates that the specified resource might be required by the next navigation, and so it may be beneficial to not only preemptively [fetch](#) the resource, but also to process it, e.g. by [fetching](#) its subresources or performing some rendering. User agents must implement the processing model of the [preconnect](#) keyword described in [Resource Hints \[RESOURCETHINTS\]](#).

There is no default type for resources given by the [preconnect](#) keyword.

4.6.6.20 Link type "search"

The [search](#) keyword may be used with [link](#), [a](#), [area](#), and [form](#) elements. This keyword creates a [hyperlink](#).

The [search](#) keyword indicates that the referenced document provides an interface specifically for searching the document and its related resources.

Note

OpenSearch description documents can be used with [link](#) elements and the [search](#) link type to enable user agents to autodiscover search interfaces. [\[OPENSEARCH\]](#)

4.6.6.21 Link type "stylesheet"

[AMDN](#)

[Alternative style sheets](#)

Support in one engine only.

Firefox3+Safari?Chrome?

OperaYesEdge?

Edge (Legacy)?Internet Explorer?

Firefox Android4+Safari iOS?Chrome Android?WebView Android?Samsung Internet?Opera Android?

The [stylesheet](#) keyword may be used with [link](#) elements. This keyword creates an [external resource link](#) that contributes to the styling processing model. This keyword is [body-ok](#).

The specified resource is a [CSS style sheet](#) that describes how to present the document.

If the [stylesheet](#) keyword is also specified on the [link](#) element, then the *link* is an [alternative style sheet](#); in this case, the [title](#) attribute must be specified on the [link](#) element, with a non-empty value.

The default type for resources given by the [stylesheet](#) keyword is [text/css](#).

The appropriate times to [fetch and process](#) this type of link are:

- When the [external resource link](#) is created on a [link](#) element that is already [browsing-context connected](#).
- When the [external resource link](#)'s [link](#) element [becomes browsing-context connected](#).
- When the [title](#) attribute of the [link](#) element of an [external resource link](#) that is already [browsing-context connected](#) is changed.
- When the [processinginfo](#) attribute of the [link](#) element of an [external resource link](#) that is already [browsing-context connected](#) is set, changed, or removed.
- When the [type](#) attribute of the [link](#) element of an [external resource link](#) that is already [browsing-context connected](#) is set or changed to a value that does not or no longer matches the [Content-Type metadata](#) of the previous obtained external resource, if any.
- When the [type](#) attribute of the [link](#) element of an [external resource link](#) that is already [browsing-context connected](#), but was previously not obtained due to the [type](#) attribute specifying an unsupported type, is set, removed, or changed.
- When the [external resource link](#) that is already [browsing-context connected](#) changes from being an [alternative style sheet](#) to not being one, or vice versa.

Quirk: If the document has been set to [quirks mode](#), has the [same origin](#) as the [URL](#) of the external resource, and the [Content-Type metadata](#) of the external resource is not a supported style sheet type, the user agent must instead assume it to be [text/css](#).

The [linked resource fetch setup steps](#) for this type of linked resource, given a [link](#) element *el* (ignoring the [request](#)) are:

1. If *el* contributes a [script-blocking style sheet](#), increment *el*'s [node document's script-blocking style sheet counter](#) by 1.
2. Return true.

See [issue #968](#) for plans to use the CSSOM [fetch a CSS style sheet](#) algorithm instead of the [default fetch and process the linked resource](#) algorithm.

To [process this type of linked resource](#) given a [link](#) element *el*, boolean *success*, and [response](#) response, the user agent must run these steps:

1. If the resource's [Content-Type metadata](#) is not [text/css](#), then set *success* to false.
2. If *el* no longer creates an [external resource link](#) that contributes to the styling processing model, or if, since the resource in question was [fetched](#), it has become appropriate to [fetch](#) it again, then return.
3. If *el* has an [associated CSS style sheet](#), remove the [CSS style sheet](#).
4. If *success* is true, then:

1. Create a [CSS style sheet](#) with the following properties:

type

[text/css](#)

location

The [resulting URL string](#) determined during the [fetch and process the linked resource](#) algorithm.

Note

This is before any redirects get applied.

owner node

element

media

The [media](#) attribute of [element](#).

Note

This is a reference to the (possibly absent at this time) attribute, rather than a copy of the attribute's current value. CSSOM defines what happens when the attribute is dynamically set, changed, or removed.

title

The [title](#) attribute of [element](#), if [element](#) is [in a document tree](#), or the empty string otherwise.

Note

This is similarly a reference to the attribute, rather than a copy of the attribute's current value.

alternate flag

Set if [the link is an alternative style sheet](#); unset otherwise.

origin-clean flag

Set if the resource is [CORS-same-origin](#); unset otherwise.

parent CSS style sheet

owner CSS rule

null

disabled flag

Left at its default value.

CSS rules

Left uninitialized.

This doesn't seem right. Presumably we should be using the response body? Tracked as [issue #2997](#).

The CSS [environment encoding](#) is the result of running the following steps: [\[CSSSYNTAX\]](#)

1. If the element has a [charset](#) attribute, [get an encoding](#) from that attribute's value. If that succeeds, return the resulting encoding. [\[ENCODING\]](#)

2. Otherwise, return the [document's character encoding](#). [\[DOM\]](#)

2. [Fire an event](#) named [load](#) at *el*.

6. If *e*'s [contributes a script-blocking style sheet](#), then:

1. Assert: *e*'s [node document's script-blocking style sheet counter](#) is greater than 0.
2. Decrement *e*'s [node document's script-blocking style sheet counter](#) by 1.

4.6.6.22 Link type "tag"

The `tag` keyword may be used with `a` and `area` elements. This keyword creates a [hyperlink](#).

The `tag` keyword indicates that the `tag` that the referenced document represents applies to the current document.

Note

Since it indicates that the tag *applies to the current document*, it would be inappropriate to use this keyword in the markup of a [tag cloud](#), which lists the popular tags across a set of pages.

Example

This document is about some gems, and so it is tagged with "<https://en.wikipedia.org/wiki/Gemstone>" to unambiguously categorize it as applying to the "jewel" kind of gems, and not to, say, the towns in the US, the Ruby package format, or the Swiss locomotive class:

```
<!DOCTYPE HTML>
<html lang="en">
<head>
  <title>My Precious</title>
</head>
<body>
  <h1>My precious!</h1> <p>Summer 2012</p>
  <p>Recently I managed to dispose of a red gem that had been bothering me. I now have a much nicer blue sapphire.</p>
  <p>I recently found a small green gem in my garden. I was digging out the office level, but nobody was willing to haul it away. The same red gem stayed there for literally years.</p>
  <p>Tags:<a rel="tag" href="https://en.wikipedia.org/wiki/Gemstone">Gemstone</a>
  </p>
</body>
</html>
```

Example

In this document, there are two articles. The `*tag` link, however, applies to the whole page (and would do so wherever it was placed, including if it was within the `article` elements).

```
<!DOCTYPE HTML>
<html lang="en">
<head>
  <title>Gem 4/4</title>
</head>
<body>
  <article>
    <h1>Old Steinbock</h1>
    <p>Number 801 Gem 4/4 electro-diesel has an ibex and was rebuilt in 2002.</p>
  </article>
  <article>
    <h1>Murmellier</h1>
    <figure>
      <img alt="The 802 was red with pantographs and tall vents on the sides."/>
      <p>The 802 was red with pantographs and tall vents on the sides.</p>
    </figure>
    <p>The number 802 Gem 4/4 electro-diesel has a maroco and was rebuilt in 2003.</p>
  </article>
  <p><a href="#" rel="topic">topic</a> <a href="https://en.wikipedia.org/wiki/Rhaetian_Railway_Gem_4/4">Gem 4/4</a></p>
</body>
</html>
```

4.6.6.23 Standard link types

Some documents form part of a sequence of documents.

A sequence of documents is one where each document can have a *previous sibling* and a *next sibling*. A document with no previous sibling is the start of its sequence, a document with no next sibling is the end of its sequence.

A document may be part of multiple sequences.

4.6.6.23.1 Link type "prev"

The `prev` keyword may be used with `link`, `a`, `area`, and `form` elements. This keyword creates a [hyperlink](#).

The `prev` keyword indicates that the document is part of a sequence, and that the link is leading to the document that is the next logical document in the sequence.

When the `prev` keyword is used with a `link` element, user agents should implement one of the processing models described in [Resource Hints](#), i.e. should process such links as if they were using one of the `dns-prefetch`, `preconnect`, `prefetch`, or `prerender` keywords. Which resource hint the user agent wishes to use is implementation-dependent; for example, a user agent may wish to use the less-costly `preconnect` hint when trying to conserve data, battery power, or processing power, or may wish to pick a resource hint depending on heuristic analysis of past user behavior in similar scenarios. [\[RESOURCEHINTS\]](#)

4.6.6.23.2 Link type "prev"

The `prev` keyword may be used with `link`, `a`, `area`, and `form` elements. This keyword creates a [hyperlink](#).

The `prev` keyword indicates that the document is part of a sequence, and that the link is leading to the document that is the previous logical document in the sequence.

Synonyms: For historical reasons, user agents must also treat the keyword "previous" like the `prev` keyword.

4.6.6.24 Other link types

Extensions to the predefined set of link types may be registered in the [microformats wiki existing-rel-values page](#) [\[MFREL\]](#).

Anyone is free to edit the microformats wiki existing-rel-values page at any time to add a type. Extension types must be specified with the following information:

Keyword

The actual value being defined. The value should not be confusingly similar to any other defined value (e.g. differing only in case).

If the value contains a U+003A COLON character (:), it must also be an [absolute URL](#).

Effect on... `link`

One of the following:

Not allowed

The `prev` keyword must not be specified on `link` elements.

Hyperlink

The keyword may be specified on a `link` element; it creates a [hyperlink](#).

External Resource

The keyword may be specified on a `link` element; it creates an [external resource link](#).

Effect on... `a` and `area`

One of the following:

Not allowed

The `prev` keyword must not be specified on `a` and `area` elements.

Hyperlink

The keyword may be specified on `a` and `area` elements; it creates a [hyperlink](#).

External Resource

The keyword may be specified on `a` and `area` elements; it creates an [external resource link](#).

Hyperlink Annotation

The keyword may be specified on `a` and `area` elements; it [annotates](#) other [hyperlinks](#) created by the element.

Effect on... `form`

One of the following:

Not allowed

The `prev` keyword must not be specified on `form` elements.

Hyperlink

The keyword may be specified on `form` elements; it creates a [hyperlink](#).

External Resource

The keyword may be specified on `form` elements; it creates an [external resource link](#).

Hyperlink Annotation

The keyword may be specified on `form` elements; it [annotates](#) other [hyperlinks](#) created by the element.

Brief description

A short non-normative description of what the keyword's meaning is.

Specification

A link to a more detailed description of the keyword's semantics and requirements. It could be another page on the Wiki, or a link to an external page.

Synonyms

A list of other keyword values that have exactly the same processing requirements. Authors should not use the values defined to be synonyms, they are only intended to allow user agents to support legacy content. Anyone may remove synonyms that are not used in practice; only names that need to be processed as synonyms for compatibility with legacy content are to be registered in this way.

Status

One of the following:

Proposed

The keyword has not received wide peer review and approval. Someone has proposed it and is, or soon will be, using it.

Ratified

The keyword has received wide peer review and approval. It has a specification that unambiguously defines how to handle pages that use the keyword, including when they use it in incorrect ways.

Discontinued

The keyword has received wide peer review and it has been found wanting. Existing pages are using this keyword, but new pages should avoid it. The "brief description" and "specification" entries will give details of what authors should use instead, if anything.

If a keyword is found to be redundant with existing values, it should be removed and listed as a synonym for the existing value.

If a keyword is registered in the "proposed" state for a period of a month or more without being used or specified, then it may be removed from the registry.

If a keyword is added with the "proposed" status and found to be redundant with existing values, it should be removed and listed as a synonym for the existing value. If a keyword is added with the "proposed" status and found to be harmful, then it should be changed to "discontinued" status.

Anyone can change the status at any time, but should only do so in accordance with the definitions above.

Conformance checkers must use the information given on the microformats wiki existing-rel-values page to establish if a value is allowed or not: values defined in this specification or marked as "proposed" or "ratified" must be accepted when used on the elements for which they apply as described in the "Effect on..." field, whereas values marked as "discontinued" or not listed in either this specification or on the aforementioned page must be rejected as invalid. Conformance checkers may cache this information (e.g. for performance reasons or to avoid the use of unreliable network connectivity).

When an author uses a new type not defined by either this specification or the Wiki page, conformance checkers should offer to add the value to the Wiki, with the details described above, with the "proposed" status.

Types defined as extensions in the [microformats wiki existing-rel-values page](#) with the status "proposed" or "ratified" may be used with the `rel` attribute on `link`, `a`, and `area` elements in accordance to the "Effect on..." field. [\[MFREL\]](#)

4.7 Edits

The `link` and `rel` elements [concurrently edit](#) the document.

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

4.7.1 The `ins` element

MDN

[Element](#)[ins](#)

Support in all current engines.

Firefox+1+Safari+Yes+Chrome+Yes

Opera+Yes+Edge+Yes

Edge (Legacy)12+Internet Explorer+Yes

Firefox+Android44+Safari+iOS+Yes+Chrome+Android+Yes+WebView+Android+Yes+Samsung+Internet+Yes+Opera+Android+Yes

Categories:

Flow content.

Phrasing content.

Palpable content.

Contexts in which this element can be used:

Where [phrasing content](#) is expected.

Content model:

Transparent.

Tag omission in `text/html`:

Neither tag is omitted.

Content attributes:

`cite` — Link to the source of the quotation or more information about the edit.

`datetime` — Date and (optionally) time of the change.

Accessibility considerations:

For authors.

For implementers.

DOM interface:

Uses [HTMLModElement](#).

The `ins` element represents an addition to the document.

Example

The following represents the addition of a single paragraph:

```
<aside>
<ins>
  I like fruit. </p>
</ins>
</aside>
```

As does the following, because everything in the `aside` element here counts as [phrasing content](#) and therefore there is just one [paragraph](#):

```
<aside>
<ins>
  Apples are <em>tasty</em>.
</ins>
<ins>
  So are pears.
</ins>
</aside>
```

`ins` elements should not cross [implied paragraph](#) boundaries.

Example

The following example represents the addition of two paragraphs, the second of which was inserted in two parts. The first `ins` element in this example thus crosses a paragraph boundary, which is considered poor form.

```
<aside>
<!-- don't do this -->
<ins datetime="2005-03-16 00:00Z">
  I like fruit. </p>
</ins>
Apples are <em>tasty</em>.
<ins>
  So are pears.
</ins>
</aside>
```

Here is a better way of marking this up. It uses more elements, but none of the elements cross implied paragraph boundaries.

```
<aside>
<ins datetime="2005-03-16 00:00Z">
  I like fruit. </p>
</ins>
<ins datetime="2005-03-16 00:00Z">
  Apples are <em>tasty</em>.
</ins>
<ins datetime="2007-12-19 00:00Z">
  So are pears.
</ins>
</aside>
```

4.7.2 The `del` element

MDN

Edge (Legacy)12+Internet Explorer+Yes

Firefox+Android44+Safari+iOS+Yes+Chrome+Android+Yes+WebView+Android+Yes+Samsung+Internet+Yes+Opera+Android+Yes

Categories:

Flow content.

Phrasing content.

Contexts in which this element can be used:

Where [phrasing content](#) is expected.

Content model:

Transparent.

Tag omission in `text/html`:

Neither tag is omitted.

Content attributes:

`Global attributes`

`cite` — Link to the source of the quotation or more information about the edit.

`datetime` — Date and (optionally) time of the change.

Accessibility considerations:

For authors.

For implementers.

DOM interface:

Uses [HTMLModElement](#).

The `del` element represents a removal from the document.

`del` elements should not cross [implied paragraph](#) boundaries.

Example

The following shows a “to do” list where items that have been done are crossed-off with the date and time of their completion.

```
<ul><li>Do</li>
<li><del>Empty the dishwasher</del>
<del>2009-10-17T01:25-07:00</del>Watch Walter Lewin's lectures</li>
<li><del>2009-10-10T23:38-07:00</del>Download more tracks</li>
<li>Buy a printer</li>
</ul>
```

4.7.3 Attributes common to `ins` and `del` elements

The `cite` attribute may be used to specify the [URL](#) of a document that explains the change. When that document is long, for instance the minutes of a meeting, authors are encouraged to include a [fragment](#) pointing to the specific part of that document that discusses the change.

If the `cite` attribute is present, it must be a [valid URL potentially surrounded by spaces](#) that explains the change. To obtain the corresponding citation link, the value of the attribute must be [parsed](#) relative to the element's [node document](#). User agents may allow users to follow such citation links, but they are primarily intended for private use (e.g., by server-side scripts collecting statistics about a site's edits), not for readers.

The `datetime` attribute may be used to specify the time and date of the change.

If present, the `datetime` attribute's value must be a [valid date string with optional time](#).

User agents must parse the `datetime` attribute according to the [parse a date or time string](#) algorithm. If that doesn't return a `date` or a `global date and time`, then the modification has no associated timestamp (the value is non-conforming: it is not a [valid date string with optional time](#)). Otherwise, the modification is marked as having been made at the given `date` or `global date and time`. If the given value is a `global date and time` then user agents should use the associated time-zone offset information to determine which time zone to present the given `datetime`.

This value may be shown to the user, but it is primarily intended for private use.

The `ins` and `del` elements must implement the [HTMLModElement](#) interface:

MDN

[HTML ModElement](#)

Support in all current engines.

Firefox+1+Safari+Yes+Chrome+Yes

Opera+Yes+Edge+Yes

Edge (Legacy)12+Internet Explorer+Yes

Firefox+Android44+Safari+iOS+Yes+Chrome+Android+Yes+WebView+Android+Yes+Samsung+Internet+Yes+Opera+Android+Yes

```
IDL Exposed<W3C>
interface HTMLModElement : HTMLElement {
  [HTMLConstructor] constructor();
}
```

[CFReactions] attribute DOMString `dateTime`
 The `cite` IDL attribute must `reflect` the element's `cite` content attribute. The `dateTime` IDL attribute must `reflect` the element's `datetime` content attribute.

4.7.4 Edits and paragraphs

This section is non-normative.

Since the `ins` and `del` elements do not affect `paragraphing`, it is possible, in some cases where paragraphs are `implied` (without explicit `p` elements), for an `ins` or `del` element to span both an entire paragraph or other non-`phrasing content` elements and part of another paragraph. For example:

```
<section>
<ins>
  This is a paragraph that was inserted.
</p>
  This is another paragraph whose first sentence was inserted
  at the same time as the paragraph above.
<ins>
  This is a second sentence, which was there all along.
</section>
```

By only wrapping some paragraphs in `p` elements, one can even get the end of one paragraph, a whole second paragraph, and the start of a third paragraph to be covered by the same `ins` or `del` element (though this is very confusing, and not considered good practice):

```
<section>
This is the first paragraph. <ins>This sentence was
inserted.
<p>This second paragraph was inserted.</p>
This sentence was inserted too. <ins> This is the
third paragraph in this example.
<!-- (don't do this) -->
</section>
```

However, due to the way `implied paragraphs` are defined, it is not possible to mark up the end of one paragraph and the start of the very next one using the same `ins` or `del` element. You instead have to use one (or two) `p` element(s) and two `ins` or `del` elements, as for example:

```
<section>
<p>This is the first paragraph. <del>This sentence was
deleted</del>
<p><del>This sentence was deleted too.</del> That
sentence needed a separate <del>[del]</del> element.</p>
</section>
```

Partly because of the confusion described above, authors are strongly encouraged to always mark up all paragraphs with the `p` element, instead of having `ins` or `del` elements that cross `implied paragraphs` boundaries.

4.7.5 Edits and lists

This section is non-normative.

The content models of the `ul` and `ol` elements do not allow `ins` and `del` elements as children. Lists always represent all their items, including items that would otherwise have been marked as deleted.

To indicate that an item is inserted or deleted, an `ins` or `del` element can be wrapped around the contents of the `li` element. To indicate that an item has been replaced by another, a single `li` element can have one or more `del` elements followed by one or more `ins` elements.

Example

In the following example, a list that started empty had items added and removed from it over time. The bits in the example that have been emphasized show the parts that are the "current" state of the list. The list item numbers don't take into account the edits, though.

```
<ul><li><del>ship bugs</del><br/>
<li><ins>datetime="2008-02-12T15:02Z">Bug 225:
Rain detector doesn't work in snow</ins></li>
<li><ins>datetime="2008-02-14T12:02Z">Bug 226:
Water buffer overflows in April</ins><del></del></li>
<li><ins>datetime="2008-02-16T13:50Z">Bug 227:
Solar system detection</ins><del></del></li>
<li><del><ins>datetime="2008-02-17T11:15Z"></ins><ins>datetime="2008-02-16T14:25Z">Bug 232:
Carbon dioxide emissions detected after startup</ins></del></li>
</ul>
```

Example

In the following example, a list that started with just fruit was replaced by a list with just colors.

```
<ul><li><del>fruits</del><ins>colors</ins></li>
<li><del>apple</del><ins>green</ins></li>
<li><del>banana</del><ins>yellow</ins></li>
<li><del>orange</del><ins>red</ins></li>
<li><del>pear</del><ins>blue</ins></li>
<li><del>lemon</del><ins>yellow</ins></li>
<li><del>olive</del><ins>purple</ins></li>
</ul>
```

4.7.6 Edits and tables

This section is non-normative.

The elements that form part of the table model have complicated content model requirements that do not allow for the `ins` and `del` elements, so indicating edits to a table can be difficult.

To indicate that an entire row or an entire column has been added or removed, the entire contents of each cell in that row or column can be wrapped in `ins` or `del` elements (respectively).

Example

Here, a table's row has been added:

```
<table>
<thead>
<tr> <th> Game name </th> Game publisher <th> Verdict
</thead>
<tbody>
<tr> <td> Diablo 2 </td> Blizzard <td> 8/10
<tr> <td> Portal </td> Valve <td> 10/10
<tr> <td> <ins>Portal 2</ins> </td> Valve <td> <ins>10</ins>
</tbody>
</table>
```

Here, a column has been removed (the time at which it was removed is given also, as is a link to the page explaining why):

```
<table>
<thead>
<tr> <th> Game name </th> <del>Game publisher </del> <th> Verdict</th>
</thead>
<tbody>
<tr> <td> Diablo 2 </td> <del>Blizzard </del> <td> <del>8/10</del>
<tr> <td> Portal </td> <del>Valve </del> <td> <del>10/10</del>
<tr> <td> Portal 2 </td> Valve <td> <del>8/10</del>
</tbody>
</table>
```

Generally speaking, there is no good way to indicate more complicated edits (e.g. that a cell was removed, moving all subsequent cells up or to the left).

Content model:

One or more `source` elements, followed by one `img` element, optionally intermixed with `script-supporting elements`.

Tag omission in `text/html`:

Neither tag is omitted.

Content attributes:

Global attributes

Accesskey considerations:

For authors

For implementers

DOM interface:

```
IDLExposedWindow
interface HTMLPictureElement : HTMLElement {
  [HTMLPictureElement] constructor();
}
```

The `picture` element is a container which provides multiple sources to its contained `img` element to allow authors to declaratively control or give hints to the user agent about which image resource to use, based on the screen pixel density, `viewport` size, image format, and other factors. It `represents` its children.

Note

The `picture` element is somewhat different from the similar-looking `video` and `audio` elements. While all of them contain `source` elements, the `source` element's `src` attribute has no meaning when the element is nested within a `picture` element, and the resource selection algorithm is different. Also, the `picture` element itself does not display anything; it `represents` its children.

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

Categories:None
Contexts in which this element can be used:
As a child of a `picture` element, before the `img` element.
As a child of a `media` element, before any `flow_content` or `track` elements.**Content model:**None
No end tag.**Content attributes:****Global attributes**
`src` — Address of the resource
`type` — Type of embedded resource
`width` — Images to use in different situations (e.g., high-resolution displays, small monitors, etc.)
`sizes` — Image sizes for different page layouts
`media` — Applicable media**Accessibility considerations:**For authors
For implementers**DOM interface**

```
IDL([Exposed=Window])
interface HTMLSourceElement : HTMLElement {
  [HTMLConstructor] constructor();
  [CSSReactions] attribute USVString src;
  [CSSReactions] attribute DOMString type;
  [CSSReactions] attribute DOMString width;
  [CSSReactions] attribute DOMString sizes;
  [CSSReactions] attribute DOMString media;
}
```

The `source` element allows authors to specify multiple alternative `source sets` for `img` elements or multiple alternative `media resources` for `media elements`. It does not `represent` anything on its own.The `type` attribute may be present. If present, the value must be a [valid MIME type string](#).The remainder of the requirements depend on whether the parent is a `picture` element or a `media element`:`source` element's parent is a `picture` elementThe `srcset` attribute must be present, and is a `srcset attribute`.The `srcset` attribute contributes the `image sources` to the `source set`, if the `source` element is selected.If the `source` attribute has any `image candidate strings` using a `width descriptor`, the `sizes` attribute must also be present, and is a `sizes attribute`. The `sizes` attribute contributes the `source size` to the `source set`, if the `source` element is selected.The `media` attributes may also be present. If present, the value must contain a [valid media query list](#). The user agent will skip to the next `source` element if the value does not [match the environment](#).The `type` attribute gives the type of the images in the `source set`, to allow the user agent to skip to the next `source` element if it does not support the given type.**Note**If the `type` attribute is *not* specified, the user agent will not select a different `source` element if it finds that it does not support the image format after fetching it.When a `source` element has a following sibling `source` element or `img` element with a `srcset` attribute specified, it must have at least one of the following:

- A `media` attribute specified with a value that, after [stripping leading and trailing ASCII whitespace](#), is not the empty string and is not an [ASCII case-insensitive](#) match for the string "`all`".
- A `type` attribute specified.

The `src` attribute must not be present.`source` element's parent is a `media element`The `src` attribute gives the [URL](#) of the `media resource`. The value must be a [valid non-empty URL potentially surrounded by spaces](#). This attribute must be present.**Note**Dynamically modifying a `source` element and its attribute when the element is already inserted in a `video` or `audio` element will have no effect. To change what is playing, just use the `src` attribute on the `media element` directly, possibly making use of the `canPlayType()` method to pick from amongst available resources. Generally, manipulating `source` elements manually after the `source` has been parsed is an unnecessarily complicated approach.The `type` attribute gives the type of the `media resource`, to help the user agent determine if it can play this `media resource` before fetching it. The `codecs` parameter, which certain MIME types define, might be necessary to specify exactly how the resource is encoded. [\[RFC6381\]](#)**Example**The following list shows some examples of how to use the `codecs` MIME parameter in the `type` attribute.

H.264 Constrained baseline profile video (main and extended video compatible) level 3 and Low-Complexity AAC audio in MP4 container

<source src="video.mp4" type="video/mp4; codecs="avc1.42E01E, mp4a.40.2"**>

H.264 Extended profile video (baseline-compatible) level 3 and Low-Complexity AAC audio in MP4 container

<source src="video.mp4" type="video/mp4; codecs="avc1.58A01E, mp4a.40.2"**>

H.264 Main profile video level 3 and Low-Complexity AAC audio in MP4 container

<source src="video.mp4" type="video/mp4; codecs="avc1.4D401E, mp4a.40.2"**>

H.264 'High' profile video (incompatible with main, baseline, or extended profiles) level 3 and Low-Complexity AAC audio in MP4 container

<source src="video.mp4" type="video/mp4; codecs="avc1.64001E, mp4a.40.2"**>

MPEG-4 Visual Simple Profile Level 0 video and Low-Complexity AAC audio in MP4 container

<source src="video.mp4" type="video/mp4; codecs="mp4v.20.8, mp4a.40.2"**>

MPEG-4 Advanced Simple Profile Level 0 video and Low-Complexity AAC audio in MP4 container

<source src="video.mp4" type="video/mp4; codecs="mp4v.20.240, mp4a.40.2"**>

MPEG-4 Visual Simple Profile Level 0 video and AMR audio in 3GPP container

<source src="video.3gp" type="video/3gpp; codecs="mp4v.20.8, samr"**>

Theora video and Vorbis audio in Ogg container

<source src="video.ogv" type="video/ogg; codecs="theora, vorbis"**>

Theora video and Speex audio in Ogg container

<source src="video.ogv" type="video/ogg; codecs="theora, speex"**>

Vorbis audio alone in Ogg container

<source src="audio.oga" type="audio/ogg; codecs=vorbis"**>

Speex audio alone in Ogg container

<source src="audio.spx" type="audio/ogg; codecs=speex"**>

FLAC audio alone in Ogg container

<source src="audio.oga" type="audio/ogg; codecs=flac"**>

Dirac video and Vorbis audio in Ogg container

<source src="video.ogv" type="video/ogg; codecs="dirac, vorbis"**>

The `srcset`, `sizes`, and `media` attributes must not be present.If a `source` element is inserted as a child of a `media element` that has no `src` attribute and whose `networkState` has the value `NETWORK_EMPTY`, the user agent must invoke the `media element's` [resource selection algorithm](#).The IDL attributes `src`, `type`, `srcset`, `sizes` and `media` must `reflect` the respective content attributes of the same name.**Example**If the author isn't sure if user agents will all be able to render the media resources provided, the author can listen to the `error` event on the last `source` element and trigger fallback behavior:

```
<script>
  function fallback(video) {
    // replace <video> with its contents
    while (video.firstChild) {
      if (video.firstChild.nodeType === Node.TEXT_NODE) {
        video.removeChild(video.firstChild);
      } else {
        video.parentNode.insertBefore(video.firstChild, video);
      }
    }
    video.parentNode.removeChild(video);
  }

  document.querySelector('video').addEventListener('error', fallback);
</script>

Edge (Legacy) 12+ Internet Explorer Yes

Firefox, Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `crossorigin` attribute is a [CORS settings attribute](#). Its purpose is to allow images from third-party sites that allow cross-origin access to be used with [caniuse](#).The `referrerpolicy` attribute is a [referrer policy attribute](#). Its purpose is to set the `referrer policy` used when [fetching](#) the image. [\[REFERRERPOLICY\]](#)The `decoding` attribute indicates the preferred method to [decode](#) this image. The attribute, if present, must be an [image decoding hint](#). This attribute's [missing value default](#) and [invalid value default](#) are both the `auto` state.The `img` element must not be used as a layout tool. In particular, `img` elements should not be used to display transparent images, as such images rarely convey meaning and rarely add anything useful to the document.What an `img` element represents depends on the `src` attribute and the `alt` attribute.If the `src` attribute is set and the `alt` attribute is set to the empty string

The image is either decorative or supplemental to the rest of the content, redundant with some other information in the document.

If the image is [available](#) and the user agent is configured to display that image, then the element `represents` the element's image data.Otherwise, the element `represents` nothing, and may be omitted completely from the rendering. User agents may provide the user with a notification that an image is present but has been omitted from the rendering.If the `src` attribute is set and the `alt` attribute is set to a value that isn't emptyThe image is a key part of the content, the `alt` attribute gives a textual equivalent or replacement for the image.If the image is [available](#) and the user agent is configured to display that image, then the element `represents` the element's image data.Otherwise, the element `represents` the text given by the `alt` attribute. User agents may provide the user with a notification that an image is present but has been omitted from the rendering.If the `src` attribute is set and the `alt` attribute is not set

The image might be a key part of the content, and there is no textual equivalent of the image available.

Note In a conforming document, the absence of the `alt` attribute indicates that the image is a key part of the content but that a textual replacement for the image was not available when the image was generated.If the image is [available](#) and the user agent is configured to display that image, then the element `represents` the element's image data.If the image has a `src` attribute whose value is the empty string, then the element `represents` nothing.

Otherwise, the user agent should display some sort of indicator that there is an image that is not being rendered, and may, if requested by the user, or if so configured, or when required to provide contextual information in response to navigation, provide caption information for the image, derived as follows:

1. If the image has a `title` attribute whose value is not the empty string, then return the value of that attribute.2. If the image is a descendant of a `figure` element that has a child `figcaption` element, and, ignoring the `figcaption` element and its descendants, the `figure` element has no `flow content` descendants other than `inter-element whitespace` and the `img` element, then return the contents of the first such `figcaption` element.

3. Return nothing. (There is no caption information.)

If the `src` attribute is not set and either the `alt` attribute is set to the empty string or the `alt` attribute is not set at allThe element `represents` nothing.

Otherwise

The element `represents` the text given by the `alt` attribute.

User agents may always provide the user with the option to display any image, or to prevent any image from being displayed. User agents may also apply heuristics to help the user make use of the image when the user is unable to see it, e.g. due to a visual disability or because they are using a text terminal with no graphics capabilities. Such heuristics could include, for instance, optical character recognition (OCR) of text found within the image.

⚠️ Warning!

While user agents are encouraged to repair cases of missing `alt` attributes, authors must not rely on such behavior. Requirements for providing text to act as an alternative for images are described in detail below.

The contents of `img` elements, if any, are ignored for the purposes of rendering.

The `usemap` attribute, if present, can indicate that the image has an associated [image map](#).

The `ismap` attribute, when used on an element that is a descendant of an `a` element with an `href` attribute, indicates by its presence that the element provides access to a server-side image map. This affects how events are handled on the corresponding `a` element.

The `ismap` attribute is a [boolean attribute](#). The attribute must not be specified on an element that does not have an ancestor `a` element with an `href` attribute.

Note

The `usemap` and `ismap` attributes can result in confusing behavior when used together with `source` elements with the `media` attribute specified in a `picture` element.

The `img` element supports [dimension attributes](#).

The `width` IDL attribute must reflect the `width` content attribute, limited to only known values.

For web developers (non-normative)

`image: url [= value]`

`image: image [= value]`

These attributes return the actual rendered dimensions of the image, or zero if the dimensions are not known.

They can be set, to change the corresponding content attributes.

`image: naturalWidth`

`image: naturalHeight`

These attributes return the intrinsic dimensions of the image, or zero if the dimensions are not known.

`image: complete`

Returns true if the image has been completely downloaded or if no image is specified; otherwise, returns false.

`image: currentSrc`

Returns the image's absolute URL.

`image: decode()`

This method causes the user agent to `decode` the image in `parallel`, returning a promise that fulfills when decoding is complete.

The promise will be rejected with an `"encodingError"` `DOMException` if the image cannot be decoded.

`image = new Image([width [, height]])`

Returns a new `Image` element, with the `width` and `height` attributes set to the values passed in the relevant arguments, if applicable.

The `decode()` method, when invoked, must perform the following steps:

- Let `promise` be a new promise.
- Queue a microtask** to perform the following steps:

Note

This is done because updating the `image data` takes place in a microtask as well. Thus, to make code such as
`img.src = "stars.jpg";
img.decode();`

properly decode `stars.jpg`, we need to delay any processing by one microtask.

- If any of the following conditions are true about this `img` element:
 - its `node document` is not an `active document`.
 - its `current request's state` is `broken`.

then reject `promise` with an `"encodingError"` `DOMException`.

- Otherwise, **in parallel**, wait for one of the following cases to occur, and perform the corresponding actions:

This `img` element's `node document` stops being an `active document`.
This `img` element's `current request` changes or is muted.
This `img` element's `current request's state` becomes `broken`.

Reject `promise` with an `"encodingError"` `DOMException`.

This `img` element's `current request's state` becomes `completely available`.

Decode the image.

If decoding does not need to be performed for this image (for example because it is a vector graphic), resolve `promise` with undefined.

If decoding fails (for example due to invalid image data), reject `promise` with an `"encodingError"` `DOMException`.

If the decoding process completes successfully, resolve `promise` with undefined.

User agents should ensure that the decoded media data stays readily available until at least the end of the next successful `update the rendering` step in the `event loop`. This is an important part of the API contract, and should not be broken if at all possible. (Typically, this would only be violated in low-memory situations that require evicting decoded image data, or when the image is too large to keep in decoded form for this period of time.)

Note

Animated images will become `completely available` only after all their frames are loaded. Thus, even though an implementation could decode the first frame before that point, the above steps will not do so, instead waiting until all frames are available.

- Return `promise`.

Example

Without the `decode()` method, the process of loading an `img` element and then displaying it might look like the following:

```

img.onload = () => {
  document.body.appendChild(img);
}

img.onerror = () => {
  document.body.appendChild(new Text("Could not load the nebula :("));
}

However, this can cause notable dropped frames, as the paint that occurs after inserting the image into the DOM causes a synchronous decode on the main thread.

```

This can instead be rewritten using the `decode()` method:

```

const img = new Image();
img.src = "nebula.jpg";
img.decode();
document.body.appendChild(img);

img.onerror = () => {
  document.body.appendChild(new Text("Could not load the nebula :("));
}

```

This latter form avoids the dropped frames of the original, by allowing the user agent to decode the image `in parallel`, and only inserting it into the DOM (and thus causing it to be painted) once the decoding process is complete.

Example

Because the `decode()` method attempts to ensure that the decoded image data is available for at least one frame, it can be combined with the `requestAnimationFrame()` API. This means it can be used with coding styles or frameworks that ensure that all DOM modifications are batched together as [animation frame callbacks](#):

```

const container = document.querySelector("#container");
const containerWidth = container.clientWidth;
const containerHeight = container.clientHeight;

requestAnimationFrame(() => {
  container.style.width = containerWidth + "px";
  container.style.height = containerHeight + "px";
});

// ...

const img = new Image();
img.src = "supernova.jpg";
img.decode();
requestAnimationFrame(() => container.appendChild(img));

```

HTMLImageElement/Image

Support in all current engines.

Firefox+ Safari 10.1+ Chrome 1+

Opera 8+ Edge 79+

Edge (Legacy) 12+ Internet Explorer 9+

Firefox Android 4.0+ Safari iOS 1+ Chrome Android 18+ WebView Android 1+ Samsung Internet 1.0+ Opera Android?

A constructor is provided for creating `HTMLImageElement` objects (in addition to the factory methods from DOM such as `createElement('img')`: `Image(width, height)`). When invoked, the constructor must perform the following steps:

- Let `document` be the `current global object's associated document`.
- Let `img` be the result of `creating an element` given `document`, `img`, and the [HTML namespace](#).
- If `width` is given, then `set an attribute value` for `img` using `"width"` and `width`.
- If `height` is given, then `set an attribute value` for `img` using `"height"` and `height`.
- Return `img`.

Example

A single image can have different appropriate alternative text depending on the context.

In each of the following cases, the same image is used, yet the `alt` text is different each time. The image is the coat of arms of the Carouge municipality in the canton Geneva in Switzerland.

Here it is used as a supplementary icon:

```
<p>I lived in  Carouge.</p>
```

Here it is used as an icon representing the town:

```
<p>Home town:  Carouge</p>
```

Here it is used as part of a text on the town:

```
<p>Carouge has a coat of arms.</p>
<p> The coat of arms depicts a lion, sitting in front of a tree.</p>
It is used as decoration all over the town.</p>
```

Here it is used as a way to support a similar text where the description is given as well as, instead of as an alternative to, the image:

```
<p>Carouge has a coat of arms.</p>
<p> The coat of arms depicts a lion, sitting in front of a tree.</p>
It is used as decoration all over the town.</p>
```

Here it is used as part of a story:

```
<p>She picked up the folder and a piece of paper fell out.</p>
<p> Shaped like a shield, the paper had a picture of a lion on it. It was the coat of arms of the town of Carouge, whose tail was shaped like an S.</p>
<p>She stared at the folder. !? The answer she had been looking for all this time! She had been looking for that before? It all came together now. The phone call where Hector had referred to a lion's tail, the time Maria had stuck her tongue out...</p>
```

Here it is not known at the time of publication what the image will be, only that it will be a coat of arms of some kind, and thus no replacement text can be provided, and instead only a brief caption for the image is provided, in the `title` attribute:

```
<p>The last user to have uploaded a coat of arms uploaded this one:</p>
<p></p>
```

Ideally, the author would find a way to provide real replacement text even in this case, e.g. by asking the previous user. Not providing replacement text makes the document more difficult to use for people who are unable to view images, e.g. blind users, or users on very low-bandwidth connections or who pay by the byte, or users who are forced to use a text-only Web browser.

Example

Here are some more examples showing the same picture used in different contexts, with different appropriate alternate texts each time.

```

  <aside></aside>
  <p>She would play in the morning, she would play in the evening.</p>
</article>

```

4.8.4 Images

4.8.4.1 Introduction

This section is non-normative.

To embed an image in HTML, when there is only a single image resource, use the `img` element and its `src` attribute.

Example

```

<div>Today's featured article</div>

<p><a href="/wiki/Marie_Lloyd">Marie Lloyd</a> (1870-1922) was an English <a href="#">music hall</a> singer, ...

```

However, there are a number of situations for which the author might wish to use multiple image resources that the user agent can choose from:

- Different users might have different environmental characteristics:
 - The users' physical screen size might be different from one another.

Example

A mobile phone's screen might be 4 inches diagonally, while a laptop's screen might be 14 inches diagonally.

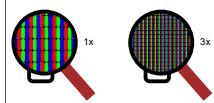

Note
This is only relevant when an image's rendered size depends on the [viewport](#) size.

- The users' screen pixel density might be different from one another.

Example

A mobile phone's screen might have three times as many physical pixels per inch compared to another mobile phone's screen, regardless of their physical screen size.

- The users' zoom level might be different from one another, or might change for a single user over time.

Example

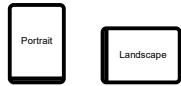

A user might zoom in to a particular image to be able to get a more detailed look.

The zoom level and the screen pixel density (the previous point) can both affect the number of physical screen pixels per [CSS pixel](#). This ratio is usually referred to as *device-pixel-ratio*.

- The users' screen orientation might be different from one another, or might change for a single user over time.

Example

A tablet can be held upright or rotated 90 degrees, so that the screen is either "portrait" or "landscape".

- The users' network speed, network latency and bandwidth cost might be different from one another, or might change for a single user over time.

Example

A user might be on a fast, low-latency and constant-cost connection while at work, on a slow, low-latency and constant-cost connection at home, and on a variable-speed, high-latency and variable-cost connection anywhere else.

- Authors might want to show the same image content but with different rendered size depending on, usually, the width of the [viewport](#). This is usually referred to as *viewport-based selection*.

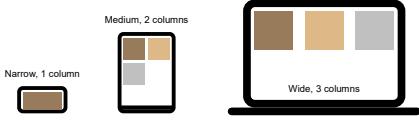

Example

A Web page might have a banner at the top that always spans the entire [viewport](#) width. In this case, the rendered size of the image depends on the physical size of the screen (assuming a maximised browser window).

Example

Another Web page might have images in columns, with a single column for screens with a small physical size, two columns for screens with medium physical size, and three columns for screens with big physical size, with the images varying in rendered size in each case to fill up the [viewport](#). In this case, the rendered size of an image might be *bigger* in the one-column layout compared to the two-column layout, despite the screen being smaller.

- Authors might want to show different image content depending on the rendered size of the image. This is usually referred to as *art direction*.

Example

When a Web page is viewed on a screen with a large physical size (assuming a maximised browser window), the author might wish to include some less relevant parts surrounding the critical part of the image. When the same Web page is viewed on a screen with a small physical size, the author might wish to show only the critical part of the image.

- Authors might want to show the same image content but using different image formats, depending on which image formats the user agent supports. This is usually referred to as *image format-based selection*.

Example

A Web page might have some images in the JPEG, WebP and JPEG XR image formats, with the latter two having better compression abilities compared to JPEG. Since different user agents can support different image formats, with some formats offering better compression ratios, the author would like to serve the better formats to user agents that support them, while providing JPEG fallback for user agents that don't.

The above situations are not mutually exclusive. For example, it is reasonable to combine different resources for different *device-pixel-ratio* with different resources for *art direction*.

While it is possible to solve these problems using scripting, doing so introduces some other problems:

- Some user agents aggressively download images specified in the HTML markup, before scripts have had a chance to run, so that Web pages complete loading sooner. If a script changes which image to download, the user agent will potentially start two separate downloads, which can instead cause worse page loading performance.
- If the author avoids specifying any image in the HTML markup and instead instantiates a single download from script, that avoids the double download problem above but then no image will be downloaded at all for users with scripting disabled and the aggressive image downloading optimization will also be disabled.

With this in mind, this specification introduces a number of features to address the above problems in a declarative manner.

Device-pixel-ratio-based selection when the rendered size of the image is fixed

The [src](#) and [srcset](#) attributes on the [img](#) element can be used, using the [x](#) descriptor, to provide multiple images that only vary in their size (the smaller image is a scaled-down version of the bigger image).

Note

The [x](#) descriptor is not appropriate when the rendered size of the image depends on the [viewport](#) width (*viewport-based selection*), but can be used together with *art direction*.

Example

```
<h2>From today's featured article</h2>

  <img alt="A portrait photograph of Marie Lloyd." srcset="/uploads/150-marie-lloyd.jpg 1.5x, /uploads/200-marie-lloyd.jpg 2x" x="150"/>
  
  <p><a href="https://en.wikipedia.org/w/index.php?title=Marie_Lloyd&oldid=18701922" x="200">was an English singer</a><br/><a href="https://en.wikipedia.org/w/index.php?title=Music_hall&oldid=18701922" x="200">music hall singer, ...</a></p>
```

The user agent can choose any of the given resources depending on the user's screen's pixel density, zoom level, and possibly other factors such as the user's network conditions.

For backwards compatibility with older user agents that don't yet understand the [srcset](#) attribute, one of the URLs is specified in the [img](#) element's [src](#) attribute. This will result in something useful (though perhaps lower-resolution than the user would like) being displayed even in older user agents. For new user agents, the [src](#) attribute participates in the resource selection, as it was specified in [srcset](#) with a [x](#) descriptor.

The image's rendered size is given in the [width](#) and [height](#) attributes, which allows the user agent to allocate space for the image before it is downloaded.

Viewport-based selection

The [srcset](#) and [sizes](#) attributes can be used, using the [v](#) descriptor, to provide multiple images that only vary in their size (the smaller image is a scaled-down version of the bigger image).

Example

In this example, a banner image takes up the entire [viewport](#) width (using appropriate CSS).

```
<h1></h1>
```

The user agent will calculate the effective pixel density of each image from the specified [x](#) descriptor and the specified rendered size in the [srcset](#) attribute. It can then choose any of the given resources depending on the user's screen's pixel density, zoom level, and possibly other factors such as the user's network conditions.

If the user's screen is 320 [CSS pixels](#) wide, this is equivalent to specifying [wolf-400.jpg 400w, wolf-800.jpg 800w, wolf-1600.jpg 1600w](#). If the user's screen is 1200 [CSS pixels](#) wide, this is equivalent to specifying [wolf-400.jpg 0.33x, wolf-800.jpg 0.67x, wolf-1600.jpg 1.33x](#). By using the [v](#) descriptors and the [srcset](#) attribute, the user agent can choose the correct image source to download regardless of how large the user's device is.

For backwards compatibility, one of the URLs is specified in the [img](#) element's [src](#) attribute. In new user agents, the [src](#) attribute is ignored when the [srcset](#) attribute uses [x](#) descriptors.

Example

In this example, the Web page has three layouts depending on the width of the [viewport](#). The narrow layout has one column of images (the width of each image is about 100%), the middle layout has two columns of images (the width of each image is about 50%), and the widest layout has three columns of images, and some page margin (the width of each image is about 33%). It breaks between these layouts when the [viewport](#) is 320m wide and 500m wide, respectively.

```

```

EXPAND

The `sizes` attribute sets up the layout breakpoints at `30em` and `50em`, and declares the image sizes between these breakpoints to be `100vw`, `50vw`, or `calc(33vw + 100px)`. These sizes do not necessarily have to match up exactly with the actual image width as specified in the CSS. The user agent will pick a width from the `sizes` attribute, using the first item with a `(media-condition)` (the part in parentheses) that evaluates to true, or using the last item (`calc(33vw + 100px)`) if they all evaluate to false.

For example, if the `viewport` width is `25em`, then `(max-width: 30em)` evaluates to true and `50vw` is used, so the image size, for the purpose of resource selection, is `16em` (half the `viewport` width). Note that the slightly wider `viewport` results in a smaller image because of the different layout.

The user agent can then calculate the effective pixel density and choose an appropriate resource similarly to the previous example.

4.8.4.1.1 `direction`-based selection

The `picture` element and the `source` element, together with the `media` attribute, can be used, to provide multiple images that vary the image content (for instance the smaller image might be a cropped version of the bigger image).

Example

```
<picture>
  <source media="(min-width: 45em)" srcset="large.jpg">
  <source media="(min-width: 32em)" srcset="med.jpg">
  
</picture>
```

The user agent will choose the first `source` element for which the media query in the `media` attribute matches, and then choose an appropriate URL from its `srcset` attribute.

The rendered size of the image varies depending on which resource is chosen. To specify dimensions that the user agent can use before having downloaded the image, CSS can be used.

```
CSS: img { width: 300px; height: 300px; }
Media: (min-width: 32em) { img { width: 300px; height: 300px; } }
Media: (min-width: 45em) { img { width: 700px; height: 400px; } }
```

Example

This example combines `art direction` and `device-pixel-ratio`-based selection. A banner that takes half the `viewport` is provided in two versions, one for wide screens and one for narrow screens.

```
<h1>
<picture>
  <source media="(max-width: 500px)" srcset="banner-phone.jpeg, banner-phone@2x.jpeg 2x">
  <img alt="Bananas.jpeg" srcset="banana@2x.jpeg 2x" alt="The Breakfast Combo">
</picture>
</h1>
```

Image format-based selection

The `type` attribute on the `source` element can be used, to provide multiple images in different formats.

Example

```
<h2>From today's featured article</h2>
<picture>
  <source srcset="uploads/100-marie-lloyd.webp" type="image/webp">
  <source srcset="uploads/100-marie-lloyd.jpeg" type="image/jpg">
  
</picture>
<a href="#">Marie Lloyd</a> (1870-1922)
was an English singer, ...
```

In this example, the user agent will choose the first source that has a `type` attribute with a supported MIME type. If the user agent supports WebP images, the first `source` element will be chosen. If not, but the user agent does support JPEG XR images, the second `source` element will be chosen. If neither of those formats are supported, the `img` element will be chosen.

4.8.4.1.1 Adaptive images

This section is non-normative.

CSS and media queries can be used to construct graphical page layouts that adapt dynamically to the user's environment, in particular to different `viewport` dimensions and pixel densities. For content, however, CSS does not help; instead, we have the `img` element's `srcset` attribute and the `picture` element. This section walks through a sample case showing how to use these features.

Consider a situation where on wide screens (wider than 600 [CSS pixels](#)) a `300×150` image named `a-rectangle.png` is to be used, but on smaller screens (600 [CSS pixels](#) and less), a smaller `100×100` image called `a-square.png` is to be used. The markup for this would look like this:

```
<figure>
  
  
  <caption>Barney Frank, 2011</caption>
</figure>
```

Note

For details on what to put in the `alt` attribute, see the Requirements for providing text to act as an alternative for images section.

The problem with this is that the user agent does not necessarily know what dimensions to use for the image when the image is loading. To avoid the layout having to be reflowed multiple times as the page is loading, CSS and CSS media queries can be used to provide the dimensions:

```
<style>
  #a { width: 100px; height: 100px; }
  @media (max-width: 600px) { #a { width: 100px; height: 100px; } }
</style>
<figure>
  
  
  <caption>Barney Frank, 2011</caption>
</figure>
```

Alternatively, the `width` and `height` attributes can be used to provide the width and height for legacy user agents, using CSS just for the user agents that support `picture`:

```
<style media="(max-width: 600px)">
  #a { width: 100px; height: 100px; }
</style>
<figure>
  
  
  <caption>Barney Frank, 2011</caption>
</figure>
```

The `img` element is used with the `src` attribute, which gives the URL of the image to use for legacy user agents that do not support the `picture` element. This leads to a question of which image to provide in the `src` attribute.

If the author wants the biggest image in legacy user agents, the markup could be as follows:

```
<picture>
  <source srcset="pear-mobile.jpeg" media="max-width: 720px">
  <source srcset="pear-tablet.jpeg" media="max-width: 1280px">
  
</picture>
```

However, if legacy mobile user agents are more important, one can list all three images in the `source` elements, overriding the `src` attribute entirely.

```
<picture>
  <source srcset="pear-mobile.jpeg" media="max-width: 720px">
  <source srcset="pear-tablet.jpeg" media="max-width: 1280px">
  <source srcset="pear-desktop.jpeg" media="max-width: 1280px">
  
</picture>
```

Since at this point the `src` attribute is actually being ignored entirely by `picture`-supporting user agents, the `src` attribute can default to any image, including one that is neither the smallest nor biggest:

```
<picture>
  <source srcset="pear-mobile.jpeg" media="max-width: 720px">
  <source srcset="pear-tablet.jpeg" media="max-width: 1280px">
  <source srcset="pear-desktop.jpeg" media="max-width: 1280px">
  
</picture>
```

Above the `max-width` media feature is used, giving the maximum (`viewport`) dimensions that an image is intended for. It is also possible to use `min-width` instead.

```
<picture>
  <source srcset="pear-desktop.jpeg" media="min-width: 1280px">
  <source srcset="pear-tablet.jpeg" media="min-width: 721px">
  
</picture>
```

4.8.4.2 Attributes common to `source`, `img`, and `link` elements

4.8.4.2.1 `secret` attribute

A `secret` attribute is an attribute with requirements defined in this section.

If present, its value must consist of one or more `image candidate string`, each separated from the next by a U+002C COMMA character (,),. If an `image candidate string` contains no descriptors and no `ASCII whitespace` after the URL, the following `image candidate string`, if there is one, must begin with one or more `ASCII whitespace`.

An `image candidate string` consists of the following components, in order, with the further restrictions described below this list:

1. Zero or more `ASCII whitespace`.
2. A `valid non-empty URL` that does not start or end with a U+002C COMMA character (,), referencing a non-interactive, optionally animated, image resource that is neither paged nor scripted.
3. Zero or more `ASCII whitespace`.
4. Zero or one of the following:

- A `width descriptor`, consisting of: `ASCII whitespace`, a `valid non-negative integer` giving a number greater than zero representing the `width descriptor value`, and a U+0077 LATIN SMALL LETTER W character.
- A `pixel density descriptor`, consisting of: `ASCII whitespace`, a `valid floating-point number` giving a number greater than zero representing the `pixel density descriptor value`, and a U+0078 LATIN SMALL LETTER X character.

5. Zero or more `ASCII whitespace`.

There must not be an `image candidate string` for an element that has the same `width descriptor value` as another `image candidate string`'s `width descriptor value` for the same element.

There must not be an `image candidate string` for an element that has the same `pixel density descriptor value` as another `image candidate string`'s `pixel density descriptor value` for the same element. For the purpose of this requirement, an `image candidate string` with no descriptors is equivalent to an `image candidate string` with a `1x` descriptor.

If an `image candidate string` for an element has the `width descriptor` specified, all other `image candidate strings` for that element must also have the `width descriptor` specified.

The specified width in an `image candidate string`'s `width descriptor` must match the `intrinsic width` in the resource given by the `image candidate string`'s URL, if it has an `intrinsic width`.

If an element has a `sizes` attribute present, all `image candidate strings` for that element must have the `width descriptor` specified.

4.8.4.2.2 `sizes` attribute

A `sizes` attribute is an attribute with requirements defined in this section.

If present, the value must be a `valid source size list`.

A `valid source size list` is a string that matches the following grammar: [\[CSSVALUES\] \[MO\]](#)

```
<source-size-list> = 1<source-size> | 1<source-size> , 1<source-size>-value
```

A `<source-size-value>` must not be negative, and must not use CSS functions other than the [math functions](#).

The `<source-size-value>` gives the intended layout width of the image. The author can specify different widths for different environments with `<media-condition>`.

Note

Percentages are not allowed in a `<source-size-value>`, to avoid confusion about what it would be relative to. The `'vw'` unit can be used for sizes relative to the `viewport` width.

4.8.4.3 Processing model

The [task source](#) for the [tasks queued](#) by algorithms in this section is the [DOM manipulation task source](#).

An `img` element has a [current request](#) and a [pending request](#). The [current request](#) is initially set to a new [image request](#). The [pending request](#) is initially set to null.

An [image request](#) has a [state](#), [current URL](#), and [image data](#).

An [image request's state](#) is one of the following:

Unavailable

The user agent hasn't obtained any image data, or has obtained some or all of the image data but hasn't yet decoded enough of the image to get the image dimensions.

Partially available

The user agent has obtained some of the image data and at least the image dimensions are available.

Completely available

The user agent has obtained all of the image data and at least the image dimensions are available.

Broken

The user agent has obtained all of the image data that it can, but it cannot even decode the image enough to get the image dimensions (e.g. the image is corrupted, or the format is not supported, or no data could be obtained).

An [image request's current URL](#) is initially the empty string.

An [image request's image data](#) is the decoded image data.

When an [image request's state](#) is either *partially available* or *completely available*, the [image request](#) is said to be *available*.

When an `img` element's [current request's state](#) is *completely available* and the user agent can decode the media data without errors, then the `img` element is said to be *fully decodable*.

An [image request's state](#) is initially *unavailable*.

When an `img` element's [current request's state](#) is *available*, the `img` element provides a [paint source](#) whose width is the image's [density-corrected intrinsic width](#) (if any), whose height is the image's [density-corrected intrinsic height](#) (if any), and whose appearance is the intrinsic appearance of the image.

An `img` element is said to *use a srcset or picture* if it has a [srcset](#) attribute specified or if it has a parent that is a [picture](#) element.

Each `img` element has a *last selected source*, which must initially be null.

Each [image request](#) has a *current pixel density*, which must initially be undefined.

When an `img` element has a [current pixel density](#) that is not 1.0, the element's image data must be treated as if its resolution, in device pixels per [CSS pixels](#), was the [current pixel density](#). The image's [density-corrected intrinsic width and height](#) are the [intrinsic width and height](#) after taking into account the [current pixel density](#).

Example

For example, if the [current pixel density](#) is 3.125, that means that there are 300 device pixels per [CSS inch](#), and thus if the image data is 300x600, it has [intrinsic dimensions](#) of 96 [CSS pixels](#) by 192 [CSS pixels](#).

All `img` and `link` elements are associated with a [source set](#).

A [source set](#) is an ordered set of zero or more [image sources](#) and a [source size](#).

An [image source](#) is a [URL](#), and optionally either a [pixel density descriptor](#), or a [width descriptor](#).

A [source size](#) is a `<source-size-value>`. When a [source size](#) has a unit relative to the [viewport](#), it must be interpreted relative to the `img` element's [node document's viewport](#). Other units must be interpreted the same as in Media Queries. [\[MO\]](#)

A [parse error](#) for algorithms in this section indicates a non-fatal mismatch between input and requirements. User agents are encouraged to expose [parse errors](#) somehow.

Whether the image is fetched successfully or not (e.g. whether the response status was an [ok status](#)) must be ignored when determining the image's type and whether it is a valid image.

Note

This allows servers to return images with error responses, and have them displayed.

The user agent should apply the [image sniffing rules](#) to determine the type of the image, with the image's [associated Content-Type headers](#) giving the [official type](#). If these rules are not applied, then the type of the image must be the type given by the image's [associated Content-Type headers](#).

User agents must not support non-image resources with the `img` element (e.g. XML files whose [document element](#) is an HTML element). User agents must not run executable code (e.g. scripts) embedded in the image resource. User agents must only display the first page of a multipage resource (e.g. a PDF file). User agents must not allow the resource to act in an interactive fashion, but should honour any animation in the resource.

This specification does not specify which image types are to be supported.

4.8.4.3.1 Where to obtain images

In a [browsing context](#) where [scripting is disabled](#), user agents may obtain images immediately or on demand. In a [browsing context](#) where [scripting is enabled](#), user agents must obtain images immediately.

A user agent that obtains images immediately must synchronously [update the image data](#) of an `img` element, with the [restart animation](#) flag set if so stated, whenever that element is created or has experienced [relevant mutations](#).

A user agent that obtains images on demand must [update the image data](#) of an `img` element whenever it needs the image data (i.e., on demand), but only if the `img` element's [current request's state](#) is *unavailable*. When an `img` element has experienced [relevant mutations](#), if the user agent only obtains images on demand, the `img` element's [current request's state](#) must return to *unavailable*.

4.8.4.3.2 Reoring to DOM mutations

The relevant mutations for an `img` element are as follows:

- The element's [src](#), [srcset](#), [sizes](#), or [size](#) attributes are set, changed, or removed.
- The element's [src](#) attribute is set to the same value as the previous value. This must set the [restart animation](#) flag for the [update the image data](#) algorithm.
- The element's [crossorigin](#) attribute's state is changed.
- The element is inserted into or removed from a [picture](#) parent element.
- The element's parent is a [picture](#) element and a [source element is inserted](#) as a previous sibling.
- The element's parent is a [picture](#) element and a [source element](#) that was a previous sibling is [removed](#).
- The element's parent is a [picture](#) element and a [source element](#) that is a previous sibling has its [srcset](#), [sizes](#), [width](#), or [height](#) attributes set, changed, or removed.
- The element's [adoption steps](#) are run.

4.8.4.3.3 The list of available images

Each [Document](#) object must have a *list of available images*. Each image in this list is identified by a tuple consisting of an [absolute URL](#), a [CORS settings attribute](#) mode, and, if the mode is not [NoCORS](#), an [origin](#). Each image furthermore has an [ignore higher-layer caching](#) flag. User agents may copy entries from one [Document](#) object's *list of available images* to another at any time (e.g. when the [document](#) is created, user agents can add to it all the images that are loaded in other [Documents](#)), but must not change the keys of entries copied in this way when doing so, and must unset the [ignore higher-layer caching](#) flag for the copied entry. User agents may also remove images from such lists at any time (e.g. to save memory). User agents must remove entries in the *list of available images* as appropriate given higher-layer caching semantics for the resource (e.g. the HTTP [Cache-Control](#) response header) when the [ignore higher-layer caching](#) flag is unset.

Note

The *list of available images* is intended to enable synchronous switching when changing the [src](#) attribute to a URL that has previously been loaded, and to avoid re-downloading images in the same document even when they don't allow caching per HTTP. It is not used to avoid re-downloading the same image while the previous image is still loading.

Note

The user agent can also store the image data separately from the *list of available images*.

Example

For example, if a resource has the HTTP response header `'cache-control: must-revalidate'`, and its [ignore higher-layer caching](#) flag is unset, the user agent would remove it from the *list of available images* but could keep the image data separately, and use that if the server responds with a `304 Not Modified` status.

4.8.4.4 Decoding images

Image data is usually encoded in order to reduce file size. This means that in order for the user agent to present the image to the screen, the data needs to be decoded. [Decoding](#) is the process which converts an image's media data into a bitmap form, suitable for presentation to the screen. Note that this process can be slow relative to other processes involved in presenting content. Thus, the user agent can choose when to perform decoding, in order to create the best user experience.

Image decoding is said to be synchronous if it presents presentation of other content until it is finished. Typically, this has an effect of atomically presenting the image and any other content at the same time. However, this presentation is delayed by the amount of time it takes to perform the decode.

Image decoding is said to be asynchronous if it does not prevent presentation of other content. This has an effect of presenting non-image content faster. However, the image content is missing on screen until the decode finishes. Once the decode is finished, the screen is updated with the image.

In both synchronous and asynchronous decoding modes, the final content is presented to screen after the same amount of time has elapsed. The main difference is whether the user agent presents non-image content ahead of presenting the final content.

AMDN

SVGImageElement/decoding

Support in one engine only.

Firfox/Safari/Chrome5+

Opera/Edge79+

Edge (Legacy)NoInternet Explorer?

Firfox/Android/Safari/IOS/Chrome Android65+WebView Android65+Samsung Internet9.0+Opera Android?

In order to aid the user agent in deciding whether to perform synchronous or asynchronous decode, the [decoding](#) attribute can be set on `img` elements. The possible values of the [decoding](#) attribute are the following *image decoding hint* keywords:

Keyword State Description

`sync` Sync Indicates a preference to [decode](#) this image synchronously for atomic presentation with other content.

`async` Async Indicates a preference to [decode](#) this image asynchronously to avoid delaying presentation of other content.

`auto` Auto Indicates no preference in decoding mode (the default).

When [decoding](#) an image, the user agent should respect the preference indicated by the [decoding](#) attribute's state. If the state indicated is `auto`, then the user agent is free to choose any decoding behavior.

Note

It is also possible to control the decoding behavior using the [decode\(\)](#) method. Since the [decode\(\)](#) method performs [decoding](#) independently from the process responsible for presenting content to screen, it is unaffected by the [decoding](#) attribute.

4.8.4.5 Updating the image data

When the user agent is to [update the image data](#) of an `img` element, optionally with the [restart animations](#) flag set, it must run the following steps:

1. If the element's [node document](#) is not the [active document](#), then:

1. Continue running this algorithm [in parallel](#).

2. Wait until the element's [node document](#) is the [active document](#).

3. If another instance of this algorithm for this `img` element was started after this instance (even if it aborted and is no longer running), then return.

4. [Cause a microtask to continue this algorithm](#).

2. If the user agent cannot support images, or its support for images has been disabled, then abort the image request for the current request and the pending request, set current request's state to unavailable, set pending request to null, and return.

3. Let selected source be null and selected pixel density be undefined.

4. If the element does not have srcset or picture and it has a src attribute specified whose value is not the empty string, then set selected source to the value of the element's src attribute and set selected pixel density to 1.0.

5. Set the element's last selected source to selected source.

6. If selected source is not null, then:

1. Parse selected source, relative to the element's node document. If that is not successful, then abort this inner set of steps. Otherwise, let urlString be the resulting URL string.

2. Let key be a tuple consisting of urlString, the img element's crossorigin attribute's mode, and, if that mode is not No-CORS, the node document's origin.

3. If the list of available images contains an entry for that key, then:

1. Set the ignore higher-layer caching flag for that entry.

2. Abort the image request for the current request and the pending request.

3. Set pending request to null.

4. Let current request be a new image request whose image data is that of the entry and whose state is completely available.

5. Update the presentation of the image appropriately.

6. Set current request's current pixel density to selected pixel density.

7. Queue an element task on the DOM manipulation task source given the img element and following steps:

1. If restart animation is set, then restart the animation.

2. Set current request's current URL to urlString.

3. Fire an event named load at the img element.

8. Abort the update the image data algorithm.

7. Await a stable state, allowing the task that invoked this algorithm to continue. The synchronous section consists of all the remaining steps of this algorithm until the algorithm says the synchronous section has ended. (Steps in synchronous sections are marked with ☒.)

8. ☒ If another instance of this algorithm for this img element was started after this instance (even if it aborted and is no longer running), then return.

Note

Only the last instance takes effect, to avoid multiple requests when, for example, the src, srcset, and picture attributes are all set in succession.

9. ☒ Let selected source and selected pixel density be the URL and pixel density that results from selecting an image source, respectively.

10. ☒ If selected source is null, then:

1. ☒ Set the current request's state to broken, abort the image request for the current request and the pending request, and set pending request to null.

2. ☒ Queue an element task on the DOM manipulation task source given the img element and the following steps:

1. Change the current request's current URL to the empty string.

2. If the element has a src attribute or it uses srcset or picture, fire an event named error at the img element.

3. ☒ Return.

11. ☒ Parse selected source, relative to the element's node document, and let urlString be the resulting URL string. If that is not successful, then:

1. ☒ Abort the image request for the current request and the pending request.

2. ☒ Set the current request's state to broken.

3. ☒ Set pending request to null.

4. ☒ Queue an element task on the DOM manipulation task source given the img element and the following steps:

1. Change the current request's current URL to selected source.

2. Fire an event named error at the img element.

5. ☒ Return.

12. ☒ If the pending request is not null and urlString is the same as the pending request's current URL, then return.

13. ☒ If urlString is the same as the current request's current URL and current request's state is partially available, then abort the image request for the pending request, queue a task to restart the animation if restart animation is set, and return.

14. ☒ If the pending request is not null, then abort the image request for the pending request.

15. ☒ Set image request to a new image request whose current URL is urlString.

16. ☒ If current request's state is unavailable or broken, then set the current request to image request. Otherwise, set the pending request to image request.

17. ☒ Let request be the result of creating a potential-CORS request given urlString, "image", and the current state of the element's crossorigin content attribute.

18. ☒ Set request's client to the element's node document's relevant settings object.

19. ☒ If the element uses srcset or picture, set request's initiator to "imageset".

20. ☒ Set request's referer policy to the current state of the element's refererpolicy attribute.

21. ☒ Fetch request. Let this instance of the fetching algorithm be associated with image request.

The resource obtained in this fashion, if any, is image request's image data. It can be either CORS-same-origin or CORS-cross-origin; this affects the origin of the image itself (e.g. when used on a canvas).

Fetching the image must delay the load event of the element's node document until the task that is queued by the networking task source once the resource has been fetched (defined below) has been run.

⚠ Warning!

This, unfortunately, can be used to perform a rudimentary port scan of the user's local network (especially in conjunction with scripting, though scripting isn't actually necessary to carry out such an attack). User agents may implement cross-origin access control policies that are stricter than those described above to mitigate this attack, but unfortunately such policies are typically not compatible with existing Web content.

22. End the synchronous section, continuing the remaining steps in parallel, but without missing any data from fetching.

23. As soon as possible, jump to the first applicable entry from the following list:

If the resource type is multipart/x-mixed-replace:

The next task that is queued by the networking task source while the image is being fetched must run the following steps:

1. If image request is the pending request and at least one body part has been completely decoded, abort the image request for the current request, upgrade the pending request to the current request.

2. Otherwise, if image request is the pending request and the user agent is able to determine that image request's image is corrupted in some fatal way such that the image dimensions cannot be obtained, abort the image request for the current request, upgrade the pending request to the current request, and set the current request's state to broken.

3. Otherwise, if image request is the current request, its state is unavailable, and the user agent is able to determine image request's image's width and height, set the current request's state to partially available.

4. Otherwise, if image request is the current request, its state is unavailable, and the user agent is able to determine that image request's image is corrupted in some fatal way such that the image dimensions cannot be obtained, set the current request's state to broken.

Each task that is queued by the networking task source while the image is being fetched must update the presentation of the image, but as each new body part comes in, it must replace the previous image. Once one body part has been completely decoded, the user agent must set the img element's current request's state to completely available and queue a task to fire an event named load at the img element.

If the resource type and data corresponds to a supported image format, as described below:

The next task that is queued by the networking task source while the image is being fetched must run the following steps:

1. If the user agent is able to determine image request's image's width and height, and image request is pending request, set image request's state to partially available.

2. Otherwise, if the user agent is able to determine image request's image's width and height, and image request is current request, update the img element's presentation appropriately and set image request's state to partially available.

3. Otherwise, if the user agent is able to determine that image request's image is corrupted in some fatal way such that the image dimensions cannot be obtained, and image request is pending request, abort the image request for the current request and the pending request, upgrade the pending request to the current request, set current request's state to broken, and fire an event named error at the img element.

4. Otherwise, if the user agent is able to determine that image request's image is corrupted in some fatal way such that the image dimensions cannot be obtained, and image request is current request, abort the image request for image request and fire an event named error at the img element.

That task, and each subsequent task, that is queued by the networking task source while the image is being fetched, if image request is the current request, must update the presentation of the image appropriately (e.g., if the image is a progressive JPEG, each packet can improve the resolution of the image).

Furthermore, the last task that is queued by the networking task source once the resource has been fetched must additionally run these steps:

1. If image request is the pending request, abort the image request for the current request, upgrade the pending request to the current request and update the img element's presentation appropriately.

2. Set image request to the completely available.

3. Add the image to the list of available images using the key key, with the ignore higher-layer caching flag set.

4. Fire an event named load at the img element.

Otherwise

The image data is not in a supported file format; the user agent must set image request's state to broken, abort the image request for the current request and the pending request, upgrade the pending request to the current request if image request is the pending request, and then queue a task to fire an event named error at the img element.

While a user agent is running the above algorithm for an element x, there must be a strong reference from the element's node document to the element x, even if that element is not connected.

To abort the image request for an image request means to run the following steps:

1. Forget image request's image data, if any.

2. Abort any instance of the fetching algorithm for image request, discarding any pending tasks generated by that algorithm.

To upgrade the pending request to the current request for an img element means to run the following steps:

1. Let the img element's current request be the pending request.

2. Let the img element's pending request be null.

4.8.3.6 Selecting an image source

When asked to select an image source for a given img or link element e, user agents must do the following:

1. Update the source set for e.

2. If e's source set is empty, return null as the URL and undefined as the pixel density.

4. If an entry *b* in *source set* has the same associated [pixel density descriptor](#) as an earlier entry *a* in *source set*, then remove entry *b*. Repeat this step until none of the entries in *source set* have the same associated [pixel density descriptor](#) as an earlier entry.

5. In a user agent-specific manner, choose one [image source](#) from *source set*. Let this be *selected source*.

6. Return *selected source* and its associated pixel density.

4.8.4.3.7 Updating the source set

When asked to update the *source set* for a given [img](#) or [link](#) element *el*, user agents must do the following:

1. Set *el*'s [source set](#) to an empty [source set](#).
2. Let *elements* be *el*.
3. If *el* is a [img](#) element whose parent node is a [picture](#) element, then replace the contents of *elements* with *el*'s parent node's child elements, retaining relative order.
4. Let *width* be null.
5. If *el* is a [img](#) element with a [width](#) attribute, and parsing that attribute's value using the [rules for parsing dimension values](#) doesn't generate an error or a percentage value, then set *width* to the returned integer value.
6. For each child in *elements*:
 1. If *child* is *el*:
 1. Let *source set* be an empty [source set](#).
 2. If *child* has a [srcset](#) or [imsrcset](#) attribute, parse *child*'s [srcset attribute](#) and set *source set* to the returned [source set](#).
 3. Parse *child*'s [sizes](#) attribute with the fallback width *width*, and let *source set*'s [source size](#) be the returned value.
 4. If *child* has a [src](#) or [href](#) attribute whose value is not the empty string and *source set* does not contain an [image source](#) with a [pixel density descriptor](#) value of 1, and no [image source](#) with a [width descriptor](#), append *child*'s [src](#) or [href](#) attribute value to *source set*.
 5. Normalize the source densities of *source set*.
 6. Let *el*'s [source set](#) be *source set*.
 7. Return

Note
If *el* is a [link](#) element, then *elements* contains only *el*, so this step will be reached immediately and the rest of the algorithm will not run.
2. Assert: *child* is not a [link](#) element.
3. If *child* is not a [source](#) element, continue to the next child. Otherwise, *child* is a [source](#) element.
4. If *child* does not have a [srcset](#) attribute, continue to the next child.
5. Parse *child*'s [srcset attribute](#) and let the returned [source set](#) be *source set*.
6. If *source set* has zero [image sources](#), continue to the next child.
7. If *child* has a [width](#) attribute, and its value does not [match the environment](#), continue to the next child.
8. Parse *child*'s [sizes attribute](#) with the fallback width *width*, and let *source set*'s [source size](#) be the returned value.
9. If *child* has a [type](#) attribute, and its value is an unknown or unsupported [MIME type](#), continue to the next child.
10. Normalize the source densities of *source set*.
11. Let *el*'s [source set](#) be *source set*.
12. Return.

Note
[img](#) element independently considers its previous sibling [source](#) elements plus the [img](#) element itself for selecting an [image source](#), ignoring any other (invalid) elements, including other [img](#) elements in the same [picture](#) element, or [source](#) elements that are following siblings of the relevant [img](#) element.

4.8.4.3.8 Parsing a [srcset](#) attribute

When asked to parse a [srcset](#) attribute from an element, parse the value of the element's [srcset attribute](#) as follows:

1. Let *input* be the value passed to this algorithm.
2. Let *candidates* be a pointer into *input*, initially pointing at the start of the string.
3. Let *candidates* be an initially empty [source set](#).
4. Splitting loop: Collect a sequence of code points that are ASCII whitespace or U+002C COMMA characters from *input* given *position*. If any U+002C COMMA characters were collected, that is a [parse error](#).
5. If *position* is past the end of *input*, return *candidates*.
6. Collect a sequence of code points that are not ASCII whitespace from *input* given *position*, and let that be *url*.
7. Let *descriptors* be a new empty list.
8. If *url* ends with U+002C (,), then
 1. Remove all trailing U+002C COMMA characters from *url*. If this removed more than one character, that is a [parse error](#).

Otherwise:

1. Descriptor tokenizer: Skip ASCII whitespace within *input* given *position*.
2. Let *current descriptor* be the empty string.
3. Let *state* be *in descriptor*.
4. Let *c* be the character at *position*. Do the following depending on the value of *state*. For the purpose of this step, "EOF" is a special character representing that *position* is past the end of *input*.

In descriptor

Do the following, depending on the value of *c*:

ASCII whitespace

If *current descriptor* is not empty, append *current descriptor* to *descriptors* and let *current descriptor* be the empty string. Set *state* to *after descriptor*.

U+002C COMMA (,)

Advance *position* to the next character in *input*. If *current descriptor* is not empty, append *current descriptor* to *descriptors*. Jump to the step labeled *descriptor parser*.

U+0028 LEFT PARENTHESIS ()

Append *c* to *current descriptor*. Set *state* to *in parens*.

EOF

If *current descriptor* is not empty, append *current descriptor* to *descriptors*. Jump to the step labeled *descriptor parser*.

Anything else

Append *c* to *current descriptor*.

In parens

Do the following, depending on the value of *c*:

U+0029 RIGHT PARENTHESIS ()

Append *c* to *current descriptor*. Set *state* to *in descriptor*.

EOF

Append *current descriptor* to *descriptors*. Jump to the step labeled *descriptor parser*.

Anything else

Append *c* to *current descriptor*.

After descriptor

Do the following, depending on the value of *c*:

ASCII whitespace

Stay in this state.

EOF

Jump to the step labeled *descriptor parser*.

Anything else

Set *state* to *in descriptor*. Set *position* to the previous character in *input*.

Advance *position* to the next character in *input*. Repeat this step.

Note

In order to be compatible with future additions, this algorithm supports multiple descriptors and descriptors with parens.

9. Descriptor parser: Let *error* be no.

10. Let *width* be absent.

11. Let *density* be absent.

12. Let *future-compat-h* be absent.

13. For each descriptor in *descriptors*, run the appropriate set of steps from the following list:

If the descriptor consists of a [valid non-negative integer](#) followed by a U+0077 LATIN SMALL LETTER W character

1. If the user agent does not support the [sizes](#) attribute, let *error* be yes.

Note

A conforming user agent will support the [sizes](#) attribute. However, user agents typically implement and ship features in an incremental manner in practice.

3. Apply the [rules for parsing non-negative integers](#) to the descriptor. If the result is zero, let *error* be yes. Otherwise, let *width* be the result.

If the descriptor consists of a [valid floating-point number](#) followed by a U+0078 LATIN SMALL LETTER X character

1. If *width*, *density* and *future-compat-h* are not all *absent*, then let *error* be yes.

2. Apply the [rules for parsing floating-point number values](#) to the descriptor. If the result is less than zero, let *error* be yes. Otherwise, let *density* be the result.

Note

If *density* is zero, the [intrinsic dimensions](#) will be infinite. User agents are expected to have limits in how big images can be rendered, which is allowed by the [hardware limitations](#) clause.

If the descriptor consists of a [valid non-negative integer](#) followed by a U+0068 LATIN SMALL LETTER H character

This is a [parse error](#).

1. If *future-compat-h* and *density* are not both *absent*, then let *error* be yes.

2. Apply the [rules for parsing non-negative integers](#) to the descriptor. If the result is zero, let *error* be yes. Otherwise, let *future-compat-h* be the result.

Anything else

Let *error* be yes.

14. If *future-compat-h* is not *absent* and *width* is *absent*, let *error* be yes.

15. If *error* is still no, then append a new [image source](#) to *candidates* whose URL is *url*, associated with a width *width* if not *absent* and a pixel density *density* if not *absent*. Otherwise, there is a [parse error](#).

16. Return to the step labeled *splitting loop*.

4.8.4.3.9 Parsing a sizes attribute

When asked to *parse a sizes attribute* from an element, with a fallback width *width*, *parse a comma-separated list of component values* from the value of the element's [sizes attribute](#) (or the empty string, if the attribute is absent), and let *unparsed sizes list* be the result. [\(CSSSYNTAX\)](#)

For each *unparsed size* in *unparsed sizes list*:

1. Remove all consecutive [whitespace-tokens](#) from the end of *unparsed size*. If *unparsed size* is now empty, that is a [parse error](#); continue to the next iteration of this algorithm.

2. If the last [component value](#) in *unparsed size* is a valid non-negative [source-size-value](#), let *size* be its value and remove the [component value](#) from *unparsed size*. Any CSS function other than the [math functions](#) is invalid. Otherwise, there is a [parse error](#), continue to the next iteration of this algorithm.

3. Remove all consecutive [whitespace-tokens](#) from the end of *unparsed size*. If *unparsed size* is now empty, return *size* and exit this algorithm. If this was not the last item in *unparsed sizes list*, that is a [parse error](#).

4. Parse the remaining [component values](#) in *unparsed size* as a [<media-condition>](#). If it does not parse correctly, or it does parse correctly but the [<media-condition>](#) evaluates to false, continue to the next iteration of this algorithm. [\(MO\)](#)

5. Return *size* and exit this algorithm.

If the above algorithm exhausts *unparsed sizes list* without returning a *size* value, follow these steps:

1. If *width* is not null, return a [clength](#) with the value *width* and the unit [px](#).

2. Return [100vw](#).

Note

While a [valid source size list](#) only contains a bare [<source-size-value>](#) (without an accompanying [<media-condition>](#)) as the last entry in the [<source-size-list>](#), the parsing algorithm technically allows such at any point in the list, and will accept it immediately as the size if the preceding entries in the list weren't used. This is to enable future extensions, and protect against simple author errors such as a final trailing comma.

4.8.4.3.10 Normalizing the source densities

An [image source](#) can have a [pixel density descriptor](#), a [width descriptor](#), or no descriptor at all accompanying its URL. Normalizing a [source set](#) gives every [image source](#) a [pixel density descriptor](#).

When asked to *normalize the source densities* of a [source set](#) source set, the user agent must do the following:

1. Let *source size* be *source set*'s [source size](#).

2. For each [image source](#) in *source set*:

1. If the [image source](#) has a [pixel density descriptor](#), continue to the next [image source](#).

2. Otherwise, if the [image source](#) has a [width descriptor](#), replace the [width descriptor](#) with a [pixel density descriptor](#) with a [value](#) of the [width descriptor value](#) divided by the [source size](#) and a unit of [x](#).

Note

If the [source size](#) is zero, the density would be infinity, which results in the [intrinsic dimensions](#) being zero by zero.

3. Otherwise, give the [image source](#) a [pixel density descriptor](#) of [1x](#).

4.8.4.3.11 Reading in environment changes

The user agent may at any time run the following algorithm to update an [img](#) element's image in order to react to changes in the environment. (User agents are *not required* to ever run this algorithm; for example, if the user is not looking at the page any more, the user agent might want to wait until the user has returned to the page before determining which image to use, in case the environment changes again in the meantime.)

Note

User agents are encouraged to run this algorithm in particular when the user changes the [viewport](#)'s size (e.g. by resizing the window or changing the page zoom), and when an [img](#) element is [inserted into a document](#), so that the [density-corrected intrinsic width and height](#) match the new [viewport](#), and so that the correct image is chosen when [art direction](#) is [involved](#).

1. [Await a stable state](#). The [synchronous section](#) consists of all the remaining steps of this algorithm until the algorithm says the [synchronous section](#) has ended. (Steps in [synchronous sections](#) are marked with [█](#).)

2. [█ If the \[img\]\(#\) element does not \[use aspect or picture\]\(#\), its \[node document\]\(#\) is not the \[active document\]\(#\), has image data whose resource type is \[multipart/x-mixed-replace\]\(#\), or the \[pending request\]\(#\) is not null, then return.](#)

3. [█ Let selected source and selected pixel density be the URL and pixel density that results from \[selecting an image source\]\(#\), respectively.](#)

4. [█ If selected source is null, then return.](#)

5. [█ If selected source and selected pixel density are the same as the element's \[last selected source\]\(#\) and \[current pixel density\]\(#\), then return.](#)

6. [█ Parse selected source](#), relative to the element's [node document](#), and let *urString* be the [resulting URL string](#). If that is not successful, then return.

7. [█ Let corsAttributeState be the state of the element's \[crossorigin\]\(#\) content attribute.](#)

8. [█ Let origin be the \[origin\]\(#\) of the \[img\]\(#\) element's \[node document\]\(#\).](#)

9. [█ Let client be the \[img\]\(#\) element's \[node document's relevant settings object\]\(#\).](#)

10. [█ Let key be a tuple consisting of *urString*, *corsAttributeState*, and, if *corsAttributeState* is not \[No CORS\]\(#\), *origin*.](#)

11. [█ Let *image request* be a new \[image request\]\(#\) whose \[current URL\]\(#\) is *urString*](#)

12. [█ Let the element's \[pending request\]\(#\) be *image request*.](#)

13. End the [synchronous section](#), continuing the remaining steps [in parallel](#).

14. If the [list of available images](#) contains an entry for *key*, then set *image request's image data* to that of the entry. Continue to the next step.

Otherwise:

1. Let *request* be the result of [creating a potential-CORS request](#) given *urString*, ["image"](#), and *corsAttributeState*.

2. Set *request's client* to *client*, *initiator* to ["image"](#), and set *request's synchronous flag*.

3. Set *request's referer policy* to the current state of the element's [referrerpolicy](#) attribute.

4. Let *response* be the result of [fetching request.](#)

5. If *response's unsafe response* is a [network error](#) or the image format is unsupported (as determined by applying the [image sniffing rules](#), again as mentioned earlier), or if the user agent is able to determine that *image request's* image is corrupted in some fatal way such that the image dimensions cannot be obtained, or if the resource type is [multipart/x-mixed-replace](#), then let *pending request* be null and abort these steps.

6. Otherwise, *response's unsafe response* is *image request's image data*. It can be either [CORS-same-origin](#) or [CORS-cross-origin](#); this affects the [origin](#) of the image itself (e.g., when used on a [canvas](#)).

15. [Queue an element task](#) on the [DOM manipulation task queue](#) given the [img](#) element and the following steps:

1. If the [img](#) element has experienced [relevant mutations](#) since this algorithm started, then let [pending request](#) be null and abort these steps.

2. Let the [img](#) element's [last selected source](#) be [selected source](#) and the [img](#) element's [current pixel density](#) be [selected pixel density](#).

3. Set the [image request's state](#) to [completely available](#).

4. Add the image to the [list of available images](#) using the key *key*, with the [ignore higher layer caching](#) flag set.

5. [Upgrade the pending request to the current request](#).

6. Update the [img](#) element's presentation appropriately.

7. [Fire an event named \[load\]\(#\) at the \[img\]\(#\) element](#)

4.8.4.4 Requirements for providing text to act as an alternative for images

4.8.4.4.1 General guidelines

Except where otherwise specified, the [alt](#) attribute must be specified and its value must not be empty; the value must be an appropriate replacement for the image. The specific requirements for the [alt](#) attribute depend on what the image is intended to represent, as described in the following sections.

The most general rule to consider when writing alternative text is the following: **the intent is that replacing every image with the text of its alt attribute not change the meaning of the page**.

So, in general, alternative text can be written by considering what one would have written had one not been able to include the image.

A corollary to this is that the alt attribute's value should never contain text that could be considered the image's [caption](#), [title](#), or [legend](#). It is supposed to contain replacement text that could be used by users instead of the image; it is not meant to supplement the image. The [title](#) attribute can be used for supplemental information.

Another corollary is that the alt attribute's value should not repeat information that is already provided in the prose next to the image.

Note
One way to think of alternative text is to think about how you would read the page containing the image to someone over the phone, without mentioning that there is an image present. Whatever you say instead of the image is typically a good start for writing the alternative text.

4.8.4.4.2 A link or button containing nothing but the image

When an element that creates a [hyperlink](#), or a [button](#) element, has no textual content but contains one or more images, the alt attributes must contain text that together convey the purpose of the link or button.

Example

In this example, a user is asked to pick their preferred color from a list of three. Each color is given by an image, but for users who have configured their user agent not to display images, the color names are used instead:

```
<ul>
  <li><img alt="green" href="green.htm"/>
  <li><img alt="blue" href="blue.htm"/>
</ul>
```

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Example

In this example, each button has a set of images to indicate the kind of color output desired by the user. The first image is used in each case to give the alternative text.

```
<button name="rgb"></button>
<button name="cmyk"></button>

Since each image represents one part of the text, it could also be written like this:
<button name="rgb"></button>

However, with other alternative text, this might not work, and putting all the alternative text into one image in each case might make more sense:
<button name="rgb"><img alt="green" profile="green"></button>
```

4.8.4.43 A phrase or paragraph with an alternative graphical representation: charts, diagrams, graphs, maps, illustrations

Sometimes something can be more clearly stated in graphical form, for example as a flowchart, a diagram, a graph, or a simple map showing directions. In such cases, an image can be given using the `img` element, but the lesser textual version must still be given, so that users who are unable to view the image (e.g. because they have a very slow connection, or because they are using a text-only browser, or because they are listening to the page being read out by a hands-free automobile voice Web browser, or simply because they are blind) are still able to understand the message being conveyed.

The text must be given in the `alt` attribute, and must convey the same message as the image specified in the `src` attribute.

It is important to realize that the alternative text is a *replacement* for the image, not a description of the image.

Example

In the following example we have a `flowchart` in image form, with text in the `alt` attribute rephrasing the flowchart in prose form:

```
<p>In the common case, the data handled by the tokenization stage<br/>comes from the network, but it can also come from <code>script</code>.</p>
<p><code></code> The Network<br/>passes data to the Input Stage, which passes it to the<br/>DOM. The DOM then passes it to the Tree Construction Stage. Finally, the<br/>data goes to both the DOM and to Script Execution. Script Execution is<br/>linked to the DOM, and, using <code>document.write()</code>, passes data to the<br/>DOM again. </p>
```

Example

Here's another example, showing a good solution and a bad solution to the problem of including an image in a description.

First, here's the good solution. This sample shows how the alternative text should just be what you would have put in the prose if the image had never existed.

```
<!-- This is the correct way to do things. -->
<p>You are standing in an open field west of a house.<br/> The house is white, with a boarded front door.<br/>There is a small mailbox here.</p>
```

Second, here's the bad solution. In this incorrect way of doing things, the alternative text is simply a description of the image, instead of a textual replacement for the image. It's bad because when the image isn't shown, the text doesn't flow as well as in the first example.

```
<!-- This is the wrong way to do things. -->
<p>You are standing in an open field west of a house.<br/> A white house, with a boarded front door.<br/>There is a small mailbox here.</p>
```

Text such as "Photo of white house with boarded door" would be equally bad alternative text (though it could be suitable for the `title` attribute or in the `figcaption` element of a `figure` with this image).

4.8.4.4 A short phrase or label with an alternative graphical representation: icons, logos

A document can contain information in iconic form. The icon is intended to help users of visual browsers to recognize features at a glance.

In some cases, the icon is supplemental to a text label conveying the same meaning. In those cases, the `alt` attribute must be present but must be empty.

Example

Here the icons are next to text that conveys the same meaning, so they have an empty `alt` attribute:

```
<nav><a href="/help"> Help</a></p>
<nav><a href="/configuration"> Configuration Tools</a></p>
</nav>
```

In other cases, the icon has no text next to it describing what it means; the icon is supposed to be self-explanatory. In those cases, an equivalent textual label must be given in the `alt` attribute.

Example

Here, posts on a news site are labeled with an icon indicating their topic.

```
<body>
<article>
  <h1>Tintin wins Best Movie of the Year! award</h1>
  <p> Movies</p>
  <p>Pixar has won yet another Best Movie of the Year award, making this its 8th win in the last 12 years.</p>
</article>
<article>
  <h1>Latest TWiT episode is online!</h1>
  <p> Podcasts</p>
  <p>The latest TWiT episode has been posted, in which we hear several tech news stories as well as learning much more about the iPhone. This week, the panellists compare how reflective their iPhone's Apple logos are.</p>
</article>
</body>
```

Many pages include logos, insignia, flags, or emblems, which stand for a particular entity such as a company, organization, project, band, software package, country, or some such.

If the logo is being used to represent the entity, e.g. as a page heading, the `alt` attribute must contain the name of the entity being represented by the logo. The `alt` attribute must *not* contain text like the word "logo", as it is not the fact that it is a logo that is being conveyed, it's the entity itself.

If the logo is being used next to the name of the entity that it represents, then the logo is supplemental, and its `alt` attribute must instead be empty.

If the logo is merely used as decorative material (as branding, or, for example, as a side image in an article that mentions the entity to which the logo belongs), then the entry below on purely decorative images applies. If the logo is actually being discussed, then it is being used as a phrase or paragraph (the description of the logo) with an alternative graphical representation (the logo itself), and the first entry above applies.

Example

In the following snippets, all four of the above cases are present. First, we see a logo used to represent a company:

```
<h1> The XYZ company</h1>
```

Next, we see a paragraph which uses a logo right next to the company name, and so doesn't have any alternative text:

```
<article>
  <h2>News</h2>
  <p>We recently been looking at buying the  ABC company, a small Greek company specializing in our type of product.</p>
```

In this third snippet, we have a logo being used in an aside, as part of the larger article discussing the acquisition:

```
<aside> ABC company has had a good quarter, and our pie chart studies of their accounts suggest a much bigger blue slice than its green and orange slices, which is always a good sign.</p>
</aside>
```

Finally, we have an opinion piece talking about a logo, and the logo is therefore described in detail in the alternative text.

```
<p>Consider for a moment their logo:</p>
<p> It consists of a green circle with a green question mark centered inside it.</p>
<p>How unoriginal can you get? I mean, ooooh, a question mark, how <em>revolutionary</em>, how utterly <em>ground-breaking</em>. I'm sure everyone will rush to adopt those specifications now! They could be keeping it a secret for a while, though. After all, it's rounded squares with varying shades of green and bold white outlines, at least that would look good on the cover of a blue book.</p>
```

This example shows how the alternative text should be written such that if the image isn't *available*, and the text is used instead, the text flows seamlessly into the surrounding text, as if the image had never been there in the first place.

4.8.4.45 Text that has been rendered to a graphic for typographical effect

Sometimes, an image just consists of text, and the purpose of the image is not to highlight the actual typographic effects used to render the text, but just to convey the text itself.

In such cases, the `alt` attribute must be present but must consist of the same text as written in the image itself.

Example

Consider a graphic containing the text "Earth Day", but with the letters all decorated with flowers and plants. If the text is merely being used as a heading, to spice up the page for graphical users, then the correct alternative text is just the same text "Earth Day", and no mention need be made of the decorations:

```
<h1> Earth Day</h1>
```

Example

An illuminated manuscript might use graphics for some of its images. The alternative text in such a situation is just the character that the image represents.

```
<p> Once upon a time and a long long time ago, late at night, when it was dark, over the hills, through the woods, across a great ocean, in a land far away, in a small house, on a hill, under a full moon...</p>
```

When an image is used to represent a character that cannot otherwise be represented in Unicode, for example gaiji, itaiji, or new characters such as novel currency symbols, the alternative text should be a more conventional way of writing the same thing, e.g. using the phonetic hiragana or katakana to give the character's pronunciation.

Example

In this example from 1997, a new-fangled currency symbol that looks like a curly E with two bars in the middle instead of one is represented using an image. The alternative text gives the character's pronunciation.

```
<p>Only  euro >5.991
```

An image should not be used if characters would serve an identical purpose. Only when the text cannot be directly represented using text, e.g., because of decorations or because there is no appropriate character (as in the case of gaiji), would an image be appropriate.

If an author is tempted to use an image because their default system font does not support a given character, then Web Fonts are a better solution than images.

4.8.4.4 A graphical representation of some of the surrounding text

In many cases, the image is actually just supplementary, and its presence merely reinforces the surrounding text. In these cases, the `alt` attribute must be present but its value must be the empty string.

In general, an image falls into this category if removing the image doesn't make the page any less useful, but including the image makes it a lot easier for users of visual browsers to understand the concept.

Example

A flowchart that repeats the previous paragraph in graphical form:

```
<p>The Network passes data to the Input Stream Preprocessor, which passes it to the Tokenizer, which passes it to the Tree Construction stage. From there, data goes to both the DOM and to Script Execution. Script Execution is linked to the DOM, and, using document.write(), passes data to the Tokenizer.</p>
<p><img alt="images/parsing-model-overview.svg" alt=""></p>
```

In these cases, it would be wrong to include alternative text that consists of just a caption. If a caption is to be included, then either the `title` attribute can be used, or the `figure` and `figcaption` elements can be used. In the latter case, the image would in fact be a phrase or paragraph with an alternative graphical representation, and would thus require alternative text.

<!-- Using the `title` attribute -->

```
<p>The Network passes data to the Input Stream Preprocessor, which passes it to the Tokenizer, which passes it to the Tree Construction stage. From there, data goes to both the DOM and to Script Execution. Script Execution is linked to the DOM, and, using document.write(), passes data to the Tokenizer.</p>
```

<!-- Using <figure> and <figcaption> -->

```
<p>The Network passes data to the Input Stream Preprocessor, which passes it to the Tokenizer, which passes it to the Tree Construction stage. From there, data goes to both the DOM and to Script Execution. Script Execution is linked to the DOM, and, using document.write(), passes data to the Tokenizer.</p>
```

<!-- Figure -->

<!-- Figure -->

<!-- This is WRONG. Do not do this. Instead, do what the above examples do. -->

```
<p>The Network passes data to the Input Stream Preprocessor, which passes it to the Tokenizer, which passes it to the Tree Construction stage. From there, data goes to both the DOM and to Script Execution. Script Execution is linked to the DOM, and, using document.write(), passes data to the Tokenizer.</p>
```

<!-- Never put the image's caption in the alt="" attribute! -->

Example

A graph that repeats the previous paragraph in graphical form:

```
<p>According to a study covering several billion pages, about 62% of documents on the Web in 2007 triggered the Quirks mode, while 37% triggered the Almost Standards mode, and about 9% triggered the Standards mode.</p>
```

4.8.4.4.7 Ancillary images

Sometimes, an image is not critical to the content, but is nonetheless neither purely decorative nor entirely redundant with the text. In these cases, the `alt` attribute must be present, and its value should either be the empty string, or a textual representation of the information that the image conveys. If the image has a caption giving the image's title, then the `alt` attribute's value must not be empty (as that would be quite confusing for non-visual readers).

Example

Consider a news article about a political figure, in which the individual's face was shown in an image that, through a style sheet, is floated to the right. The image is not purely decorative, as it is relevant to the story. The image is not entirely redundant with the story either, as it shows what the politician looks like. Whether any alternative text need be provided is an authoring decision, in part influenced by whether the image colors the interpretation of the prose.

In this first variant, the image is shown without context, and no alternative text is provided:

```
<img alt="alexsalmond.jpg" alt="Ahead of today's referendum, the First Minister of Scotland, Alex Salmond, wrote an open letter to all registered voters. In it, he admitted that all countries make mistakes." alt="">
```

If the picture is just a face, there might be no value in describing it. It's of no interest to the reader whether the individual has red hair or blond hair, whether the individual has white skin or black skin, whether the individual has one eye or two eyes.

However, if the picture is more dynamic, for instance showing the politician as angry, or particularly happy, or devastated, some alternative text would be useful in setting the tone of the article, a tone that might otherwise be missed:

```
<img alt="alexsalmond.jpg" alt="Alex Salmond is sad." alt="">
Ahead of today's referendum, the First Minister of Scotland, Alex Salmond, wrote an open letter to all registered voters. In it, he admitted that all countries make mistakes.</p>
```

```
<img alt="alexsalmond.jpg" alt="Alex Salmond is ecstatic!" alt="">
Ahead of today's referendum, the First Minister of Scotland, Alex Salmond, wrote an open letter to all registered voters. In it, he admitted that all countries make mistakes.</p>
```

Whether the individual was "sad" or "ecstatic" makes a difference to how the rest of the paragraph is to be interpreted: is he likely saying that he is resigned to the populace making a bad choice in the upcoming referendum, or is he saying that the election was a mistake but the likely turnout will make it irrelevant? The interpretation varies based on the image.

Example

If the image has a caption, then including alternative text avoids leaving the non-visual user confused as to what the caption refers to.

```
<p>Ahead of today's referendum, the First Minister of Scotland, Alex Salmond, wrote an open letter to all registered voters. In it, he admitted that all countries make mistakes.</p>
```

<figure>

 <figcaption>Alex Salmond, SNP. Photo © 2014 PolitiPhoto. </figcaption>
</figure>

4.8.4.4.8 A purely decorative image that doesn't add any information

If an image is decorative but isn't especially page-specific — for example an image that forms part of a site-wide design scheme — the image should be specified in the site's CSS, not in the markup of the document.

However, a decorative image that isn't discussed by the surrounding text but still has some relevance can be included in a page using the `img` element. Such images are decorative, but still form part of the content. In these cases, the `alt` attribute must be present but its value must be the empty string.

Example

Examples where the image is purely decorative despite being relevant would include things like a photo of the Black Rock City landscape in a blog post about an event at Burning Man, or an image of a painting inspired by a poem, on a page reciting that poem. The following snippet shows an example of the latter case (only the first verse is included in this snippet):

```
<div> Early in November /<br>
<img alt="shallow.jpg" alt=""></div>
<p>On either side the river lie<br>
  Body of water, both sides bare<br>
  That catche the wild and meete the sky<br>
  And through the field the road run by<br>
  To the high hill, the hill so bare<br>
  And up and down the people go,<br>
  Garing where the lilles blow<br>
  Bourne, Ile, Ile, Bourne Bourne<br>
  The island i Shalott.</p>
```

4.8.4.4.9 A group of images that form a single larger picture with no links

When a picture has been sliced into smaller image files that are then displayed together to form the complete picture again, one of the images must have its `alt` attribute set as per the relevant rules that would be appropriate for the picture as a whole, and then all the remaining images must have their `alt` attribute set to the empty string.

Example

In the following example, a picture representing a company logo for XYZ Corp has been split into two pieces, the first containing the letters "XYZ" and the second with the word "Corp". The alternative text ("XYZ Corp") is all in the first image.

```
<img alt="XYZ Corp" alt=""><img alt="logoz.png" alt="XYZ Corp" alt=""><img alt="logoz2.png" alt=""></h1>
```

Example

In the following example, a rating is shown as three filled stars and two empty stars. While the alternative text could have been "★★★☆☆", the author has instead decided to more helpfully give the rating in the form "3 out of 5". That is the alternative text of the first image, and the rest have blank alternative text.

```
<img alt="Rating: 3 out of 5" alt="">
<img alt="filled_star.png" alt=""><img alt="empty_star.png" alt=""><img alt="empty_star.png" alt="">
```

4.8.4.4.10 A group of images that form a single larger picture with links

Generally, [image maps](#) should be used instead of slicing an image for links.

However, if an image is indeed sliced and any of the components of the sliced picture are the sole contents of links, then one image per link must have alternative text in its `alt` attribute representing the purpose of the link.

Example

In the following example, a picture representing the flying spaghetti monster emblem, with each of the left noodly appendages and the right noodly appendages in different images, so that the user can pick the left side or the right side in an adventure.

```
<div>The Church</div>
<p>You come across a flying spaghetti monster. Which side of His noodly appendages would you wish to reach out for?</p>
<img alt="fsm-left.png" alt="Left side of the Flying Spaghetti Monster's noodly appendages." alt="">
<img alt="fsm-middle.png" alt="Middle section of the Flying Spaghetti Monster's noodly appendages." alt="">
<img alt="fsm-right.png" alt="Right side of the Flying Spaghetti Monster's noodly appendages." alt="">
```

4.8.4.4.11 A key part of the content

In some cases, the image is a critical part of the content. This could be the case, for instance, on a page that is part of a photo gallery. The image is the whole *point* of the page containing it.

How to provide alternative text for an image that is a key part of the content depends on the image's provenance.

The general case

When it is possible for detailed alternative text to be provided, for example if the image is part of a series of screenshots in a magazine review, or part of a comic strip, or is a photograph in a blog entry about that photograph, text that can serve as a substitute for the image must be given as the contents of the `alt` attribute.

Example

```
<figure>

  alt="The desktop is blue, with icons along the left hand side in the dock. A window is open showing that menus wrap to a second line if they cannot fit in the window. The window has a list of icons along the top edge, two icons for tabs along the left edge, a status bar at the bottom, and two panes in the middle. The desktop has a bar at the top with standard icons, a page, a list of open applications, and a clock."/>
</figure>
```

Example

A graph in a financial report:

```

  title="Sales graph"
  alt="From 1998 to 2005, sales increased by the following percentages
  with each year: 624%, 75%, 138%, 40%, 35%, 9%, 21%>
```

Note that "sales graph" would be inadequate alternative text for a sales graph. Text that would be a good `caption` is not generally suitable as replacement text.

Images that defy a complete description

In certain cases, the nature of the image might be such that providing thorough alternative text is impractical. For example, the image could be indistinct, or could be a complex fractal, or could be a detailed topographical map.

In these cases, the `alt` attribute must contain some suitable alternative text, but it may be somewhat brief.

Example

Sometimes there simply is no text that can do justice to an image. For example, there is little that can be said to usefully describe a Rorschach inkblot test. However, a description, even if brief, is still better than nothing:

```
<figure>

  alt="A sheet of paper, left-right symmetrical, with irregular edges, with a small gap in the center. Two larger gaps offset slightly from the center, with two similar gaps under them. The outline is wider in the top half than the bottom half. The inkblot area extends higher than the center, and the center extending below the sides."/>
</figure>
```

Note that the following would be a very bad use of alternative text:

```
<!-- This example is wrong. Do not copy it. -->

  alt="A black outline of the first of the ten cards in the Rorschach inkblot test."/>
</img>
```

Including the caption in the alternative text like this isn't useful because it effectively duplicates the caption for users who don't have images, taunting them twice yet not helping them any more than if they had only read or heard the caption once.

Example

Another example of an image that defies description is a fractal, which, by definition, is infinite in detail.

The following example shows one possible way of providing alternative text for the full view of an image of the Mandelbrot set.

```

```

Example

Similarly, a photograph of a person's face, for example in a biography, can be considered quite relevant and key to the content, but it can be hard to fully substitute text for:

```
<section class="bio">
<p><a href="#">Biography of Isaac Asimov</a><br/>
   In 1920, Isaac was a prolific author.</p>
<p><br/>
  Isaac was born in Russia, and moved to the US when he was three years old.</p>
</section>
```

In such cases it is unnecessary (and indeed discouraged) to include a reference to the presence of the image itself in the alternative text, since such text would be redundant with the browser itself reporting the presence of the image. For example, if the alternative text was "A photo of Isaac Asimov", then a conforming user agent might read that out as "(Image) A photo of Isaac Asimov" rather than the more useful "(Image) Isaac Asimov had dark hair, a tall forehead, and wore glasses...".

Images whose contents are not known

In some unfortunate cases, there might be no alternative text available at all, either because the image is obtained in some automated fashion without any associated alternative text (e.g. a Webcam), or because the page is being generated by a script using user-provided images where the user did not provide suitable or usable alternative text (e.g. photograph sharing sites), or because the author does not themselves know what the images represent (e.g. a blind photographer sharing an image on their blog).

In such cases, the `alt` attribute may be omitted, but one of the following conditions must be met as well:

- The `img` element is in a `figure` element that contains a `figcaption` element that contains content other than `inter-element whitespace`, and, ignoring the `figcaption` element and its descendants, the `figure` element has no `flow_content` descendants other than `inter-element whitespace` and the `img` element.
- The `title` attribute is present and has a non-empty value.

Note
Relying on the `title` attribute is currently discouraged as many user agents do not expose the attribute in an accessible manner as required by this specification (e.g. requiring a pointing device such as a mouse to cause a tooltip to appear, which excludes keyboard-only users and touch-only users, such as anyone with a modern phone or tablet).

Note
Such cases are to be kept to an absolute minimum. If there is even the slightest possibility of the author having the ability to provide real alternative text, then it would not be acceptable to omit the `alt` attribute.

Example

A photo on a photo-sharing site, if the site received the image with no metadata other than the caption, could be marked up as follows:

```
<figure>

</figure>
```

It would be better, however, if a detailed description of the important parts of the image obtained from the user and included on the page.

Example

A blind user's blog in which a photo taken by the user is shown. Initially, the user might not have any idea what the photo they took shows:

```
<article>
<h1>I took a photo!</h1>
<p>I went out today and took a photo!</p>
<figure>

</figure>
```

Eventually though, the user might obtain a description of the image from their friends and could then include alternative text:

```
<article>
<h1>I took a photo!</h1>
<p>I went out today and took a photo!</p>
<figure>

  alt="The photograph shows my squirrel feeder hanging from the edge of my roof. It is half full, but there are no squirrels around. In the background you can see the hill the house is on, made of wood with a metal grate, and it contains peanuts. The edge of the roof is wooden too, and is painted white. There are blue streaks."/>
</figure>
```

Notice that even in this example, as much useful information as possible is still included in the `title` attribute.

Note
Since some users cannot use images at all (e.g. because they have a very slow connection, or because they are using a text-only browser, or because they are listening to the page being read out by a hands-free automobile voice Web browser, or simply because they are blind), the `alt` attribute is only allowed to be omitted rather than being provided with replacement text when no alternative text is available and none can be made available, as in the above examples. Lack of effort from the part of the author is not an acceptable reason for omitting the `alt` attribute.

Another example would be software that displays images and asks for alternative text precisely for the purpose of then writing a page with correct alternative text. Such a page could have a table of images, like this:

Image	Description
	Image 640 by 100, filename 'banner.gif'
	Image 200 by 480, filename 'ad3.gif'

Notice that even in this example, as much useful information as possible is still included in the `title` attribute.

Note
An image is not intended for the user

Generally authors should avoid using `img` elements for purposes other than showing images.

If an `img` element is being used for purposes other than showing an image, e.g. as part of a service to count page views, then the `alt` attribute must be the empty string.

In such cases, the `width` and `height` attributes should both be set to zero.

An image is a e-mail or private document intended for a specific person who is known to be able to view images

This section does not apply to documents that are publicly accessible, or whose target audience is not necessarily personally known to the author, such as documents on a Web site, e-mails sent to public mailing lists, or software documentation.

When an image is included in a private communication (such as an HTML e-mail) aimed at a specific person who is known to be able to view images, the `alt` attribute may be omitted. However, even in such cases authors are strongly urged to include alternative text (as appropriate according to the kind of image involved, as described in the above entries), so that the e-mail is still usable should the user use a mail client that does not support images, or should the document be forwarded on to other users whose abilities might not include easily seeing images.

When an `iframe` element `element` is [inserted into a document](#) whose `browsing context` is non-null, the user agent must run these steps:

1. Create a new nested browsing context for `element`.
2. Process the `iframe` attributes for the "first time".

When an `iframe` element is [removed from a document](#), the user agent must [discard](#) the element's `nested browsing context`, if it is not null, and then set the element's `nested browsing context` to null.

Note

This happens without any `unload` events firing (the element's `nested browsing context` and its `document` are [discarded](#), not [unloaded](#)).

Whenever an `iframe` element with a non-null `nested browsing context` has its `srcdoc` attribute set, changed, or removed, the user agent must [process the `iframe` attributes](#).

Similarly, whenever an `iframe` element with a non-null `nested browsing context` but with no `srcdoc` attribute specified has its `src` attribute set, changed, or removed, the user agent must [process the `iframe` attributes](#).

When the user agent is to [process the `iframe` attributes](#), it must run the first appropriate steps from the following list:

If the `srcdoc` attribute is specified

Navigate the element's `nested browsing context` to a new `response` whose `url` list consists of `about:srcdoc`, `header` list consists of '`Content-Type`/'`text/html`', `body` is the value of the attribute. `CSP list` is a `clone` of the `iframe` element's `node document`'s `CSP list`, `HTTPS state` is the `HTTPS state` of the `iframe` element's `node document`.

The resulting `Document` must be considered `an iframe srcdoc document`.

Otherwise, if the element has no `src` attribute specified, and the user agent is processing the `iframe` attributes for the "first time"

[Queue an element task](#) on the `DOM manipulation task source` given the `iframe` element and the `iframe load event steps`.

Otherwise

Run the [otherwise steps for `iframe` or `frame` elements](#).

The [otherwise steps for `iframe` or `frame` elements](#) are as follows:

1. If the element has no `src` attribute specified, or its value is the empty string, let `url` be the `URL` "`about:blank`".

Otherwise, `parse` the value of the `src` attribute, relative to the element's `node document`.

If that is not successful, then let `url` be the `URL` "`about:blank`". Otherwise, let `url` be the `resulting URL record`.

2. If there exists an `ancestor browsing context` whose `active document's URL`, ignoring `fragments`, is equal to `url`, then return.

3. Let `resource` be a new `request` whose `url` is `url` and whose `referrer policy` is the current state of the element's `referrer policy` content attribute.

4. [Navigate](#) the element's `nested browsing context` to `resource`.

Any [navigation](#) required of the user agent in the `process the iframe attributes` algorithm must use the `iframe` element's `node document`'s `browsing context` as the `source browsing context`.

Furthermore, if the `active document` of the element's `nested browsing context` before such a `navigation` was not [completely loaded](#) at the time of the new `navigation`, then the `navigation` must be completed with `replacement enabled`.

Similarly, if the element's `nested browsing context's session history` contained only one `Document` when the `process the iframe attributes` algorithm was invoked, and that was the `about:blank Document` created when the element's `nested browsing context` was created, then any `navigation` required of the user agent in that algorithm must be completed with `replacement enabled`.

When a `Document` in an `iframe` is marked as [completely loaded](#), the user agent must run the `iframe load event steps`.

Note

A `load` event is also fired at the `iframe` element when it is created if no other data is loaded in it.

Each `Document` has an `iframe load in progress` flag and a `mute iframe load` flag. When a `Document` is created, these flags must be unset for that `Document`.

The `iframe load event steps` are as follows:

1. Let `child document` be the `active document` of the `iframe` element's `nested browsing context` (which cannot be null at this point).

2. If `child document` has its `mute iframe load` flag set, return.

3. Set `child document's iframe load in progress` flag.

4. [Fire an event](#) named `load` at the `iframe` element.

5. Unset `child document's iframe load in progress` flag.

⚠️ Warning!

This, in conjunction with scripting, can be used to probe the URL space of the local network's HTTP servers. User agents may implement `cross-origin` access control policies that are stricter than those described above to mitigate this attack, but unfortunately such policies are typically not compatible with existing Web content.

If an element type potentially delays the `load` event, then for each element `element` of that type, the user agent must [delay the load event](#) of `element's node document` if `element's nested browsing context` is non-null and any of the following are true:

- `element's nested browsing context's active document` is not ready for post-load tasks.
- Anything is [delaying the load event](#) of `element's nested browsing context's active document`.
- `element's nested browsing context` is in the [delaying load events mode](#).

Note

If, during the handling of the `load` event, `element's nested browsing context` is again [navigated](#), that will further [delay the load event](#).

The `iframe` element potentially delays the `load` event.

Note

If, when the element is created, the `srcdoc` attribute is not set, and the `src` attribute is either also not set or set but its value cannot be `parsed`, the browsing context will remain at the initial `about:blank` page.

Note

If the user [navigates](#) away from this page, the `iframe's nested browsing context's WindowProxy` object will proxy new `Document` objects for new `Document` objects, but the `src` attribute will not change.

The `name` attribute, if present, must be a `valid browsing context name`. The given value is used to name the element's `nested browsing context` if present when that is created.

The `sandbox` attribute, when specified, enables a set of extra restrictions on any content hosted by the `iframe`. Its value must be an [unordered set of unique space-separated tokens](#) that are `ASCII case-insensitive`. The allowed values are `allow-forms`, `allow-modals`, `allow-orientation-lock`, `allow-pointer-lock`, `allow-popups`, `allow-popups-to-escape-sandbox`, `allow-presentation`, `allow-same-origin`, `allow-scripts`, `allow-top-navigation`, and `allow-top-navigation-by-user-activation`.

Support: iframe-sandboxChrome for Android 8.1+Chrome 4+iOS Safari 4.2+Safari 5+Firefox 28+Samsung Internet 4+Edge 12+UC Browser for Android 12.12+IE 10+Opera 15+Opera Mini NoneFirefox for Android 68+

Source: [caniuse.com](#)

When the attribute is set, the content is treated as being from a unique `origin`, forms, scripts, and various potentially annoying APIs are disabled, links are prevented from targeting other `browsing contexts`, and plugins are secured. The `allow-top-navigation` keyword causes the content to be treated as being from its real origin instead of forcing it into a unique origin; the `allow-top-navigation` keyword allows the content to [navigate its top-level browsing context](#); the `allow-top-navigation-by-user-activation` keyword behaves similarly but allows such [navigation](#) only when the browsing context's `WindowProxy`'s [[Window]] value has `transient activation`; and the `allow-forms`, `allow-modals`, `allow-orientation-lock`, `allow-pointer-lock`, `allow-popups`, `allow-presentation`, `allow-scripts`, and `allow-top-navigation-by-user-activation` keywords re-enable forms, modal dialogs, screen orientation lock, the pointer lock API, popups, the presentation API, scripts, and the creation of un sandboxed `auxiliary browsing contexts` respectively. [POINTLOCK] [SCREENERIENTATION] [PRESENTATION]

The `allow-top-navigation` and `allow-top-navigation-by-user-activation` keywords must not both be specified, as doing so is redundant; only `allow-top-navigation` will have an effect in such non-conformant markup.

⚠️ Warning!
Setting both the `allow-scripts` and `allow-same-origin` keywords together when the embedded page has the `same origin` as the page containing the `iframe` allows the embedded page to simply remove the `sandbox` attribute and then reload itself, effectively breaking out of the sandbox altogether.

⚠️ Warning!
These flags only take effect when the `nested browsing context` of the `iframe` element is [navigated](#). Removing them, or removing the entire `sandbox` attribute, has no effect on an already-loaded page.

⚠️ Warning!
Potentially hostile files should not be served from the same server as the file containing the `iframe` element. Sandboxing hostile content is of minimal help if an attacker can convince the user to just visit the hostile content directly, rather than in the `iframe`. To limit the damage that can be caused by hostile HTML content, it should be served from a separate dedicated domain. Using a different domain ensures that scripts in the files are unable to attack the site, even if the user is tricked into visiting those pages directly, without the protection of the `sandbox` attribute.

When an `iframe` element with a `sandbox` attribute has its `nested browsing context` created (before the initial `about:blank Document` is created), and when an `iframe` element's `sandbox` attribute is set or changed while it has a `nested browsing context`, the user agent must [parse the sandboxing directive](#) using the attribute's value as the `input` and the `iframe` element's `nested browsing context's iframe sandboxing flag set` as the output.

When an `iframe` element's `sandbox` attribute is removed while it has a non-null `nested browsing context`, the user agent must empty the `iframe` element's `nested browsing context's iframe sandboxing flag set`.

Example

In this example, some completely-unknown, potentially hostile, user-provided HTML content is embedded in a page. Because it is served from a separate domain, it is affected by all the normal cross-site restrictions. In addition, the embedded page has scripting disabled, plugins disabled, forms disabled, and it cannot navigate any frames or windows other than itself (or any frames or windows it itself embeds).

```
<p>We're not scared of you! Here is your content, unedited:</p>
<iframe sandbox src="https://usercontent.example.net/getusercontent.cgi?id=12193"></iframe>
```

⚠️ Warning!
It is important to use a separate domain so that if the attacker convinces the user to visit that page directly, the page doesn't run in the context of the site's origin, which would make the user vulnerable to any attack found in the page.

Example

In this example, a gadget from another site is embedded. The gadget has scripting and forms enabled, and the origin sandbox restrictions are lifted, allowing the gadget to communicate with its originating server. The sandbox is still useful, however, as it disables plugins and popups, thus reducing the risk of the user being exposed to malware and other annoyances.

```
<iframe sandbox="allow-same-origin allow-forms allow-scripts" src="https://maps.example.com/embedded.html"></iframe>
```

Example

Suppose a file A contained the following fragment:

```
<iframe sandbox="allow-same-origin allow-forms" src=B></iframe>
```

Suppose that file B contained an `iframe` also:

```
<iframe sandbox="allow-scripts" src=C></iframe>
```

Further, suppose that file C contained a link:

```
<a href=D>Link</a>
```

For this example, suppose all the files were served as `text/html`.

Page C in this scenario has all the sandboxing flags set. Scripts are disabled, because the `iframe` in A has scripts disabled, and this overrides the `allow-scripts` keyword set on the `iframe` in B. Forms are also disabled, because the inner `iframe` (in B) does not have the `allow-forms` keyword set.

Suppose now that a script in A removes all the `sandbox` attributes in A and B. This would change nothing immediately. If the user clicked the link in C, loading page D into the `iframe` in B, page D would now act as if the `iframe` in B had the `allow-same-origin` and `allow-forms` keywords set, because that was the state of the `nested browsing context` in the `iframe` in A when page B was loaded.

Generally speaking, dynamically removing or changing the `sandbox` attribute is ill-advised, because it can make it quite hard to reason about what will be allowed and what will not.

The `allow` attribute, when specified, determines the `container policy` that will be used when the `feature policy` for a `Document` in the `iframe's nested browsing context` is initialized. Its value must be a `serialized feature policy`. [FEATUREPOLICY]

Example

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

`<iframe src="https://maps.example.com/" allow="geolocation"></iframe>`

The `allowfullscreen` attribute is a [boolean attribute](#). When specified, it indicates that [document](#) objects in the [iframe element's nested browsing context](#) will be initialized with a [feature policy](#) which allows the `"fullscreen"` feature to be used from any [origin](#). This is enforced by the [Process feature policy attributes algorithm](#). [\[FEATUREPOLICY\]](#)

Example

Here, an [iframe](#) is used to embed a player from a video site. The `allowfullscreen` attribute is needed to enable the player to show its video fullscreen.

```
<article>
<header>
 <span>Fred Flintstone</span>
<p><a href="#">Create my new ride!</a>
<iframe src="https://video.example.com/embed?id=92469812" allowfullscreen></iframe>
</p>
</header>
<content>
</content>
</article>
```

The `allowpaymentrequest` attribute is a [boolean attribute](#). When specified, it indicates that [document](#) objects in the [iframe element's nested browsing context](#) will be initialized with a [feature policy](#) which allows the `"payment"` feature to be used to make payment requests from any [origin](#). This is enforced by the [Process feature policy attributes algorithm](#). [\[FEATUREPOLICY\]](#)

Note

None of these attributes, `allowfullscreen` or `allowpaymentrequest`, can grant access to a feature in an [iframe element's nested browsing context](#) if the element's [node document](#) is not already allowed to use that feature.

To determine whether a [Document](#) object [document](#) is allowed to use the policy-controlled-feature/*feature*, run these steps:

1. If *document*'s [browsing context](#) is null, then return false.
2. If *document*'s [browsing context's active document](#) is not *document*, then return false.
3. If the result of running [Is feature enabled in document for origin](#) on *feature*, *document*, and *document*'s [origin](#) is "Enabled", then return true.
4. Return false.

⚠️ Warning!

Because they only influence the [feature policy](#) of the nested browsing context's active document, the `allowfullscreen` and `allowpaymentrequest` attributes only take effect when the nested browsing context of the [iframe](#) is navigated. Adding or removing them has no effect on an already-loaded document.

The [iframe](#) element supports [dimension attributes](#) for cases where the embedded content has specific dimensions (e.g. ad units have well-defined dimensions).

An [iframe](#) element never has [fallback content](#), as it will always [create a new nested browsing context](#), regardless of whether the specified initial contents are successfully used.

The [referrerpolicy](#) attribute is a [referrer policy attribute](#). Its purpose is to set the [referrer policy](#) used when [processing the iframe attributes](#). [\[REFERREDERPOLICY\]](#)

Descendants of [iframe](#) elements represent nothing. (In legacy user agents that do not support [iframe](#) elements, the contents would be parsed as markup that could act as fallback content.)

Note

The [HTML parser](#) treats markup inside [iframe](#) elements as text.

Categories:

Flow content

Phrasing content

Validable content
Context: in which this element can be used:
 Where embedded content is expected.

Content model:
 Nothing

Tag omission in text/html:
 end tag

Content attributes:

Global attributes
`src` — Address of the resource
`type` — Type of embedded resource
`width` — Horizontal dimension
`height` — Vertical dimension
 Any other attribute that has no namespace (see prose).

Accessibility considerations:

For authors

For implementers

DOM interface:

```
IDL[Exposed=HTMLGlobalObject]
interface RTNGlobbedElement : HTMLElement {
  [HTMLConstructor] constructor();
  [CRAactions] attribute USVString src;
  [CRAactions] attribute DOMString type;
  [CRAactions] attribute DOMString width;
  [CRAactions] attribute DOMString height;
  [CRAactions] attribute DOMString title;
  [CRAactions] attribute DOMString manifest;
  [CRAactions] attribute Document? getSVODocument();
};

// also has obsolete members
```

Depending on the type of content instantiated by the `embed` element, the node may also support other interfaces.

The `embed` element provides an integration point for an external (typically non-HTML) application or interactive content.

The `src` attribute gives the [URL](#) of the resource being embedded. The attribute, if present, must contain a [valid non-empty URL, potentially surrounded by spaces](#).

⚠️ Warning!

Authors should avoid referencing untrusted resources, as such a resource can be used to instantiate plugins or run scripts, even if the author has used features such as the Flash "allowScriptAccess" parameter.

If the `srctype` attribute is specified on an `object` element, then the `src` attribute must also be specified.

The `type` attribute, if present, gives the [MIME type](#) by which the plugin to instantiate is selected. The value must be a [valid MIME type string](#). If both the `type` attribute and the `src` attribute are present, then the `type` attribute must specify the same type as the [explicit Content-Type metadata](#) of the resource given by the `src` attribute.

While any of the following conditions are occurring, any `plugin` instantiated for the element must be removed, and the `embed` element `represents` nothing:

- The element has neither `src` attribute nor a `type` attribute.
- The element has a [media element](#) ancestor.
- The element has an ancestor [object](#) element that is not showing its [fallback content](#).

An `embed` element is said to be [potentially active](#) when the following conditions are all met simultaneously:

- The element is in a [document](#) or was in a [document](#) the last time the [event loop](#) reached [step 1](#).
- The element's [node document](#) is [fully active](#).
- The element has either a `src` attribute or a `type` attribute set (or both).
- The element's `src` attribute has an absolute URL; its value is not the empty string.
- The element is not a descendant of a [media element](#).
- The element is not a descendant of an [object](#) element that is not showing its [fallback content](#).
- The element is [being rendered](#), or was [being rendered](#) the last time the [event loop](#) reached [step 1](#).

Whenever an `embed` element that was not [potentially active](#) becomes [potentially active](#), and whenever a [potentially active embed](#) element that is remaining [potentially active](#) and has its `src` attribute set, changed, or removed or its `type` attribute set, changed, or removed, the user agent must [queue a task](#) using the [embed task source](#) to run the [embed element setup steps](#) for that element.

The `embed element setup steps` for a given `embed` element `element` are as follows:

1. If another [task](#) has since been queued to run [the embed element setup steps](#) for `element`, then return.
2. If the [Should element be blocked a priori by Content Security Policy?](#) algorithm returns "Blocked" when executed on `element`, then return. [\[CSP\]](#)
3. If `element` has a `src` attribute set, then:
 1. Let `url` be the result of [parsing](#) the value of `element`'s `src` attribute, relative to `element`'s `node document`.
 2. If `url` is failure, then return.
 3. Let `request` be a new [request](#) whose `url` is `url`, `client` is `element`'s `node document`'s [relevant settings object](#), `destination` is "embed", `credentials mode` is "include", and whose `use-URL-credentials flag` is set.
 4. [Fetch request](#).

Fetching the resource must [delay the load event](#) of `element`'s `node document`.

To [process response](#) for the [response](#) response:

1. If another [task](#) has since been queued to run [the embed element setup steps](#) for `element`, then return.
2. Let `type` be the result of determining the [type of content](#) given `element` and `response`.
3. Switch on `type`:
 1. [Display no plugin](#) for `element`.
 - [image/svg+xml](#)
 1. If `element`'s [nested browsing context](#) is null, then [create a new nested browsing context](#) for `element`.
 2. [Navigate](#) `element`'s [nested browsing context](#) to `response`, with [replacement enabled](#), and with `element`'s `node document`'s [browsing context](#) as the [source browsing context](#).

Note
`element`'s `src` attribute does not get updated if the browsing context gets further navigated to other locations.

3. `element` now `represents` its [nested browsing context](#).
4. When the `document` of `element`'s [nested browsing context](#) is marked as [completely loaded](#), [queue a task](#) to [fire an event](#) named `load` at `element`.

Otherwise

1. [Display a plugin](#) for `element`, given `type` and `response`.

4. Otherwise:

1. Let `type` be the value of `element`'s `type` attribute.
2. If `type` is a type that a [plugin](#) supports, then [display a plugin](#) for `element` given `type`.
3. Otherwise, [display no plugin](#) for `element`.

To determine the [type of content](#) given an `embed` element `element` and a [response](#) response, run the following steps:

1. If `element` has a `type` attribute, and that attribute's value is a type that a [plugin](#) supports, then return the value of the `type` attribute.
2. If the `path` component of `response`'s `url` matches a pattern that a [plugin](#) supports, then return the type that that plugin can handle.

Example
 For example, a plugin might say that it can handle URLs with `path` components that end with the four character string ".xvt".

3. If `response` has [explicit Content-Type metadata](#), and that value is a type that a [plugin](#) supports, then return that value.
4. Return null.

Note

It is intentional that the above algorithm allows `response` to be a [network error](#) or to have a [non-ok status](#). This allows servers to return data for plugins even with error responses (e.g., HTTP 500 Internal Server Error codes can still contain plugin data).

To [display a plugin](#) for an `embed` element, given a string `type` and optionally a [response](#) response:

1. If `element`'s [nested browsing context](#) is not null, then:
 1. [Discard](#) `element`'s [nested browsing context](#).
 2. Set `element`'s [nested browsing context](#) to null.
2. Find and instantiate an appropriate [plugin](#) based on `type`, replacing any previously-instantiated plugin for `element`. If `response` was given, forward it to the plugin.
3. Element now `represents` this [plugin](#) instance.
4. Once the plugin, and `response` if given, are completely loaded, [queue a task](#) to [fire an event](#) named `load` at `element`.

To [display no plugin](#) for an `embed` element:

1. If `element`'s [nested browsing context](#) is not null, then:
 1. [Discard](#) `element`'s [nested browsing context](#).
 2. Set `element`'s [nested browsing context](#) to null.
2. Display an indication that no [plugin](#) could be found for `element`, replacing any previously-instantiated plugin for `element`.
3. `element` now `represents` nothing.

Note
`Element` has no [fallback content](#); its descendants are ignored.

Whenever an `embed` element that was [potentially active](#) stops being [potentially active](#), any [plugin](#) that had been instantiated for that element must be unloaded.

When a [plugin](#) is to be instantiated but it cannot be [secured](#) and the [sandboxed plugins browsing context flag](#) is set on the `embed` element's `node document`'s [active sandboxing flag set](#), then the user agent must not instantiate the [plugin](#), and must instead render the `embed` element in a manner that conveys that the [plugin](#) was disabled. The user agent may offer the user the option to override the sandbox and instantiate the [plugin](#) anyway; if the user invokes such an option, the user agent must act as if the conditions above did not apply for the purposes of this element.

⚠️ Warning!

Plugins that cannot be [secured](#) are disabled in sandboxed browsing contexts because they might not honor the restrictions imposed by the sandbox (e.g., they might allow scripting even when scripting in the sandbox is disabled). User agents should convey the danger of overriding the sandbox to the user if an option to do so is provided.

The `embed` element [potentially delays the load event](#).

Any namespace-less attribute other than `name`, `align`, `baseline`, and `valign` may be specified on the `embed` element, so long as its name is `XML-compatible` and contains no `ASCII upper alphas`. These attributes are then passed as parameters to the `plugin`.

Note

All attributes in `HTML documents` get lowercased automatically, so the restriction on uppercase letters doesn't affect such documents.

Note

The four exceptions are to exclude legacy attributes that have side-effects beyond just sending parameters to the `plugin`.

The user agent should pass the names and values of all the attributes of the `embed` element that have no namespace to the `plugin` used, when one is instantiated.

The `HTMLEmbedElement` object representing the element must expose the scriptable interface of the `plugin` instantiated for the `embed` element, if any.

The `embed` element supports `dimension` attributes.

The IDL attributes `src` and `type` each must `reflect` the respective content attributes of the same name.

Example

Here's a way to embed a resource that requires a proprietary plugin, like Flash:

```
<embed src="catgame.swf">
```

If the user does not have the plugin (for example if the plugin vendor doesn't support the user's platform), then the user will be unable to use the resource.

To pass the plugin a parameter "quality" with the value "high", an attribute can be specified:

```
<embed src="catgame.swf" quality="high">
```

The would be equivalent to the following, when using an `object` element instead:

```
<object data="catgame.swf">
<param name="quality" value="high">
</object>
```

`Emboldened content`

If the element has a `usemap` attribute: `Interactive content`

`Listed and submittable form-associated element`

`Paintable content`

`Content` in which this element can be used:

Where embedded content is expected.

`Content model`:

Zero or more `param` elements, then, `transparent`.

`Tag omission in text/html`:

Neither tag ismissible.

`Content attributes`:

`Global attributes`

```
data — Address of the resource
type — Type of embedded resource
name — Name of nested browsing context
usemap — Name of image map to use
alt — Associated alt text with a form element
width — Horizontal dimension
height — Vertical dimension
```

Accessibility considerations:

`For authors`

`For implementors`

DOM interface

```
interface HTMLEmbedElement : HTMLElement {
  [HTMLConstructor] constructor();
  [CRAactions] attribute USVString data;
  [CRAactions] attribute DOMString type;
  [CRAactions] attribute DOMString name;
  [CRAactions] attribute DOMString useMap;
  readonly attribute HTMLFormElement? form;
  [CRAactions] attribute DOMString alt;
  [CRAactions] attribute DOMString width;
  [CRAactions] attribute DOMString height;
  readonly attribute Document? contentDocument;
  readonly attribute Document? contentWindow;
  readonly attribute Document? getSVODocument();
  readonly attribute boolean willValidate;
  readonly attribute ValidityState validity;
  readonly attribute string validationMessage;
  boolean checkValidity();
  boolean isDefaultValid();
  void setCustomValidity(DOMString error);
  // also has obsolete members
}
```

Depending on the type of content instantiated by the `object` element, the node also supports other interfaces.

The `object` element can represent an external resource, which, depending on the type of the resource, will either be treated as an image, as a `child browsing context`, or as an external resource to be processed by a `plugin`.

The `data` attribute, if present, specifies the `URL` of the resource. If present, the attribute must be a `valid non-empty URL potentially surrounded by spaces`.

⚠️Warning!

Authors should avoid referencing untrusted resources, as such a resource can be used to instantiate plugins or run scripts, even if the author has used features such as the Flash "allowScriptAccess" parameter.

The `type` attribute, if present, specifies the type of the resource. If present, the attribute must be a `valid MIME-type string`.

At least one of either the `data` attribute or the `type` attribute must be present.

If the `itemprop` attribute is specified on an `object` element, then the `data` attribute must also be specified.

The `name` attribute, if present, must be a `valid browsing context name`. The given value is used to name the element's `nested browsing context`, if applicable, and if present when the element's `nested browsing context` is created.

Whenever one of the following conditions occur:

- the element is created
- the element is popped off the `stack of open elements` of an `HTML parser` or `XML parser`
- the element is not on the `stack of open elements` of an `HTML parser` or `XML parser`, and it is either `inserted into a document` or `removed from a document`,
- the element's `node document` changes whether it is `fully active`.
- one of the element's ancestor `object` elements changes to or from showing its `fallback content`.
- the element's `useMap` attribute is not present, or its `data` attribute is set, changed, or removed.
- neither the element's `useMap` nor its `data` attribute are present, and its `type` attribute is set, changed, or removed,
- the element changes from being `rendered` to not being rendered, or vice versa.

...the user agent must `queue a task` to run the following steps to (re)determine what the `object` element represents. This `task` being `queued` or actively running must `delay the load event` of the element's `node document`.

1. If the user has indicated a preference that the `object` element's `fallback content` be shown because that content uses a format that the user finds more accessible.

Note
For example, a user could ask for the element's `fallback content` to be shown because that content uses a format that the user finds more accessible.

2. If the element has an ancestor `media element`, or has an ancestor `object` element that is `not showing its fallback content`, or if the element is `not in a document` whose `browsing context` is non-null, or if the element's `node document` is `not fully active`, or if the element is still in the `stack of open elements` of an `HTML parser` or `XML parser`, or if the element is `not being rendered`, or if the `Should element be blocked a priori by Content Security Policy?` algorithm returns `"blocked"` when executed on the element, then jump to the step below labeled `fallback`. (CSP)

3. If the `useMap` attribute is present, and has a value that isn't the empty string, then if the user agent can find a `plugin` suitable according to the value of the `classid` attribute, and either `plugins aren't being sandboxed` or that `plugin` can be `secured`, then that `plugin should be used`, and the value of the `data` attribute, if any, should be passed to the `plugin`. If no suitable `plugin` can be found, or if the `plugin` reports an error, jump to the step below labeled `fallback`.

4. If the `data` attribute is present and its value is not the empty string, then:

1. If the `type` attribute is present and its value is not a type that the user agent supports, and is not a type that the user agent can find a `plugin` for, then the user agent may jump to the step below labeled `fallback` without fetching the content to examine its real type.

2. `Parse the URL` specified by the `data` attribute, relative to the element's `node document`.

3. If that failed, `fire an event named error` at the element, then jump to the step below labeled `fallback`.

4. Let `request` be a new `request` whose `url` is the `resulting URL record`, `client` is the element's `node document's relevant settings object`, `destination` is `"object"`, `credentials mode` is `"include"`, and whose `use-URL-credentials flag` is set.

5. `Fetch request`.

Fetching the resource must `delay the load event` of the element's `node document` until the `task` that is `queued` by the `networking task source` once the resource has been fetched (defined next) has been run.

For the purposes of the `application cache` networking model, this fetch operation is not for a `child browsing context` (though it might end up being used for one after all, as defined below).

6. If the resource is not yet available (e.g. because the resource was not available in the cache, so that loading the resource required making a request over the network), then jump to the step below labeled `fallback`. The `task` that is `queued` by the `networking task source` once the resource is available must restart this algorithm from this step. Resources can load incrementally; user agents may opt to consider a resource "available" whenever enough data has been obtained to begin processing the resource.

8. Determine the *resource type*, as follows:

1. Let the *resource type* be unknown.

2. If the user agent is configured to strictly obey Content-Type headers for this resource, and the resource has [associated Content-Type metadata](#), then let the *resource type* be the type specified in [the resource's Content-Type metadata](#), and jump to the step below labeled *handler*.

⚠️ Warning!

This can introduce a vulnerability, wherein a site is trying to embed a resource that uses a particular plugin, but the remote site overrides that and instead furnishes the user agent with a resource that triggers a different plugin with different security characteristics.

3. If there is a `type` attribute present on the `object` element, and that attribute's value is not a type that the user agent supports, but it is a type that a `plugin` supports, then let the *resource type* be the type specified in that `type` attribute, and jump to the step below labeled *handler*.

4. Run the appropriate set of steps from the following list:

If the resource has [associated Content-Type metadata](#)

1. Let *binary* be false.

2. If the type specified in [the resource's Content-Type metadata](#) is `"text/plain"`, and the result of applying the [rules for distinguishing if a resource is text or binary](#) to the resource is that the resource is not `text/plain`, then set *binary* to true.

3. If the type specified in [the resource's Content-Type metadata](#) is `"application/octet-stream"`, then set *binary* to true.

4. If *binary* is false, then let the *resource type* be the type specified in [the resource's Content-Type metadata](#), and jump to the step below labeled *handler*.

5. If there is a `type` attribute present on the `object` element, and its value is not `application/octet-stream`, then run the following steps:

1. If the attribute's value is a type that a `plugin` supports, or the attribute's value is a type that starts with `"image/"` that is not also an [XML MIME type](#), then let the *resource type* be the type specified in that `type` attribute.

2. Jump to the step below labeled *handler*.

Otherwise, if the resource does not have [associated Content-Type metadata](#)

1. If there is a `type` attribute present on the `object` element, then let the *tentative type* be the type specified in that `type` attribute.

Otherwise, let *tentative type* be the [computed type of the resource](#).

2. If *tentative type* is not `application/octet-stream`, then let *resource type* be *tentative type* and jump to the step below labeled *handler*.

5. If applying the `URLParser` algorithm to the `URL` of the specified resource (after any redirects) results in a `URLRecord` whose `path` component matches a pattern that a `plugin` supports, then let *resource type* be the type that that plugin can handle.

Example

For example, a plugin might say that it can handle resources with `path` components that end with the four character string `".swf"`.

Note

If it is possible for this step to finish, or for one of the substeps above to jump straight to the next step, with *resource type* still being unknown. In both cases, the next step will trigger fallback.

9. *Handler*: Handle the content as given by the first of the following cases that matches:

If the *resource type* is not a type that the user agent supports, but it is a type that a `plugin` supports

If the `object` element's [nested browsing context](#) is non-null, then it must be [discarded](#) and then set to null.

If `plugins are being sandboxed` and the plugin that supports *resource type* cannot be [secured](#), jump to the step below labeled *fallback*.

Otherwise, the user agent should [use the plugin that supports resource type](#) and pass the content of the resource to that `plugin`. If the `plugin` reports an error, then jump to the step below labeled *fallback*.

If the *resource type* is a [XML MIME type](#), or if the *resource type* does not start with `"image/"`

If the `object` element's [nested browsing context](#) is null, then [create a new nested browsing context](#) for the element.

If the `URL` of the given resource is not [about:blank](#), the element's [nested browsing context](#) must then be [navigated](#) to that resource, with [replacement enabled](#), and with the `object` element's `nodeDocument's` [browsing context](#) as the [source browsing context](#). (The `data` attribute of the `object` element doesn't get updated if the browsing context gets further navigated to other locations.)

If the `URL` of the given resource is `about:blank`, then, instead, the user agent must [queue a task to fire an event named](#) `load` at the `object` element.

Note
No `load` event is fired at the `about:blank` document itself.

The `object` element [represents](#) its [nested browsing context](#).

Note

In certain situations, e.g., if the resource was fetched from a [application cache](#) but it is an HTML file with a `manifest` attribute that points to a different [application cache manifest](#), the [navigation](#) of the [browsing context](#) will be restarted so as to load the resource afresh from the network or a different [application cache](#). Even if the resource is then found to have a different type, it is still used as part of a [browsing context](#); only the [navigate](#) algorithm is restarted, not this `object` algorithm.

If the *resource type* starts with `"image/"`, and support for images has not been disabled

If the `object` element's [nested browsing context](#) is non-null, then it must be [discarded](#) and then set to null.

Apply the [image sniffing](#) rules to determine the type of the image.

The `object` element [represents](#) the specified image.

If the image cannot be rendered, e.g. because it is malformed or in an unsupported format, jump to the step below labeled *fallback*.

Otherwise

The given *resource type* is not supported. Jump to the step below labeled *fallback*.

Note

If the previous step ended with the *resource type* being unknown, this is the case that is triggered.

10. The element's contents are not part of what the `object` element represents.

11. Return Once the resource is completely loaded, [queue a task to fire an event named](#) `load` at the element.

5. If the `data` attribute is absent but the `type` attribute is present, and the user agent can find a `plugin` suitable according to the value of the `type` attribute, and either `plugins aren't being sandboxed` or the `plugin` can be [secured](#), then that `plugin` should be used. If these conditions cannot be met, or if the `plugin` reports an error, jump to the step below labeled *fallback*. Otherwise return; once the plugin is completely loaded, [queue a task to fire an event named](#) `load` at the element.

6. *Fallback*: The `object` element [represents](#) the element's children, ignoring any leading `param` element children. This is the element's [fallback content](#). If the element has an instantiated `plugin`, then unload it. If the element's [nested browsing context](#) is non-null, then it must be [discarded](#) and then set to null.

When the algorithm above instantiates a `plugin`, the user agent should pass to the `plugin` used the names and values of all the attributes on the element, in the order they were added to the element, with the attributes added by the parser being ordered in source order, followed by a parameter named "PARAM" whose value is null, followed by all the names and values of `parameters` given by `param` elements that are children of the `object` element, in `tree order`. If the `plugin` supports a scriptable interface, the `HTMLObjectElement` object representing the element should expose that interface. The `object` element [represents](#) the `plugin`. The `plugin` is not a nested [browsing context](#).

Plugins are considered sandboxed for the purpose of an `object` element if the `sandboxedPlugins.browsingContextFlag` is set on the `object` element's `nodeDocument's active sandboxing flag set`.

Due to the algorithm above, the contents of `object` elements act as `fallback content`, used only when referenced resources can't be shown (e.g. because it returned a 404 error). This allows multiple `object` elements to be nested inside each other, targeting multiple user agents with different capabilities, with the user agent picking the first one it supports.

The `object` element potentially delays the load event.

The `task source` for the tasks mentioned in this section is the [DOM manipulation task source](#).

The `usage` attribute, if present while the `object` element represents an image, can indicate that the object has an associated `image map`. The attribute must be ignored if the `object` element doesn't represent an image.

The `form` attribute is used to explicitly associate the `object` element with its `form owner`.

Constraint validation: `object` elements are always [banned](#) from constraint validation.

The `object` element supports [dimension attributes](#).

The `contentWindow` IDL attribute must return the `WindowProxy` object of the `object` element's `nested browsing context`, if its `nested browsing context` is non-null; otherwise, it must return null.The `willValidate`, `validity`, and `validationMessage` attributes, and the `checkValidity()`, `reportValidity()`, and `setCustomValidity()` methods, are part of the `constraint validation API`. The `form` IDL attribute is part of the element's forms API.**Example**In this example, an HTML page is embedded in another using the `object` element.

```
<figure>
<object data="clock.html"></object>
<figcaption>My HTML Clock</figcaption>
</figure>
```

ExampleThe following example shows how a plugin can be used in HTML (in this case the Flash plugin, to show a video file). Fallback is provided for users who do not have Flash enabled, in this case using the `video` element to show the video for those using user agents that support `video`, and finally providing a link to the video for those who have neither Flash nor `video`-capable browser.

```
<object type="my video">
<param name="movie" value="a-shockwave-flash">
<param name="allowFullScreen" value="true">
<param name="allowScriptAccess" value="always">
<video controls src="https://video.example.com/vids/315981">
  <a href="https://video.example.com/vids/315981">View video</a>
</video>
</object>
</>
```

4.8.8 The `param` element[MDN](#)[Element/param](#)

Firefox AndroidYesSafari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

Categories:**Contexts in which this element can be used:**As a child of an `object` element, before any `flow content`.**Content model:****Nothing****Tag omission in text/html:**`<param>` and `<param>`**Contact attributes:****Global attributes**`name` — Name of parameter`value` — Value of parameter**Accessibility considerations:****For screen readers****For input helpers****DOM interface:**

```
IDL Exports<Windows>
interface HTMLParamElement : HTMLElement {
  [HTMLConstructor] constructor();
}
```

```
  [CEReactions] attribute DOMString name;
  [CEReactions] attribute DOMString value;
  // also has obsolete members
};
```

The `param` element defines parameters for plugins invoked by `object` elements. It does not `represent` anything on its own.The `name` attribute gives the name of the parameter.The `value` attribute gives the value of the parameter.

Both attributes must be present. They may have any value.

If both attributes are present, and the parent element of the `param` is an `object` element, then the element defines a `parameter` with the given name-value pair.If either the name or value of a `parameter` defined by a `param` element that is the child of an `object` element that `represents` an instantiated `plugin` changes, and if that `plugin` is communicating with the user agent using an API that features the ability to update the `plugin` when the name or value of a `parameter` so changes, then the user agent must appropriately exercise that ability to notify the `plugin` of the change.The IDL attributes `name` and `value` must both `reflect` the respective content attributes of the same name.**Example**The following example shows how the `param` element can be used to pass a parameter to a plugin, in this case the O3D plugin.

```
<!DOCTYPE HTML>
<html lang="en">
<head>
<title>O3D Utah Teapot</title>
</head>
<body>
<object type="application/vnd.o3d.auto">
<param name="old_features" value="FloatingPointTextures">

<title>3D Utah Teapot illustration rendered using O3D.</title>
<p>This is a 3D rendering of the Utah teapot as a squat teapot with a shiny metallic finish on white. The surroundings are reflected, with a faint shadow caused by the light source. To see the teapot actually rendered by O3D on your computer, please download and install the <a href="http://code.google.com/apis/o3d/docs/gettingstarted.html#install">O3D plugin</a>.</p>
</object>
<script src="o3d-teapot.js"></script>
</body>
</html>

attribute USVString poster;
[REactions]
attribute boolean playinline;
```

A `video` element is used for playing videos or movies, and audio files with captions.

Content may be provided inside the `video` element. User agents should not show this content to the user; it is intended for older Web browsers which do not support `video`, so that legacy video plugins can be tried, or to show text to the users of these older browsers informing them of how to access the video contents.

Note

In particular, this content is not intended to address accessibility concerns. To make video content accessible to the partially sighted, the blind, the hard-of-hearing, the deaf, and those with other physical or cognitive disabilities, a variety of features are available. Captions can be provided, either embedded in the video stream or as external files using the `track` element. Sign-language tracks can be embedded in the video stream. Audio descriptions can be embedded in the video stream or in text form using a [WebVTT file](#) referenced using the `track` element and synthesized into speech by the user agent. WebVTT can also be used to provide chapter titles. For users who would rather not use a media element at all, transcripts or other textual alternatives can be provided by simply linking to them in the `poster` element ([WEBVTT](#)).

The `video` element is a `media element` whose `media data` is ostensibly video data, possibly with associated audio data.

The `src`, `crossorigin`, `preload`, `autoplay`, `loop`, `muted`, and `controls` attributes are the attributes common to all `media elements`.

The `poster` attribute gives the `URL` of an image file that the user agent can show while no video data is available. The attribute, if present, must contain a [valid non-empty URL potentially surrounded by spaces](#).

If the specified resource is to be used, then, when the element is created or when the `poster` attribute is set, changed, or removed, the user agent must run the following steps to determine the element's `poster frame` (regardless of the value of the element's `show poster` flag):

- If there is an existing instance of this algorithm running for this `video` element, abort that instance of this algorithm without changing the `poster frame`.
- If the `poster` attribute's value is the empty string or if the attribute is absent, then there is no `poster frame`; return.
- Parse the `poster` attribute's value relative to the element's `node document`. If this fails, then there is no `poster frame`; return.
- Let `request` be a new `request` whose `url` is the `resulting URL record`, `client` is the element's `node document's relevant settings object`, `destination` is "image", `credentials mode` is "include", and whose `use-URL-credentials flag` is set.
- `Fetch request`. This must [delay the load event](#) of the element's `node document`.
- If an image is thus obtained, the `poster frame` is that image. Otherwise, there is no `poster frame`.

Note

The image given by the `poster` attribute, the `poster frame`, is intended to be a representative frame of the video (typically one of the first non-blank frames) that gives the user an idea of what the video is like.

The `playinline` attribute is a [boolean attribute](#). If present, it serves as a hint to the user agent that the video ought to be displayed "inline" in the document by default, constrained to the element's playback area, instead of being displayed fullscreen or in an independent resizable window.

Note

The absence of the `playinline` attributes does not imply that the video will display fullscreen by default. Indeed, most user agents have chosen to play all videos inline by default, and in such user agents the `playinline` attribute has no effect.

A `video` element represents what is given for the first matching condition in the list below:

When no video data is available (the element's `readyState` attribute is either `have_nothing` or `have_incomplete` but no video data has yet been obtained at all, or the element's `readyState` attribute is any subsequent value but the `media resource` does not have a video channel)
 The `video` element `represents` its `poster frame`, if any, or else `transparent` black with no `intrinsic dimensions`.

When the `video` element is `paused`, the `current playback position` is the first frame of video, and the element's `show poster` flag is set

The `video` element `represents` its `poster frame`, if any, or else the first frame of the video.

When the `video` element is `paused`, and the frame of video corresponding to the `current playback position` is not available (e.g. because the video is seeking or buffering)

When the `video` element is `paused` and potentially playing, and the frame of video corresponding to the `current playback position` is not available (e.g. when seeking or stalled)

The `video` element `represents` the last frame of the video to have been rendered.

When the `video` element is `paused`

The `video` element `represents` the frame of video corresponding to the `current playback position`.

Otherwise (the `video` element has a video channel and is potentially playing)

The `video` element `represents` the frame of video at the continuously increasing `current position`. When the `current playback position` changes such that the last frame rendered is no longer the frame corresponding to the `current playback position` in the video, the new frame must be rendered.

Frames of video must be obtained from the video track that was `selected` when the `event loop` last reached `step 1`.

Note

Which frame in a video stream corresponds to a particular playback position is defined by the video stream's format.

The `video` element also `represents` any `text track cue` whose `text track cue active flag` is set and whose `text track` is in the `showing` mode, and any audio from the `media resource`, at the `current playback position`.

Any audio associated with the `media resource` must, if played, be played synchronized with the `current playback position`, at the element's `effective media volume`. The user agent must play the audio from audio tracks that were `enabled` when the `event loop` last reached step 1.

In addition to the above, the user agent may provide messages to the user (such as "buffering", "no video loaded", "error", or more detailed information) by overlaying text or icons on the video or other areas of the element's playback area, or in another appropriate manner.

User agents that cannot render the video may instead make the element `represent` a link to an external video playback utility or to the video data itself.

When a `video` element's `media resource` has a video channel, the element provides a `paint source` whose width is the `media resource's intrinsic width`, whose height is the `media resource's intrinsic height`, and whose appearance is the frame of video corresponding to the `current playback position`, if that is available, or else (e.g. when the video is seeking or buffering) its previous appearance, if any, or else (e.g. because the video is still loading the first frame) blackness.

For web developers (non-normative)

`video`, `videoWidth`

`video`, `videoHeight`

These attributes return the intrinsic dimensions of the video, or zero if the dimensions are not known.

The `intrinsic width` and `intrinsic height` of the `media resource` are the dimensions of the resource in `CSS pixels` after taking into account the resource's dimensions, aspect ratio, clean aperture, resolution, and so forth, as defined for the format used by the resource. If an anamorphic format does not define how to apply the aspect ratio to the video data's dimensions to obtain the "correct" dimensions, then the user agent must apply the ratio by increasing one dimension and leaving the other unchanged.

MDN

[HTMLVideoElement::videoWidth](#)

Support in all current engines.

Firefox+ Safari+ Chrome+ Yes

Opera 10.5+ Edge+ Yes

Edge (Legacy) 12+ Internet Explorer 9+

Firefox+ Safari+ Yes+ Chrome+ Yes

Opera 10.5+ Edge+ Yes

Edge (Legacy) 12+ Internet Explorer 9+

Foxit Reader+ Android 4+ Safari+ iOS+ Chrome+ Android+ WebView+ Android+ Samsung+ Internet+ Yes+ Opera+ Android+ Yes

The `videoWidth` IDL attribute must return the `intrinsic width` of the video in `CSS pixels`. The `videoWidth` IDL attribute must return the `intrinsic height` of the video in `CSS pixels`. If the element's `readyState` attribute is `HAVE NOTHING`, then the attributes must return 0.

Whenever the `intrinsic width` or `intrinsic height` of the video changes (including, for example, because the `selected video track` was changed), if the element's `readyState` attribute is not `HAVE NOTHING`, the user agent must `queue a task` to `fire an event` named `resize` at the `media element`.

The `video` element supports `dimension attributes`.

In the absence of style rules to the contrary, video content should be rendered inside the element's playback area such that the video content is shown centered in the playback area at the largest possible size that fits completely within it, with the video content's aspect ratio being preserved. Thus, if the aspect ratio of the playback area does not match the aspect ratio of the video, the video will be shown letterboxed or pillarboxed. Areas of the element's playback area that do not contain the video represent nothing.

Note

In user agents that implement CSS, the above requirement can be implemented by using the `style rule suggested in the rendering section`.

The `intrinsic width` of a `video` element's playback area is the `intrinsic width` of the `poster frame`, if that is available and the element currently `represents` its poster frame; otherwise, it is the `intrinsic width` of the video resource, if that is available; otherwise the `intrinsic width` is missing.

The `intrinsic height` of a `video` element's playback area is the `intrinsic height` of the `poster frame`, if that is available and the element currently `represents` its poster frame; otherwise it is the `intrinsic height` of the video resource, if that is available; otherwise the `intrinsic height` is missing.

The `default object size` is a width of 300 `CSS pixels` and a height of 150 `CSS pixels`. (`CSSIMAGES`)

A `video` element is said to `intersect the viewport` when it is `being rendered` and its associated CSS layout box intersects the `viewport`.

User agents should provide controls to enable or disable the display of closed captions, audio description tracks, and other additional data associated with the video stream, though such features should, again, not interfere with the page's normal rendering.

User agents may allow users to view the video content in manners more suitable to the user, such as fullscreen or in an independent resizable window. User agents may even trigger such a viewing mode by default upon playing a video, although they should not do so when the `playinline` attribute is specified. As with the other user interface features, controls to enable this should not interfere with the page's normal rendering unless the user agent is `exposing a user interface`. In such an independent viewing mode, however, user agents may make full user interfaces visible, even if the `controls` attribute is absent.

The `poster` IDL attribute must reflect the `poster` content attribute.

The `playinline` IDL attribute must reflect the `playinline` content attribute.

Example

```
<script>
function failed(e) {
  // video playback failed - show a message saying why
  switch(e.errorCode) {
    case e.error.MEDIA_ERR_ABORTED:
      alert('You aborted the video playback.');
    case e.error.MEDIA_ERR_NETWORK:
      alert('A network error caused the video download to fail part-way.');
    case e.error.MEDIA_ERR_DECODE:
      alert('The video playback was aborted due to a corruption problem or because the video used features your browser did not support.');
    case e.error.MEDIA_ERR_SRC_NOT_SUPPORTED:
      alert('The video could not be loaded, either because the server or network failed or because the format is not supported.');
    default:
      alert('An unknown error occurred.');
  }
}
</script>
<p><video src="tgif.vid" autoplay controls onerror="failed(event)"></video></p>
<p><a href="tgif.vid">Download the video file</a>.</p>

Categories:

As a child of a `media element`, before any `flow content`.

Content model:

`Nothing`

Tag omission in text/html:

No end tag.

Content attributes:

Global attributes

- `id` — The type of text track
- `src` — Address of the resource
- `srclang` — Language of the text track
- `label` — User-visible label
- `default` — Enable the track if no other `text track` is more suitable

Accessibility considerations:

For authors

For implementers

DOM interface:

```
IDLExposedWindow
interface HTMLTextTrackElement : HTMLElement {
  [HTMLTextTrackElement] construct();
  [CSSProperties] attribute DOMString kind;
  [CSSProperties] attribute DOMString srclang;
  [CSSProperties] attribute DOMString label;
  [CSSProperties] attribute boolean default;
  const unsigned short DRCN = 0;
  const unsigned short DRCN1 = 1;
  const unsigned short DRCN2 = 2;
  const unsigned short DRCN3 = 3;
  readyOnly attribute unsigned short readyState;
  readonly attribute TextTrack track;
}
```

The `track` element allows authors to specify explicit external timed `text tracks` for `media elements`. It does not `present` anything on its own.

The `kind` attribute is an [enumerated attribute](#). The following table lists the keywords defined for this attribute. The keyword given in the first cell of each row maps to the state given in the second cell.

Keyword	State	Brief description
<code>subtitles</code>	<code>Subtitles</code>	Transcription or translation of the dialogue, suitable for when the sound is available but not understood (e.g. because the user does not understand the language of the <code>media resource</code> 's audio track). Overlaid on the video.
<code>captions</code>	<code>Captions</code>	Transcription or translation of the dialogue, sound effects, relevant musical cues, and other relevant audio information, suitable for when sound is unavailable or not clearly audible (e.g. because it is muted, drowned-out by ambient noise, or because the user is deaf). Overlaid on the video; labeled as appropriate for the hard-of-hearing.
<code>descriptions</code>	<code>Descriptions</code>	Textual descriptions of the video component of the <code>media resource</code> , intended for audio synthesis when the visual component is obscured, unavailable, or not usable (e.g. because the user is interacting with the application without a screen while driving, or because the user is blind). Synthesized as audio.
<code>chapters</code>	<code>Chapters</code>	<code>metaData</code>
<code>metadata</code>	<code>Metadata</code>	Tracks intended for use from script. Not displayed by the user agent.

The attribute may be omitted. The `missing value default` is the `subtitles` state. The `invalid value default` is the `metadata` state.

The `src` attribute gives the [URL](#) of the text track data. The value must be a [valid non-empty URL potentially surrounded by spaces](#). This attribute must be present.

If the element has a `src` attribute whose value is not the empty string and whose value, when the attribute was set, could be successfully [parsed](#) relative to the element's `node document`, then the element's `track URL` is the [resulting URL string](#). Otherwise, the element's `track URL` is the empty string.

If the element's `track URL` identifies a WebVTT resource, and the element's `kind` attribute is not in the `chapters metadata` or `metadata` state, then the WebVTT file must be a [WebVTT file using cue text \(WEBVTT\)](#).

The `srclang` attribute gives the language of the text track data. The value must be a valid BCP 47 language tag. This attribute must be present if the element's `kind` attribute is in the `subtitles` state. [\[BCP47\]](#)

If the element has a `srclang` attribute whose value is not the empty string, then the element's `track language` is the value of the attribute. Otherwise, the element has no `track language`.

The `label` attribute gives a user-readable title for the track. This title is used by user agents when listing `subtitle`, `caption`, and `audio description` tracks in their user interface.

The value of the `label` attribute, if the attribute is present, must not be the empty string. Furthermore, there must not be two `track` element children of the same `media element` whose `kind` attributes are in the same state, whose `srclang` attributes are both missing or have values that represent the same language, and whose `label` attributes are again both missing or both have the same value.

If the element has a `label` attribute whose value is not the empty string, then the element's `track label` is the value of the attribute. Otherwise, the element's `track label` is an empty string.

The `default` attribute is a [boolean attribute](#), which, if specified, indicates that the track is to be enabled if the user's preferences do not indicate that another track would be more appropriate.

Each `media element` must have no more than one `track` element child whose `kind` attribute is in the `subtitles` or `captions` state and whose `default` attribute is specified.

Each `media element` must have no more than one `track` element child whose `kind` attribute is in the `description` state and whose `default` attribute is specified.

Each `media element` must have no more than one `track` element child whose `kind` attribute is in the `chapters metadata` state and whose `default` attribute is specified.

Note

There is no limit on the number of `track` elements whose `kind` attribute is in the `metadata` state and whose `default` attribute is specified.

For web developers (non-normative)

`track.readyState`

Returns the `text track readiness state`, represented by a number from the following list:

`track.state(0)`

The `text track not loaded` state.

`track.state(1)`

The `text track loading` state.

`track.state(2)`

The `text track loaded` state.

`track.state(3)`

The `text track failed to load` state.

`track.state`

Returns the `TextTrack` object corresponding to the `text track` of the `track` element.

The `readyState` attribute must return the numeric value corresponding to the `text track readiness state` of the `track` element's `text track`, as defined by the following list:

`NOUE` (numeric value 0)

The `text track not loaded` state.

`LOADING` (numeric value 1)

The `text track loading` state.

`LOADED` (numeric value 2)

The `text track loaded` state.

`ERROR` (numeric value 3)

The `text track failed to load` state.

The `track IDL` attribute must, on getting, return the `track` element's `text track`'s corresponding `TextTrack` object.

MDN

[HTMLTrackElement/src](#)

Opera12+Edge79+

Edge (Legacy)12+Internet ExplorerNo

Foxfire Android31+Safari iOSYesChrome Android25+WebView AndroidYesSamsung Internet1.5+Opera Android12+

The `src`, `srclang`, `label`, and `default` IDL attributes must `reflect` the respective content attributes of the same name. The `kind` IDL attribute must `reflect` the content attribute of the same name, [limited to only known values](#).

Example

This video has subtitles in several languages:

```
<video src="Brave.webm">
<track kind="subtitles" src="brave.en.vtt" srclang="en" label="English">
<track kind="captions" src="brave.en.hsb.vtt" srclang="en" label="English for the Hard of Hearing">
<track kind="subtitles" src="brave.fr.vtt" srclang="fr" label="French">
<track kind="subtitles" src="brave.de.vtt" srclang="de" label="German">
```

(The `lang` attributes on the last two describe the language of the `label` attribute, not the language of the subtitles themselves. The language of the subtitles is given by the `srclang` attribute.)

}

```

The `media` element attributes, `src`, `crossorigin`, `preload`, `autoplay`, `loop`, `muted`, and `controls`, apply to all `media` elements. They are defined in this section.

Media elements are used to present audio data, or video and audio data, to the user. This is referred to as `media data` in this section, since this section applies equally to `media elements` for audio or for video. The term `media resource` is used to refer to the complete set of media data, e.g. the complete video file, or complete audio file.

A `media resource` can have multiple audio and video tracks. For the purposes of a `media element`, the video data of the `media resource` is only that of the currently selected track (if any) as given by the element's `videoTracks` attribute when the `event loop` last reached `step 1`, and the audio data of the `media resource` is the result of mixing all the currently enabled tracks (if any) given by the element's `audioTracks` attribute when the `event loop` last reached `step 1`.

Note

Both `media` and `video` elements can be used for both audio and video. The main difference between the two is simply that the `media` element has no playback area for visual content (such as video or captions), whereas the `video` element does.

Except where otherwise explicitly specified, the `task source` for all the tasks `queued` in this section and its subsections is the `media element event task source` of the `media element` in question.

4.8.12.1 Error codes

For web developers (non-normative)

media.error

Returns a `MediaError` object representing the current error state of the element.

Returns null if there is no error.

MDN

HTML MediaElement.error

Support in all current engines.

Firefox3.5+Safari6+Chrome43+

OperaYesEdge79+

Edge (Legacy)12+Internet Explorer9+

Firefox AndroidYesSafari iOSYesChrome Android43+WebView AndroidYesSamsung InternetYesOpera AndroidYes

All `media elements` have an associated error status, which records the last error the element encountered since its `resource selection algorithm` was last invoked. The `error` attribute, on getting, must return the `MediaError` object created for this last error, or null if there has not been an error.

MDN

MediaError

Support in all current engines.

Firefox3.5+SafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet Explorer9+

Firefox AndroidYesSafari iOSYesChrome Android43+WebView AndroidYesSamsung InternetYesOpera AndroidYes

```

IDNAut MediaError {
  const unsigned short MEDIA_ERR_ABORTED = 1;
  const unsigned short MEDIA_ERR_NETWORK = 2;
  const unsigned short MEDIA_ERR_DECODE = 3;
  const unsigned short MEDIA_ERR_SRC_NOT_SUPPORTED = 4;
  readonly attribute unsigned short code;
  readonly attribute DOMString message;
}

```

For web developers (non-normative)

media.error.code

Returns the current error's error code, from the list below.

media.error.message

Returns a specific informative diagnostic message about the error condition encountered. The message and message format are not generally uniform across different user agents. If no such message is available, then the empty string is returned.

Every `MediaError` object has a `message`, which is a string, and a `code`, which is one of the following:

MEDIA_ERR_ABORTED (numeric value 1)

The fetch process for the `media resource` was aborted by the user agent at the user's request.

MEDIA_ERR_NETWORK (numeric value 2)

A network error of some description caused the user agent to stop fetching the `media resource`, after the resource was established to be usable.

MEDIA_ERR_DECODE (numeric value 3)

An error of some kind of conversion occurred while decoding the `media resource`, after the resource was established to be usable.

MEDIA_ERR_SRC_NOT_SUPPORTED (numeric value 4)

The `media resource` indicated by the `src` attribute or assigned `media provider object` was not suitable.

To create a `MediaError`, given an error code which is one of the above values, return a new `MediaError` object whose `code` is the given error code and whose `message` is a string containing any details the user agent is able to supply about the cause of the error condition, or the empty string if the user agent is unable to supply such details. This message string must not contain only the information already available via the supplied error code; for example, it must not simply be a translation of the code into a string format. If no additional information is available beyond that provided by the error code, the `message` must be set to the empty string.

The `currentSrc` IDL attribute must initially be set to the empty string. Its value is changed by the `resource selection algorithm` defined below.

MDN

[HTML MediaElement/srcObject](#)

Partial support in some engines.

Firefox42+SafariNoChrome52+

Opera39+Edge79+

Edge (Legacy)12+Internet ExplorerNo

Firefox Android42+Safari iOSNo Chrome Android52+WebView Android52+Samsung Internet5.0+Opera Android41+

The `srcObject` IDL attribute, on getting, must return the element's assigned `media provider object`, if any, or null otherwise. On setting, it must set the element's assigned `media provider object` to the new value, and then invoke the element's `media element load algorithm`.

Note

There are three ways to specify a `media resource`: the `srcObject` IDL attribute, the `src` content attribute, and `source` elements. The IDL attribute takes priority, followed by the content attribute, followed by the elements.

4.8.12.3 MIME types

A `media resource` can be described in terms of its type, specifically a `MIME type`, in some cases with a `codecs` parameter. (Whether the `codecs` parameter is allowed or not depends on the MIME type.) [RFC6381]Types are usually somewhat incomplete descriptions; for example "`video/mp4`" doesn't say anything except what the container type is, and even a type like "`video/mp4; codecs="avc1.42E01E, mp4a.40.2"`" doesn't include information like the actual bitrate (only the maximum bitrate). Thus, given a type, a user agent can often only know whether it might be able to play media of that type (with varying levels of confidence), or whether it definitely cannot play media of that type.

A type that the user agent knows it cannot render is one that describes a resource that the user agent definitely does not support, for example because it doesn't recognize the container type, or it doesn't support the listed codecs.

The `MIME type "application/octet-stream"` with no parameters is never a type that the user agent knows it cannot render. User agents must treat that type as equivalent to the lack of any explicit `Content-Type metadata` when it is used to label a potential `media resource`.

Note

Only the `MIME type "application/octet-stream"` with no parameters is special-cased here; if any parameter appears with it, it will be treated just like any other `MIME type`. This is a deviation from the rule that unknown `MIME type` parameters should be ignored.

For web developers (non-normative)

`media .canPlayType(type)`

Returns the empty string (a negative response), "maybe", or "probably" based on how confident the user agent is that it can play media resources of the given type.

MDN

[HTML MediaElement/canPlayType](#)

Support in all current engines.

Firefox3.5+Safari6+ChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet Explorer9+

Firefox AndroidYes Safari iOSYes Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidYes

The `canPlayType(type)` method must return the empty string if type is a type that the user agent knows it cannot render or is the type "`application/octet-stream`"; it must return "probably" if the user agent is confident that the type represents a `media resource` that it can render if used in with this `audio` or `video` element; and it must return "maybe" otherwise. Implementors are encouraged to return "probable" unless the type can be confidently established as being supported or not. Generally, a user agent should never return "probably" for a type that allows the `codecs` parameter if that parameter is not present.

Example

This script tests to see if the user agent supports a (fictional) new format to dynamically decide whether to use a `video` element or a plugin:

```
<section id="video">
<a href="#playing-cats.nrf">Download video</a></p>
<script>
var videoSection = document.getElementById('video');
var videoElement = videoSection.createElement('video');
var support = videoElement.canPlayType("video/x-new-fictional-format; codecs='kittens,bunnies'");
if (support == "probably") {
    // New Fictional Video Plugin
} else if (support == "maybe") {
    // we have a plugin instead
} else if (support == "") {
    // no support from browser and no plugin
}
videoElement = null;
if (videoElement) {
    while (videoSection.hasChildNodes()) {
        videoSection.removeChild(videoSection.firstChild);
    }
    videoElement.setAttribute("src", "#playing-cats.nrf");
    videoSection.appendChild(videoElement);
}</script>
```

Note

The `type` attribute of the `source` element allows the user agent to avoid downloading resources that use formats it cannot render.

4.8.12.4 Network states

For web developers (non-normative)

`media .networkState`

Returns the current state of network activity for the element, from the codes in the list below.

MDN

[HTML MediaElement/networkState](#)

Support in all current engines.

Firefox3.5+Safari6+Chrome43+

OperaYesEdge79+

Firefox AndroidYes Safari iOSYes Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidYes

As `media elements` interact with the network, their current network activity is represented by the `networkState` attribute. On getting, it must return the current network state of the element, which must be one of the following values:

`NETWORK_EMPTY` (numeric value 0)

The element has not yet been initialized. All attributes are in their initial states.

`NETWORK_IDLE` (numeric value 1)

The element's `resource selection algorithm` is active and has selected a `resource`, but it is not actually using the network at this time.

`NETWORK_LOADING` (numeric value 2)

The user agent is actively trying to download data.

The element's `resource selection algorithm` is active, but it has not yet found a `resource` to use.

The `resource selection algorithm` defined below describes exactly when the `networkState` attribute changes value and what events fire to indicate changes in this state.

4.8.12.5 Loading the media resource

For web developers (non-normative)

`media` `:load()`

Causes the element to reset and start selecting and loading a new `media resource` from scratch.

All `media elements` have a `canAutoplay` flag, which must begin in the true state, and a `delayingTheLoadEvent` flag, which must begin in the false state. While the `delayingTheLoadEvent` is true, the element must `delay the load event` of its document.

MDN

[HTML MediaElement.load](#)

Support in all current engines.

Firefox 3.6+ Safari 4+ Chrome 1+

Opera Yes Edge 79+

Edge (Legacy) 12+ Internet Explorer?

Firefox Android4+Safari iOSYes Chrome Android18+WebView Android1+Samsung Internet1.0+Opera AndroidYes

When the `load()` method on a `media element` is invoked, the user agent must run the `media element load algorithm`.

The `media element load algorithm` consists of the following steps.

1. Abort any already-running instance of the `resource selection algorithm` for this element.

2. Let `pending tasks` be a list of all `tasks` from the `media element's media element event task source` in one of the `task queues`.

3. For each task in `pending tasks` that would `resolve pending play promises` or `reject pending play promises`, immediately resolve or reject those promises in the order the corresponding tasks were queued.

4. Remove each `task` in `pending tasks` from its `task queue`.

Note

Basically, pending events and callbacks are discarded and promises in-flight to be resolved/rejected are resolved/rejected immediately when the `media element` starts loading a new resource.

5. If the `media element's networkState` is set to `NETWORK_LOADING` or `NETWORK_IDLE`, queue a task to `fire an event` named `abort` at the `media element`.

6. If the `media element's networkState` is not set to `NETWORK_EMPTY`, then:

1. Queue an element task on the `media element event task source` given the `media element` to `fire an event` named `emptied` at the `media element`.

2. If a fetching process is in progress for the `media element`, the user agent should stop it.

3. If the `media element's assigned media provider object` is a `MediaSource` object, then `detach` it.

4. Forget the `media element's media-resource-specific tracks`.

5. If `readyState` is not set to `HAVE_NOTHING`, then set it to that state.

6. If the `paused` attribute is false, then:

1. Set the `paused` attribute to true.

2. Take pending play promises and `reject pending play promises` with the result and an `"AbortError"` `DOMException`.

7. If `seeking` is true, set it to false.

8. Set the `currentPlaybackPosition` to 0.

Set the `officialPlaybackPosition` to 0.

If this changed the `officialPlaybackPosition`, then queue a task to `fire an event` named `timeupdate` at the `media element`.

9. Set the `timelineOffset` to Not-a-Number (NaN).

10. Update the `duration` attribute to Not-a-Number (NaN).

Note

The user agent will not fire a `durationchange` event for this particular change of the duration.

7. Set the `playbackRate` attribute to the value of the `defaultPlaybackRate` attribute.

8. Set the `error` attribute to null and the `canAutoplay` flag to true.

9. Invoke the `media element's resource selection algorithm`.

Note

Playback of any previously playing `media resource` for this element stops.

The `resource selection algorithm` for a `media element` is as follows. This algorithm is always invoked as part of a `task`, but one of the first steps in the algorithm is to return and continue running the remaining steps `in parallel`. In addition, this algorithm interacts closely with the `event loop` mechanism; in particular, it has `synchronous sections` (which are triggered as part of the `event loop` algorithm). Steps in such sections are marked with `☒`.

1. Set the element's `networkState` attribute to the `NETWORK_NO_SOURCE` value.

2. Set the element's `showPoster` flag to true.

3. Set the `media element's delaying-the-load-event` flag to true (this `delays the load event`).

4. `Await a stable state`, allowing the `task` that invoked this algorithm to continue. The `synchronous section` consists of all the remaining steps of this algorithm until the algorithm says the `synchronous section` has ended. (Steps in `synchronous sections` are marked with `☒`.)

5. `☒` If the `media element's blocked-on-user` flag is false, then `populate the list of pending text tracks`.

6. `☒` If the `media element` has an `assigned media provider object`, then let `mode` be `object`.

`☒` Otherwise, if the `media element` has no `assigned media provider object` but has a `src` attribute, then let `mode` be `attribute`.

`☒` Otherwise, if the `media element` does not have an `assigned media provider object` and does not have a `src` attribute, but does have a `source` element child, then let `mode` be `children` and let `candidate` be the first such `source` element child in `tree order`.

`☒` Otherwise the `media element` has no `assigned media provider object` and neither a `src` attribute nor a `source` element child: set the `networkState` to `NETWORK_EMPTY`, and return; the `synchronous section` ends.

7. `☒` Set the `media element's networkState` to `NETWORK_LOADING`.

8. `☒` Queue an element task on the `media element event task source` given the `media element` to `fire an event` named `loadstart` at the `media element`.

9. Run the appropriate steps from the following list:

If `mode` is `object`

1. `☒` Set the `currentSrc` attribute to the empty string.

2. End the `synchronous section`, continuing the remaining steps `in parallel`.

3. Run the `resource fetch algorithm` with `assigned media provider object`. If that algorithm returns without aborting `this` one, then the load failed.

4. `Failed with media provider`: Reaching this step indicates that the media resource failed to load. `Take pending play promises` and `queue a task` to run the `dedicated media source failure steps` with the result.

5. Wait for the `task` queued by the previous step to have executed.

6. Return. The element won't attempt to load another resource until this algorithm is triggered again.

If `mode` is `attribute`

1. `☒` If the `src` attribute's value is the empty string, then end the `synchronous section`, and jump down to the `failed with attribute` step below.

2. `☒` Let `urlString` and `uriRecord` be the `resulting URL string` and the `resulting URL record`, respectively, that would have resulted from `parsing the URL` specified by the `src` attribute's value relative to the `media element's node document` when the `src` attribute was last changed.

3. `☒` If `urlString` was obtained successfully, set the `currentSrc` attribute to `urlString`.

4. End the `synchronous section`, continuing the remaining steps `in parallel`.

5. If `uriRecord` was obtained successfully, run the `resource fetch algorithm` with `uriRecord`. If that algorithm returns without aborting `this` one, then the load failed.

6. `Failed with attribute`: Reaching this step indicates that the media resource failed to load or that the given `URL` could not be `parsed`. `Take pending play promises` and `queue a task` to run the `dedicated media source failure steps` with the result.

7. Wait for the `task` queued by the previous step to have executed.

8. Return. The element won't attempt to load another resource until this algorithm is triggered again.

Otherwise (`mode` is `children`)

1. `☒` Let `pointer` be a position defined by two adjacent nodes in the `media element's` child list, treating the start of the list (before the first child in the list, if any) and end of the list (after the last child in the list, if any) as nodes in their own right. One node is the node before `pointer`, and the other node is the node after `pointer`. Initially, let `pointer` be the position between the `candidate` node and the next node, if there are any, or the end of the list, if it is the last node.

As `nodes are inserted` and `removed` into the `media element`, `pointer` must be updated as follows:

Let `pointer` be the point between the node before `pointer` and the new node. In other words, insertions at `pointer` go after `pointer`.

If the node before `pointer` is removed

Let `pointer` be the point between the node after `pointer` and the node before `pointer`. In other words, `pointer` doesn't move relative to the remaining nodes.

If the node after `pointer` is removed

Let `pointer` be the point between the node before `pointer` and the node after `pointer`. Just as with the previous case, `pointer` doesn't move relative to the remaining nodes.

Other changes don't affect `pointer`.

2. ☒ *Process candidate*: If *candidate* does not have a `src` attribute, or if its `src` attribute's value is the empty string, then end the *synchronous section*, and jump down to the *failed with elements* step below.
3. ☒ Let *urlString* and *urlRecord* be the *resulting URL string* and the *resulting URL record*, respectively, that would have resulted from *parsing the URL* specified by *candidate*'s `src` attribute's value relative to the *candidate*'s *node document* when the `src` attribute was last changed.
4. ☒ If *urlString* was not obtained successfully, then end the *synchronous section*, and jump down to the *failed with elements* step below.
5. ☒ If *candidate* has a `type` attribute whose value, when parsed as a *MIME type* (including any codecs described by the `codecs` parameter, for types that define that parameter), represents a *type that the user agent knows it cannot render*, then end the *synchronous section*, and jump down to the *failed with elements* step below.
6. ☒ Set the `currentSrc` attribute to *urlString*.
7. End the *synchronous section*, continuing the remaining steps *in parallel*.
8. Run the *resource fetch algorithm* with *urlRecord*. If that algorithm returns without aborting this one, then the load failed.
9. *Failed with elements*: Queue an element task on the *media element event task source* given *candidate* to *fire an event* named `suspend` at *candidate*.
10. *Await a stable state*: The *synchronous section* consists of all the remaining steps of this algorithm until the algorithm says the *synchronous section* has ended. (Steps in *synchronous sections* are marked with ☒.)
11. ☒ Forget the media element's media-resource-specific tracks.
12. ☒ Find next candidate: Let *candidate* be null.
13. ☒ Search loop: If the node after *pointer* is the end of the list, then jump to the *waiting* step below.
14. ☒ If the node after *pointer* is a `source` element, let *candidate* be that element.
15. ☒ Advance *pointer* so that the node before *pointer* is now the node that was after *pointer*, and the node after *pointer* is the node after the node that used to be after *pointer*, if any.
16. ☒ If *candidate* is null, jump back to the *search loop* step. Otherwise, jump back to the process *candidate* step.
17. ☒ Waiting: Set the element's `networkState` attribute to the `NETWORK_NO_SOURCE` value.
18. ☒ Set the element's `showPosterFlag` to true.
19. ☒ Queue an element task on the *media element event task source* given the element to set the element's `delaying-the-load-event-flag` to false. This stops *delaying the load event*.
20. End the *synchronous section*, continuing the remaining steps *in parallel*.
21. Wait until the node after *pointer* is a node other than the end of the list. (This step might wait forever.)
22. *Await a stable state*: The *synchronous section* consists of all the remaining steps of this algorithm until the algorithm says the *synchronous section* has ended. (Steps in *synchronous sections* are marked with ☒.)
23. ☒ Set the element's `delaying-the-load-event-flag` back to true (this *delays the load event* again, in case it hasn't been fired yet).
24. ☒ Set the `networkState` back to `NETWORK_LOADING`.
25. ☒ Jump back to the *find next candidate* step above.

The dedicated media source failure steps with a list of promises *promises* are the following steps:

1. Set the `error` attribute to the result of *creating a MediaError* with `MEDIA_ERR_SRC_NOT_SUPPORTED`.
2. Forget the media element's media-resource-specific tracks.
3. Set the element's `networkState` attribute to the `NETWORK_NO_SOURCE` value.
4. Set the element's `showPosterFlag` to true.
5. *Fire an event* named `suspend` at the *media element*.
6. *Reject pending play promises* with *promises* and a `"NotSupportedError"` `COREException`.
7. Set the element's `delaying-the-load-event-flag` to false. This stops *delaying the load event*.

The *resource fetch algorithm* for a *media element* and a given *URL record* or *media provider object* is as follows:

1. If the algorithm was invoked with *media provider object* or a *URL record* whose *object* is a *media provider object*, then let *mode* be *local*. Otherwise let *mode* be *remote*.
2. If *mode* is *remote*, then let the *current media resource* be the resource given by the *URL record* passed to this algorithm; otherwise, let the *current media resource* be the resource given by the *media provider object*. Either way, the *current media resource* is now the element's *media resource*.
3. Remove all *media-resource-specific text tracks* from the *media element's list of pending text tracks*, if any.
4. Run the appropriate steps from the following list:

If *mode* is *remote*:

1. Optionally, run the following substeps. This is the expected behavior if the user agent intends to not attempt to fetch the resource until the user requests it explicitly (e.g. as a way to implement the `preload` attribute's `none` keyword).
 1. Set the `networkState` to `NETWORK_IDLE`.
 2. Queue an element task on the *media element event task source* given the element to *fire an event* named `suspend` at the element.
 3. Queue an element task on the *media element event task source* given the element to set the element's `delaying-the-load-event-flag` to false. This stops *delaying the load event*.
4. Wait for the task to be run.
5. Wait for an implementation-defined event (e.g. the user requesting that the media element begin playback).
6. Set the element's `delaying-the-load-event-flag` back to true (this *delays the load event* again, in case it hasn't been fired yet).
7. Set the `networkState` to `NETWORK_LOADING`.

2. Let *destination* be "auto" if the *media element* is an *audio* element and to "video" otherwise.

Let *request* be the result of *creating a potential-CORS request* given *current media resource's URL record*, *destination*, and the *media element's crossorigin* content attribute value.

Set *request's client* to the *media element's node document's relevant settings object*.

Fetch request.

The response's `unsafeResponse` obtained in this fashion, if any, contains the *media data*. It can be *CORS-same-origin* or *CORS-cross-origin*; this affects whether subtitles referenced in the *media data* are exposed in the API and, for *video* elements, whether a *canvas* gets tainted when the video is drawn on it.

The *stall timeout* is a user-agent defined length of time, which should be about three seconds. When a *media element* that is actively attempting to obtain *media data* has failed to receive any data for a duration equal to the *stall timeout*, the user agent must *queue a task* to *fire an event* named `stalled` at the element.

User agents may allow users to selectively block or slow *media data* downloads. When a *media element's* download has been blocked altogether, the user agent must act as if it was stalled (as opposed to acting as if the connection was closed). The rate of the download may also be throttled automatically by the user agent, e.g. to balance the download with other connections sharing the same bandwidth.

User agents may decide to not download more content at any time, e.g. after buffering five minutes of a one hour media resource, while waiting for the user to decide whether to play the resource or not, while waiting for user input in an interactive resource, or when the user navigates away from the page. When a *media element's* download has been suspended, the user agent must *queue a task* to set the `networkState` to `NETWORK_IDLE` and *fire an event* named `suspend` at the element. If and when downloading of the resource resumes, the user agent must *queue a task* to set the `networkState` to `NETWORK_LOADING`. Between the queuing of these tasks, the load is suspended (so *progress* events don't fire, as described above).

Note

The `preload` attribute provides a hint regarding how much buffering the author thinks is advisable, even in the absence of the `autoplay` attribute.

When a user agent decides to completely suspend a download, e.g. if it is waiting until the user starts playback before downloading any further content, the user agent must *queue a task* to set the element's `delaying-the-load-event-flag` to false. This stops *delaying the load event*.

The user agent may use whatever means necessary to fetch the resource (within the constraints put forward by this and other specifications); for example, reconnecting to the server in the face of network errors, using HTTP range retrieval requests, or switching to a streaming protocol. The user agent must consider a resource erroneous only if it has given up trying to fetch it.

To determine the format of the *media resource*, the user agent must use the *rules for sniffing audio and video specifically*.

While the load is not suspended (see below), every 350ms (± 200 ms) or for every byte received, whichever is least frequent, *queue a task* to *fire an event* named `progress` at the element.

The *networking task source tasks* to process the data as it is being fetched must each *immediately queue a task* to run the first appropriate steps from the *media data processing steps list* below. (A new task is used for this so that the work described below occurs relative to the *media element event task source* rather than the *networking task source*.)

When the *networking task source* has *queued* the last *task* as part of fetching the *media resource* (i.e. once the download has completed), if the fetching process completes without errors, including decoding the media data, and if all of the data is available to the user agent without network access, then, the user agent must move on to the *final step* below. This might never happen, e.g. when streaming an infinite resource such as Web radio, or if the resource is longer than the user agent's ability to cache data.

While the user agent might still need network access to obtain parts of the *media resource*, the user agent must remain on this step.

Example

For example, if the user agent has discarded the first half of a video, the user agent will remain at this step even once the *playback has ended*, because there is always the chance the user will seek back to the start. In fact, in this situation, once *playback has ended*, the user agent will end up firing a `suspend` event, as described earlier.

Otherwise (*mode* is *local*)

The resource described by the *current media resource*, if any, contains the *media data*. It is *CORS-same-origin*.

If the *current media resource* is a raw data stream (e.g. from a *File* object), then to determine the format of the *media resource*, the user agent must use the *rules for sniffing audio and video specifically*. Otherwise, if the data stream is pre-decoded, then the format is the format given by the relevant specification.

Whenever new data for the *current media resource* becomes available, *queue a task* to run the first appropriate steps from the *media data processing steps list* below.

When the *current media resource* is permanently exhausted (e.g. all the bytes of a *File* have been processed), if there were no decoding errors, then the user agent must move on to the *final step* below. This might never happen, e.g. if the *current media resource* is a *MediaStream*.

The *media data processing steps list* is as follows:

If the *media data* cannot be fetched at all, due to network errors, causing the user agent to give up trying to fetch the resource

If the *media data* can be fetched but is found to be in an unsupported format, or can otherwise not be rendered at all

DNS errors, HTTP 4xx and 5xx errors (and equivalents in other protocols), and other fatal network errors that occur before the user agent has established whether the *current media resource* is usable, as well as the file using an unsupported container format, or using unsupported codecs for all the data, must cause the user agent to execute the following steps:

1. The user agent should cancel the fetching process.

2. Abort this subalgorithm, returning to the *resource selection algorithm*.

If the *media resource* is found to have an audio track

1. Create an *AudioTrack* object to represent the audio track.

2. Update the *media element's audioTracks* attribute's *audioTrackList* object with the new *AudioTrack* object.

3. Let *enable* be *unknown*.

4. If either the *media resource* or the *URL* of the *current media resource* indicate a particular set of audio tracks to enable, or if the user agent has information that would facilitate the selection of specific audio tracks to improve the user's experience, then: if this audio track is one of the ones to enable, then set *enable* to *true*, otherwise, set *enable* to *false*.

This could be triggered by *media fragment syntax*, but it could also be triggered e.g. by the user agent selecting a 5.1 surround sound audio track over a stereo audio track.

5. If *enable* is still *unknown*, then, if the *media element* does not yet have an *enabled* audio track, then set *enable* to *true*, otherwise, set *enable* to *false*.

6. If *enable* is *true*, then enable this audio track, otherwise, do not enable this audio track.

If the `media_resource` is found to have a video track:

1. Create a `VideoTrack` object to represent the video track.
 2. Update the `media_element`'s `videoTracks` attribute's `VideoTrackList` object with the new `VideoTrack` object.
 3. Let `enable` be `unknown`.
 4. If either the `media_resource` or the `URL` of the current `media_resource` indicate a particular set of video tracks to enable, or if the user agent has information that would facilitate the selection of specific video tracks to improve the user's experience, then: if this video track is the first such video track, then set `enable` to `true`, otherwise, set `enable` to `false`.
- Example**
This could again be triggered by `media fragment syntax`.
5. If `enable` is still `unknown`, then, if the `media_element` does not yet have a `selected` video track, then set `enable` to `true`, otherwise, set `enable` to `false`.
 6. If `enable` is `true`, then select this track and unselect any previously selected video tracks, otherwise, do not select this video track. If other tracks are unselected, then a `change event` will be fired.
 7. Fire an event named `adetrack` at this `VideoTrackList` object, using `track@event`, with the `track` attribute initialized to the new `VideoTrack` object.

Once enough of the `media_data` has been fetched to determine the duration of the `media_resource`, its dimensions, and other metadata

This indicates that the resource is usable. The user agent must follow these substeps:

1. Establish the `media_timing` for the purposes of the `current playback position` and the `earliest possible position`, based on the `media_data`.
2. Update the `timeline_offset` to the date and time that corresponds to the zero time in the `media_timing` established in the previous step, if any. If no explicit time and date is given by the `media_resource`, the `timeline_offset` must be set to Not-a-Number (NaN).
3. Set the `current playback position` and the `official playback position` to the `earliest possible position`.
4. Update the `duration` attribute with the time of the last frame of the resource, if known, on the `media_timing` established above. If it is not known (e.g. a stream that is in principle infinite), update the `duration` attribute to the value positive Infinity.

Note

The user agent will queue a task to fire an event named `durationchange` at the element at this point.

5. For `video` elements, set the `videoWidth` and `videoHeight` attributes, and queue a task to fire an event named `resize` at the `media_element`.

Note

Further `resize` events will be fired if the dimensions subsequently change.

6. Set the `readyState` attribute to `HAVE_METADATA`.

Note

A `loadmetadata` DOM event will be fired as part of setting the `readyState` attribute to a new value.

7. Let `jumped` be false.
8. If the `media_element`'s `default playback start position` is greater than zero, then `seek` to that time, and let `jumped` be true.

9. Let the `media_element`'s `default playback start position` be zero.

10. Let the `initial playback position` be zero.

11. If either the `media_resource` or the `URL` of the current `media_resource` indicate a particular start time, then set the `initial playback position` to that time and, if `jumped` is still false, `seek` to that time.

Example

For example, with media formats that support `media fragment syntax`, the `fragment` can be used to indicate a start position.

12. If there is no `enabled` audio track, then enable an audio track. This will cause a `change` event to be fired.

13. If there is no `selected` video track, then select a video track. This will cause a `change` event to be fired.

Once the `readyState` attribute reaches `HAVE_CURRENT_DATA`, after the `loadmetadata` event has been fired, set the element's `delaying-the-load-event_flag` to false. This stops `delaying-the-load event`.

Note

A user agent that is attempting to reduce network usage while still fetching the metadata for each `media_resource` would also stop buffering at this point, following the rules described previously, which involve the `networkState` attribute switching to the `NETWORK_IDLE` value and a `suspend` event firing.

Note

The user agent is required to determine the duration of the `media_resource` and go through this step before playing.

Once the entire `media_resource` has been fetched (but potentially before any of it has been decoded)

Fire an event named `progress` at the `media_element`.

Set the `networkState` to `NETWORK_IDLE` and fire an event named `suspend` at the `media_element`.

If the user agent ever discards any `media_data` and then needs to resume the network activity to obtain it again, then it must queue a task to set the `networkState` to `NETWORK_LOADING`.

Note

If the user agent can keep the `media_resource` loaded, then the algorithm will continue to its final step below, which aborts the algorithm.

If the connection is interrupted after some `media_data` has been received, causing the user agent to give up trying to fetch the resource

Fatal network errors that occur after the user agent has established whether the `current media resource` is usable (i.e. once the `media_element`'s `readyState` attribute is no longer `HAVE_NETWORK`) must cause the user agent to execute the following steps:

1. The user agent should cancel the fetching process.
2. Set the `error` attribute to the result of creating a `MediaError` with `MEDIA_ERR_NETWORK`.
3. Set the element's `networkState` attribute to the `NETWORK_IDLE` value.
4. Set the element's `delaying-the-load-event_flag` to false. This stops `delaying-the-load event`.
5. Fire an event named `error` at the `media_element`.
6. Abort the overall `resource selection algorithm`.

If the `media_data` is corrupted

Fatal errors in decoding the `media_data` that occur after the user agent has established whether the `current media resource` is usable (i.e. once the `media_element`'s `readyState` attribute is no longer `HAVE_NETWORK`) must cause the user agent to execute the following steps:

1. The user agent should cancel the fetching process.
2. Set the `error` attribute to the result of creating a `MediaError` with `MEDIA_ERR_DECODE`.
3. Set the element's `networkState` attribute to the `NETWORK_IDLE` value.
4. Set the element's `delaying-the-load-event_flag` to false. This stops `delaying-the-load event`.
5. Fire an event named `error` at the `media_element`.
6. Abort the overall `resource selection algorithm`.

If the `media_data` fetching process is aborted by the user

The fetching process is aborted by the user, e.g. because the user pressed a "stop" button, the user agent must execute the following steps. These steps are not followed if the `load()` method itself is invoked while these steps are running, as the steps above handle that particular kind of abort.

1. The user agent should cancel the fetching process.
2. Set the `error` attribute to the result of creating a `MediaError` with `MEDIA_ERR_ABORTED`.
3. Fire an event named `abort` at the `media_element`.
4. If the `media_element`'s `readyState` attribute has a value equal to `HAVE NOTHING`, set the element's `networkState` attribute to the `NETWORK_EMPTY` value, set the element's `showPosterFlag` to true, and fire an event named `emptied` at the element. Otherwise, set the element's `networkState` attribute to the `NETWORK_IDLE` value.
5. Set the element's `delaying-the-load-event_flag` to false. This stops `delaying-the-load event`.
6. Abort the overall `resource selection algorithm`.

If the `media_data` can be fetched but has non-fatal errors or uses, in part, codecs that are unsupported, preventing the user agent from rendering the content completely correctly but not preventing playback altogether

The server returning data that is partially usable but cannot be optimally rendered must cause the user agent to render just the bits it can handle, and ignore the rest.

If the `media_resource` is found to declare a `media-resource-specific-text-track` that the user agent supports

If the `media_data` is `CORS-same-origin`, run the steps to expose a `media-resource-specific-text-track` with the relevant data.

Note

Cross-origin videos do not expose their subtitles, since that would allow attacks such as hostile sites reading subtitles from confidential videos on a user's intranet.

5. Final step: If the user agent ever reaches this step (which can only happen if the entire resource gets loaded and kept available): abort the overall `resource selection algorithm`.

When a `media_element` is forced to forget the `media_element`'s `media-resource-specific-tracks`, the user agent must remove from the `media_element`'s `list of text tracks` all the `media-resource-specific-text-tracks`, then empty the `media_element`'s `audioTracks` attribute's `audioTrackList` object, then empty the `media_element`'s `videoTracks` attribute's `VideoTrackList` object. No events (in particular, no `removeTrack` events) are fired as part of this; the `error` and `emptied` events, fired by the algorithms that invoke this one, can be used instead.

The `preloadAttribute` is an `enumerated attribute`. The following table lists the keywords and states for the attribute — the keywords in the left column map to the states in the cell in the second column on the same row as the keyword. The attribute can be changed even once the `media_resource` is being buffered or played; the descriptions in the table below are to be interpreted with that in mind.

Keyword	State	Description
<code>none</code>	<code>None</code>	Hints to the user agent that either the author does not expect the user to need the media resource, or that the server wants to minimize unnecessary traffic. This state does not provide a hint regarding how aggressively to actually download the media resource if buffering starts anyway (e.g. once the user hits "play").
<code>metadata</code>	<code>Metadata</code>	Hints to the user agent that the author does not expect the user to need the media resource, but that fetching the resource metadata (dimensions, track list, duration, etc.) and maybe even the first few frames, is reasonable. If the user agent precisely fetches no more than the metadata, then the <code>media_element</code> will end up with its <code>readyState</code> set to <code>NETWORK_LOADED</code> . This state provides a hint that bandwidth is to be considered scarce, e.g. suggesting throttling the download so that the media data is obtained at the slowest possible rate that still maintains consistently playback.
<code>auto</code>	<code>Automatic</code>	Hints to the user agent that the user agent can put the user's needs first without risk to the server, up to and including optimistically downloading the entire resource.

The empty string is also a valid keyword, and maps to the `Automatic` state. The attributes `missingValueDefault` and `invalidValueDefault` are user-agent defined, though the `Metadata` state is suggested as a compromise between reducing server load and providing an optimal user experience.

Note

Authors might switch the attribute from `"none"` or `"metadata"` to `"auto"` dynamically once the user begins playback. For example, on a page with many videos this might be used to indicate that the many videos are not to be downloaded unless requested, but that once one is requested it is to be downloaded aggressively.

The `preload` attribute is intended to provide a hint to the user agent about what the author thinks will lead to the best user experience. The attribute may be ignored altogether, for example based on explicit user preferences or based on the available connectivity.

The `preload` IDL attribute must `reflect` the content attribute of the same name, `limited to only known values`.

Note
The `autoplay` attribute can override the `preload` attribute (since if the media plays, it naturally has to buffer first, regardless of the hint given by the `preload` attribute). Including both is not an error, however.

For web developers (non-normative)

`media.buffered`

Returns a `TimeRanges` object that represents the ranges of the `media resource` that the user agent has buffered.

The `buffered` attribute must return a new static `normalized TimeRanges` object that represents the ranges of the `media resource`, if any; that the user agent has buffered, at the time the attribute is evaluated. User agents must accurately determine the ranges available, even for media streams where this can only be determined by tedious inspection.

Note

Typically this will be a single range anchored at the zero point, but if, e.g. the user agent uses HTTP range requests in response to seeking, then there could be multiple ranges.

User agents may discard previously buffered data.

Note

Thus, a time position included within a range of the objects returned by the `buffered` attribute at one time can end up being not included in the range(s) of objects returned by the same attribute at later times.

⚠️ Warning!

Returning a new object each time is a bad pattern for attribute getters and is only enshrined here as it would be costly to change it. It is not to be copied to new APIs.

4.8.12.6 Offsets into the media resource

For web developers (non-normative)

`media.duration`

Returns the length of the `media resource`, in seconds, assuming that the start of the `media resource` is at time zero.

Returns NaN if the duration isn't available.

Returns Infinity for unbounded streams.

`media.currentTime [= value]`

Returns the `official playback position`, in seconds.

Can be set, to seek to the given time.

A `media resource` has a `media timeline` that maps times (in seconds) to positions in the `media resource`. The origin of a timeline is its earliest defined position. The duration of a timeline is its last defined position.

Establishing the `media timeline` if the `media resource` somehow specifies an explicit timeline whose origin is not negative (i.e. gives each frame a specific time offset and gives the first frame a zero or positive offset), then the `media timeline` should be that timeline. (Whether the `media resource` can specify a timeline or not depends on the `media resource's` format.) If the `media resource` specifies an explicit start time and date, then that time and date should be considered the zero point in the `media timeline`; the `timeline offset` will be the time and date, exposed using the `getStartTime()` method.

If the `media resource` has a discontinuous timeline, the user agent must extend the timeline used at the start of the resource across the entire resource, so that the `media timeline` of the `media resource` increases linearly starting from the `earliest possible position` (as defined below), even if the underlying `media data` has out-of-order or even overlapping time codes.

Example

For example, if two clips have been concatenated into one video file, but the video format exposes the original times for the two clips, the video data might expose a timeline that goes, say, 00:15..00:29 and then 00:05..00:38. However, the user agent would not expose those times; it would instead expose the times as 00:15..00:29 and 00:29..01:02, as a single video.

In the rare case of a `media resource` that does not have an explicit timeline, the zero time on the `media timeline` should correspond to the first frame of the `media resource`. In the even rarer case of a `media resource` with no explicit timings of any kind, not even frame durations, the user agent must itself determine the time for each frame in a user-agent-defined manner.

Note

An example of a file format with no explicit timeline but with explicit frame durations is the Animated GIF format. An example of a file format with no explicit timings at all is the JPEG-push format (`multipart/x-mixed-replace` with JPEG frames, often used as the format for MJPEG streams).

If, in the case of a resource with no timing information, the user agent will nonetheless be able to seek to an earlier point than the first frame originally provided by the server, then the zero time should correspond to the earliest seekable time of the `media resource`; otherwise, it should correspond to the first frame received from the server (the point in the `media resource` at which the user agent began receiving the stream).

Note

At the time of writing, there is no known format that lacks explicit frame time offsets yet still supports seeking to a frame before the first frame sent by the server.

Example

Consider a stream from a TV broadcaster, which begins streaming on a sunny Friday afternoon in October, and always sends connecting user agents the media data on the same media timeline, with its zero time set to the start of this stream. Months later, user agents connecting to this stream will find that the first frame they receive has a time with millions of seconds. The `getStartTime()` method would always return the date that the broadcast started; this would allow controllers to display real times in their scrubber (e.g. "2:30pm") rather than a time relative to when the broadcast began ("8 months, 4 hours, 12 minutes, and 23 seconds").

Consider a stream that carries a video with several concatenated fragments, broadcast by a server that does not allow user agents to request specific times, but instead just streams the video data in a predetermined order, with the first frame delivered always being identified as the frame with time zero. If a user agent connects to this stream and receives fragments defined as covering timestamps 2010-03-20T23:15:00 UTC to 2010-03-21T00:05:00 UTC and 2010-02-12T14:25:00 UTC to 2010-02-12T14:35:00 UTC, it would expose this with a `media timeline` starting at 0s and extending to 3,600s (one hour). Assuming the streaming server disconnected at the end of the second clip, the `getStartTime()` attribute would then return 3,600. The `getStartTime()` method would return a `date` object with a time corresponding to 2010-03-20T23:15:00 UTC. However, if a different user agent connected five minutes later, it would (presumably) receive fragments covering timestamps 2010-03-20T23:20:00 UTC to 2010-02-12T14:35:00 UTC, and would expose this with a `media timeline` starting at 0s and extending to 3,300s (fifty five minutes). In this case, the `getStartTime()` method would return a `date` object with a time corresponding to 2010-03-20T23:20:00 UTC.

In both of these examples, the `getStartTime` attribute would give the ranges that the controller would want to actually display in its UI; typically, if the servers don't support seeking to arbitrary times, this would be the range of time from the moment the user agent connected to the stream up to the latest frame that the user agent has obtained; however, if the user agent starts discarding earlier information, the actual range might be shorter.

In any case, the user agent must ensure that the `earliest possible position` (as defined below) using the established `media timeline`, is greater than or equal to zero.

The `media timeline` also has an associated clock. Which clock is used is user-agent-defined, and may be `media resource`-dependent, but it should approximate the user's wall clock.

`Media elements` have a `current playback position`, which must initially (i.e. in the absence of `media data`) be zero seconds. The `current playback position` is a time on the `media timeline`.

`Media elements` also have an `official playback position`, which must initially be set to zero seconds. The `official playback position` is an approximation of the `current playback position` that is kept stable while scripts are running.

`Media elements` also have a `default playback start position`, which must initially be set to zero seconds. This time is used to allow the element to be seeked even before the media is loaded.

Each `media element` has a `show poster` flag. When a `media element` is created, this flag must be set to true. This flag is used to control when the user agent is to show a poster frame for a `video element` instead of showing the video contents.

⚠️ DMN

HTML MediaElement/currentTime

Support in all current engines.

Firefox3.5+afari6+Chrome43+

OperaYesEdge79+

Edge (Legacy)12+Internet Explorer9+

Firefox AndroidYesSafari iOSYesChrome Android43+WebView Android43+Samsung Internet4.0+Opera AndroidYes

The `currentTime` attribute, on getting, returns the `media element's default playback start position`, unless that is zero, in which case it must return the element's `official playback position`. The returned value must be expressed in seconds. On setting, if the `media element's readyState` is `HAVE NOTHING`, then it must set the `media element's default playback start position` to the new value; otherwise, it must set the `official playback position` to the new value and then `seek` to the new value. The new value must be interpreted as being in seconds.

If the `media resource` is a streaming resource, then the user agent might be unable to obtain certain parts of the resource after it has expired from its buffer. Similarly, some `media resources` might have a `media timeline` that doesn't start at zero. The `earliest possible position` is the earliest position in the stream or resource that the user agent can ever obtain again. It is also a time on the `media timeline`.

Note

The `earliest possible position` is not explicitly exposed in the API; it corresponds to the start time of the first range in the `seekable` attribute's `TimeRanges` object, if any, or the `current playback position` otherwise.

When the `earliest possible position` changes, then: if the `current playback position` is before the `earliest possible position`, the user agent must `seek` to the `earliest possible position`; otherwise, if the user agent has not fired a `timeupdate` event at the element in the past 15 to 250ms and is not still running event handlers for such an event, then the user agent must `queue a task to fire an event named timenotify at the element`.

Note

Because of the above requirement and the requirement in the `resource fetch algorithm` that kicks in when the `metadata` of the clip becomes known, the `current playback position` can never be less than the `earliest possible position`.

If at any time the user agent learns that an audio or video track has ended and all `media data` relating to that track corresponds to parts of the `media timeline` that are *before* the `earliest possible position`, the user agent may `queue a task` to run these steps:

1. Remove the track from the `audioTracks` attribute's `AudioTrackList` object or the `videoTracks` attribute's `VideoTrackList` object as appropriate.

2. Fire an event named `panesettrack` on the `media element`'s aforementioned `audioTracks` or `videoTracks` object, using `TrackEvent`, with the `track` attribute initialized to the `AudioTrack` or `VideoTrack` object representing the track.

⚠️ DMN

HTML MediaElement/duration

Support in all current engines.

Firefox3.5+afari6+Chrome43+

OperaYesEdge79+

Edge (Legacy)12+Internet Explorer9+

Firefox AndroidYesSafari iOSYesChrome Android43+WebView Android43+Samsung Internet4.0+Opera AndroidYes

The `duration` attribute must return the time of the end of the `media resource`, in seconds, on the `media timeline`. If no `media data` is available, then the attributes must return the Not-a-Number (NaN) value. If the `media resource` is not known to be bounded (e.g. streaming radio, or a live event with no announced end time), then the attribute must return the positive Infinity value.

The user agent must determine the duration of the `media resource` before playing any part of the `media data` and before setting `readyState` to a value equal to or greater than `HAVE_METADATA`, even if doing so requires fetching multiple parts of the resource.

When the length of the `media resource` changes to a known value (e.g. from being unknown to known, or from a previously established length to a new length) the user agent must `queue a task to fire an event named durationchange at the media element`. (The event is not fired when the duration is reset as part of loading a new media resource.) If the duration is changed such that the `current playback position` ends up being greater than the time of the end of the `media resource`, then the user agent must also `seek` to the time of the end of the `media resource`.

Example

If an "infinite" stream ends for some reason, then the duration would change from positive Infinity to the time of the last frame or sample in the stream, and the `durationchange` event would be fired. Similarly, if the user agent initially estimated the `media resource's` duration instead of determining it precisely, and later revises the estimate based on new information, then the duration would change and the `durationchange` event would be fired.

Some video files also have an explicit date and time corresponding to the zero time the `media timeline`, known as the `timeline offset`. Initially, the `timeline offset` must be set to Not-a-Number (NaN).

The `getStartTime()` method must return a `new Date` object representing the current `timeline offset`.

The `loop` attribute is a `boolean attribute` that, if specified, indicates that the `media element` is to seek back to the start of the `media resource` upon reaching the end.

4.8.12.7 Ready states

For web developers (non-normative)

media . readyState

Returns a value that expresses the current state of the element with respect to rendering the `current playback position`, from the codes in the list below.

Media elements have a `ready state`, which describes to what degree they are ready to be rendered at the `current playback position`. The possible values are as follows; the ready state of a media element at any particular time is the greatest value describing the state of the element:

`HAVE NOTHING` (numeric value 0)

No information regarding the `media resource` is available. No data for the `current playback position` is available. Media elements whose `networkState` attribute are set to `NETWORK_EMPTY` are always in the `HAVE NOTHING` state.

`HAVE_METADATA` (numeric value 1)

Enough of the resource has been obtained that the duration of the resource is available. In the case of a `video` element, the dimensions of the video are also available. No `media data` is available for the immediate `current playback position`.

`HAVE_CURRENT_DATA` (numeric value 2)

Data for the immediate `current playback position` is available, but either not enough data is available that the user agent could successfully advance the `current playback position` in the `direction of playback` at all without immediately reverting to the `HAVE_METADATA` state, or there is no more data to obtain in the `direction of playback`. For example, in video this corresponds to the user agent having data from the current frame, but not the next frame, when the `current playback position` is at the end of the current frame; and to when `playback has ended`.

`HAVE_FUTURE_DATA` (numeric value 3)

Data for the immediate `current playback position` is available, as well as enough data for the user agent to advance the `current playback position` in the `direction of playback` at least a little without immediately reverting to the `HAVE_METADATA` state, and the `text tracks are ready`. For example, in video this corresponds to the user agent having data for at least the current frame and the next frame when the `current playback position` is at the instant in time between the two frames, or to the user agent having the video data for the current frame and audio data to keep playing at least a little when the `current playback position` is in the middle of a frame. The user agent cannot be in this state if `playback has ended`, as the `current playback position` can never advance in this case.

`HAVE_ENOUGH_DATA` (numeric value 4)

All the conditions described for the `HAVE_FUTURE_DATA` state are met, and, in addition, either of the following conditions is also true:

- The user agent estimates that data is being fetched at a rate where the `current playback position`, if it were to advance at the element's `playbackRate`, would not overtake the available data before playback reaches the end of the `media resource`.
- The user agent has entered a state where waiting longer will not result in further data being obtained, and therefore nothing would be gained by delaying playback any further. (For example, the buffer might be full.)

Note

In practice, the difference between `HAVE_METADATA` and `HAVE_CURRENT_DATA` is negligible. Really the only time the difference is relevant is when painting a `video` element onto a `canvas`, where it distinguishes the case where something will be drawn (`HAVE_CURRENT_DATA` or greater) from the case where nothing is drawn (`HAVE_METADATA` or less). Similarly, the difference between `HAVE_CURRENT_DATA` (only the current frame) and `HAVE_FUTURE_DATA` (at least this frame and the next) can be negligible (in the extreme, only one frame). The only time that distinction really matters is when a page provides an interface for "frame-by-frame" navigation.

When the ready state of a `media element` whose `networkState` is not `NETWORK_EMPTY`, changes, the user agent must follow the steps given below:

1. Apply the first applicable set of substeps from the following list:

If the previous ready state was `HAVE NOTHING`, and the new ready state is `HAVE_METADATA`

Note Queue an element task on the media element event task source given the element to fire an event named `loadedmetadata` at the element.

Note Before this task is run, as part of the event loop mechanism, the rendering will have been updated to resize the `video` element if appropriate.

If the previous ready state was `HAVE_METADATA` and the new ready state is `HAVE_CURRENT_DATA` or greater

If this is the first time this occurs for this `media element` since the `load()` algorithm was last invoked, the user agent must queue a task to fire an event named `loadeddata` at the element.

If the new ready state is `HAVE_FUTURE_DATA` or `HAVE_ENOUGH_DATA`, then the relevant steps below must then be run also.

If the previous ready state was `HAVE_FUTURE_DATA` or more, and the new ready state is `HAVE_CURRENT_DATA` or less

If the `media element` was potentially playing before its `readystate` attribute changed to a value lower than `HAVE_FUTURE_DATA`, and the element has not `ended playback`, and playback has not `stopped due to errors`, `paused for user interaction`, or `paused for in-band content`, the user agent must queue a task to fire an event named `timeupdate` at the element, and queue a task to fire an event named `waiting` at the element.

If the previous ready state is less, the user agent must notify about playing for the element.

If the new ready state is `HAVE_ENOUGH_DATA`

If the previous ready state was `HAVE_CURRENT_DATA` or less, the user agent must queue a task to fire an event named `canplay` at the element, and, if the element's `caused` attribute is false, `notify about playing` for the element.

The user agent must queue a task to fire an event named `canplaythrough` at the element.

If the element is not `eligible for autoplay`, then the user agent must abort these substeps.

The user agent may run the following substeps:

Note

This specification doesn't define the precise timing for when the intersection is tested, but it is suggested that the timing match that of the Intersection Observer API. [INTERSECTIONOBSERVER]

1. Set the `paused` attribute to false.

2. If the element's `show poster` flag is true, set it to false and run the `time marches on` steps.

3. Queue an element task on the media element event task source given the element to fire an event named `play` at the element.

4. Notify about playing for the element.

Alternatively, if the element is a `video` element, the user agent may start observing whether the element `intersects the viewport`. When the element starts `intersecting the viewport`, if the element is still `eligible for autoplay`, run the substeps above. Optionally, when the element stops `intersecting the viewport`, if the `can autoplay` flag is still true and the `autoplay` attribute is still specified, run the following substeps:

Note

This specification doesn't define the precise timing for when the intersection is tested, but it is suggested that the timing match that of the Intersection Observer API. [INTERSECTIONOBSERVER]

1. Run `internal pause steps` and set the `can autoplay` flag to true.

2. Queue an element task on the media element event task source given the element to fire an event named `pause` at the element.

Note

The substeps for playing and pausing can run multiple times as the element starts or stops `intersecting the viewport`, as long as the `can autoplay` flag is true.

Note

User agents do not need to support `autoplay`, and it is suggested that user agents honor user preferences on the matter. Authors are urged to use the `autoplay` attribute rather than using script to force the video to play, so as to allow the user to override the behavior if so desired.

Note It is possible for the ready state of a media element to jump between these states discontinuously. For example, the state of a media element can jump straight from `HAVE_METADATA` to `HAVE_ENOUGH_DATA` without passing through the `HAVE_CURRENT_DATA` and `HAVE_FUTURE_DATA` states.

MDN

HTML MediaElement.readyState

Support in all current engines.

Firefox 3.5+afari6+Chrome43+

OperaYesEdge79+

Firefox AndroidYesSafari iOSYesChrome Android43+WebView Android43+Samsung Internet4.0+Opera AndroidYes

The `readyState` IDL attribute must, on getting, return the value described above that describes the current ready state of the `media element`.

The `autoplay` attribute is a `boolean attribute`. When present, the user agent (as described in the algorithm described herein) will automatically begin playback of the `media resource` as soon as it can do so without stopping.

Note

Authors are urged to use the `autoplay` attribute rather than using script to trigger automatic playback, as this allows the user to override the automatic playback when it is not desired, e.g. when using a screen reader. Authors are also encouraged to consider not using the automatic playback behavior at all, and instead to let the user agent wait for the user to start playback explicitly.

MDN

The `autoplay` IDL attribute must reflect the content attribute of the same name.

4.8.12.8 Playing the media resource

For web developers (non-normative)

media . paused

Returns true if playback is paused; false otherwise.

media . ended

Returns true if playback has reached the end of the `media resource`.

media . defaultPlaybackRate [= value]

Returns the default rate of playback, for when the user is not fast-forwarding or reversing through the `media resource`.

Can be set, to change the default rate of playback.

The default rate has no direct effect on playback, but if the user switches to a fast-forward mode, when they return to the normal playback mode, it is expected that the rate of playback will be returned to the default rate of playback.

media . playbackRate [= value]

Returns the current rate of playback, where 1.0 is normal speed.

Can be set, to change the rate of playback.

media . played

Returns a `TimeRanges` object that represents the ranges of the `media resource` that the user agent has played.

media . play()

media : paused()

Sets the `paused` attribute to true, loading the `media resource` if necessary.

MDN**HTML MediaElement/pause**

Support in all current engines.

Firefox3.5+afari6+Chrome43+

OperaYesEdge79+

Edge (Legacy)12+Internet Explorer9+

Firefox AndroidYesSafari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

The `paused` attribute represents whether the `media element` is paused or not. The attribute must initially be true.

A `media element` is a *blocked media element* if its `readyState` attribute is in the `HAVE NOTHING` state, the `HAVE_METADATA` state, or if the element has `paused for user interaction` or `paused for in-band content`.

A `media element` is said to be *potentially playing* when its `paused` attribute is false, the element has not `ended playback`, playback has not `stopped due to errors`, and the element is not a `blocked media element`.

Note

A `playing` DOM event can be fired as a result of an element that is *potentially playing* stopping playback due to its `readyState` attribute changing to a value lower than `HAVE_FUTURE_DATA`.

A `media element` is said to be *eligible for autoplay* when all of the following conditions are met:

- Its `canAutoplay flag` is true.
- Its `paused` attribute is true.
- Its `src` attribute is specified.
- Its `node document's active sandboxing flag set` does not have the `sandboxed automatic features browsing context flag` set.
- Its `node document` is allowed to use the `"autoplay"` feature.

A `media element` is said to be *allowed to play* if the user agent and the system allow media playback in the current context.

Example

For example, a user agent could allow playback only when the `media element's Window object` has `transient activation`, but an exception could be made to allow playback while muted.

A `media element` is said to have *ended playback* when:

- The element's `readyState` attribute is `HAVE_METADATA` or greater, and
- Either:
 - The `current playback position` is the end of the `media resource`, and
 - The `direction of playback` is forwards, and
 - The `media element` does not have a `loop` attribute specified.

Or:

- The `current playback position` is the `earliest possible position`, and
- The `direction of playback` is backwards.

MDN**HTML MediaElement/ended**

Support in all current engines.

Firefox3.5+afari6+Chrome43+

OperaYesEdge79+

Edge (Legacy)12+Internet Explorer9+

Firefox AndroidYesSafari iOSYesChrome Android43+WebView Android43+Samsung Internet4.0+Opera AndroidYes

The `ended` attribute must return true if, the last time the `event loop` reached `step 1`, the `media element` had `ended playback` and the `direction of playback` was forwards, and false otherwise.

A `media element` is said to have *stopped due to errors* when the element's `readyState` attribute is `HAVE_METADATA` or greater, and the user agent encounters a non-fatal error during the processing of the `media data`, and due to that error, is not able to play the content at the `current playback position`.

A `media element` is said to have *paused for user interaction* when its `paused` attribute is false, the `readyState` attribute is either `HAVE_FUTURE_DATA` or `HAVE_ENOUGH_DATA`, and the user agent has reached a point in the `media resource` where the user has to make a selection for the resource to continue.

It is possible for a `media element` to have both `ended playback` and `paused for user interaction` at the same time.

When a `media element` that is *potentially playing* stops playing because it has `paused for user interaction`, the user agent must `queue a task` to `fire an event` named `timeupdate` at the element.

A `media element` is said to have *paused for in-band content* when its `paused` attribute is false, the `readyState` attribute is either `HAVE_FUTURE_DATA` or `HAVE_ENOUGH_DATA` and the user agent has suspended playback of the `media resource` in order to play content that is temporally anchored to the `media resource` and has a nonzero length, or to play content that is temporally anchored to a segment of the `media resource` but has a length longer than that segment.

Example

One example of when a `media element` would be *paused for in-band content* is when the user agent is playing `audio descriptions` from an external WebVTT file, and the synthesized speech generated for a cue is longer than the time between the `text track cue start time` and the `text track cue end time`.

When the `current playback position` reaches the end of the `media resource` when the `direction of playback` is forwards, then the user agent must follow these steps:

1. If the `media element` has a `loop` attribute specified, then `seek` to the `earliest possible position` of the `media resource` and return.
2. As defined above, the `ended` IDL attribute starts returning true once the `event loop` returns to `step 1`.
3. `Queue an event task` on the `media element event task source` given the `media element` and the following steps:
 1. `Fire an event` named `timeupdate` at the `media element`.
 2. If the `media element` has `ended playback`, the `direction of playback` is forwards, and `paused` is false, then:
 1. Set the `paused` attribute to true.
 2. `Fire an event` named `pause` at the `media element`.
 3. `Take pending play promises` and `reject pending play promises` with the result and an `"abortError"` `DOMException`.
 4. `Fire an event` named `ended` at the `media element`.

When the `current playback position` reaches the `earliest possible position` of the `media resource` when the `direction of playback` is backwards, then the user agent must only `queue a task` to `fire an event` named `timeupdate` at the element.

Note

The word "reaches" here does not imply that the `current playback position` needs to have changed during normal playback; it could be via `seeking`, for instance.

MDN**HTML MediaElement/defaultPlaybackRate**

Support in all current engines.

Firefox20+SafariYesChrome43+

OperaYesEdge79+

Edge (Legacy)12+Internet Explorer9+

Firefox Android20+Safari iOSYesChrome Android43+WebView Android43+Samsung Internet4.0+Opera Android?

The `defaultPlaybackRate` attribute gives the desired speed at which the `media resource` is to play, as a multiple of its intrinsic speed. The attribute is mutable: on getting it must return the last value it was set to, or 1.0 if it hasn't yet been set; on setting the attribute must be set to the new value.

Note

The `defaultPlaybackRate` is used by the user agent when it exposes a user interface to the user.

MDN**HTML MediaElement/playbackRate**

Support in all current engines.

Firefox20+SafariYesChrome43+

OperaYesEdge79+

Edge (Legacy)12+Internet Explorer9+

Firefox Android20+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera Android?

The `playbackRate` attribute gives the effective playback rate, which is the speed at which the `media resource` plays, as a multiple of its intrinsic speed. If it is not equal to the `defaultPlaybackRate`, then the implication is that the user is using a feature such as fast forward or slow motion playback. The attribute is mutable: on getting it must return the last value it was set to, or 1.0 if it hasn't yet been set; on setting, the user agent must follow these steps:

1. If the given value is not supported by the user agent, then throw a `"notSupported"` `DOMException`.
2. Set `playbackRate` to the new value, and if the element is *potentially playing*, change the playback speed.

When the `defaultPlaybackRate` or `playbackRate` attributes change value (either by being set by script or by being changed directly by the user agent, e.g. in response to user control) the user agent must `queue a task` to `fire an event` named `ratechange` at the `media element`.

The `played` attribute must return a new static `normalized Range object` that represents the ranges of points on the `media timeline` of the `media resource` reached through the usual monotonic increase of the `current playback position` during normal playback, if any, at the time the attribute is evaluated.

⚠ Warning!

Returning a new object each time is a bad pattern for attribute getters and is only enshrined here as it would be costly to change it. It is not to be copied to new APIs.

Each `media element` has a list of `pending play promises`, which must initially be empty.

To take pending play promises for a `media element`, the user agent must run the following steps:

1. Let `promises` be an empty list of promises.
2. Copy the `media element's list of pending play promises` to `promises`.
3. Clear the `media element's list of pending play promises`.
4. Return `promises`.

To reject pending play promises for a `media element` with a list of promise `promises` and an exception name `error`, the user agent must reject each promise in `promises` with `error`.

To notify about playing for a `media element`, the user agent must run the following steps:

1. Take pending play promises and let `promises` be the result.
2. Queue an element task on the `media element event task source` give the element and the following steps:
 1. Fire an event named `playing` at the element.
 2. Resolve pending play promises with `promises`.

OMN

HTML MediaElement/play

Support in all current engines.

Firefox3.5+Safari6+Chrome1+

Opera10.5+Edge79+

Edge (Legacy)12+Internet Explorer9+

Firefox Android4+Safari iOS6+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android11+

When the `play()` method on a `media element` is invoked, the user agent must run the following steps.

1. If the `media element` is not allowed to play, return a promise rejected with a "`NotAllowedError`" `POMEception`.
2. If the `media element`'s `error` attribute is not null and its `code` is `MEDIA_ERR_SRC_NOT_SUPPORTED`, return a promise rejected with a "`NotSupportedError`" `POMEception`.

Note

This means that the dedicated media source failure steps have run. Playback is not possible until the `media element load algorithm` clears the `error` attribute.

3. Let `promise` be a new promise and append `promise` to the `list of pending play promises`.
4. Run the `internal play steps` for the `media element`.
5. Return `promise`.

The `internal play steps` for a `media element` are as follows:

1. If the `media element`'s `networkState` attribute has the value `NETWORK_EMPTY`, invoke the `media element's resource selection algorithm`.
2. If the `playback has ended` and the `direction of playback` is forwards, seek to the `earliest possible position` of the `media resource`.
3. If the `media element`'s `paused` attribute is true, then:
 1. Change the value of `paused` to false.
 2. If the `show poster flag` is true, set the element's `show poster flag` to false and run the `time marches on` steps.
 3. Queue an element task on the `media element event task source` given the element to fire an event named `play` at the element.
 4. If the `media element`'s `readyState` attribute has the value `HAVE NOTHING`, `HAVE_METADATA`, or `HAVE CURRENT DATA`, queue a task to fire an event named `waiting` at the element.
- Otherwise, the `media element`'s `readyState` attribute has the value `HAVE FUTURE DATA` or `HAVE ENOUGH DATA`; notify about playing for the element.
4. Otherwise, if the `media element`'s `readyState` attribute has the value `HAVE FUTURE DATA` or `HAVE ENOUGH DATA`, take pending play promises and queue a task to resolve pending play promises with the result.

Note

The media element is already playing. However, it's possible that `promise` will be rejected before the queued task is run.

5. Set the `media element`'s `can autoplay flag` to false.

OMN

When the `pause()` method is invoked, and when the user agent is required to pause the `media element`, the user agent must run the following steps:

1. If the `media element`'s `networkState` attribute has the value `NETWORK_EMPTY`, invoke the `media element's resource selection algorithm`.
2. Run the `internal pause steps` for the `media element`.

The `internal pause steps` for a `media element` are as follows:

1. Set the `media element`'s `can autoplay flag` to false.
2. If the `media element`'s `paused` attribute is false, run the following steps:
 1. Change the value of `paused` to true.
 2. Take pending play promises and let `promises` be the result.
 3. Queue an element task on the `media element event task source` given the element and the following steps:
 1. Fire an event named `timeupdate` at the element.
 2. Fire an event named `pause` at the element.
 3. Reject pending play promises with `promises` and an "`abortError`" `POMEception`.
 4. Set the `official playback position` to the `current playback position`.

If the element's `playbackRate` is positive or zero, then the `direction of playback` is forwards. Otherwise, it is backwards.

When a `media element` is potentially playing and its `document` is a fully active `Document`, its `current playback position` must increase monotonically at the element's `playbackRate` units of media time per unit time of the `media timeline`'s clock. (This specification always refers to this as an *increase*, but that increase could actually be a *decrease* if the element's `playbackRate` is negative.)

Note

The element's `playbackRate` can be 0.0, in which case the `current playback position` doesn't move, despite playback not being paused (`paused` doesn't become true, and the `pause` event doesn't fire).

Note

This specification doesn't define how the user agent achieves the appropriate playback rate — depending on the protocol and media available, it is plausible that the user agent could negotiate with the server to have the server provide the media data at the appropriate rate, so that (except for the period between when the rate is changed and when the server updates the stream's playback rate) the client doesn't actually have to drop or interpolate any frames.

Any time the user agent provides a stable state, the `official playback position` must be set to the `current playback position`.

While the `direction of playback` is backwards, any corresponding audio must be muted. While the element's `playbackRate` is so low or so high that the user agent cannot play audio usefully, the corresponding audio must also be muted. If the element's `playbackRate` is not 1.0, the user agent may apply pitch adjustments to the audio as necessary to render it faithfully.

When a `media element` is potentially playing, its audio data played must be synchronized with the `current playback position` at the element's `effective media volume`. The user agent must play the audio from audio tracks that were enabled when the `event loop` last reached `step 1`.

When a `media element` is not potentially playing, audio must not play for the element.

`Media elements` that are potentially playing while not in a `document` must not play any video, but should play any audio component. Media elements must not stop playing just because all references to them have been removed; only once a media element is in a state where no further audio could ever be played by that element may the element be garbage collected.

Note

It is possible for an element to which no explicit references exist to play audio, even if such an element is not still actively playing: for instance, it could be unpause and stalled waiting for content to buffer, or it could be still buffering, but with a `queued` event listener that begins playback. Even a media element whose `media resource` has no audio tracks could eventually play audio again if it had an event listener that changes the `media resource`.

Each `media element` has a `list of newly introduced cues`, which must be initially empty. Whenever a `text track cue` is added to the `list of cues` of a `text track` that is in the `list of text tracks` for a `media element`, that `cue` must be added to the `media element's list of newly introduced cues`. Whenever a `text track` is added to the `list of text tracks` for a `media element`, all the `cues` in that `text track's list of cues` must be added to the `media element's list of newly introduced cues`. When a `media element's list of newly introduced cues` has new cues added while the `media element's show poster flag` is not set, then the user agent must run the `time marches on` steps.

When a `text track cue` is removed from the `list of cues` of a `text track` that is in the `list of text tracks` for a `media element`, and whenever a `text track` is removed from the `list of text tracks` of a `media element`, if the `media element's show poster flag` is not set, then the user agent must run the `time marches on` steps.

When the `current playback position` of a `media element` changes (e.g. due to playback or seeking), the user agent must run the `time marches on` steps. If the `current playback position` changes while the steps are running, then the user agent must wait for the steps to complete, and then must immediately rerun the steps. (These steps are thus run as often as possible or needed — if one iteration takes a long time, this can cause certain `cues` to be skipped over as the user agent rushes the `time marches on` steps.)

The `time marches on` steps are as follows:

1. Let `current cues` be a list of `cues`, initialized to contain all the `cues` of all the `hidden` or `showing text tracks` of the `media element` (not the `disabled` ones) whose `start times` are less than or equal to the `current playback position` and whose `end times` are greater than the `current playback position`.
2. Let `other cues` be a list of `cues`, initialized to contain all the `cues` of `hidden` and `showing text tracks` of the `media element` that are not present in `current cues`.
3. Let `last time` be the `current playback position` at the time this algorithm was last run for this `media element`, if this is not the first time it has run.
4. If the `current playback position` has, since the last time this algorithm was run, only changed through its usual monotonic increase during normal playback, then let `missed cues` be the list of `cues` in `other cues` whose `start times` are greater than or equal to `last time` and whose `end times` are less than or equal to the `current playback position`. Otherwise, let `missed cues` be an empty list.
5. Remove all the `cues` in `missed cues` that are also in the `media element's list of newly introduced cues`, and then empty the element's `list of newly introduced cues`.
6. If the time was reached through the usual monotonic increase of the `current playback position` during normal playback, and if the user agent has not fired a `timeupdate` event at the element in the past 15 to 250ms and is not still running event handlers for such an event, then the user agent must queue a task to fire an event named `timeupdate` at the element. (In the other cases, such as explicit seeks, relevant events get fired as part of the overall process of changing the `current playback position`.)

Note

The event thus is not be fired faster than about 60Hz or slower than 4Hz (assuming the event handlers don't take longer than 250ms to run). User agents are encouraged to vary the frequency of the event based on the system load and the average cost of processing the event each time, so that the UI updates are not any more frequent than the user agent can comfortably handle while decoding the video.

7. If all the `cues` in `current cues` have their `text track cue active flag` set, none of the `cues` in `other cues` have their `text track cue active flag` set, and `missed cues` is empty, then return.

8. If the time was reached through the usual monotonic increase of the `current playback position` during normal playback, and there are `cues` in `other cues` that have their `text track cue pause-on-exit flag` set and that either have their `text track cue active flag` set or are also in `missed cues`, then immediately pause the `media element`.

Note

In the other cases, such as explicit seeks, playback is not paused by going past the end time of a `cue`, even if that `cue` has its `text track cue pause-on-exit flag` set.

Let *affected tracks* be a list of `text track`, initially empty.

When the steps below say to *prepare an event named* for a `text track cue` target with a time *time*, the user agent must run these steps:

1. Let *track* be the `text track` with which the `text track cue` target is associated.
2. Create a `task` to fire an event named *event* at *target*.
3. Add the newly created `task` to events, associated with the time *time*, the `text track` *track*, and the `text track cue` target.
4. Add *track* to *affected tracks*.

10. For each `text track cue` in *missed cues*, *prepare an event* named `enter` for the `TextTrackCue` object with the `text track cue start time`.

11. For each `text track cue` in *other cues* that set or is in *missed cues*, *prepare an event* named `exit` for the `TextTrackCue` object with the later of the `text track cue end time` and the `text track cue start time`.

12. For each `text track cue` in *current cues* that does not have its `text track cue active flag` set, *prepare an event* named `enter` for the `TextTrackCue` object with the `text track cue start time`.

13. Sort the `tasks` in events in ascending time order (`tasks` with earlier times first).

Further sort `tasks` in events that have the same time by the relative `text track cue order` of the `text track cues` associated with these `tasks`.

Finally, sort `tasks` in events that have the same time and same `text track cue order` by placing `tasks` that fire `enter` events before those that fire `exit` events.

14. *Queue each task* in events, in list order.

15. Sort *affected tracks* in the same order as the `text tracks` appear in the `media element's` list of `text tracks`, and remove duplicates.

16. For each `text track` in *affected tracks*, in the list order, *queue a task* to fire an event named `cuechange` at the `TextTrack` object, and, if the `text track` has a corresponding `track` element, to then fire an event named `cuechange` at the `track` element as well.

17. Set the `text track cue active flag` of all the `cues` in the *current cues*, and unset the `text track cue active flag` of all the `cues` in the *other cues*.

18. Run the rules for updating the `text track rendering` of each of the `text tracks` in *affected tracks* that are *showing*, providing the `text track's` `text track language` as the fallback language if it is not the empty string. For example, for `text tracks` based on WebVTT, the [rules for updating the display of WebVTT text tracks](#) (WEBVTT)

For the purposes of the algorithm above, a `text track cue` is considered to be part of a `text track` only if it is listed in the `text track list of cues`, not merely if it is associated with the `text track`.

Note

If the `media element's` `node document` stops being a `fully active` document, then the playback will stop until the document is active again.

When a `media element` is removed from a `Document`, the user agent must run the following steps:

1. *Await a stable state*, allowing the `task` that removed the `media element` from the `document`, to continue. The `synchronous section` consists of all the remaining steps of this algorithm. (Steps in the `synchronous section` are marked with ☒)
2. ☒ If the `media element` is in a `document`, return.
3. ☒ Run the `internal pause steps` for the `media element`.

4.8.12.9 Seeking

For web developers (non-normative)

`media . seeking`

Returns true if the user agent is currently seeking.

`media . seekable`

Returns a `TimeRanges` object that represents the ranges of the `media resource` to which it is possible for the user agent to seek.

`media . fastseek(time)`

Seeks to near the given `time` as fast as possible, trading precision for speed. (To seek to a precise time, use the `currentTime` attribute.)

This does nothing if the media resource has not been loaded.

The `seeking` attribute must initially have the value false.

MDN

[HTML MediaElement/fastSeek](#)

Firefox31+SafariYesChromeNo

OperaEdgeNo

Edge (Legacy)NoInternet Explorer?

Firefox Android31+Safari iOS/Chrome Android?WebView Android?Samsung Internet?Opera Android?

The `fastseek()` method must `seek` to the time given by the method's argument, with the `approximate-for-speed` flag set.

When the user agent is required to seek to a particular `new playback position` in the `media resource`, optionally with the `approximate-for-speed` flag set, it means that the user agent must run the following steps. This algorithm interacts closely with the `event loop` mechanism; in particular, it has a `synchronous section` (which is triggered as part of the `event loop` algorithm). Steps in that section are marked with ☒.

1. Set the `media element's` `show poster flag` to false.
2. If the `media element's` `readyState` is `PAGE NOTHING`, return.
3. If the element's `seeking` IDL attribute is true, then another instance of this algorithm is already running. Abort that other instance of the algorithm without waiting for the step that it is running to complete.
4. Set the `seeking` IDL attribute to true.
5. If the seek was in response to a DOM method call or setting of an IDL attribute, then continue the script. The remainder of these steps must be run in parallel. With the exception of the steps marked with ☒, they could be aborted at any time by another instance of this algorithm being invoked.
6. If the new `playback position` is later than the end of the `media resource`, then let it be the end of the `media resource` instead.
7. If the new `playback position` is less than the `earliest possible position`, let it be that position instead.
8. If the (possibly now changed) `new playback position` is not in one of the ranges given in the `seekable` attribute, then let it be the position in one of the ranges given in the `seekable` attribute that is the nearest to the `new playback position`. If two positions both satisfy that constraint (i.e. the `new playback position` is exactly in the middle between two ranges in the `seekable` attribute) then use the position that is closest to the `current playback position`. If there are no ranges given in the `seekable` attribute then set the `seeking` IDL attribute to false and return.
9. If the `approximate-for-speed` flag is set, adjust the `new playback position` to a value that will allow for playback to resume promptly. If `new playback position` before this step is before `current playback position`, then the adjusted `new playback position` must also be before the `current playback position`. Similarly, if the `new playback position` before this step is after `current playback position`, then the adjusted `new playback position` must also be after the `current playback position`.

Example

For example, the user agent could snap to a nearby key frame, so that it doesn't have to spend time decoding then discarding intermediate frames before resuming playback.

10. *Queue an element task* on the `media element event task source` given the element to fire an event named `seeking` at the element.

11. Set the `current playback position` to the new `playback position`.

Note

If the `media element` was potentially playing immediately before it started seeking, but seeking caused its `readystate` attribute to change to a value lower than `HAVE_PICTURE DATA`, then a `waiting` event will be fired at the element.

Note

This step sets the `current playback position`, and thus can immediately trigger other conditions, such as the rules regarding when playback "reaches the end of the media resource" (part of the logic that handles looping), even before the user agent is actually able to render the media data for that position (as determined in the next step).

Note

The `currentTime` attribute returns the `official playback position`, not the `current playback position`, and therefore gets updated before script execution, separate from this algorithm.

12. Wait until the user agent has established whether or not the `media data` for the new `playback position` is available, and, if it is, until it has decoded enough data to play back that position.

13. *Await a stable state*. The `synchronous section` consists of all the remaining steps of this algorithm. (Steps in the `synchronous section` are marked with ☒)

14. ☒ Set the `seeking` IDL attribute to false.

15. ☒ Run the `time marches on` steps.

16. ☒ *Queue an element task* on the `media element event task source` given the element to fire an event named `seekended` at the element.

17. ☒ *Queue an element task* on the `media element event task source` given the element to fire an event named `seeked` at the element.

MDN

[HTML MediaElement/seekable](#)

Support in all current engines.

Firefox8+SafariYesChrome43+

OperaYesFirefox79+

Edge (Legacy)12+Internet Explorer9+

Firefox Android8/Safari iOS/Chrome Android?WebView Android?Samsung Internet?Opera Android?

The `seekable` attribute must return a new static `normalized TimeRanges` object that represents the ranges of the `media resource`, if any, that the user agent is able to seek to, at the time the attribute is evaluated.

Note

If the user agent can seek to anywhere in the `media resource`, e.g. because it is a simple movie file and the user agent and the server support HTTP Range requests, then the attribute would return an object with one range, whose start is the time of the first frame (the `earliest possible position`, typically zero), and whose end is the same as the time of the first frame plus the `duration` attribute's value (which would equal the time of the last frame, and might be positive infinity).

Note

The range might be continuously changing, e.g. if the user agent is buffering a sliding window on an infinite stream. This is the behavior seen with DVRs viewing live TV, for instance.

⚠Warning!

Returning a new object each time is a bad pattern for attribute getters and is only enshrined here as it would be costly to change it. It is not to be copied to new APIs.

User agents should adopt a very liberal and optimistic view of what is seekable. User agents should also buffer recent content where possible to enable seeking to be fast.

Example

In this instance, consider a large video file served on an HTTP server without support for HTTP Range requests. A browser could implement this by only buffering the current frame and data obtained for subsequent frames, never allow seeking, except for seeking to the very start by restarting the playback. However, this would be a poor implementation. A high quality implementation would buffer the last few minutes of content (or more, if sufficient storage space is available), allowing the user to jump back and rewatch something surprising without any latency, and would in addition allow arbitrary seeking by reloading the file from the start if necessary, which would be slower but still more convenient than having to literally restart the video and watch it all the way through just to get to an earlier unbuffered spot.

`Media resources` might be internally scripted or interactive. Thus, a `media element` could play in a non-linear fashion. If this happens, the user agent must act as if the algorithm for `seeking` was used whenever the `current playback position` changes in a discontinuous fashion (so that the relevant events fire).

4.8.12.10 Media resources with multiple media tracks

A `media resource` can have multiple embedded audio and video tracks. For example, in addition to the primary video and audio tracks, a `media resource` could have foreign-language dubbed dialogues, director's commentaries, audio descriptions, alternative angles, or sign-language overlays.

Returns an [AudioTrackList](#) object representing the audio tracks available in the [media](#) resource.

`media .videoTracks`

Returns a [VideoTrackList](#) object representing the video tracks available in the [media](#) resource.

 readonly attribute DOMString `language`;
 attribute boolean `selected`;
};

For web developers (non-normative)

`media .audioTracks .length`

`media .videoTracks .length`

Returns the number of tracks in the list.

`audioTrack = media .audioTracks [index]`

`videoTrack = media .videoTracks [index]`

Returns the specified [AudioTrack](#) or [VideoTrack](#) object.

`audioTrack = media .audioTracks .gettrackByIndex (id)`

`videoTrack = media .videoTracks .gettrackByIndex (id)`

Returns the [AudioTrack](#) or [VideoTrack](#) object with the given identifier, or null if no track has that identifier.

`audioTrack .id`

`videoTrack .id`

Returns the ID of the given track. This is the ID that can be used with a [fragment](#) if the format supports [media fragment syntax](#), and that can be used with the `getTrackById()` method.

`audioTrack .kind`

`videoTrack .kind`

Returns the category the given track falls into. The [possible track categories](#) are given below.

`audioTrack .label`

`videoTrack .label`

Returns the label of the given track, if known, or the empty string otherwise.

`audioTrack .language`

`videoTrack .language`

Returns the language of the given track, if known, or the empty string otherwise.

`audioTrack .enabled [= value]`

Returns true if the given track is active, and false otherwise.

media.videoTracks.selectedIndex

Returns the index of the currently selected track, if any, or `-1` otherwise.

videoTrack.selected [= value]

Returns true if the given track is active, and false otherwise.

Can be set, to change whether the track is selected or not. Either zero or one video track is selected; selecting a new track while a previous one is selected will unselect the previous one.

An `AudioTrackList` object represents a dynamic list of zero or more audio tracks, of which zero or more can be enabled at a time. Each audio track is represented by an `AudioTrack` object.

A `VideoTrackList` object represents a dynamic list of zero or more video tracks, of which zero or one can be selected at a time. Each video track is represented by a `VideoTrack` object.

Tracks in `AudioTrackList` and `VideoTrackList` objects must be consistently ordered. If the `media resource` is in a format that defines an order, then that order must be used; otherwise, the order must be the relative order in which the tracks are declared in the `media resource`. The order used is called the *natural order* of the list.

Note

Each track in one of these objects thus has an index; the first has the index `0`, and each subsequent track is numbered one higher than the previous one. If a `media resource` dynamically adds or removes audio or video tracks, then the indices of the tracks will change dynamically. If the `media resource` changes entirely, then all the previous tracks will be removed and replaced with new tracks.

Opera 32+ Edge 79+

Edge (Legacy) 12+ Internet Explorer 10+

Fox Firefox Android 33+ Safari iOS7+ Chrome Android 45+ WebView Android 45+ Samsung Internet No Opera Android 32+

The `AudioTrackList.getTrackById(id)` and `VideoTrackList.getTrackById(id)` methods must return the first `AudioTrack` or `VideoTrack` object (respectively) in the `AudioTrackList` or `VideoTrackList` object (respectively) whose identifier is equal to the value of the `id` argument (in the natural order of the list, as defined above). When no tracks match the given argument, the methods must return null.

The `AudioTrack` and `VideoTrack` objects represent specific tracks of a `media resource`. Each track can have an identifier, category, label, and language. These aspects of a track are permanent for the lifetime of the track; even if a track is removed from a `media resource`'s `audioTrackList` or `videoTrackList` objects, those aspects do not change.

In addition, `AudioTrack` objects can each be enabled or disabled; this is the audio track's *enabled state*. When an `AudioTrack` is created, its *enabled state* must be set to false (disabled). The `resource fetch algorithm` can override this.

Similarly, a single `VideoTrack` object per `VideoTrackList` object can be selected, this is the video track's *selection state*. When a `VideoTrack` is created, its *selection state* must be set to false (not selected). The `resource fetch algorithm` can override this.

AudioTrack.role

The `AudioTrack.role` attribute must return the category of the track, if it has one, or the empty string otherwise.

The category of a track is the string given in the first column of the table below that is the most appropriate for the track based on the definitions in the table's second and third columns, as determined by the metadata included in the track in the `media resource`. The cell in the third column of a row says what the category given in the cell in the first column of that row applies to; a category is only appropriate for an audio track if it applies to audio tracks, and a category is only appropriate for video tracks if it applies to video tracks. Categories must only be returned for `AudioTrack` objects if they are appropriate for audio, and must only be returned for `VideoTrack` objects if they are appropriate for video.

For Ogg files, the `Role` header field of the track gives the relevant metadata. For DASH media resources, the `Role` element conveys the information. For WebM, only the `FlagDefault` element currently maps to a value. Sourcing In-band Media Resource Tracks from Media Containers into HTML has further details. [OGGSKELETONHEADERS] [DASH] [WEBMCG] [INBAND]

AMDN**Category****Definition****Applies to...**

Return values for `AudioTrack.kind` and `VideoTrack.kind`

Category A possible alternative to the main track, e.g. a different take of a song (audio), or a different angle (video).

caption A version of the main video track with captions burn in. (For legacy content; new content would use text tracks.) Video only. DASH: "caption" and "main" roles together (other roles ignored).

description An audio description of a video track.

main The primary audio or video track.

main-desc The primary audio track, mixed with audio descriptions.

sign A sign-language interpretation of an audio track.

subtitles A version of the main video track with subtitles burn in. (For legacy content; new content would use text tracks.) Video only. DASH: "subtitle" and "main" roles together (other roles ignored).

translation A translated version of the main audio track.

commentary Commentary on the primary audio or video track, e.g. a director's commentary.

(empty string) No explicit kind, or the kind given by the track's metadata is not recognized by the user agent.

Audio and video. Ogg: "audio/alternate" or "video/alternate"; DASH: "alternate" without "main" and "commentary" roles, and, for audio, without the "dub" role (other roles ignored).

Audio only. Ogg: "audio/audiodesc".

Audio and video. Ogg: "audio/main" or "video/main"; WebM: the "FlagDefault" element is set; DASH: "main" role without "caption", "subtitle", and "dub" roles (other roles ignored).

Audio only. AC3 audio in MPEG-2 TS: bsmod=2 and full_sve=1.

Video only. Ogg: "video/sign".

Video only. DASH: "subtitle" and "main" roles together (other roles ignored).

Audio only. Ogg: "audio/dub". DASH: "dub" and "main" roles together (other roles ignored).

Audio and video. DASH: "commentary" role without "main" role (other roles ignored).

Audio and video.

Examples**Return values for `AudioTrack.kind` and `VideoTrack.kind`**

Applies to...

Category A possible alternative to the main track, e.g. a different take of a song (audio), or a different angle (video).

caption A version of the main video track with captions burn in. (For legacy content; new content would use text tracks.) Video only. DASH: "caption" and "main" roles together (other roles ignored).

description An audio description of a video track.

main The primary audio or video track.

main-desc The primary audio track, mixed with audio descriptions.

Edge (Legacy)12+Internet Explorer?

Firefox Android?Safari iOS?Chrome Android?WebView Android?Samsung Internet?Opera Android?

The `AudioTrack.language` and `VideoTrack.language` attributes must return the BCP 47 language tag of the language of the track, if it has one, or the empty string otherwise. If the user agent is not able to express that language as a BCP 47 language tag (for example because the language information in the `media resource`'s format is a free-form string without a defined interpretation), then the method must return the empty string, as if the track had no language. [\[INBAND\]](#)

AMDN

[AudioTrackEnabled](#)

Support in one engine only.

Firefox?Safari?Chrome?

Opera?Edge?

Edge (Legacy)12+Internet Explorer?

Firefox Android?Safari iOS?Chrome Android?WebView Android?Samsung Internet?Opera Android?

The `AudioTrack.enabled` attribute, on getting, must return true if the track is currently enabled, and false otherwise. On setting, it must enable the track if the new value is true, and disable it otherwise. (If the track is no longer in an `AudioTrackList` object, then the track being enabled or disabled has no effect beyond changing the value of the attribute on the `AudioTrack` object.)

Whenever an audio track in an `AudioTrackList` was disabled and then enabled again, the user agent must queue a task to fire an event named `change` at the `AudioTrackList` object.

An audio track that has no data for a particular position on the `media timeline`, or that does not exist at that position, must be interpreted as being silent at that point on the timeline.

AMDN

[VideoTrackListSelectedIndex](#)

Support in all current engines.

Firefox 33+Safari 6.1+Chrome 45+

Opera 32+Edge 79+

Edge (Legacy)12+Internet Explorer 10+

Firefox Android 33+Safari iOS?+Chrome Android 45+WebView Android 45+Samsung Internet?Opera Android 32+

The `VideoTrackList.selectedIndex` attribute must return the index of the currently selected track, if any. If the `VideoTrackList` object does not currently represent any tracks, or if none of the tracks are selected, it must instead return -1.

AMDN

[VideoTrackSelected](#)

Support in one engine only.

Firefox?Safari?Chrome?

Opera?Edge?

Edge (Legacy)12+Internet Explorer?

Firefox Android?Safari iOS?Chrome Android?WebView Android?Samsung Internet?Opera Android?

The `VideoTrack.selected` attribute, on getting, must return true if the track is currently selected, and false otherwise. On setting, it must select the track if the new value is true, and unselect it otherwise. If the track is in a `VideoTrackList`, then all the other `VideoTrack` objects in that list must be unselected. (If the track is no longer in a `VideoTrackList` object, then the track being selected or unselected has no effect beyond changing the value of the attribute on the `VideoTrack` object.)

Whenever a track in a `VideoTrackList` was previously not selected and then selected, and whenever the selected track in a `VideoTrackList` is unselected without a new track being selected in its stead, the user agent must queue a task to fire an event named `change` at the `VideoTrackList` object. This task must be queued before the task that fires the `resize` event, if any.

A video track that has no data for a particular position on the `media timeline` must be interpreted as being `transparent black` at that point on the timeline, with the same dimensions as the last frame before that position, or, if the position is before all the data for that track, the same dimensions as the first frame for that track. A track that does not exist at all at the current position must be treated as if it existed but had no data.

Example

For instance, if a video has a track that is only introduced after one hour of playback, and the user selects that track then goes back to the start, then the user agent will act as if that track started at the start of the `media resource` but was simply transparent until one hour in.

The following are the `event handlers` (and their corresponding `event handler event types`) that must be supported, as `event handler IDL attributes`, by all objects implementing the `AudioTrackList` and `VideoTrackList` interfaces:

4.8.12.2 Selecting specific audio and video tracks declaratively

The `audioTracks` and `videoTracks` attributes allow scripts to select which track should play, but it is also possible to select specific tracks declaratively, by specifying particular tracks in the `fragment` of the `URL` of the `media resource`. The format of the `fragment` depends on the `MIME-type` of the `media resource` [RFC2046] [URL].

Example

In this example, a video that uses a format that supports `media fragment syntax` is embedded in such a way that the alternative angles labeled "Alternative" are enabled instead of the default video track.

```
<video src="myVideo#track=alternative"></video>
```

4.8.12.11 Timed text tracks

4.8.12.11.1 Text track model

A `media element` can have a group of associated `text tracks`, known as the `media element's list of text tracks`. The `text tracks` are sorted as follows:

1. Any `text tracks` corresponding to `track` element children of the `media element`, in `tree order`.
2. Any `text tracks` added using the `addTextTrack()` method, in the order they were added, oldest first.
3. Any `media resource-specific text tracks` (`text tracks` corresponding to data in the `media resource`), in the order defined by the `media resource's` format specification.

A `text track` consists of:

The kind of text track

This decides how the track is handled by the user agent. The kind is represented by a string. The possible strings are:

- subtitles
- captions
- descriptions
- chapters
- metadata

The `kind` of `track` can change dynamically, in the case of a `text track` corresponding to a `track` element.

A label

This is a human-readable string intended to identify the track for the user.

The `label` of a `track` can change dynamically, in the case of a `text track` corresponding to a `track` element.

When a `text track label` is the empty string, the user agent should automatically generate an appropriate label from the text track's other properties (e.g. the kind of text track and the text track's language) for use in its user interface. This automatically-generated label is not exposed in the API.

An in-band metadata track dispatch type

This is a string extracted from the `media resource` specifically for in-band metadata tracks to enable such tracks to be dispatched to different scripts in the document.

Example
For example, a traditional TV station broadcast streamed on the Web and augmented with Web-specific interactive features could include text tracks with metadata for ad targeting, trivia game data during game shows, player states during sports games, recipe information during food programs, and so forth. As each program starts and ends, new tracks might be added or removed from the stream, and as each one is added, the user agent could bind them to dedicated script modules using the value of this attribute.

Other than for in-band metadata text tracks, the `in-band metadata track dispatch type` is the empty string. How this value is populated for different media formats is described in [steps to expose a media-resource-specific text track](#).

A language

This is a string (a BCP 47 language tag) representing the language of the text track's cues. [BCP47]

The `language` of a `text track` can change dynamically, in the case of a `text track` corresponding to a `track` element.

A readiness state

One of the following:

Not loaded

Indicates that the text track's cues have not been obtained.

Loading

Indicates that the text track is loading and there have been no fatal errors encountered so far. Further cues might still be added to the track by the parser.

Loaded

Indicates that the text track has been loaded with no fatal errors.

Failed to load

Indicates that the text track was enabled, but when the user agent attempted to obtain it, this failed in some way (e.g. `URL` could not be `parsed`, network error, unknown text track format). Some or all of the cues are likely missing and will not be obtained.

The `readiness state` of a `text track` changes dynamically as the track is obtained.

A mode

One of the following:

Disabled

Indicates that the text track is not active. Other than for the purposes of exposing the track in the DOM, the user agent is ignoring the text track. No cues are active, no events are fired, and the user agent will not attempt to obtain the track's cues.

Hidden

Indicates that the text track is active, but that the user agent is not actively displaying the cues. If no attempt has yet been made to obtain the track's cues, the user agent will perform such an attempt momentarily. The user agent is maintaining a list of which cues are active, and events are being fired accordingly.

Showing

Indicates that the text track is active. If no attempt has yet been made to obtain the track's cues, the user agent will perform such an attempt momentarily. The user agent is maintaining a list of which cues are active, and events are being fired accordingly. In addition, for text tracks whose `kind` is `subtitles` or `captions`, the cues are being overlaid in the video as appropriate; for text tracks whose `kind` is `descriptions`, the user agent is making the cues available to the user in a non-visual fashion; and for text tracks whose `kind` is `chapters`, the user agent is making available to the user a mechanism by which the user can navigate to any point in the `media resource` by selecting a cue.

A list of zero or more cues

A list of `text track cues`, along with `rules for updating the text track rendering`. For example, for WebVTT, the `rules for updating the display of WebVTT text tracks` [WEBVTT]

The `list of cues of a text track` can change dynamically, either because the `text track` has `not yet been loaded` or is still `loading`, or due to DOM manipulation.

Each `text track` has a corresponding `TextTrack` object.

Each `media element` has a list of pending text tracks, which must initially be empty, a `blocked-on-parser` flag, which must initially be false, and a `did-perform-automatic-track-selection` flag, which must also initially be false.

When the user agent is required to populate the list of pending text tracks of a `media element`, the user agent must add to the element's `list of pending text tracks` each `text track` in the element's `list of text tracks` whose `text track mode` is `disabled` and whose `text track readiness state` is `loading`.

Whenever a `track` element's parent node changes, the user agent must remove the corresponding `text track` from any `list of pending text tracks` that it is in.

Whenever a `text track's text track readiness state` changes to either `loaded` or `failed to load`, the user agent must remove it from any `list of pending text tracks` that it is in.

When a `media element` is created by an `HTML parser` or `XML parser`, the user agent must set the element's `blocked-on-parser` flag to true. When a `media element` is popped off the stack of open elements of an `HTML parser` or `XML parser`, the user agent must honor user preferences for automatic text track selection, populate the list of pending text tracks, and set the element's `blocked-on-parser` flag to false.

The `text track of a media element` are ready when both the element's `list of pending text tracks` is empty and the element's `blocked-on-parser` flag is false.

Each `media element` has a pending `text track change notification flag`, which must initially be unset.

Whenever a `text track` that is in a `media element's list of text tracks` has its `text track mode` change value, the user agent must run the following steps for the `media element`:

1. If the `media element's pending text track change notification flag` is set, return.
2. Set the `media element's pending text track change notification flag`.
3. Queue an element task on the `media element event task source` given the `media element` to run these steps:

1. Unset the `media element's pending text track change notification flag`.
2. Fire an event named `change` at the `media element's textTracks attribute's TextTrackList` object.

4. If the `media element's show poster flag` is not set, run the `time marches on` steps.

The `task source` for the `tasks` listed in this section is the `DOM manipulation task source`.

A `text track cue` is the unit of time-sensitive data in a `text track`, corresponding for instance for subtitles and captions to the text that appears at a particular time and disappears at another time.

Each `text track cue` consists of:

An arbitrary string.

A start time

The time, in seconds and fractions of a second, that describes the beginning of the range of the `media_data` to which the cue applies.

An end time

The time, in seconds and fractions of a second, that describes the end of the range of the `media_data` to which the cue applies.

A pause-on-exit flag

A boolean indicating whether playback of the `media_resource` is to pause when the end of the range to which the cue applies is reached.

Some additional format-specific data

Additional fields, as needed for the format, including the actual data of the cue. For example, WebVTT has a `text track cue writing direction` and so forth. [WEBVTT]

Note

The `text track cue start time` and `text track cue end time` can be negative. (The `current playback position` can never be negative, though, so cues entirely before time zero cannot be active.)

Each `text track cue` has a corresponding `TextTrackCue` object (or more specifically, an object that inherits from `TextTrackObject` — for example, WebVTT cues use the `VTextCue` interface). A `text track cue`'s in-memory representation can be dynamically changed through this `TextTrackCue API`. [WEBVTT]

A `text track cue` is associated with `rules for updating the text track rendering`, as defined by the specification for the specific kind of `text track cue`. These rules are used specifically when the object representing the cue is added to a `TextTrack` object using the `addCue()` method.

In addition, each `text track cue` has two pieces of dynamic information:

The active flag

This flag must be initially unset. The flag is used to ensure events are fired appropriately when the cue becomes active or inactive, and to make sure the right cues are rendered.

The user agent must synchronously unset this flag whenever the `text track cue` is removed from its `text track's` `text track list of cues`; whenever the `text track` itself is removed from its `media element's` `list of text tracks` or has its `text track mode` changed to `disabled`; and whenever the `media element's` `readystate` is changed back to `HTML_LOADED`. When the flag is unset in this way for one or more cues in `text tracks` that were `showing` prior to the relevant incident, the user agent must, after having unset the flag for all the affected cues, apply the `rules for updating the text track rendering` of those `text tracks`. For example, for `text tracks` based on WebVTT, the `rules for updating the display of WebVTT text tracks` [WEBVTT]

The display state

This is used as part of the rendering model, to keep cues in a consistent position. It must initially be empty. Whenever the `text track cue active flag` is unset, the user agent must empty the `text track cue display state`.

The `text track cues` of a `media element's` `text tracks` are ordered relative to each other in the `text track cue order`, which is determined as follows: first group the `cues` by their `text track`, with the groups being sorted in the same order as their `text tracks` appear in the `media element's` `list of text tracks`; then, within each group, `cues` must be sorted by their `start time`, earliest first; then, any `cues` with the same `start time` must be sorted by their `end time`, latest first; and finally, any `cues` with identical `end times` must be sorted in the order they were last added to their respective `text track list of cues`, oldest first (e.g. for cues from a WebVTT file, that would initially be the order in which the cues were listed in the file). [WEBVTT]

4.8.12.1.1.2 Sourcing in-band text tracks

A `media-resource-specific text track` is a `text track` that corresponds to data found in the `media resource`.

Rules for processing and rendering such data are defined by the relevant specifications, e.g. the specification of the video format if the `media resource` is a video. Details for some legacy formats can be found in *Sourcing In-band Media Resource Tracks from Media Containers into HTML*. [INBAND]

When a `media resource` contains data that the user agent recognizes and supports as being equivalent to a `text track`, the user agent `must` take the steps to expose a `media-resource-specific text track` with the relevant data, as follows.

1. Associate the relevant data with a new `text track` and its corresponding new `TextTrack` object. The `text track` is a `media-resource-specific text track`.

2. Set the new `text track's` `kind`, `label`, and `language` based on the semantics of the relevant data, as defined by the relevant specification. If there is no label in that data, then the `label` must be set to the empty string.

3. Associate the `text track list of cues` with the `rules for updating the text track rendering` appropriate for the format in question.

4. If the new `text track's` `kind` is `chapters` or `metadata`, then set the `text track in-band metadata track dispatch type` as follows, based on the type of the `media resource`:

If the `media resource` is an Ogg file:

The `text track in-band metadata track dispatch type` must be set to the value of the `Name header field`. [OGGSELEFTONHEADERS]

If the `media resource` is a WebM file:

The `text track in-band metadata track dispatch type` must be set to the value of the `CodecID element`. [WEBMCG]

If the `media resource` is an MP4 file:

Let `stream type` be the value of the "stream type" field describing the text track's type in the file's program map section, interpreted as an 8-bit unsigned integer. Let `length` be the value of the "ES info length" field for the track in the same part of the program map section, interpreted as an integer as defined by *Generic coding of moving pictures and associated audio information*. Let `descriptor bytes` be the length bytes following the "ES_info_length" field. The `text track in-band metadata track dispatch type` must be set to the concatenation of the `stream type` and the zero or more `descriptor bytes`, expressed in hexadecimal using `ASCII upper hex digits`. [MPFG4]

If the `media resource` is an MP4-G file:

Let the first `std box` of the first `std box` of the first `min box` of the first `moov box` of the file be the `std box`, if any. If the file has no `std box`, or if the `std box` has neither a `meta box` nor a `meta box`, then the `text track in-band metadata track dispatch type` must be set to the empty string. Otherwise, if the `std box` has a `meta box` then the `text track in-band metadata track dispatch type` must be set to the concatenation of the string "meta", a U+0020 SPACE character, and the value of the first `namespace` field of the first `meta box` of the `std box`, or the empty string if that field is absent in that box. Otherwise, if the `std box` has no `meta box` then the `text track in-band metadata track dispatch type` must be set to the concatenation of the string "meta", a U+0020 SPACE character, and the value of the first `namespace` field of the first `meta box` of the `std box`, or the empty string if that field is absent in that box. [MPFG4]

5. Populate the new `text track's` `list of cues` with the cues passed so far, following the `guidelines for exposing cues`, and begin updating it dynamically as necessary.

6. Set the new `text track's` `readiness state` to `loaded`.

7. Set the new `text track's` `mode` to the mode consistent with the user's preferences and the requirements of the relevant specification for the data.

Note

For instance, if there are no other active subtitles, and this is a forced subtitle track (a subtitle track giving subtitles in the audio track's primary language, but only for audio that is actually in another language), then those subtitles might be activated here.

8. Add the new `text track` to the `media element's` `list of text tracks`.

9. Fire an event named `addtrack` at the `media element's` `TextTracks` attribute's `TextTrackList` object, using `TrackEvent`, with the `track` attribute initialized to the `text track's` `TextTrack` object.

4.8.12.1.3 Sourcing out-of-band text tracks

When a `track` element is created, it must be associated with a new `text track` (with its value set as defined below) and its corresponding new `TextTrack` object.

The `text track kind` is determined from the state of the element's `kind` attribute according to the following table; for a state given in a cell of the first column, the `kind` is the string given in the second column:

State	String
<code>Subtitles</code>	<code>subtitle</code>
<code>Captions</code>	<code>caption</code>
<code>Descriptions</code>	<code>description</code>
<code>Chapters metadata</code>	<code>chapters</code>
<code>Metadata</code>	<code>metadata</code>

The `text track label` is the element's `track label`.

The `text track language` is the element's `track language`, if any, or the empty string otherwise.

As the `kind`, `label`, and `language` attributes are set, changed, or removed, the `text track` must update accordingly, as per the definitions above.

Note
Changes to the `track URL` are handled in the algorithm below.

The `text track readiness state` is initially `not loaded`, and the `text track mode` is initially `disabled`.

The `text track list of cues` is initially empty. It is dynamically modified when the referenced file is parsed. Associated with the list are the `rules for updating the text track rendering` appropriate for the format in question; for WebVTT, this is the `rules for updating the display of WebVTT text tracks`. [WEBVTT]

When a `track` element's parent element changes and the new parent is a `media element`, then the user agent must add the `track` element's corresponding `text track` to the `media element's` `list of text tracks`, and then `queue a task` to fire an event named `addtrack` at the `media element's` `TextTracks` attribute's `TextTrackList` object, using `TrackEvent`, with the `track` attribute initialized to the `text track's` `TextTrack` object.

When a `track` element's parent element changes and the old parent was a `media element`, then the user agent must remove the `track` element's corresponding `text track` from the `media element's` `list of text tracks`, and then `queue a task` to fire an event named `removetrack` at the `media element's` `TextTracks` attribute's `TextTrackList` object, using `TrackEvent`, with the `track` attribute initialized to the `text track's` `TextTrack` object.

When a `text track` corresponding to a `track` element is added to a `media element's` `list of text tracks`, the user agent must `queue a task` to run the following steps for the `media element`:

- If the element's `blocked-on-pause` flag is true, then return.
- If the element's `did-perform-automatic-track-selection` flag is true, then return.
- Honor user preferences for automatic text track selection for this element.

When the user agent is required to honor user preferences for automatic text track selection for a `media element`, the user agent must run the following steps:

- Perform automatic text track selection for `subtitles` and `captions`.
- Perform automatic text track selection for `descriptions`.
- If there are any `text track`s in the `media element's` `list of text tracks` whose `text track kind` is `chapters` or `metadata` that correspond to `track` elements with a `default` attribute set whose `text track mode` is set to `disabled`, then set the `text track mode` of all such tracks to `hidden`.
- Set the element's `did-perform-automatic-track-selection` flag to true.

When the steps above say to perform automatic text track selection for one or more `text track kinds`, it means to run the following steps:

- Let `candidates` be a list consisting of the `text track`s in the `media element's` `list of text tracks` whose `text track kind` is one of the kinds that were passed to the algorithm, if any, in the order given in the `list of text tracks`.
- If `candidates` is empty, then return.
- If any of the `text track`s in `candidates` have a `text track mode` set to `showing`, return.
- If the user has expressed an interest in having a track from `candidates` enabled based on its `text track kind`, `text track language`, and `text track label`, then set its `text track mode` to `showing`.

Note
For example, the user could have set a browser preference to the effect of "I want French captions whenever possible", or "If there is a subtitle track with 'Commentary' in the title, enable it", or "If there are audio description tracks available, enable one, ideally in Swiss German, but failing that in Standard Swiss German or Standard German".

Otherwise, if there are any `text track`s in `candidates` that correspond to `track` elements with a `default` attribute set whose `text track mode` is set to `disabled`, then set the `text track mode` of the first such track to `showing`.

When a `text track` corresponding to a `track` element experiences any of the following circumstances, the user agent must `start the track processing model` for that `text track` and its `track` element:

- The `track` element is created.
- The `text track` has its `text track mode` changed.
- The `track` element's parent element changes and the new parent is a `media element`.

When a user agent is to `start the track processing model` for a `text track` and its `track` element, it must run the following algorithm. This algorithm interacts closely with the `event loop` mechanism; in particular, it has a `synchronous section` (which is triggered as part of the `event loop` algorithm). The steps in that section are marked with

- If another occurrence of this algorithm is already running for this `text track` and its `track` element, return, letting that other algorithm take care of this element.
- If the `text track's` `text track mode` is not set to one of `hidden` or `showing`, then return.
- If the `text track's` `track` element does not have a `media element` as a parent, return.
- Run the remainder of these steps `in parallel`, allowing whatever caused these steps to run to continue.
- Top: `Await a stable state`. The `synchronous section` consists of the following steps. (The steps in the `synchronous section` are marked with)
- Set the `text track readiness state` to `loading`.
- Let `URL` be the `track URL` of the `track` element.

9. End the [synchronous section](#), continuing the remaining steps [in parallel](#).

10. If *URL* is not the empty string, then:

1. Let *request* be the result of [creating a potential-CORS request](#) given *URL*, **track**, and *cors.getAttributeState*, and with the *same-origin fallback flag* set.

2. Set *request's client* to the *track* element's *node document's relevant settings object*.

3. [Fetch request](#).

The [tasks queued](#) by the fetching algorithm on the [networking task source](#) to process the data as it is being fetched must determine the type of the resource. If the type of the resource is not a supported text track format, the load will fail, as described below. Otherwise, the resource's data must be passed to the appropriate parser (e.g., the [WebVTT parser](#)) as it is received, with the [text track list of cues](#) being used for that parser's output. ([WEBVTT](#))

Note
The appropriate parser will incrementally update the [text track list of cues](#) during these [networking task source tasks](#), as each such task is run with whatever data has been received from the network.

This specification does not currently say whether or how to check the MIME types of text tracks, or whether or how to perform file type sniffing using the actual file data. Implementors differ in their intentions on this matter and it is therefore unclear what the right solution is. In the absence of any requirement here, the HTTP specifications' strict requirement to follow the Content-Type header prevails ("Content-Type specifies the media type of the underlying data." ... "If and only if the media type is not given by a Content-Type field, the recipient MAY attempt to guess the media type via inspection of its content and/or the name extension(s) of the URI used to identify the resource.")

If fetching fails for any reason (network error, the server returns an error code, CORS fails, etc), or if *URL* is the empty string, then [queue a task](#) to first change the [text track readiness state](#) to [failed to load](#) and then [fire an event](#) named [error](#) at the *track* element. This [task](#) must use the [DOM manipulation task source](#).

If fetching does not fail, but the type of the resource is not a supported text track format, or the file was not successfully processed (e.g., the format in question is an XML format and the file contained a well-formedness error that *XML* requires to be detected and reported to the application), then the [task](#) that is [queued](#) by the [networking task source](#) in which the aforementioned problem is found must change the [text track readiness state](#) to [failed to load](#) and [fire an event](#) named [error](#) at the *track* element.

If fetching does not fail, and the file was successfully processed, then the final [task](#) that is [queued](#) by the [networking task source](#), after it has finished parsing the data, must change the [text track readiness state](#) to [loaded](#), and [fire an event](#) named [load](#) at the *track* element.

If, while fetching is ongoing, either:

- the *track URL* changes so that it is no longer equal to *URL*, while the [text track mode](#) is set to [hidden](#) or [showing](#);
- the [text track mode](#) changes to [hidden](#) or [showing](#), while the *track URL* is not equal to *URL*;

...then the user agent must abort [fetching](#), discarding any pending [tasks](#) generated by that algorithm (and in particular, not adding any cues to the [text track list of cues](#) after the moment the URL changed), and then [queue a task](#) that first changes the [text track readiness state](#) to [failed to load](#) and then [fires an event](#) named [error](#) at the *track* element. This [task](#) must use the [DOM manipulation task source](#).

11. Wait until the [text track readiness state](#) is no longer set to [loading](#).

12. Wait until the *track URL* is no longer equal to *URL*, at the same time as the [text track mode](#) is set to [hidden](#) or [showing](#).

13. Jump to the step labeled *top*.

Whenever a *track* element has its [src](#) attribute set, changed, or removed, the user agent must [immediately](#) empty the element's [text track's text track list of cues](#). (This also causes the algorithm above to stop adding cues from the resource being obtained using the previously given URL, if any.)

4.8.12.14.4 Guideline for exposing cues in various formats in [text track](#)

How a specific format's text track cues are to be interpreted for the purposes of processing by an HTML user agent is defined by that format. In the absence of such a specification, this section provides some constraints within which implementations can attempt to consistently expose such formats.

To support the [text track](#) model of HTML, each unit of timed data is converted to a [text track cue](#). Where the mapping of the format's features to the aspects of a [text track cue](#) as defined in this specification are not defined, implementations must ensure that the mapping is consistent with the definitions of the aspects of a [text track cue](#) as defined above, as well as with the following constraints:

The [text track cue identifier](#)

Should be set to the empty string if the format has no obvious analogue to a per-cue identifier.

The [text track cue pause-on-exit flag](#)

Should be set to false.

4.8.12.14.5 [Text track API](#)

MDN

[TextTrackList](#)

```
IDBObject : TextTrackMode { "disabled", "hidden", "showing" };
unsigned long : TextTrackKind { "subtitles", "captions", "descriptions", "chapters", "metadata" };
EventDispatcher : TextTrackEventTarget;
attribute DOMString kind;
readonly attribute DOMString label;
readonly attribute DOMString language;
readonly attribute DOMString id;
```

```

attribute TextTrackMode mode;
readonly attribute TextTrackCueList cues;
readonly attribute TextTrackCueList activeCues;
void addcue(TextTrackCue cue);
void removecue(TextTrackCue cue);
attribute EventHandle prechange;
};

For web developers (non-normative)
textTrack = media.addTextTrack(kind [, label [, language]])

Creates and returns a new TextTrack object, which is also added to the media element's list of text tracks.

textTrack.kind
Returns the text track kind string.

textTrack.label
Returns the text track label, if there is one, or the empty string otherwise (indicating that a custom label probably needs to be generated from the other attributes of the object if the object is exposed to the user).

textTrack.language
Returns the text track language string.

textTrack.id
Returns the ID of the given track.

For in-band tracks, this is the ID that can be used with a fragment if the format supports media fragment syntax, and that can be used with the getTrackById() method.

For TextTrack objects corresponding to track elements, this is the ID of the track element.

textTrack.inBandMetadataTrackDispatchType
Returns the text track in-band metadata track dispatch type string.

textTrack.mode [= value]
Returns the text track mode, represented by a string from the following list:
  "disabled"
    The text track disabled mode.
  "hidden"
    The text track hidden mode.
  "showing"
    The text track showing mode.
  Can be set, to change the mode.

textTrack.cues
Returns the text track list of cues, as a TextTrackCueList object.

textTrack.activeCues
Returns the text track cues from the text track list of cues that are currently active (i.e. that start before the current playback position and end after it), as a TextTrackCueList object.

textTrack.addcue(cue)
Adds the given cue to textTrack's text track list of cues.

textTrack.removecue(cue)
Removes the given cue from textTrack's text track list of cues.

```

The `addTextTrack`(`kind`, `label`, `language`) method of `media elements`, when invoked, must run the following steps:

- Create a new `TextTrack` object.
- Create a new `TextTrack` corresponding to the new object, and set its `text track kind` to `kind`, its `text track label` to `label`, its `text track language` to `language`, its `text track readiness state` to the `text track loaded` state, its `text track mode` to the `text track hidden` mode, and its `text track list of cues` to an empty list.
- Initially, the `text track list of cues` is not associated with any `rules for updating the text track rendering`. When a `text track cue` is added to it, the `text track list of cues` has its rules permanently set accordingly.
- Add the new `TextTrack` to the `media element's` list of text tracks.
- `Queue an element task` on the `media element event task source` given the `media element` to fire an event named `addtrack` at the `media element's` `TextTracks` attribute's `TextTrackList` object, using `trackEvent`, with the `track` attribute initialized to the new `TextTrack`'s `TextTrack` object.
- Return the new `TextTrack` object.

The `kind` attribute must return the `text track kind` of the `TextTrack` that the `TextTrack` object represents.

The `label` attribute must return the `text track label` of the `TextTrack` that the `TextTrack` object represents.

The `language` attribute must return the `text track language` of the `TextTrack` that the `TextTrack` object represents.

The `id` attribute returns the track's identifier, if it has one, or the empty string otherwise. For tracks that correspond to `track` elements, the track's identifier is the value of the element's `id` attribute, if any. For in-band tracks, the track's identifier is specified by the `media resource`. If the `media resource` is in a format that supports `media fragment syntax`, the identifier returned for a particular track must be the same identifier that would enable the track if used as the name of a track in the track dimension of such a `fragment`.

The `inBandMetadataTrackDispatchType` attribute must return the `text track in-band metadata track dispatch type` of the `TextTrack` that the `TextTrack` object represents.

MDN

TextTrackMode

Support for all current engines.

Firefox3-Safari6+Chrome18+

Opera15+Edge79+

Edge (Legacy)12+Internet Explorer10+

Firefox Android11+Safari iOS7+Chrome Android18+WebView Android4.4+Samsung Internet1.0+Opera AndroidNo

The `mode` attribute, on getting, must return the string corresponding to the `text track mode` of the `TextTrack` that the `TextTrack` object represents, as defined by the following list:

- "disabled"
 - The `text track disabled` mode.
- "hidden"
 - The `text track hidden` mode.
- "showing"
 - The `text track showing` mode.

On setting, if the new value isn't equal to what the attribute would currently return, the new value must be processed as follows:

If the new value is "`disabled`"

Set the `text track mode` of the `TextTrack` that the `TextTrack` object represents to the `text track disabled` mode.

If the new value is "`hidden`"

Set the `text track mode` of the `TextTrack` that the `TextTrack` object represents to the `text track hidden` mode.

If the new value is "`showing`"

Set the `text track mode` of the `TextTrack` that the `TextTrack` object represents to the `text track showing` mode.

If the `text track mode` of the `TextTrack` that the `TextTrack` object represents is not the `text track disabled` mode, then the `cues` attribute must return a `live TextTrackCueList` object that represents the subset of the `text track list of cues` of the `TextTrack` that the `TextTrack` object represents whose `end times` occur at or after the `earliest possible position when the script started` in `text track cue order`. Otherwise, it must return null. For each `TextTrack` object, when an object is returned, the same `TextTrackCueList` object must be returned each time.

The earliest possible position for the script started is whatever the `earliest possible position` was the last time the `event loop` reached step 1.

If the `text track mode` of the `TextTrack` that the `TextTrack` object represents is not the `text track disabled` mode, then the `activeCues` attribute must return a `live TextTrackCueList` object that represents the subset of the `text track list of cues` of the `TextTrack` that the `TextTrack` object represents whose `active flag was set when the script started`, in `text track cue order`. Otherwise, it must return null. For each `TextTrack` object, when an object is returned, the same `TextTrackCueList` object must be returned each time.

A `Text track cue's active flag was set when the script started` if its `text track cue active flag` was set the last time the `event loop` reached step 1.

The `addcue(cue)` method of `TextTrack` objects, when invoked, must run the following steps:

- If the `text track list of cues` does not yet have any associated `rules for updating the text track rendering`, then associate the `text track list of cues` with the `rules for updating the text track rendering` appropriate to `cue`.
- If `text track list of cues'` associated `rules for updating the text track rendering` are not the same `rules for updating the text track rendering` as appropriate for `cue`, then throw an `"invalidstateerror"` `DOMException`.
- If the given `cue` is in a `text track list of cues`, then remove `cue` from that `text track list of cues`.

4. Add `cue` to the `TextTrack` object's `text track's text track list of cues`.

The `removecue(cue)` method of `TextTrack` objects, when invoked, must run the following steps:

- If the given `cue` is not in the `TextTrack` object's `text track's text track list of cues`, then throw a `"notfounderror"` `DOMException`.
- Remove `cue` from the `TextTrack` object's `text track's text track list of cues`.

Example

In this example, an `audio` element is used to play a specific sound-effect from a sound file containing many sound effects. A cue is used to pause the audio, so that it ends exactly at the end of the clip, even if the browser is busy running some script. If the page had relied on script to pause the audio, then the start of the next clip might be heard if the browser was not able to run the script at the exact time specified.

```

var audio = document.querySelector('audio');
var sounds = stx.addTextTrack('metadata');

// add sounds we care about
function addFX(start, end, name) {
  var cue = new VTTcue(start, end, '');
  cue.name = name;
  cue.pauseOnExit = true;
  sounds.addCue(cue);
}

```

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

```

addSPX(13.612, 15.091, 'kitten new')
function playSound(id) {
    sfx.currentTime = sounds.getcueById(id).startTime;
    sfx.play();
}

// play a bark as soon as we can
sfx.oncompleteplaythrough = function () {
    playSound('kitten new');
}

// Show when the user tries to leave,
// and have the browser ask them to stay
window.onbeforeunload = function (e) {
    playSound('kitten new');
    e.preventDefault();
}

```

```

IDLExposed=Window
interface TextTrackCueList {
    unsigned long length;
    getter TextTrackCue (unsigned long index);
    TextTrackCue* getcueById(DOMString id);
}

```

For web developers (non-normative)

`cueList.length`

Returns the number of `cue`s in the list.

`cueList[index]`

Returns the `text track cue` with index `index` in the list. The cues are sorted in `text track cue order`.

`cueList.getcueById(id)`

Returns the first `text track cue` (in `text track cue order`) with `text track cue identifier` `id`.

Returns null if none of the cues have the given identifier or if the argument is the empty string.

A `TextTrackCueList` object represents a dynamically updating list of `text track cues` in a given order.

The `length` attribute must return the number of `cue`s in the list represented by the `TextTrackCueList` object.

The `supportedPropertyIndices` of a `TextTrackCueList` object at any instant are the numbers from zero to the number of `cue`s in the list represented by the `TextTrackCueList` object minus one, if any. If there are no `cue`s in the list, there are no `supportedPropertyIndices`.

To determine the value of an `indexed property` for a given index `index`, the user agent must return the `index`th `text track cue` in the list represented by the `TextTrackCueList` object.

The `getcueById(id)` method, when called with an argument other than the empty string, must return the first `text track cue` in the list represented by the `TextTrackCueList` object whose `text track cue identifier` is `id`, if any, or null otherwise. If the argument is the empty string, then the method must return null.

AMDN

`TextTrackCue`

Support in one engine only.

    readonly attribute TextTrack track;
    attribute DOMString id;
    attribute double startTime;
    attribute double endTime;
    attribute double duration;
    attribute EventHandler onstart;
    attribute EventHandler onend;
}

```

For web developers (non-normative)

`cue.track`

Returns the `TextTrack` object to which this `text track cue` belongs, if any, or null otherwise.

`cue.id [= value]`

Returns the `text track cue identifier`.

Can be set.

`cue.startTime [= value]`

Returns the `text track cue start time`, in seconds.

Can be set.

`cue.endTime [= value]`

Returns the `text track cue end time`, in seconds.

Can be set.

`cue.pauseOnExit [= value]`

Returns true if the `text track cue pause-on-exit flag` is set, false otherwise.

Can be set.

The `track` attribute, on getting, must return the `TextTrack` object of the `text track` in whose `list` of `cue`s the `text track cue` that the `TextTrackCue` object represents finds itself, if any; or null otherwise.

The `id` attribute, on getting, must return the `text track cue identifier` of the `text track cue` that the `TextTrackCue` object represents. On setting, the `text track cue identifier` must be set to the new value.

The `startTime` attribute, on getting, must return the `text track cue start time` of the `text track cue` that the `TextTrackCue` object represents, in seconds. On setting, the `text track cue start time` must be set to the new value, interpreted in seconds; then, if the `TextTrackCue` object's `text track cue` is in a `text track`'s `list` of `cue`s, and that `text track` is in a `media element`'s `list` of `text tracks`, and the `media element`'s `show poster` flag is not set, then run the `time marches on` steps for that `media element`.

The `duration` attribute, on getting, must return the `text track cue end time` of the `text track cue` that the `TextTrackCue` object represents, in seconds. On setting, the `text track cue end time` must be set to the new value, interpreted in seconds; then, if the `TextTrackCue` object's `text track cue` is in a `text track`'s `list` of `cue`s, and that `text track` is in a `media element`'s `list` of `text tracks`, and the `media element`'s `show poster` flag is not set, then run the `time marches on` steps for that `media element`.

The `pauseOnExit` attribute, on getting, must return true if the `text track cue pause-on-exit flag` of the `TextTrackCue` object represents is set; or false otherwise. On setting, the `text track cue pause-on-exit flag` must be set if the new value is true, and must be unset otherwise.

4.8.12.11.6 Event handlers for objects of the text track API

The following are the `event handlers` that (and their corresponding `event handler event types`) that must be supported, as `event handler IDL attributes`, by all objects implementing the `TextTrackList` interface:

Event handler Event handler event type

`onchange change`

`onaddtrack addtrack`

`onremovetrack removetrack`

The following are the `event handlers` that (and their corresponding `event handler event types`) that must be supported, as `event handler IDL attributes`, by all objects implementing the `TextTrack` interface:

Event handler Event handler event type

`onchange change`

`onstart start`

`onend end`

4.8.12.11.7 Best practices for metadata text tracks

This section is non-normative.

Text tracks can be used for storing data relating to the media data, for interactive or augmented views.

For example, a page showing a sports broadcast could include information about the current score. Suppose a robotics competition was being streamed live. The image could be overlaid with the scores, as follows:

In order to make the score display render correctly whenever the user seeks to an arbitrary point in the video, the metadata text track cues need to be as long as is appropriate for the score. For example, in the frame above, there would be maybe one cue that lasts the length of the match that gives the match number, one cue that lasts until the blue alliance's score changes, and one cue that lasts until the red alliance's score changes. If the video is just a stream of the live event, the time in the bottom right would presumably be automatically derived from the current video time, rather than based on a cue. However, if the video was just the highlights, then that might be given in cues also.

The following shows what fragments of this could look like in a WebVTT file:

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

```
...
05:10:00.000 --> 05:12:15.000
matchtype:global
matchnumber:37
...
05:11:02.251 --> 05:11:17.198
red:178
05:11:03.672 --> 05:11:154.198
blue:66
05:11:17.198 --> 05:11:25.912
red:80
05:11:25.912 --> 05:11:26.522
red:83
05:11:26.522 --> 05:11:26.982
red:86
05:11:26.982 --> 05:11:27.499
red:89
...
```

The key here is to notice that the information is given in cues that span the length of time to which the relevant event applies. If, instead, the scores were given as zero-length (or very brief, nearly zero-length) cues when the score changes, for example saying "red+2" at 05:11:17.198, "red+3" at 05:11:25.912, etc, problems arise: primarily, seeking is much harder to implement, as the script has to walk the entire list of cues to make sure that no notifications have been missed; but also, if the cues are short it's possible the script will never see that they are active unless it listens to them specifically.

When using cues in this manner, authors are encouraged to use the `cuechange` event to update the current annotations. (In particular, using the `timeupdate` event would be less appropriate as it would require doing work even when the cues haven't changed, and, more importantly, would introduce a higher latency between when the metadata cues become active and when the display is updated, since `timeupdate` events are rate-limited.)

4.8.12.12 Identifying a track kind through a URL

Other specifications or formats that need a [URL](#) to identify the return values of the `audioTrack.kind` or `videoTrack.kind` IDL attributes, or identify the `kindOfTextTrack`, must use the [about:html1-kind](#) URL.

4.8.12.13 User interface

The `controls` attribute is a [boolean attribute](#). If present, it indicates that the author has not provided a scripted controller and would like the user agent to provide its own set of controls.

If the attribute is present, or if `scriptingDisabled` for the `media element`, then the user agent should expose a user interface to the user. This user interface should include features to begin playback, pause playback, seek to an arbitrary position in the content (if the content supports arbitrary seeking), change the volume, change the display of closed captions or embedded sign-language tracks, select different audio tracks or turn on audio descriptions, and show the media content in manners more suitable to the user (e.g. fullscreen video or in an independent resizable window). Other controls may also be made available.

Even when the attribute is absent, however, user agents may provide controls to affect playback of the media resource (e.g. play, pause, seeking, track selection, and volume controls), but such features should not interfere with the page's normal rendering. For example, such features could be exposed in the `media element`'s context menu, platform media keys, or a remote control. The user agent may implement this simply by exposing a user interface to the user as described above (as if the `controls` attribute was present).

If the user agent exposes a user interface to the user by displaying controls over the `media element`, then the user agent should suppress any user interaction events while the user agent is interacting with this interface. (For example, if the user clicks on a video's playback control, `mousedown` events and so forth would not simultaneously be fired at elements on the page.)

Where possible (specifically, for starting, stopping, pausing, and unpauseing playback, for seeking, for changing the rate of playback, for fast-forwarding or rewinding, for listing, enabling, and disabling text tracks, and for muting or changing the volume of the audio), user interface features exposed by the user agent must be implemented in terms of the DOM API described above, so that, e.g., all the same events fire.

Features such as fast-forward or rewind must be implemented by only changing the `playbackRate` attribute (and not the `defaultPlaybackRate` attribute).

Seeking must be implemented in terms of `seeking` to the requested position in the `media element`'s `media timeline`. For media resources where seeking to an arbitrary position would be slow, user agents are encouraged to use the `approximate-for-speed` flag when seeking in response to the user manipulating an approximate position interface such as a seek bar.

MDN

HTML MediaElement/controls

Support in all current engines.

Firefox3.5+Safari6+Chrome43+

OperaYesEdge79+

Edge (Legacy)12+Internet Explorer9+

Foxfox AndroidYesSafari iOSYesChrome Android43+WebView Android43+Samsung Internet4.0+Opera AndroidYes

The `controls` IDL attribute must `reflect` the `content` attribute of the same name.

For web developers (non-normative)

`media : volume [= value]`

Returns the current playback volume, as a number in the range 0.0 to 1.0, where 0.0 is the quietest and 1.0 the loudest.

Can be set, to change the volume.

Throws an `"udecodeSizeError"` `DOMException` if the new value is not in the range 0 .. 1.0.

`media : muted [= value]`

Returns true if audio is muted, overriding the `volume` attribute, and false if the `volume` attribute is being honored.

Can be set, to change whether the audio is muted or not.

A `media element` has a `playback volume`, which is a fraction in the range 0.0 (silent) to 1.0 (loudest). Initially, the volume should be 1.0, but user agents may remember the last set value across sessions, on a per-site basis or otherwise, so the volume may start at other values.

MDN

HTML MediaElement/volume

Support in all current engines.

Firefox3.5+Safari6+Chrome43+

OperaYesEdge79+

Edge (Legacy)12+Internet Explorer9+

Foxfox AndroidYesSafari iOSYesChrome Android43+WebView Android43+Samsung Internet4.0+Opera AndroidYes

The `volume` IDL attribute must return the `playback volume` of any audio portions of the `media element`. On setting, if the new value is in the range 0.0 to 1.0 inclusive, the `media element`'s `playback volume` must be set to the new value. If the new value is outside the range 0.0 to 1.0 inclusive, then, on setting, an `"udecodeSizeError"` `DOMException` must be thrown instead.

A `media element` can also be `muted`. If anything is muting the element, then it is muted. (For example, when the `directionOfPlayback` is backwards, the element is muted.)

MDN

HTML MediaElement/muted

Support in all current engines.

Firefox3.5+Safari6+Chrome43+

OperaYesEdge79+

Edge (Legacy)12+Internet Explorer9+

Foxfox AndroidYesSafari iOSYesChrome Android43+WebView Android43+Samsung Internet4.0+Opera AndroidYes

The `muted` IDL attribute must return the value to which it was last set. When a `media element` is created, if the element has a `muted` content attribute specified, then the `muted` IDL attribute should be set to true; otherwise, the user agents may set the value to the user's preferred value (e.g. remembering the last set value across sessions, on a per-site basis or otherwise). While the `muted` IDL attribute is set to true, the `media element` must be muted.

Whenever either of the values that would be returned by the `volume` and `muted` IDL attributes change, the user agent must queue a task to fire an event named `volumechange` at the `media element`. Then, if the `media element` is not allowed to play, the user agent must run the `internal_pause_steps` for the `media element`.

An element's `effective media volume` is determined as follows:

1. If the user has indicated that the user agent is to override the volume of the element, then return the volume desired by the user.
2. If the element's audio output is `muted`, then return zero.
3. Let `volume` be the `playback volume` of the audio portions of the `media element`, in range 0.0 (silent) to 1.0 (loudest).
4. Return `volume`, interpreted relative to the range 0.0 to 1.0, with 0.0 being silent, and 1.0 being the loudest setting, values in between increasing in loudness. The range need not be linear. The loudest setting may be lower than the system's loudest possible setting; for example the user could have set a maximum volume.

The `muted` content attribute on `media elements` is a [boolean attribute](#) that controls the default state of the audio output of the `media resource`, potentially overriding user preferences.

MDN

HTML MediaElement/defaultMuted

Support in all current engines.

Firefox1+Safari6+Chrome43+

OperaYesEdge79+

Edge (Legacy)12+Internet Explorer?

Foxfox Android14+Safari iOSYesChrome Android43+WebView Android43+Samsung Internet4.0+Opera AndroidYes

The `defaultMuted` IDL attribute must `reflect` the `muted` content attribute.

Note

This attribute has no dynamic effect (it only controls the default state of the element).

Example

This video (an advertisement) autoplays, but to avoid annoying users, it does so without sound, and allows the user to turn the sound on. The user agent can pause the video if it's unmuted without a user interaction.

```
<video src="adverts.cgi?kIndivideo" controls autoplay loop muted></video>
```

4.8.12.14 Time ranges

MDN

TimeRanges

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

Objects implementing the `TimeRanges` interface represent a list of ranges (periods) of time.

```
IDL([Exposed=Window])
interface TimeRanges {
  readonly attribute long length;
  double start(unsigned long index);
  double end(unsigned long index);
};
```

For web developers (non-normative)`media.length`

Returns the number of ranges in the object.

`time = media.start(index)`

Returns the time for the start of the range with the given index.

Throws an "`IndexSizeError`" `DOMException` if the index is out of range.`time = media.end(index)`

Returns the time for the end of the range with the given index.

Throws an "`IndexSizeError`" `DOMException` if the index is out of range.**MDN**[TimeRanges.length](#)

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `length` IDL attribute must return the number of ranges represented by the object.**MDN**[TimeRanges.start](#)

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `start(index)` method must return the position of the start of the `index`th range represented by the object, in seconds measured from the start of the timeline that the object covers.**MDN**[TimeRanges.end](#)

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `end(index)` method must return the position of the end of the `index`th range represented by the object, in seconds measured from the start of the timeline that the object covers.These methods must throw "`IndexSizeError`" `DOMException` if called with an `index` argument greater than or equal to the number of ranges represented by the object.When a `TimeRanges` object is said to be a *normalized TimeRanges* object, the ranges it represents must obey the following criteria:

- The start of a range must be greater than the end of all earlier ranges.
- The start of a range must be less than or equal to the end of that same range.

In other words, the ranges in such an object are ordered, don't overlap, and don't touch (adjacent ranges are folded into one bigger range). A range can be empty (referencing just a single moment in time), e.g. to indicate that only one frame is currently buffered in the case that the user agent has discarded the entire `media resource` except for the current frame, when a `media element` is paused.Ranges in a `TimeRanges` object must be inclusive.**Example**

Thus, the end of a range would be equal to the start of a following adjacent (touching but not overlapping) range. Similarly, a range covering a whole timeline anchored at zero would have a start equal to zero and an end equal to the duration of the timeline.

The timelines used by the objects returned by the `buffered`, `seekable` and `played` IDL attributes of `media elements` must be that element's `media timeline`.4.8.12.15 The `TrackEvent` interface**MDN**[TrackEvent](#)

Support in one engine only.

exit Event	The cue has stopped being active.

4.8.12.17 Security and privacy considerations

The main security and privacy implications of the [video](#) and [audio](#) elements come from the ability to embed media cross-origin. There are two directions that threats can flow: from hostile content to a victim page, and from a hostile page to victim content.

If a victim page embeds hostile content, the threat is that the content might contain scripted code that attempts to interact with the [document](#) that embeds the content. To avoid this, user agents must ensure that there is no access from the content to the embedding page. In the case of media content that uses DOM concepts, the embedded content must be treated as if it was in its own unrelated [top-level browser context](#).

Example
For instance, if an SVG animation was embedded in a [video](#) element, the user agent would not give it access to the DOM of the outer page. From the perspective of scripts in the SVG resource, the SVG file would appear to be in a lone top-level browsing context with no parent.

If a hostile page embeds victim content, the threat is that the embedding page could obtain information from the content that it would not otherwise have access to. The API does expose some information: the existence of the media, its type, its duration, its size, and the performance characteristics of its host. Such information is already potentially problematic, but in practice the same information can more or less be obtained using the [src](#) element, and so it has been deemed acceptable.

However, significantly more sensitive information could be obtained if the user agent further exposes metadata within the content, such as subtitles. That information is therefore only exposed if the video resource uses CORS. The [crossorigin](#) attribute allows authors to enable CORS. ([FETCH](#))

Example
Without this restriction, an attacker could trick a user running within a corporate network into visiting a site that attempts to load a video from a previously leaked location on the corporation's intranet. If such a video included confidential plans for a new product, then being able to read the subtitles would present a serious confidentiality breach.

4.8.12.18 Best practices for authors using media elements

This section is non-normative.

Playing audio and video resources on small devices such as set-top boxes or mobile phones is often constrained by limited hardware resources in the device. For example, a device might only support three simultaneous videos. For this reason, it is a good practice to release resources held by [media elements](#) when they are done playing, either by being very careful about removing all references to the element and allowing it to be garbage collected, or, even better, by removing the element's [src](#) attribute and any [source](#) element descendants, and invoking the element's [release](#) method.

Similarly, when the playback rate is not exactly 1.0, hardware, software, or format limitations can cause video frames to be dropped and audio to be choppy or muted.

4.8.12.19 Best practices for implementors of media elements

How accurately various aspects of the `media_element` API are implemented is considered a quality-of-implementation issue.

For example, when implementing the `buffered` attribute, how precise an implementation reports the ranges that have been buffered depends on how carefully the user agent inspects the data. Since the API reports ranges as times, but the data is obtained in byte streams, a user agent receiving a variable-bitrate stream might only be able to determine precise times by actually decoding all of the data. User agents aren't required to do this, however; they can instead return estimates (e.g. based on the average bitrate seen so far) which get revised as more information becomes available.

As a general rule, user agents are urged to be conservative rather than optimistic. For example, it would be bad to report that everything had been buffered when it had not.

Another quality-of-implementation issue would be playing a video backwards when the code is designed only for forward playback (e.g. there aren't many key frames, and they are far apart, and the intervening frames only have deltas from the previous frame). User agents could do a poor job, e.g. only showing key frames; however, better implementations would do more work and thus do a better job, e.g. actually decoding parts of the video forwards, storing the complete frames, and then playing the frames backwards.

Similarly, while implementations are allowed to drop buffered data at any time (there is no requirement that a user agent keep all the media data obtained for the lifetime of the media element), it is again a quality of implementation issue: user agents with sufficient resources to keep all the data around are encouraged to do so, as this allows for a better user experience. For example, if the user is watching a live stream, a user agent could allow the user only to view the live video; however, a better user agent would buffer everything and allow the user to seek through the earlier material, pause it, play it forward and backwards, etc.

When a `media_element` that is paused is [removed from a document](#) and not reinserted before the next time the `event loop` reaches `step 1`, implementations that are resource constrained are encouraged to take that opportunity to release all hardware resources (like video planes, networking resources, and data buffers) used by the `media_element`. (User agents still have to keep track of the playback position and so forth, though, in case playback is later restarted.)

Content model:

Transparent

Tag content in text/html:

Neither tag is omitable.

Content attributes:

Global attributes

`name` — Name of `image map` to reference from the `usemap` attribute

Accessibility considerations:

For authors

For implementors

DOM interface:

```
IDL Exports=Windows
interface HTMLEmapElement : HTMLElement {
  [HTMLConstructor] constructor();
}
```

```
[CEReactions] attribute DOMString name;
```

```
[SameObject] readonly attribute HTMLCollection areas;
```

```
}
```

The `map` element, in conjunction with an `img` element and any `area` element descendants, defines an `image map`. The element `represents` its children.

The `name` attribute gives the map a name so that it can be [referenced](#). The attribute must be present and must have a non-empty value with no [ASCII whitespace](#). The value of the `name` attribute must not be equal to the value of the `name` attribute of another `map` element in the same `tree`. If the `id` attribute is also specified, both attributes must have the same value.

For web developers (non-normative)

map · **areas**

Returns an `HTMLCollection` of the `area` elements in the `map`.

The `areas` attribute must return an `HTMLCollection` rooted at the `map` element, whose filter matches only `area` elements.

The IDL attribute `name` must `reflect` the content attribute of the same name.

Example

Image maps can be defined in conjunction with other content on the page, to ease maintenance. This example is of a page with an image map at the top of the page and a corresponding set of text links at the bottom.

```

EXPAND

```
[area] attribute URITrailing alt;
[area] attribute DOMString rel;
[SameObject, PutForwards value] readonly attribute DOMTokenList relList;
[area] attribute DOMString referrerPolicy;
// also has obsolete members
HTMLAreaElement includes HTMLHyperlinkElementUtils;
```

The `area` element represents either a hyperlink with some text and a corresponding area on an `image map`, or a dead area on an `image map`.

An `area` element with a parent node must have a `map` element ancestor.

If the `area` element has an `href` attribute, then the `area` element represents a `hyperlink`. In this case, the `alt` attribute must be present. It specifies the text of the hyperlink. Its value must be text that, when presented with the texts specified for the other hyperlinks of the `image map`, and with the alternative text of the image, but without the image itself, provides the user with the same kind of choice as the hyperlink would when used without its text but with its shape applied to the image. The `rel` attribute may be left blank if there is another `area` element in the same `image map` that points to the same resource and has a non-blank `alt` attribute.

If the `area` element has no `text` attribute, then the area represented by the element cannot be selected, and the `alt` attribute must be omitted.

In both cases, the `shape` and `coords` attributes specify the area.

The `shape` attribute is an [enumerated attribute](#). The following table lists the keywords defined for this attribute. The states given in the first cell of the rows with keywords give the states to which those keywords map. Some of the keywords are non-conforming, as noted in the last column.

State	Keywords	Notes
<code>Circle state</code>	<code>circle</code>	Non-conforming
<code>Default state</code>	<code>default</code>	
<code>Polygon state</code>	<code>polygon</code>	Non-conforming
<code>Rectangle state</code>	<code>rect</code>	Non-conforming

The attribute may be omitted. The `missing value default` and `invalid value default` are the `rectangle` state.

The `coords` attribute must, if specified, contain a [valid list of floating-point numbers](#). This attribute gives the coordinates for the shape described by the `shape` attribute. The processing for this attribute is described as part of the `image map` processing model.

In the `circle state`, `area` elements must have a `coords` attribute present, with three integers, the last of which must be non-negative. The first integer must be the distance in `CSS pixels` from the left edge of the image to the center of the circle, the second integer must be the distance in `CSS pixels` from the top edge of the image to the center of the circle, and the third integer must be the radius of the circle again in `CSS pixels`.

In the `default state`, `area` elements must not have a `coords` attribute. (The area is the whole image.)

In the `polygon state`, `area` elements must have a `coords` attribute with at least six integers, and the number of integers must be even. Each pair of integers must represent a coordinate given as the distances from the left and the top of the image in `CSS pixels` respectively, and all the coordinates together must represent the points of the polygon, in order.

In the `rectangle state`, `area` elements must have a `coords` attribute with exactly four integers, the first of which must be less than the third, and the second of which must be less than the fourth. The four points must represent, respectively, the distance from the left edge of the image to the left side of the rectangle, the distance from the top edge to the top side, the distance from the left edge to the right side, and the distance from the top edge to the bottom side, all in `CSS pixels`.

When user agents allow users to [follow hyperlinks](#) or [download hyperlinks](#) created using the `area` element, as described in the next section, the `href`, `target`, `download`, and `ping` attributes decide how the link is followed. The `rel` attribute may be used to indicate to the user the likely nature of the target resource before the user follows the link.

The `target`, `download`, `ping`, and `referrerPolicy` attributes must be omitted if the `alt` attribute is not present.

If the `itemprop` attribute is specified on an `area` element, then the `href` attribute must also be specified.

The `activation behavior` of `area` elements is to [follow the hyperlink](#) or [download the hyperlink](#) created by the `area` element, if any, and as determined by the `download` attribute and any expressed user preference.

4.8.15.1 Image maps

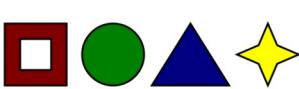

4.8.15.1.1 Authoring

An `image map` allows geometric areas on an image to be associated with [hyperlinks](#).

An image, in the form of an `img` element or an `object` element representing an image, may be associated with an image map (in the form of a `map` element) by specifying a `usemap` attribute on the `img` or `object` element. The `usemap` attribute, if specified, must be a [valid hash-name reference](#) to a `map` element.

Example

Consider an image that looks as follows:

If we wanted just the colored areas to be clickable, we could do it as follows:

```

<p>Please select a shape:</p>
<p><code></code>
  alt="Four shapes are available: a red hollow box, a green circle, a blue triangle, and a yellow four-pointed star."</p>
<map id="shapes" name="shapes">
  <area shape="rect" coords="50,50,100,100" href="#" alt="The hole in the red box -->">
  <area shape="rect" coords="25,125,125,125" href="#" alt="Red box -->">
  <area shape="circle" coords="125,125,10" href="#" alt="Green circle -->">
  <area shape="poly" coords="325,25,262,125,388,125" href="#" alt="Blue triangle -->">
  <area shape="poly" coords="450,25,435,60,400,15,435,90,450,125,465,90,500,75,465,60" href="#" alt="Yellow star -->">
</map>
```

4.8.15.2 Processing model

If an `img` element or an `object` element representing an image has a `usemap` attribute specified, user agents must process it as follows:

1. Parse the attribute's value using the [rules for parsing a hash-name reference](#) to a `map` element, with the element as the context node. This will return either an element (the `map`) or null.

2. If that returned null, then return. The image is not associated with an image map after all.

3. Otherwise, the user agent must collect all the `area` elements that are descendants of the `map`. Let those be the `areas`.

Having obtained the list of `area` elements that form the image map (`the areas`), interactive user agents must process the list in one of two ways.

If the user agent intends to show the text that the `img` element represents, then it must use the following steps.

Note

In user agents that do not support `images`, or that have `images` disabled, `object` elements cannot represent images, and thus this section never applies (the `fallback content` is shown instead). The following steps therefore only apply to `img` elements.

1. Remove all the `area` elements in `areas` that have no `alt` attribute.
2. Remove all the `area` elements in `areas` that have no `alt` attribute, whose `alt` attribute's value is the empty string, if there is another `area` element in `areas` with the same value in the `alt` attribute and with a non-empty `alt` attribute.
3. Each remaining `area` element in `areas` represents a [hyperlink](#). Those hyperlinks should all be made available to the user in a manner associated with the text of the `img`.

In this context, user agents may represent `area` and `img` elements with no specified `alt` attributes, or whose `alt` attributes are the empty string or some other non-visible text, in a user-agent-defined fashion intended to indicate the lack of suitable author-provided text.

If the user agent intends to show the image and allow interaction with the image to select hyperlinks, then the image must be associated with a set of layered shapes, taken from the `area` elements in `areas`, in reverse `tree order` (so the last specified `area` element in the `map` is the bottom-most shape, and the first element in the `map`, in `tree order`, is the top-most shape).

Each `area` element in `areas` must be processed as follows to obtain a shape to layer onto the image:

1. Find the state that the element's `shape` attribute represents.
2. Use the [rules for parsing a list of floating-point numbers](#) to parse the element's `coords` attribute, if it is present, and let the result be the `coords` list. If the attribute is absent, let the `coords` list be the empty list.
3. If the number of items in the `coords` list is less than the minimum number given for the `area` element's current state, as per the following table, then the shape is empty; return.

State	Minimum number of items
<code>Circle state</code>	3
<code>Default state</code>	0
<code>Polygon state</code>	6
<code>Rectangle state</code>	4

4. Check for excess items in the `coords` list as per the entry in the following list corresponding to the `shape` attribute's state:

`Circle state`
Drop any items in the list beyond the third.

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Note
The `dimension` attributes are not intended to be used to stretch the image.

User agent requirements: User agents are expected to use these attributes as hints for the rendering.

Flow content

Palpable content

Context in which this element can be used:

Where `table` content is expected.

Content model:

In this order: optionally a `caption` element, followed by zero or more `colgroup` elements, followed optionally by a `thead` element, followed by either zero or more `tbody` elements or one or more `tr` elements, followed optionally by a `tfoot` element, optionally intermixed with one or more `script-supporting elements`.

Tag omission in `text/html`:

None tag ismissible.

Content attributes:

Global attributes

Accessibility considerations:

For authors

For implementers

DOM interface:

```
IDL[Exposed=Window]
interface HTMLTableElement : HTMLElement {
  [HTMLTableElement] constructor();
  [HTMLSectionElement] attribute HTMLTableCaptionElement? caption;
  [HTMLTableSectionElement] attribute HTMLTableSectionElement? tHead;
  [HTMLTableSectionElement] attribute HTMLTableSectionElement? tFoot;
  [HTMLTableSectionElement] attribute HTMLTableSectionElement? tBody;
  [HTMLTableCaptionElement] createCaption();
  [HTMLTableSectionElement] createTHead();
  [HTMLTableSectionElement] createTFoot();
  [HTMLTableSectionElement] createTBody();
  [SameObject] readonly attribute HTMLCollection tBodies;
  [HTMLTableSectionElement] insertRow(optional long index = -1);
  [TableSection] void deleteRow(optional long index);
  // also has obsolete members
};
```

The `table` element represents data with more than one dimension, in the form of a `table`.

The `table` element takes part in the `table model`. Tables have rows, columns, and cells given by their descendants. The rows and columns form a grid; a table's cells must completely cover that grid without overlap.

Note

Precise rules for determining whether this conformance requirement is met are described in the description of the `table model`.

Authors are encouraged to provide information describing how to interpret complex tables. Guidance on how to [provide such information](#) is given below.

Tables must not be used as layout aids. Historically, some Web authors have misused tables in HTML as a way to control their page layout. This usage is non-conforming, because tools attempting to extract tabular data from such documents would obtain very confusing results. In particular, users of accessibility tools like screen readers are likely to find it very difficult to navigate pages with tables used for layout.

Note

There are a variety of alternatives to using HTML tables for layout, primarily using CSS positioning and the CSS table model. [[CSS](#)]

Tables can be complicated to understand and navigate. To help users with this, user agents should clearly delineate cells in a table from each other, unless the user agent has classified the table as a (non-conforming) layout table.

Note

Authors and implementers are encouraged to consider using some of the `table design techniques` described below to make tables easier to navigate for users.

User agents, especially those that do table analysis on arbitrary content, are encouraged to find heuristics to determine which tables actually contain data and which are merely being used for layout. This specification does not define a precise heuristic, but the following are suggested as possible indicators:

Feature

Indication

The use of the <code>row</code> attribute with the value <code>presentation</code>	Probably a layout table
The use of the non-conforming <code>border</code> attribute with the non-conforming value 0	Probably a layout table
The use of the non-conforming <code>cellpadding</code> and <code>cellspacing</code> attributes with the value 0	Probably a layout table
The use of the <code>caption</code> , <code>thead</code> , or <code>tbody</code> elements	Probably a non-layout table
The use of the <code>thead</code> and <code>tbody</code> attributes	Probably a non-layout table
The use of the non-conforming <code>border</code> attribute with a value other than 0	Probably a non-layout table
Explicit visible borders set using CSS	Probably a non-layout table
The use of the <code>summary</code> attribute	Not a good indicator (both layout and non-layout tables have historically been given this attribute)

Note

It is quite possible that the above suggestions are wrong. Implementors are urged to provide feedback elaborating on their experiences with trying to create a layout table detection heuristic.

If a `table` element has a (non-conforming) `summary` attribute, and the user agent has not classified the table as a layout table, the user agent may report the contents of that attribute to the user.

For web developers (non-normative)

`table . caption [= value]`

Returns the table's `caption` element.

Can be set, to replace the `caption` element.

`caption = table . createCaption()`

Ensures the table has a `caption` element, and returns it.

`table . deleteCaption()`

Ensures the table does not have a `caption` element.

`table . tHead [= value]`

Returns the table's `tHead` element.

Can be set, to replace the `tHead` element. If the new value is not a `tHead` element, throws a `"hierarchyRequestError"` `DOMException`.

`tHead = table . createTHead()`

Ensures the table has a `tHead` element.

```
table.deleteTHead()
Ensures the table does not have a thead element.

table.tfoot [ = value ]
Returns the table's tfoot element.
Can be set, to replace the tfoot element. If the new value is not a tfoot element, throws a "hierarchyRequestError" DOMException.
tfoot = table.createTFoot()
Ensures the table has a tfoot element, and returns it.

table.deleteTFoot()
Ensures the table does not have a tfoot element.

table.tBodies
Returns an HTMLCollection of the tbody elements of the table.

body = table.createTBody()
Creates a tbody element, inserts it into the table, and returns it.

table.tRows
Returns an HTMLCollection of the tr elements of the table.

r = table.insertRow([index])
Creates a tr element, along with a tbody if required, inserts them into the table at the position given by the argument, and returns the tr.
The position is relative to the rows in the table. The index -1, which is the default if the argument is omitted, is equivalent to inserting at the end of the table.
If the given position is less than -1 or greater than the number of rows, throws an "IndexSizeError" DOMException.

table.deleteRow(index)
Removes the tr element with the given position in the table.
The position is relative to the rows in the table. The index -1 is equivalent to deleting the last row of the table.
If the given position is less than -1 or greater than the index of the last row, or if there are no rows, throws an "IndexSizeError" DOMException.
```

In all of the following attribute and method definitions, when an element is to be `table-created`, that means to `create an element` given the `table` element's `node document`, the given local name, and the `HTML namespace`.

The behavior of the `insertRow(index)` method depends on the state of the table. When it is called, the method must act as required by the first item in the following list of conditions that describes the state of the table and the `index` argument:If `index` is less than -1 or greater than the number of elements in `rows`:The method must throw an `IndexSizeError` `DOMException`.If the `rows` collection has zero elements in it, and the `table` has no `tbody` elements in it:The method must `table-create` a `thead` element, then `table-create` a `tr` element, then append the `tr` element to the `tbody` element, then append the `tbody` element to the `table` element, and finally return the `tr` element.If the `rows` collection has zero elements in it:The method must `table-create` a `tr` element, append it to the last `tbody` element in the table, and return the `tr` element.If `index` is -1 or equal to the number of items in `rows` collection:The method must `table-create` a `tr` element, and append it to the parent of the last `tr` element in the `rows` collection. Then, the newly created `tr` element must be returned.

Otherwise:

The method must `table-create` a `tr` element, insert it immediately before the `index`th `tr` element in the `rows` collection, in the same parent, and finally must return the newly created `tr` element.**MDN****HTMLTableElement.deleteRow**

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android Yes Safari iOS Yes Chrome Android? Web View Android Yes Samsung Internet? Opera Android Yes

When the `deleteRow(index)` method is called, the user agent must run the following steps:

- If `index` is less than -1 or greater than or equal to the number of elements in the `rows` collection, then throw an `"IndexSizeError"` `DOMException`.
- If `index` is -1, then `remove` the last element in the `rows` collection from its parent, or do nothing if the `rows` collection is empty.
- Otherwise, `remove` the `index`th element in the `rows` collection from its parent.

Example

Here is an example of a table being used to mark up a Sudoku puzzle. Observe the lack of headers, which are not necessary in such a table.

```
<table border="1">
  <tbody>
    <tr><td>1</td><td>2</td><td>3</td><td>4</td><td>5</td><td>6</td><td>7</td><td>8</td><td>9</td>
    <td>2</td><td>3</td><td>1</td><td>4</td><td>5</td><td>6</td><td>7</td><td>8</td><td>9</td>
    <td>3</td><td>1</td><td>2</td><td>4</td><td>5</td><td>6</td><td>7</td><td>8</td><td>9</td>
    <td>4</td><td>5</td><td>6</td><td>1</td><td>2</td><td>3</td><td>7</td><td>8</td><td>9</td>
    <td>5</td><td>6</td><td>7</td><td>2</td><td>3</td><td>4</td><td>8</td><td>9</td><td>1</td>
    <td>6</td><td>7</td><td>8</td><td>3</td><td>4</td><td>5</td><td>9</td><td>1</td><td>2</td>
    <td>7</td><td>8</td><td>9</td><td>4</td><td>5</td><td>6</td><td>2</td><td>3</td><td>1</td>
    <td>8</td><td>9</td><td>1</td><td>5</td><td>6</td><td>7</td><td>3</td><td>4</td><td>2</td>
    <td>9</td><td>1</td><td>2</td><td>6</td><td>7</td><td>8</td><td>5</td><td>3</td><td>4</td>
  </tbody>
</table>
```

4.9.1.1 Techniques for describing tables

For tables that consist of more than just a grid of cells with headers in the first row and headers in the first column, and for any table in general where the reader might have difficulty understanding the content, authors should include explanatory information introducing the table. This information is useful for all users, but is especially useful for users who cannot see the table, e.g. users of screen readers.

Such explanatory information should introduce the purpose of the table, outline its basic cell structure, highlight any trends or patterns, and generally teach the user how to use the table.

For instance, the following table:

Characteristics with positive and negative sides

Negative Characteristic Positive

Sad Mood Happy

Failing Grade Passing

...might benefit from a description explaining the way the table is laid out, something like "Characteristics are given in the second column, with the negative side in the left column and the positive side in the right column".

There are a variety of ways to include this information, such as:

In prose, surrounding the table

Example

```
<p>In the following table, characteristics are given in the second column, with the negative side in the left column and the positive side in the right column.</p>
<table>
<caption>Characteristics with positive and negative sides</caption>
<thead>
<tr>
<th id="r1"> Negative
<th> Characteristic
<th> Positive
</thead>
<tbody>
<tr>
<td headers="n r1"> Sad
<td> Mood
<td Happy
</tr>
<tr>
<td headers="n r2"> Failing
<th id="r2"> Grade
<td> Passing
</tr>
</tbody>
```

In the table's `caption`

Example

```
<table>
<caption>
<strong>Characteristics with positive and negative sides.</strong>
<p>Characteristics are given in the second column, with the negative side in the left column and the positive side in the right column.</p>
</caption>
<thead>
<tr>
<th id="r1"> Negative
<th> Characteristic
<th> Positive
</thead>
<tbody>
<tr>
<td headers="n r1"> Sad
<td id="r1"> Mood
<td Happy
</tr>
<tr>
<td headers="n r2"> Failing
<th id="r2"> Grade
<td> Passing
</tr>
</tbody>
```

In the table's `caption`, in a `details` element

Example

```
<table>
<caption>
<strong>Characteristics with positive and negative sides.</strong>
<details>
<summary>Characteristics are given in the second column, with the negative side in the left column and the positive side in the right column.</summary>
<tbody>
<tr>
<th id="r1"> Negative
<th> Characteristic
<th> Positive
</tr>
<tr>
<td headers="n r1"> Sad
<td id="r1"> Mood
<td Happy
</tr>
<tr>
<td headers="n r2"> Failing
<th id="r2"> Grade
<td> Passing
</tr>
</tbody>
</table>
```

Next to the table, in the same `figure`

Example

```
<tr>
<td>
<caption>Characteristics with positive and negative sides</caption>
<p>Characteristics are given in the second column, with the negative side in the left column and the positive side in the right column.</p>
<table>
<thead>
<tr>
<th id="r1"> Negative
<th> Characteristic
<th> Positive
</thead>
<tbody>
<tr>
<td headers="n r1"> Sad
<td id="r1"> Mood
<td Happy
</tr>
<tr>
<td headers="n r2"> Failing
<th id="r2"> Grade
<td> Passing
</tr>
</tbody>
</table>
</td>
</tr>
```

Next to the table, in a `figure`'s `caption`

Example

```
<tr>
<td>
<caption>Characteristics with positive and negative sides</caption>
<p>Characteristics are given in the second column, with the negative side in the left column and the positive side in the right column.</p>
<table>
<thead>
<tr>
<th id="r1"> Negative
<th> Characteristic
<th> Positive
</thead>
<tbody>
<tr>
<td headers="n r1"> Sad
<td id="r1"> Mood
<td Happy
</tr>
<tr>
<td headers="n r2"> Failing
<th id="r2"> Grade
<td> Passing
</tr>
</tbody>
</table>
</td>
</tr>
```

Authors may also use other techniques, or combinations of the above techniques, as appropriate.

The best option, of course, rather than writing a description explaining the way the table is laid out, is to adjust the table such that no explanation is needed.

Example

In the case of the table used in the examples above, a simple rearrangement of the table so that the headers are on the top and left sides removes the need for an explanation as well as removing the need for the use of `headers` attributes:

```
<table>
<caption>Characteristics with positive and negative sides</caption>
<thead>
<tr>
<th> Characteristic
<th> Negative
<th> Positive
</thead>
<tbody>
<tr>
<td> Mood
<td Sad
<td Happy
</tr>
<tr>
<td> Grade
<td Failing
<td> Passing
</tr>
</tbody>
</table>
```

4.9.1.2 Techniques for table design

Good table design is key to making tables more readable and usable.

In visual media, providing column and row borders and alternating row backgrounds can be very effective to make complicated tables more readable.

For tables with large volumes of numeric content, using monospaced fonts can help users see patterns, especially in situations where a user agent does not render the borders. (Unfortunately, for historical reasons, not rendering borders on tables is a common default.)

In speech media, table cells can be distinguished by reporting the corresponding headers before reading the cell's contents, and by allowing users to navigate the table in a grid fashion, rather than serializing the entire contents of the table in source order.

Authors are encouraged to use CSS to achieve these effects.

User agents are encouraged to render tables using these techniques whenever the page does not use CSS and the table is not classified as a layout table.

4.9.2 The `caption` element

[Element:caption](#)

Support in all current engines

Firefox, Android 4+, Safari iOS, Chrome, Android WebView, Android Yes, Samsung Internet Yes, Opera, Android Yes

Categories:**Contexts in which this element can be used:**As the first element child of a `table` element.**Content model:**Flow content, but with no descendant `table` elements.**Tag omission in text/html:**Content of the element's `end tag` can be omitted if the `caption` element is not immediately followed by [ASCII whitespace](#) or a `comment`.**Content attributes:****Global attributes:****Accessibility considerations:****For authors:****For implementers:****DOM interface:**

```
IDL Exports<#idl>
interface RTMCTableCaptionElement : HTMLElement {
  [HTMLConstructor] constructor();
  // also has obsolete members
};
```

The `caption` element **represents** the title of the `table` that is its parent, if it has a parent and that is a `table` element.The `caption` element takes part in the `table` model.When a `table` element is the only content in a `figure` element other than the `figcaption`, the `caption` element should be omitted in favor of the `figcaption`.

A caption can introduce context for a table, making it significantly easier to understand.

Example

Consider, for instance, the following table:

1	2	3	4	5	6
2	3	4	5	6	7
3	4	5	6	7	8
4	5	6	7	8	9
5	6	7	8	9	10
6	7	8	9	10	11
7	8	9	10	11	12

In the abstract, this table is not clear. However, with a caption giving the table's number (for [reference](#) in the main prose) and explaining its use, it makes more sense:

```
<caption>
<table>1
<p>This table shows the total score obtained from rolling two six-sided dice. The first row represents the value of the first die, the first column the value of the second die. The total is given in the cell that corresponds to the values of the two dice.
</caption>
```

This provides the user with more context:

Table 1
This table shows the total score obtained from rolling two six-sided dice.
The first row represents the value of the first die, the first column the value of the second die. The total is given in the cell that corresponds to the values of the two dice.

1	2	3	4	5	6
2	3	4	5	6	7
3	4	5	6	7	8
4	5	6	7	8	9
5	6	7	8	9	10
6	7	8	9	10	11
7	8	9	10	11	12

Contexts in which this element can be used:

As a child of a `table` element, after any `caption`, `colgroup`, and `thead` elements, but only if there are no `tr` elements that are children of the `table` element.

Content model:

Zero or more `tr` and `script-supporting` elements.

Tax omission in text/html:

A `tbody` element's `start tag` can be omitted if the first `tr` inside the `tbody` element is a `tr` element, and if the element is not immediately preceded by a `thead`, `tfoot`, or `tr` element whose `end tag` has been omitted. (It can't be omitted if the element is empty.)

A `tbody` element's `end tag` can be omitted if the `tbody` element is immediately followed by a `tbody` or `tfoot` element, or if there is no more content in the parent element.

Content attributes:

`Global attributes`

Accessibility considerations:

`For authors`

`For implementers`

DOM interface:

```
interface HTMLOTableSectionElement : HTMLElement {
  [HTMLConstructor] constructor();
  [SameObject] readonly attribute HTMLCollection rows;
  HTMLOTableSectionElement insertRow(optional long index = -1);
  void deleteRow(optional long index);
  /* also has obsolete members */
}
```

The `HTMLOTableSectionElement` interface is also used for `thead` and `tfoot` elements.

The `tbody` element [represents a block of rows](#) that consist of a body of data for the parent `table` element, if the `tbody` element has a parent and it is a `table`.

The `tbody` element takes part in the [table model](#).

For web developers (non-normative)

`tbody` `rows`

Returns an `HTMLCollection` of the `tr` elements of the table section.

`r = tbody.insertRow([index])`

Creates a `tr` element, inserts it into the table section at the position given by the argument, and returns the `tr`.

The position is relative to the rows in the table section. The index -1, which is the default if the argument is omitted, is equivalent to inserting at the end of the table section.

If the given position is less than -1 or greater than the number of rows, throws an `"IndexSizeError"` `DOMException`.

`tbody.deleteRow(index)`

Removes the `tr` element with the given position in the table section.

The position is relative to the rows in the table section. The index -1 is equivalent to deleting the last row of the table section.

If the given position is less than -1 or greater than the index of the last row, or if there are no rows, throws an `"IndexSizeError"` `DOMException`.

The `rows` attribute must return an `HTMLCollection` rooted at this element, whose filters matches only `tr` elements that are children of this element.

The `insertRow(index)` method must act as follows:

1. If `index` is less than -1 or greater than the number of elements in the `rows` collection, throw an `"IndexSizeError"` `DOMException`.

2. Let `table row` be the result of [creating an element](#) given this element's `node document`, `i`, and the `HTML namespace`.

3. If `index` is -1 or equal to the number of items in the `rows` collection, then [append table row](#) to this element.

4. Otherwise, [insert table row](#) as a child of this element, immediately before the `indexth tr` element in the `rows` collection.

5. Return `table row`.

The `deleteRow(index)` method must, when invoked, act as follows:

1. If `index` is less than -1 or greater than or equal to the number of elements in the `rows` collection, then throw an `"IndexSizeError"` `DOMException`.

2. If `index` is -1, then [remove](#) the last element in the `rows` collection from this element, or do nothing if the `rows` collection is empty.

3. Otherwise, [remove](#) the `indexth` element in the `rows` collection from this element.

4.9.6 The `thead` element

[Element/Head](#)

Support in all current engines.

Firefox 1+ Safari Yes Chrome 1+

Contexts in which this element can be used:

As a child of a `table` element, after any `caption`, `colgroup`, `thead`, and `tbody` elements, but only if there are no other `tfoot` elements that are children of the `table` element.

Content model:

Zero or more `td` and `script-supporting` elements.

Tag omission in XML:

A `tfoot` element's `end tag` can be omitted if there is no more content in the parent element.

Content attributes:

Global attributes

Accessibility considerations:

For authors

For implementers

DOM interface:

Uses `HTMLTableSectionElement`, as defined for `tbody` elements.

The `tfoot` element represents the `block` of `rows` that consist of the column summaries (footers) for the parent `table` element, if the `tfoot` element has a parent and it is a `table`.

The `tfoot` element takes part in the `table model`.

4.9.8 The `tr` element

Contexts in which this element can be used:

As a child of a `thead` element.
As a child of a `tbody` element.
As a child of a `tfoot` element.
As a child of a `table` element, after any `caption`, `colgroup`, and `thead` elements, but only if there are no `tbody` elements that are children of the `table` element.

Content model:

Zero or more `td`, `th`, and `script-supporting` elements.

Tag omission in XML:

A `tr` element's `end tag` can be omitted if the `tr` element is immediately followed by another `tr` element, or if there is no more content in the parent element.

Content attributes:

Global attributes

Accessibility considerations:

For authors

For implementers

DOM interface:

```
IDL[Exposed=Window]
interface HTMLTableRowElement : HTMLElement {
  [Constructors] HTMLTableSectionElement();
  readonly attribute long rowIndex;
  readonly attribute long sectionRowIndex;
  [SameObject] readonly attribute HTMLCollection cells;
  [ObjectConstructor] void deleteCell(long index);
  [ObjectConstructor] void deleteCells(long index);
}

// also has obsolete members
```

The `tr` element represents a `row` of `cells` in a `table`.

The `tr` element takes part in the `table model`.

For web developers (non-normative)

Properties

Returns the position of the row in the table's `rows` list.
Returns -1 if the element isn't in a table.

Properties

Returns the position of the row in the table section's `rows` list.
Returns -1 if the element isn't in a table section.

Methods

Returns an `HTMLCollection` of the `td` and `th` elements of the row.

`cell = tr.insertCell([index])`

Creates a `td` element, inserts it into the table row at the position given by the argument, and returns the `td`.

The position is relative to the cells in the row. The index -1, which is the default if the argument is omitted, is equivalent to inserting at the end of the row.

If the given position is less than -1 or greater than the number of cells, throws an `"IndexSizeError"` `DOMException`.

Methods

Removes the `td` or `th` element with the given position in the row.

The position is relative to the cells in the row. The index -1 is equivalent to deleting the last cell of the row.

If the given position is less than -1 or greater than the index of the last cell, or if there are no cells, throws an `"IndexSizeError"` `DOMException`.

The `rowIndex` attribute must, if this element has a parent `thead` element, or a parent `tbody`, `tfoot` element and a `grandparent` `table` element, return the index of this `tr` element in that `table` element's `rows` collection. If there is no such `table` element, then the attribute must return -1.

The `sectionRowIndex` attribute must, if this element has a parent `table`, `tbody`, `thead`, or `tfoot` element, return the index of the `tr` element in the parent element's `rows` collection (for tables, that's `HTMLTableElement`'s `rows` collection; for table sections, that's `HTMLTableSectionElement`'s `rows` collection). If there is no such parent element, then the attribute must return -1.

The `cells` attribute must return an `HTMLCollection` rooted at this `tr` element, whose filter matches only `td` and `th` elements that are children of the `tr` element.

HTML TableRow Element/insertCell

Support in all current engines.

Firefox1+SafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet ExplorerYes

Firefox Android4+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

The `insertCell(index)` method must act as follows:

1. If `index` is less than -1 or greater than the number of elements in the `cells` collection, then throw an `"IndexSizeError"` `DOMException`.

2. Let `table cell` be the result of `creating an element` give this `tr` element's `nodeDocument`, `tr`, and the `HTML namespace`.

3. If `index` is equal to -1 or equal to the number of items in `cells` collection, then `append table cell` to this `tr` element.

4. Otherwise, `insert table cell` as a child of this `tr` element, immediately before the `indexth td` or `th` element in the `cells` collection.

5. Return `table cell`.

The `deleteCell(index)` method must act as follows:

1. If `index` is less than -1 or greater than or equal to the number of elements in the `cells` collection, then throw an `"IndexSizeError"` `DOMException`.

2. If `index` is -1, then `remove` the last element in the `cells` collection from its parent, or do nothing if the `cells` collection is empty.

3. Otherwise, `remove` the `indexth` element in the `cells` collection from its parent.

4.9.9 The `td` element

Sectioning root

Contexts in which this element can be used:

As a child of a `td` element.

Content model:

Flow content

Tag omission in HTML:

A `td` element's `end tag` can be omitted if the `td` element is immediately followed by a `td` or `th` element, or if there is no more content in the parent element.

Content attributes:

Global attributes

```
[colspan] -- Number of columns that the cell is to span
[rowspan] -- Number of rows that the cell is to span
[headers] -- The header cells for this cell
```

Accessibility considerations:

For authors

For implementers

DOM interface

```
IDL[Exposed=Window]
interface HTMLOptionCellElement : HTMLElement {
  [get, set] long headers();
  [attribute unsigned long colspan];
  [attribute unsigned long rowspan];
  [attribute DOMString headers];
  readonly attribute long cellIndex;
  [attribute DOMString scope] // only conforming for th elements
  [attribute DOMString abbr] // only conforming for th elements
  // also has obsolete members
}
```

The `HTMLOptionCellElement` interface is also used for `th` elements.

The `td` element **represents** a data `cell` in a table.

The `td` element and its `colspan`, `rowspan`, and `headers` attributes take part in the `table model`.

User agents, especially in non-visual environments or where displaying the table as a 2D grid is impractical, may give the user context for the cell when rendering the contents of a cell; for instance, giving its position in the `table model`, or listing the cell's header cells (as determined by the [algorithm for assigning header cells](#)). When a cell's header cells are being listed, user agents may use the value of `abbr` attributes on those header cells, if any, instead of the contents of the header cells themselves.

Example

In this example, we see a snippet of a Web application consisting of a grid of editable cells (essentially a simple spreadsheet). One of the cells has been configured to show the sum of the cells above it. Three have been marked as headings, which use `td` elements instead of `th` elements. A script would attach event handlers to these elements to maintain the total.

```
<table>
  <tr>
    <td><input value="Name">
    <td><input value="Paid ($)">
  </tr>
  <td><input value="Jeff">
  <td><input value="14">
  </tr>
  <td><input value="Britta">
  <td><input value="9">
  </tr>
  <td><input value="Abel">
  <td><input value="2">
  </tr>
  <td><input value="Shirley">
  <td><input value="27">
  </tr>
  <td><input value="Annie">
  <td><input value="5">
  </tr>
  <td><input value="Troy">
  <td><input value="5">
  </tr>
  <td><input value="Plato">
  <td><input value="1000">
  </tr>
  <td><input value="Total">
  <td><output value="1060">
</table>
```

4.9.10 The `th` element

MDN

Element API

OperaYesEdge79+

Edge (Legacy)12+Internet ExplorerYes

Firefox Android4+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

Categories:

None

Contexts in which this element can be used:

As a child of a `td` element.

Content model:

Flow content, but with no `header`, `footer`, `sectioning content`, or `heading` content descendants.

Tag omission in HTML5:

A `th` element's `end tag` can be omitted if the `th` element is immediately followed by a `td` or `th` element, or if there is no more content in the parent element.

Content attributes:

Global attributes

```
[colspan] -- Number of columns that the cell is to span
[rowspan] -- Number of rows that the cell is to span
[headers] -- The header cells for this cell
[scope] -- Specifies which cells the header cell applies to
[abbr] -- Alternative label to use for the header cell when referencing the cell in other contexts
```

Accessibility considerations:

For authors

For implementers

DOM interface

Uses `HTMLOptionCellElement`, as defined for `td` elements.

The `th` element **represents** a header `cell` in a table.

The `th` element may have a `scope` content attribute specified. The `scope` attribute is an [enumerated attribute](#) with five states, four of which have explicit keywords:

The `row` keyword, which maps to the `row` state.

The `row` state means the header cell applies to some of the subsequent cells in the same row(s).

The `col` keyword, which maps to the `col` state.

The `col` state means the header cell applies to some of the subsequent cells in the same column(s).

The `rowgroup` keyword, which maps to the `row group` state.

The `row group` state means the header cell applies to all the remaining cells in the row group. A `th` element's `scope` attribute must not be in the `row group` state if the element is not anchored in a `row group`.

The `column` keyword, which maps to the `column group` state.

The `column group` state means the header cell applies to all the remaining cells in the column group. A `th` element's `scope` attribute must not be in the `column group` state if the element is not anchored in a `column group`.

The `auto` state.

The `auto` state makes the header cell apply to a set of cells selected based on context.

The `scope` attribute's [missing value default](#) and [invalid value default](#) are the `auto` state.

The `th` element may have an `abbr` content attribute specified. Its value must be an alternative label for the header cell, to be used when referencing the cell in other contexts (e.g. when describing the header cells that apply to a data cell). It is typically an abbreviated form of the full header cell, but can also be an expansion, or merely a different phrasing.

The `th` element and its `colspan`, `rowspan`, `headers`, and `scope` attributes take part in the `table model`.

Example

The following example shows how the `scope` attribute's `rowgroup` value affects which data cells a header cell applies to.

Here is a markup fragment showing a table:

```
<table>
  <thead>
    <tr>
      <th> ID </th> Measurement <th> Average </th> Maximum
      <th> </th> <th> </th>
    </tr>
  <tbody>
    <tr> <td> 1 </td> <td> Cats </td> <td> 3 </td> <td> 4
    <tr> <td> 2 </td> <td> Dogs </td> <td> 5 </td> <td> 6
    <tr> <td> 3 </td> <td> Legs </td> <td> 1 </td> <td> 1
  </tbody>
</table>
```

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

<code></table></code>																															
This would result in the following table:																															
<table border="1"> <thead> <tr><th>ID</th><th>Measurement</th><th>Average</th><th>Maximum</th></tr> </thead> <tbody> <tr><td>93</td><td>Cats</td><td></td><td></td></tr> <tr><td>93</td><td>Legs</td><td>3.5</td><td>4</td></tr> <tr><td>10</td><td>Tails</td><td>1</td><td>1</td></tr> <tr><td colspan="4">English speakers</td></tr> <tr><td>32</td><td>Legs</td><td>2.67</td><td>4</td></tr> <tr><td>35</td><td>Tails</td><td>0.33</td><td>1</td></tr> </tbody> </table>				ID	Measurement	Average	Maximum	93	Cats			93	Legs	3.5	4	10	Tails	1	1	English speakers				32	Legs	2.67	4	35	Tails	0.33	1
ID	Measurement	Average	Maximum																												
93	Cats																														
93	Legs	3.5	4																												
10	Tails	1	1																												
English speakers																															
32	Legs	2.67	4																												
35	Tails	0.33	1																												
The headers in the first row all apply directly down to the rows in their column.																															
The headers with the explicit <code>scope</code> attributes apply to all the cells in their row group other than the cells in the first column.																															
The remaining headers apply just to the cells to the right of them.																															

4.9.11 Attributes common to `td` and `th` elements

The `td` and `th` elements may have a `colspan` content attribute specified, whose value must be a `valid non-negative integer` greater than zero and less than or equal to 1000.

The `td` and `th` elements may also have a `rowspan` content attribute specified, whose value must be a `valid non-negative integer` less than or equal to 65534. For this attribute, the value zero means that the cell is to span all the remaining rows in the row group.

These attributes give the number of columns and rows respectively that the cell is to span. These attributes must not be used to overlap cells, as described in the description of the [table model](#).

The `td` and `th` element may have a `headers` content attribute specified. The `headers` attribute, if specified, must contain a string consisting of an [unordered set of unique space-separated tokens](#) that are [case-sensitive](#), each of which must have the value of an `ID` of a `th` element taking part in the same `table` as the `td` or `th` element (as defined by the [table model](#)).

A `th` element with `ID id` is said to be *directly targeted* by all `td` and `th` elements in the same `table` that have `headers` attributes whose values include as one of their tokens the `ID id`. A `th` element `A` is said to be *targeted by* `B` if either `A` is *directly targeted* by `B` or if there exists an element `C` that is itself *targeted by* the element `B` and `A` is *directly targeted* by `C`.

A `th` element must not be *targeted by* itself.

The `colspan`, `rowspan`, and `headers` attributes take part in the [table model](#).

For web developers (non-normative)

`cell-cellIndex`

Returns the position of the cell in the row's `cells` list. This does not necessarily correspond to the x-position of the cell in the table, since earlier cells might cover multiple rows or columns.

Returns -1 if the element isn't in a row.

The `colspan` IDL attribute must [reflect](#) the `colspan` content attribute. It is [clamped to the range](#) [1, 1000], and its default value is 1.

The `rowspan` IDL attribute must [reflect](#) the `rowspan` content attribute. It is [clamped to the range](#) [0, 65534], and its default value is 1.

The `headers` IDL attribute must [reflect](#) the content attribute of the same name.

The `cellIndex` IDL attribute must, if the element has a parent `td` element, return the index of the cell's element in the parent element's `cells` collection. If there is no such parent element, then the attribute must return -1.

The `scope` IDL attribute must [reflect](#) the content attribute of the same name, [limited to only known values](#).

The `abbr` IDL attribute must [reflect](#) the content attribute of the same name.

4.9.12 Processing model

The various table elements and their content attributes together define the [table model](#).

A `table` consists of cells aligned on a two-dimensional grid of slots with coordinates (x, y) . The grid is finite, and is either empty or has one or more slots. If the grid has one or more slots, then the x coordinates are always in the range $0 \leq x < x_{width}$, and the y coordinates are always in the range $0 \leq y < y_{height}$. If one or both of x_{width} and y_{height} are zero, then the table is empty (has no slots). Tables correspond to `table` elements.

A `cell` is a slot aligned at a slot $(cell_x, cell_y)$ with a particular `width` and `height` such that the cell covers all the slots with coordinates (x, y) where $cell_x \leq x < cell_x + width$ and $cell_y \leq y < cell_y + height$. Cells can either be `data cells` or `header cells`. Data cells correspond to `td` elements, and header cells correspond to `th` elements. Cells of both types can have zero or more associated header cells.

It is possible, in certain error cases, for two cells to occupy the same slot.

A `row` is a complete set of slots from $x=0$ to $x=x_{width}-1$, for a particular value of y . Rows usually correspond to `tr` elements, though a `row-group` can have some implied `rows` at the end in some cases involving `cells` spanning multiple rows.

A `column` is a complete set of slots from $y=0$ to $y=y_{height}-1$, for a particular value of x . Columns can correspond to `td` elements. In the absence of `td` elements, columns are implied.

A `row-group` is a set of `rows` anchored at a slot $(0, group_y)$ with a particular `height` such that the row group covers all the slots with coordinates (x, y) where $0 \leq x < x_{width}$ and $group_y \leq y < group_y + height$. Row groups correspond to `tbody`, `thead`, and `tfoot` elements. Not every row is necessarily in a row group.

A `column-group` is a set of `columns` anchored at a slot $(group_x, 0)$ with a particular `width` such that the column group covers all the slots with coordinates (x, y) where $group_x \leq x < group_x + width$ and $0 \leq y < y_{height}$. Column groups correspond to `colgroup` elements. Not every column is necessarily in a column group.

`Row groups` cannot overlap each other. Similarly, `column groups` cannot overlap each other.

A `cell` cannot cover slots that are from two or more `row-groups`. It is, however, possible for a cell to be in multiple `column-groups`. All the slots that form part of one cell are part of zero or one `row-groups` and zero or more `column-groups`.

In addition to `cells`, `columns`, `rows`, `row-groups`, and `column-groups`, `tables` can have a `caption` element associated with them. This gives the table a heading, or legend.

A `table model error` is an error with the data represented by `table` elements and their descendants. Documents must not have table model errors.

4.9.12.1 Forming a table

To determine which elements correspond to which slots in a `table` associated with a `table` element, to determine the dimensions of the table (x_{width} and y_{height}), and to determine if there are any `table model errors`, user agents must use the following algorithm:

1. Let x_{width} be zero.
2. Let y_{height} be zero.
3. Let `pending rows` be a list of `tr` elements, initially empty.
4. Let the `table` be the `table` represented by the `table` element. The x_{width} and y_{height} variables give the `table`'s dimensions. The `table` is initially empty.
5. If the `table` element has no children elements, then return the `table` (which will be empty).
6. Associate the first `caption` element child of the `table` element with the `table`. If there are no such children, then it has no associated `caption` element.
7. Let the `current element` be the first element child of the `table` element.

If a step in this algorithm ever requires the `current element` to be advanced to the `next child of the table` when there is no such next child, then the user agent must jump to the step labeled `end`, near the end of this algorithm.

8. While the `current element` is not one of the following elements, `advance` the `current element` to the `next child` of the `table`:

- `colgroup`
- `thead`
- `tbody`
- `tfoot`
- `tr`

9. If the `current element` is a `colgroup`, follow these substeps:

1. `Column groups`: Process the `current element` according to the appropriate case below:

If the `current element` has any `td` element children

Follow these steps:

1. Let x_{start} have the value of x_{width} .
2. Let the `current column` be the first `col` element child of the `colgroup` element.
3. `Columns`: If the `current column` `td` element has a `span` attribute, then parse its value using the [rules for parsing non-negative integers](#). If the result of parsing the value is not an error or zero, then let `span` be that value. Otherwise, if the `td` element has no `span` attribute, or if trying to parse the attribute's value resulted in an error or zero, then let `span` be 1. If `span` is greater than 1000, let it be 1000 instead.
4. Increase x_{width} by `span`.
5. Let the last `span` `column` in the `table` correspond to the `current column` `col` element.
6. If `current column` is not the last `col` element child of the `colgroup` element, then let the `current column` be the next `col` element child of the `colgroup` element, and return to the step labeled `columns`.
7. Let all the last `columns` in the `table` from $x=x_{start}$ to $x=x_{width}-1$ form a new `column group`, anchored at the slot $(x_{start}, 0)$, with width $x_{width}-x_{start}$, corresponding to the `colgroup` element.

If the `current element` has no `col` element children

1. If the `colgroup` element has a `span` attribute, then parse its value using the [rules for parsing non-negative integers](#). If the result of parsing the value is not an error or zero, then let `span` be that value. Otherwise, if the `colgroup` element has no `span` attribute, or if trying to parse the attribute's value resulted in an error or zero, then let `span` be 1. If `span` is greater than 1000, let it be 1000 instead.
2. Increase x_{width} by `span`.
3. Let the last `span` `columns` in the `table` form a new `column group`, anchored at the slot $(x_{width}-span, 0)$, with width `span`, corresponding to the `colgroup` element.

3. While the *current element* is not one of the following elements, *advance* the *current element* to the next child of the `table`:

- `colgroup`
- `thead`
- `tbody`
- `tfoot`
- `tr`

4. If the *current element* is a `colgroup` element, jump to the step labeled *column groups* above.

10. Let $y_{current}$ be zero.

11. Let the *list of downward-growing cells* be an empty list.

12. *Rows*: While the *current element* is not one of the following elements, *advance* the *current element* to the next child of the `table`:

- `thead`
- `tbody`
- `tfoot`
- `tr`

13. If the *current element* is a `tr`, then run the *algorithm for processing rows*, *advance* the *current element* to the next child of the `table`, and return to the step labeled *rows*.

14. Run the *algorithm for ending a row group*.

15. If the *current element* is a `tfoot`, then add that element to the list of *pending tfoot elements*, *advance* the *current element* to the next child of the `table`, and return to the step labeled *rows*.

16. The *current element* is either a `thead` or a `tbody`.

Run the *algorithm for processing row groups*.

17. *Advance* the *current element* to the next child of the `table`.

18. Return to the step labeled *rows*.

19. *End*: For each `tfoots` element in the list of *pending tfoot elements*, in *tree order*, run the *algorithm for processing row groups*.

20. If there exists a `row` or `column` in the *table* containing only `slot`s that do not have a `cell` anchored to them, then this is a *table model error*.

21. Return the *table*.

The *algorithm for processing row groups*, which is invoked by the set of steps above for processing `thead`, `tbody`, and `tfoot` elements, is:

1. Let y_{start} have the value of y_{height} .

2. For each `tr` element that is a child of the element being processed, in tree order, run the *algorithm for processing rows*.

3. If $y_{height} > y_{start}$, then let all the last `rows` in the *table* from $y=y_{start}$ to $y=y_{height}-1$ form a new *row group*, anchored at the slot with coordinate $(0, y_{start})$, with height $y_{height}-y_{start}$, corresponding to the element being processed.

4. Run the *algorithm for ending a row group*.

The *algorithm for ending a row group*, which is invoked by the set of steps above when starting and ending a block of rows, is:

1. While $y_{current}$ is less than y_{height} , follow these steps:

1. Run the *algorithm for growing downward-growing cells*.

2. Increase $y_{current}$ by 1.

2. Empty the *list of downward-growing cells*.

The *algorithm for processing rows*, which is invoked by the set of steps above for processing `tr` elements, is:

1. If y_{height} is equal to $y_{current}$, then increase y_{height} by 1. ($y_{current}$ is never greater than y_{height} .)

2. Let $x_{current}$ be 0.

3. Run the *algorithm for growing downward-growing cells*.

4. If the `tr` element being processed has no `td` or `th` element children, then increase $y_{current}$ by 1, abort this set of steps, and return to the algorithm above.

5. Let *current cell* be the first `td` or `th` element child in the `tr` element being processed.

6. *Cells*: While $x_{current}$ is less than x_{width} and the slot with coordinate $(x_{current}, y_{current})$ already has a cell assigned to it, increase $x_{current}$ by 1.

7. If $x_{current}$ is equal to x_{width} , increase x_{width} by 1. ($x_{current}$ is never greater than x_{width} .)

8. If the *current cell* has a `colspan` attribute, then *parse that attribute's value*, and let `colspan` be the result.

If parsing that value failed, or returned zero, or if the attribute is absent, then let `colspan` be 1, instead.

If `colspan` is greater than 1000, let it be 1000 instead.

9. If the *current cell* has a `rowspan` attribute, then *parse that attribute's value*, and let `rowspan` be the result.

If parsing that value failed or if the attribute is absent, then let `rowspan` be 1, instead.

If `rowspan` is greater than 65534, let it be 65534 instead.

10. If `rowspan` is zero and the `table` element's `nodeDocument` is not set to `quirks mode`, then let *cell grows downward* be true, and set `rowspan` to 1. Otherwise, let *cell grows downward* be false.

11. If $x_{width} < x_{current}+colspan$, then let x_{width} be $x_{current}+colspan$.

12. If $y_{height} < y_{current}+rowspan$, then let y_{height} be $y_{current}+rowspan$.

13. Let the slots with coordinates (x, y) such that $x_{current} \leq x < x_{current}+colspan$ and $y_{current} \leq y < y_{current}+rowspan$ be covered by a new `cell` *c*, anchored at $(x_{current}, y_{current})$, which has width `colspan` and height `rowspan`, corresponding to the *current cell* element.

If the *current cell* element is a `td` element, let this new cell be a header cell; otherwise, let it be a data cell.

To establish which header cells apply to the *current cell* element, use the *algorithm for assigning header cells* described in the next section.

If any of the slots involved already had a `cell` covering them, then this is a *table model error*. Those slots now have two cells overlapping.

14. If *cell grows downward* is true, then add the tuple $\{c, x_{current}, colspan\}$ to the *list of downward-growing cells*.

15. Increase $x_{current}$ by `colspan`.

16. If *current cell* is the last `td` or `th` element child in the `tr` element being processed, then increase $y_{current}$ by 1, abort this set of steps, and return to the algorithm above.

17. Let *current cell* be the next `td` or `th` element child in the `tr` element being processed.

18. Return to the step labeled *rows*.

When the algorithms above require the user agent to run the *algorithm for growing downward-growing cells*, the user agent must, for each $\{cell, cell_x, width\}$ tuple in the *list of downward-growing cells*, if any, extend the `cell` cell so that it also covers the slots with coordinates $(x, y_{current})$, where $cell_x \leq x < cell_x+width$.

4.9.12.2 Forming relationships between data cells and header cells

Each cell can be assigned zero or more header cells. The *algorithm for assigning header cells* to a cell *principal cell* is as follows.

1. Let *header list* be an empty list of cells.

2. Let $(principal, principal_y)$ be the coordinate of the slot to which the *principal cell* is anchored.

3. If the *principal cell* has a `headers` attribute specified

1. Take the value of the *principal cell's headers* attribute and *split it on ASCII whitespace*, letting *id list* be the list of tokens obtained.

2. For each token in the *id list*, if the first element in the `document` with an `ID` equal to the token is a cell in the same `table`, and that cell is not the *principal cell*, then add that cell to *header list*.

If *principal cell* does not have a `headers` attribute specified

1. Let $principal_width$ be the width of the *principal cell*.

2. Let $principal_height$ be the height of the *principal cell*.

3. For each value y of y from $principal_x$ to $principal_x+principal_width-1$, run the *internal algorithm for scanning and assigning header cells*, with the *principal cell*, the *header list*, the initial coordinate $(principal_x, y)$, and the increments $\Delta x=-1$ and $\Delta y=0$.

4. For each value of x of x from $principal_x$ to $principal_x+principal_width-1$, run the *internal algorithm for scanning and assigning header cells*, with the *principal cell*, the *header list*, the initial coordinate $(x, principal_y)$, and the increments $\Delta x=0$ and $\Delta y=-1$.

5. If the *principal cell* is anchored in a `row group`, then add all header cells that are `row group headers` and are anchored in the same row group with an x-coordinate less than or equal to $principal_x+principal_width-1$ and a y-coordinate less than or equal to $principal_y+principal_height-1$ to *header list*.

6. If the *principal cell* is anchored in a `column group`, then add all header cells that are `column group headers` and are anchored in the same column group with an x-coordinate less than or equal to $principal_x+principal_width-1$ and a y-coordinate less than or equal to $principal_y+principal_height-1$ to *header list*.

4. Remove all the `empty cells` from the *header list*.

5. Remove any duplicates from the *header list*.

6. Remove *principal cell* from the *header list* if it is there.

7. Assign the headers in the *header list* to the *principal cell*.

The *internal algorithm for scanning and assigning header cells*, given a *principal cell*, a *header list*, an initial coordinate $(initial_x, initial_y)$, and Δx and Δy increments, is as follows:

1. Let x equal $initial_x$.

2. Let y equal $initial_y$.

3. Let *opaque headers* be an empty list of cells.

4. If *principal cell* is a header cell

Let *in header block* be true, and let *headers from current header block* be a list of cells containing just the *principal cell*.

Otherwise

Let *in header block* be false and let *headers from current header block* be an empty list of cells.

5. *Loop*: Increment x by Δx ; increment y by Δy .

Note

For each invocation of this algorithm, one of Δx and Δy will be -1 , and the other will be 0 .

ElementForms

4.10.1 Introduction

This section is non-normative.

A form is a component of a Web page that has form controls, such as text, buttons, checkboxes, range, or color picker controls. A user can interact with such a form, providing data that can then be sent to the server for further processing (e.g. returning the results of a search or calculation). No client-side scripting is needed in many cases, though an API is available so that scripts can augment the user experience or use forms for purposes other than submitting data to a server.

Writing a form consists of several steps, which can be performed in any order: writing the user interface, implementing the server-side processing, and configuring the user interface to communicate with the server.

4.10.1.1 Writing a form's user interface

This section is non-normative.

For the purposes of this brief introduction, we will create a pizza ordering form.

Any form starts with a `<form>` element, inside which are placed the controls. Most controls are represented by the `<input>` element, which by default provides a text control. To label a control, the `<label>` element is used; the label text and the control itself go inside the `<label>` element. Each part of a form is considered a `<paragraph>`, and is typically separated from other parts using `<p>` elements. Putting this together, here is how one might ask for the customer's name:

```
<form>
  <label>Customer name: <input type="text" name="customer-name"/>
</form>
```

To let the user select the size of the pizza, we can use a set of radio buttons. Radio buttons also use the `<input>` element, this time with a `type` attribute with the value `radio`. To make the radio buttons work as a group, they are given a common name using the `name` attribute. To group a batch of controls together, such as, in this case, the radio buttons, one can use the `<fieldset>` element. The title of such a group of controls is given by the first element in the `<fieldset>`, which has to be a `<legend>` element.

Note
Changes from the previous step are highlighted.

To pick toppings, we can use checkboxes. These use the `<input>` element with a `type` attribute with the value `checkbox`:

```
<form>
  <label>Customer name: <input type="text" name="customer-name"/>
  <label>Phone number: <input type="tel" name="customer-phone"/>
  <label>E-mail address: <input type="email" name="customer-email"/>
  <label>Size:
    <legend> Pizza Size </legend>
    <input type="radio" name="size" value="small" /> Small <label>/</label>
    <input type="radio" name="size" value="medium" /> Medium <label>/</label>
    <input type="radio" name="size" value="large" /> Large <label>/</label>
  </label>
  <label>Toppings </label>
    <input type="checkbox" value="bacon" checked="" /> Bacon <label>/</label>
    <input type="checkbox" value="cheese" checked="" /> Extra Cheese <label>/</label>
    <input type="checkbox" value="onion" checked="" /> Onion <label>/</label>
    <input type="checkbox" value="mushroom" checked="" /> Mushroom <label>/</label>
  </label>
</form>
```

The pizzeria for which this form is being written is always making mistakes, so it needs a way to contact the customer. For this purpose, we can use form controls specifically for telephone numbers (`<input>` elements with their `type` attribute set to `tel`) and e-mail addresses (`<input>` elements with their `type` attribute set to `email`):

```
<form>
  <label>Customer name: <input type="text" name="customer-name"/>
  <label>Telephone: <input type="tel" name="customer-phone"/>
  <label>E-mail address: <input type="email" name="customer-email"/>
  <label>Size:
    <legend> Pizza Size </legend>
    <input type="radio" name="size" value="small" /> Small <label>/</label>
    <input type="radio" name="size" value="medium" /> Medium <label>/</label>
    <input type="radio" name="size" value="large" /> Large <label>/</label>
  </label>
  <label>Toppings </label>
    <input type="checkbox" value="bacon" checked="" /> Bacon <label>/</label>
    <input type="checkbox" value="cheese" checked="" /> Extra Cheese <label>/</label>
    <input type="checkbox" value="onion" checked="" /> Onion <label>/</label>
    <input type="checkbox" value="mushroom" checked="" /> Mushroom <label>/</label>
  </label>
</form>
```

We can use an `<input>` element with its `type` attribute set to `time` to ask for a delivery time. Many of these form controls have attributes to control exactly what values can be specified; in this case, three attributes of particular interest are `min`, `max`, and `step`. These set the minimum time, the maximum time, and the interval between allowed values (in seconds). This pizzeria only delivers between 11am and 9pm, and doesn't promise anything better than 15 minute increments, which we can mark up as follows:

```
<form>
  <label>Customer name: <input type="text" name="customer-name"/>
  <label>Optional telephone: <input type="tel" name="customer-phone"/>
  <label>E-mail address: <input type="email" name="customer-email"/>
  <label>Size:
    <legend> Pizza Size </legend>
    <input type="radio" name="size" value="small" /> Small <label>/</label>
    <input type="radio" name="size" value="medium" /> Medium <label>/</label>
    <input type="radio" name="size" value="large" /> Large <label>/</label>
  </label>
  <label>Toppings </label>
    <input type="checkbox" value="bacon" checked="" /> Bacon <label>/</label>
    <input type="checkbox" value="cheese" checked="" /> Extra Cheese <label>/</label>
    <input type="checkbox" value="onion" checked="" /> Onion <label>/</label>
    <input type="checkbox" value="mushroom" checked="" /> Mushroom <label>/</label>
  </label>
  <label>Preferred delivery time: <input type="time" min="11:00" max="21:00" step="900"/></label>
</form>
```

The `<textarea>` element can be used to provide a multiline text control. In this instance, we are going to use it to provide a space for the customer to give delivery instructions:

```
<form>
  <label>Customer name: <input type="text" name="customer-name"/>
  <label>Telephone: <input type="tel" name="customer-phone"/>
  <label>E-mail address: <input type="email" name="customer-email"/>
  <label>Size:
    <legend> Pizza Size </legend>
    <input type="radio" name="size" value="small" /> Small <label>/</label>
    <input type="radio" name="size" value="medium" /> Medium <label>/</label>
    <input type="radio" name="size" value="large" /> Large <label>/</label>
  </label>
  <label>Toppings </label>
    <input type="checkbox" value="bacon" checked="" /> Bacon <label>/</label>
    <input type="checkbox" value="cheese" checked="" /> Extra Cheese <label>/</label>
    <input type="checkbox" value="onion" checked="" /> Onion <label>/</label>
    <input type="checkbox" value="mushroom" checked="" /> Mushroom <label>/</label>
  </label>
  <label>Preferred delivery time: <input type="time" min="11:00" max="21:00" step="900"/></label>
  <label>Delivery instructions: <textarea></textarea></label>
</form>
```

Finally, to make the form submittable we use the `<button>` element:

```
<form>
  <label>Customer name: <input type="text" name="customer-name"/>
  <label>Telephone: <input type="tel" name="customer-phone"/>
  <label>E-mail address: <input type="email" name="customer-email"/>
  <label>Size:
    <legend> Pizza Size </legend>
    <input type="radio" name="size" value="small" /> Small <label>/</label>
    <input type="radio" name="size" value="medium" /> Medium <label>/</label>
    <input type="radio" name="size" value="large" /> Large <label>/</label>
  </label>
  <label>Toppings </label>
    <input type="checkbox" value="bacon" checked="" /> Bacon <label>/</label>
    <input type="checkbox" value="cheese" checked="" /> Extra Cheese <label>/</label>
    <input type="checkbox" value="onion" checked="" /> Onion <label>/</label>
    <input type="checkbox" value="mushroom" checked="" /> Mushroom <label>/</label>
  </label>
  <label>Preferred delivery time: <input type="time" min="11:00" max="21:00" step="900"/></label>
  <label>Delivery instructions: <textarea></textarea></label>
  <button type="submit" value="Order">Order</button>
</form>
```

4.10.1.2 Implementing the server-side processing for a form

This section is non-normative.

The exact details for writing a server-side processor are out of scope for this specification. For the purposes of this introduction, we will assume that the script at <https://pizza.example.com/order.cgi> is configured to accept submissions using the `application/x-www-form-urlencoded` format, expecting the following parameters sent in an HTTP POST body:

```
customer-name
  Customer's name
customer-phone
  Customer's telephone number
customer-email
  Customer's e-mail address
size
  The pizza size, either small, medium, or large
topping
  A topping, specified once for each selected topping, with the allowed values being bacon, cheese, onion, and mushroom
delivery
  The requested delivery time
comments
  The delivery instructions
```

4.10.1.3 Configuring a form to communicate with a server

This section is non-normative.

Form submissions are exposed to servers in a variety of ways, most commonly as HTTP GET or POST requests. To specify the exact method used, the `method` attribute is specified on the `<form>` element. This doesn't specify how the form data is encoded, though; to specify that, you use the `encoding` attribute. You also have to specify the `URL` of the service that will handle the submitted data, using the `action` attribute.

For each form control you want submitted, you then have to give it a name that will be used to refer to the data in the submission. We already specified the name for the group of radio buttons; the same attribute (`name`) also specifies the submission name. Radio buttons can be distinguished from each other in the submission by giving them different values, using the `value` attribute.

Multiple controls can have the same name; for example, here we give all the checkboxes the same name, and the server distinguishes which checkbox was checked by seeing which values are submitted with that name — like the radio buttons, they are also given unique values with the `value` attribute.

Given the settings in the previous section, this all becomes:

```
<form method="post"
      encoding="application/x-www-form-urlencoded"
      action="https://pizza.example.com/order.cgi">
  <label>Customer name: <input type="text" name="customer-name"/>
  <label>Telephone: <input type="tel" name="customer-phone"/>
</form>
```

```
<legend> Pizza Size </legend>
<label><input type="radio name="size" value="small"> Small </label></p>
<label><input type="radio name="size" value="medium"> Medium </label></p>
<label><input type="radio name="size" value="large"> Large </label></p>
</fieldset>
<legend> Pizza Toppings </legend>
<label><input type="checkbox name="topping" value="bacon"> Bacon </label></p>
<label><input type="checkbox name="topping" value="cheese"> Extra Cheese </label></p>
<label><input type="checkbox name="topping" value="onion"> Onion </label></p>
<label><input type="checkbox name="topping" value="mushroom"> Mushroom </label></p>
</label>Preferred delivery time: <input type="time" min="11:00" max="21:00" step="300" name="delivery" required></label></p>
<label>Delivery instructions: <textarea name="comments"></textarea></label></p>
<button>Submit order</button></p>
</form>
```

Note

There is no particular significance to the way some of the attributes have their values quoted and others don't. The HTML syntax allows a variety of equally valid ways to specify attributes, as discussed in the [syntax section](#).

For example, if the customer entered "Denise Lawrence" as their name, "555-321-8642" as their telephone number, did not specify an e-mail address, asked for a medium-sized pizza, selected the Extra Cheese and Mushroom toppings, entered a delivery time of 7pm, and left the delivery instructions text control blank, the user agent would submit the following to the online Web service:

```
custname=Denise+Lawrence&custtel=555-321-8642&custemail=&size=medium&topping=cheese&topping=mushrooms&delivery=19:30&comments=&
```

4.10.1.4 Client-side form validation

...

Support: form-validationChrome for Android 8+|Chrome 10+iOS Safari 10.3+Safari 10.1+Firefox 4+Samsung Internet 4+Edge 12+UC Browser for Android 12.12+IE 10+Opera 10.0+Opera Mini (limited) all+Firefox for Android 68+

Source: caniuse.com

This section is non-normative.

Forms can be annotated in such a way that the user agent will check the user's input before the form is submitted. The server still has to verify the input is valid (since hostile users can easily bypass the form validation), but it allows the user to avoid the wait incurred by having the server be the sole checker of the user's input.

The simplest annotation is the **required** attribute, which can be specified on **input** elements to indicate that the form is not to be submitted until a value is given. By adding this attribute to the customer name, pizza size, and delivery time fields, we allow the user agent to notify the user when the user submits the form without filling in those fields:

```
<form method="post"
      enctype="application/x-www-form-urlencoded"
      action="https://pizza.example.com/order.cgi">
<label>Customer name: <input name="custname" required="" type="text" /></label></p>
<label>Telephone: <input type="tel" name="custtel" required="" type="tel" /></label></p>
<label>E-mail address: <input type="email" name="custmail" required="" type="email" /></label></p>
</fieldset>
<legend> Pizza Size </legend>
<label><input type="radio name="size" required value="small"> Small </label></p>
<label><input type="radio name="size" required value="medium"> Medium </label></p>
<label><input type="radio name="size" required value="large"> Large </label></p>
</fieldset>
<legend> Pizza Toppings </legend>
<label><input type="checkbox name="topping" value="bacon"> Bacon </label></p>
<label><input type="checkbox name="topping" value="cheese"> Extra Cheese </label></p>
<label><input type="checkbox name="topping" value="onion"> Onion </label></p>
<label><input type="checkbox name="topping" value="mushroom"> Mushroom </label></p>
</label>Preferred delivery time: <input type="time" min="11:00" max="21:00" step="300" name="delivery" required="" type="time" /></label></p>
<label>Delivery instructions: <textarea name="comments"></textarea></label></p>
<button>Submit order</button></p>
</form>
```

It is also possible to limit the length of the input, using the **maxlength** attribute. By adding this to the **textarea** element, we can limit users to 1000 characters, preventing them from writing huge essays to the busy delivery drivers instead of staying focused and to the point:

```
<form method="post"
      enctype="application/x-www-form-urlencoded"
      action="https://pizza.example.com/order.cgi">
<label>Customer name: <input name="custname" required="" type="text" /></label></p>
<label>Telephone: <input type="tel" name="custtel" required="" type="tel" /></label></p>
<label>E-mail address: <input type="email" name="custmail" required="" type="email" /></label></p>
</fieldset>
<legend> Pizza Size </legend>
<label><input type="radio name="size" required value="small"> Small </label></p>
<label><input type="radio name="size" required value="medium"> Medium </label></p>
<label><input type="radio name="size" required value="large"> Large </label></p>
</fieldset>
<legend> Pizza Toppings </legend>
<label><input type="checkbox name="topping" value="bacon"> Bacon </label></p>
<label><input type="checkbox name="topping" value="cheese"> Extra Cheese </label></p>
<label><input type="checkbox name="topping" value="onion"> Onion </label></p>
<label><input type="checkbox name="topping" value="mushroom"> Mushroom </label></p>
</label>Preferred delivery time: <input type="time" min="11:00" max="21:00" step="300" name="delivery" required="" type="time" /></label></p>
<label>Delivery instructions: <textarea name="comments" maxlength="1000"></textarea></label></p>
<button>Submit order</button></p>
</form>
```

Note

When a form is submitted, **invalid** events are fired at each form control that is invalid, and then at the **form** element itself. This can be useful for displaying a summary of the problems with the form, since typically the browser itself will only report one problem at a time.

4.10.1.5 Enabling client-side automatic filling of form controls

This section is non-normative.

Some browsers attempt to aid the user by automatically filling form controls rather than having the user reenter their information each time. For example, a field asking for the user's telephone number can be automatically filled with the user's phone number.

To help the user agent with this, the **autocomplete** attribute can be used to describe the field's purpose. In the case of this form, we have three fields that can be usefully annotated in this way: the information about who the pizza is to be delivered to. Adding this information looks like this:

```
<form method="post"
      enctype="application/x-www-form-urlencoded"
      action="https://pizza.example.com/order.cgi">
<label>Customer name: <input name="custname" required="" autocomplete="shipping" type="text" /></label></p>
<label>Telephone: <input type="tel" name="custtel" required="" autocomplete="shipping tel" type="tel" /></label></p>
<label>E-mail address: <input type="email" name="custmail" required="" autocomplete="shipping email" type="email" /></label></p>
</fieldset>
<legend> Pizza Size </legend>
<label><input type="radio name="size" required value="small"> Small </label></p>
<label><input type="radio name="size" required value="medium"> Medium </label></p>
<label><input type="radio name="size" required value="large"> Large </label></p>
</fieldset>
<legend> Pizza Toppings </legend>
<label><input type="checkbox name="topping" value="bacon"> Bacon </label></p>
<label><input type="checkbox name="topping" value="cheese"> Extra Cheese </label></p>
<label><input type="checkbox name="topping" value="onion"> Onion </label></p>
<label><input type="checkbox name="topping" value="mushroom"> Mushroom </label></p>
</label>Preferred delivery time: <input type="time" min="11:00" max="21:00" step="300" name="delivery" required="" type="time" /></label></p>
<label>Delivery instructions: <textarea name="comments" Maxlength="1000"></textarea></label></p>
<button>Submit order</button></p>
</form>
```

4.10.1.6 Improving the user experience on mobile devices

This section is non-normative.

Some devices, in particular those with virtual keyboards can provide the user with multiple input modalities. For example, when typing in a credit card number the user may wish to only see keys for digits 0-9, while when typing in their name they may wish to see a form field that by default capitalizes each word.

Using the **inputmode** attribute we can select appropriate input modalities:

```
<form method="post"
      enctype="application/x-www-form-urlencoded"
      action="https://pizza.example.com/order.cgi">
<label>Customer name: <input name="custname" required="" autocomplete="shipping" type="text" /></label></p>
<label>Telephone: <input type="tel" name="custtel" required="" autocomplete="shipping tel" type="tel" /></label></p>
<label>E-mail address: <input type="email" name="custmail" required="" autocomplete="shipping email" type="email" /></label></p>
</fieldset>
<legend> Pizza Size </legend>
<label><input type="radio name="size" required value="small"> Small </label></p>
<label><input type="radio name="size" required value="medium"> Medium </label></p>
<label><input type="radio name="size" required value="large"> Large </label></p>
</fieldset>
<legend> Pizza Toppings </legend>
<label><input type="checkbox name="topping" value="bacon"> Bacon </label></p>
<label><input type="checkbox name="topping" value="cheese"> Extra Cheese </label></p>
<label><input type="checkbox name="topping" value="onion"> Onion </label></p>
<label><input type="checkbox name="topping" value="mushroom"> Mushroom </label></p>
</label>Preferred delivery time: <input type="time" min="11:00" max="21:00" step="300" name="delivery" required="" type="time" /></label></p>
<label>Delivery instructions: <textarea name="comments" Maxlength="1000"></textarea></label></p>
<button>Submit order</button></p>
</form>
```

4.10.1.7 The difference between the field type, the autofocus field name, and the input modality

This section is non-normative.

The **autocomplete** and **inputmode** attributes can seem confusingly similar. For instance, in all three cases, the string "**email**" is a valid value. This section attempts to illustrate the difference between the three attributes and provides advice suggesting how to use them.

The **type** attribute on **input** elements decides what kind of control the user agent will use to expose the field. Choosing between different values of this attribute is the same choice as choosing whether to use an **input** element, a **textarea** element, a **select** element, etc.

The **autocomplete** attribute, in contrast, describes what the value that the user will enter actually represents. Choosing between different values of this attribute is the same choice as choosing what the label for the element will be.

First, consider telephone numbers. If a page is asking for a telephone number from the user, the right form control to use is **input type="tel"**. However, which **autocomplete** value to use depends on which phone number the page is asking for, whether they expect a telephone number in the international format or just the local format, and so forth.

For example, a form that parts of a checkout process on an e-commerce site for a customer buying a gift to be shipped to a friend might need both the buyer's telephone number (in case of payment issues) and the friend's telephone number (in case of delivery issues). If the site expects international phone numbers (with the country code prefix), this could thus look like this:

```
<p>Your phone number: <input type="tel" name="custtel" autocomplete="billing tel" /></p>
<p>Please enter complete phone numbers including the country code prefix, as in +44 333 123 4567.</p>
But if the site only supports British customers and recipients, it might instead look like this (notice the use of tel-national rather than tel):
```

```
<p>Your phone number: <input type="tel" name="custtel" autocomplete="billing tel-national" /></p>
<p>Please enter complete UK phone numbers, as in (01632) 986 123.</p>
```

Now, consider a person's preferred languages. The right **autocomplete** value is **language**. However, there could be a number of different form controls used for the purpose: a text control (**input type="text"**), a drop-down list (**select**), radio buttons (**input type="radio"**), etc. It only depends on what kind of interface is desired.

Finally, consider names. If a page just wants one name from the user, then the relevant control is **input type="text"**. If the page is asking for the user's full name, then the relevant **autocomplete** value is **name**.

```
<p>Japanese name: <input name="j" type="text" autocomplete="section-jp name" /></p>
<p>Romanized name: <input name="e" type="text" autocomplete="section-en name" /></p>
```

In this example, the **section-** keywords in the **autocomplete** attribute's values tell the user agent that the two fields expect *different* names. Without them, the user agent could automatically fill the second field with the value given in the first field when the user gave a value to the first field.

Note

The "->" and "-en" parts of the keywords are opaque to the user agent; the user agent cannot guess, from those, that the two names are expected to be in Japanese and English respectively.

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Consider credit card numbers. The appropriate input type is *not* `<input type="number">`, as explained below; it is instead `<input type="text">`. To encourage the user agent to use a numeric input modality anyway (e.g., a virtual keyboard displaying only digits), the page would use

```
<p><label>Credit card number:</label>
  <input name="cc" type="text" inputmode="numeric" pattern="[\d-]{8,19}" autocomplete="cc-number">
</p>
```

4.10.1.8 Date, time, and number formats

This section is non-normative.

In this pizza delivery example, the times are specified in the format "HH:MM": two digits for the hour, in 24-hour format, and two digits for the time. (Seconds could also be specified, though they are not necessary in this example.)

In some locales, however, times are often expressed differently when presented to users. For example, in the United States, it is still common to use the 12-hour clock with an am/pm indicator, as in "2pm". In France, it is common to separate the hours from the minutes using an "h" character, as in "14h00".

Similar issues exist with dates, with the added complication that even the order of the components is not always consistent — for example, in Cyprus the first of February 2003 would typically be written "1/2/03", while that same date in Japan would typically be written as "2003年02月01日" — and even with numbers, where locales differ, for example, in what punctuation is used as the decimal separator and the thousands separator.

It is therefore important to distinguish the time, date, and number formats used in HTML and in form submissions, which are always the formats defined in this specification (and based on the well-established ISO 8601 standard for computer-readable date and time formats), from the time, date, and number formats presented to the user by the browser and accepted as input from the user by the browser.

The format used "on the wire", i.e., in HTML markup and in form submissions, is intended to be computer-readable and consistent irrespective of the user's locale. Dates, for instance, are always written in the format "YYYY-MM-DD", as in "2003-02-01". While some users might see this format, others might see it as "01.02.2003" or "February 1, 2003".

The time, date, or number given by the page in the wire format is then translated to the user's preferred presentation (based on user preferences or on the locale of the page itself), before being displayed to the user. Similarly, after the user inputs a time, date, or number using their preferred format, the user agent converts it back to the wire format before putting it in the DOM or submitting it.

This allows scripts in pages and on servers to process times, dates, and numbers in a consistent manner without needing to support dozens of different formats, while still supporting the users' needs.

Notes

See also the [implementation notes](#) regarding localization of form controls.

4.10.2 Categories

Mostly for historical reasons, elements in this section fall into several overlapping (but subtly different) categories in addition to the usual ones like `flow content`, `phrasing content`, and `interactive content`.

A number of the elements are *form-associated elements*, which means they can have a [form owner](#):

- `button`
- `fieldset`
- `form`
- `input`
- `output`
- `select`
- `textarea`
- `img`
- `form-associated custom elements`

The *form-associated elements* fall into several subcategories:

Listed elements

Denotes elements that are listed in the `form_elements` and `fieldset_elements` APIs. These elements also have a `form` content attribute, and a matching `form` IDL attribute, that allow authors to specify an explicit [form owner](#):

- `button`
- `fieldset`
- `form`
- `input`
- `select`
- `output`
- `select`
- `textarea`
- `img`
- `form-associated custom elements`

Submittable elements

Denotes elements that can be used for [constructing the entry list](#) when a `form` element is `submitted`:

- `button`
- `input`
- `select`
- `output`
- `select`
- `textarea`
- `form-associated custom elements`

Some *submittable elements* can be, depending on their attributes, *buttons*. The prose below defines when an element is a button. Some buttons are specifically *submit buttons*.

Resettable elements

Denotes elements that can be affected when a `form` element is `reset`:

- `input`
- `output`
- `select`
- `form`
- `form-associated custom elements`

Autocapitalize-inheriting elements

Denotes elements that inherit the `autocapitalize` attribute from their [form owner](#):

- `button`
- `fieldset`
- `input`
- `output`
- `select`
- `form`
- `form-associated custom elements`

Some elements, not all of them *form-associated*, are categorized as *labelable elements*. These are elements that can be associated with a `label` element:

- `button`
- `input` (if the `type` attribute is *not* in the `Hidden` state)
- `select`
- `output`
- `password`
- `form`
- `form-associated custom elements`

`title`

Accessibility considerations:

For authors

For implementers

DOM interface

`IDLExposedWindow`, `OverridesBuiltIns`, `OverridesCustomElements`, `OverridesNamedProperties`

`interface HTMLFormElement : HTMLElement {`

`[HTMLConstructor] constructor();`

`[CEReactions] attribute DOMString acceptCharset;`

`[CEReactions] attribute DOMString action;`

`[CEReactions] attribute DOMString autocomplete;`

`[CEReactions] attribute DOMString encoding;`

`[CEReactions] attribute DOMString method;`

`[CEReactions] attribute DOMString name;`

`[CEReactions] attribute boolean noValidate;`

```
[SameObject, PutForwards=<value>] readonly attribute DOMTokenList relList;
[SameObject] readonly attribute HTMLFormControlsCollection elements;
readonly attribute long length;
getter Element (unsigned long index);
getter (RadioNodeList or Element) (DOMString name);

void submit();
void requestSubmit(optional HTMLInputElement submitter = null);
void reset();
boolean checkValidity();
boolean reportValidity();

```

The `form` element represents a [hypertext](#) that can be manipulated through a collection of [form-associated elements](#), some of which can represent editable values that can be submitted to a server for processing.

The `accept-charset` attribute gives the character encodings that are to be used for the submission. If specified, the value must be an [ASCII case-insensitive](#) match for "UTF-8". [\[ENCODING\]](#)

The `name` attribute represents the `form`'s name within the `forms` collection. The value must not be the empty string, and the value must be unique amongst the `form` elements in the `forms` collection that it is in, if any.

The `autocomplete` attribute is an [enumerated attribute](#). The attribute has two states. The `on` keyword maps to the `on` state, and the `off` keyword maps to the `off` state. The attribute may also be omitted. The [missing value default](#) and the [invalid value default](#) are the `on` state. The `off` state indicates that by default, form controls in the form will have their `autofill field name` set to "`on`".

The `action`, `enctype`, `method`, `novalidate`, and `target` attributes are [attributes for form submission](#).

The `rel` attribute on `form` elements controls what kinds of links the elements create. The attribute's value must be an [unordered set of unique space-separated tokens](#). The [allowed keywords and their meanings](#) are defined in an earlier section.

`rel`'s [supported tokens](#) are the keywords defined in [HTML link types](#) which are allowed on `form` elements, impact the processing model, and are supported by the user agent. The possible [supported tokens](#) are `nofollow`, `noreferrer`, and `noopener`, and `open`-`rel`'s [supported tokens](#) must only include the tokens from this list that the user agent implements the processing model for.

For web developers (non-normative)

<code>form : elements</code>	Returns an HTMLFormControlsCollection of the form controls in the form (excluding image buttons for historical reasons).
<code>form : length</code>	Returns the number of form controls in the form (excluding image buttons for historical reasons).
<code>form[index]</code>	Returns the <code>index</code> element in the form (excluding image buttons for historical reasons).
<code>form[name]</code>	Returns the form control (or, if there are several, a RadioNodeList of the form controls) in the form with the given <code>ID</code> or <code>name</code> (excluding image buttons for historical reasons); or, if there are none, returns the <code>form</code> element with the given ID. Once an element has been referenced using a particular name, that name will continue being available as a way to reference that element in this method, even if the element's actual <code>ID</code> or <code>name</code> changes, for as long as the element remains in the <code>tree</code> . If there are multiple matching items, then a RadioNodeList object containing all those elements is returned.
<code>form : submit()</code>	Submits the form, bypassing interactive constraint validation and without firing a <code>submit</code> event.
<code>form : requestSubmit(submitter)</code>	Requests to submit the form. Unlike <code>submit()</code> , this method includes interactive constraint validation and firing a <code>submit</code> event, either of which can cancel submission. The <code>submitter</code> argument can be used to point to a specific <code>submit</code> button, whose <code>formaction</code> , <code>formenctype</code> , <code>formmethod</code> , <code>formnovalidate</code> , and <code>formtarget</code> attributes can impact submission. Additionally, the submitter will be included when constructing the entry list for submission; normally, buttons are excluded.
<code>form : reset()</code>	Resets the form.
<code>form : checkValidity()</code>	Returns true if the form's controls are all valid; otherwise, returns false.
<code>form : reportValidity()</code>	Returns true if the form's controls are all valid; otherwise, returns false and informs the user.

The `autocomplete` IDL attribute must [reflect](#) the `content` attribute of the same name, [limited to only known values](#).

MDN

HTML FormElement/length

Support in all current engines.

FirefoxYesSafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet Explorer?

Firefox AndroidYes Safari iOSYes Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidYes

The `length` IDL attribute must return the number of nodes [represented](#) by the `elements` collection.

The `supportedPropertyIndices` at any instant are the indices supported by the object returned by the `elements` attribute at that instant.

To determine the value of an `indexed` property for a `form` element, the user agent must return the value returned by the `item` method on the `elements` collection, when invoked with the given index as its argument.

Each `form` element has a mapping of names to elements called the `pastNamesMap`. It is used to persist names of controls even when they change names.

The `supportedNonEmptyNames` consist of the names obtained from the following algorithm, in the order obtained from this algorithm:

- Let `sourcedNames` be an initially empty ordered list of tuples consisting of a string, an element's source, where the source is either `id`, `name`, or `past`, and, if the source is `past`, an age.
- For each `listed element` candidate whose `form-owner` is the `form` element, with the exception of any `input` elements whose `type` attribute is in the `Image Button` state:
 - If `candidate` has an `id` attribute, add an entry to `sourcedNames` with that `id` attribute's value as the string, `candidate` as the element, and `id` as the source.
 - If `candidate` has a `name` attribute, add an entry to `sourcedNames` with that `name` attribute's value as the string, `candidate` as the element, and `name` as the source.
- For each `img` element candidate whose `form-owner` is the `form` element:
 - If `candidate` has an `id` attribute, add an entry to `sourcedNames` with that `id` attribute's value as the string, `candidate` as the element, and `id` as the source.
 - If `candidate` has a `name` attribute, add an entry to `sourcedNames` with that `name` attribute's value as the string, `candidate` as the element, and `name` as the source.
- For each entry `pastEntry` in the `pastNamesMap` add an entry to `sourcedNames` with the `pastEntry`'s name as the string, `pastEntry`'s element as the element, `past` as the source, and the length of time `pastEntry` has been in the `pastNamesMap` as the age.
- Sort `sourcedNames` by `pastOrder` of the element entry of each tuple, sorting entries with the same element by putting entries whose source is `id` first, then entries whose source is `name`, and finally entries whose source is `past`, and sorting entries with the same element and source by their age, oldest first.
- Remove any entries in `sourcedNames` that have the empty string as their name.
- Remove any entries in `sourcedNames` that have the same name as an earlier entry in the map.
- Return the list of names from `sourcedNames`, maintaining their relative order.

To determine the value of a `named` property name for a `form` element, the user agent must run the following steps:

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

2. If *candidates* is empty, let *candidates* be a `live RadioNodeList` object containing all the `input` elements, whose `form owner` is the `form` element, that have either an `id` attribute or a `name` attribute equal to *name*, in *tree order*.
3. If *candidates* is empty, *name* is the name of one of the entries in the `form` element's `past names map`, return the object associated with *name* in that map.
4. If *candidates* contains more than one node, return *candidates*.
5. Otherwise, *candidates* contains exactly one node. Add a mapping from *name* to the node in *candidates* in the `form` element's `past names map`, replacing the previous entry with the same name, if any.
6. Return the node in *candidates*.

If an element listed in a `form` element's `past names map` changes `form owner`, then its entries must be removed from that map.

DOM

`HTMLFormElement.submit`

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android Yes Safari iOS Yes Chrome Android Yes Web View Android Yes Samsung Internet Yes Opera Android Yes

The `submit()` method, when invoked, must `submit` the `form` element from the `form` element itself, with the `submitted from submit()` method flag set.

DOM

`HTMLFormElement.requestSubmit`

Firefox 75+ Safari No! Chrome 76+

Opera 63+ Edge 79+

Edge (Legacy) No! Internet Explorer No

Firefox Android No! Safari iOS No! Chrome Android 76+ Web View Android 76+ Samsung Internet 12.0+ Opera Android 54+

The `requestSubmit(submitter)` method, when invoked, must run the following steps:

1. If *submitter* is not null, then:
 1. If *submitter* is not a `submit button`, then throw a `TypeError`.
 2. If *submitter*'s `form owner` is not this `form` element, then throw a `"NotFoundError" DOMException`.
2. Otherwise, set *submitter* to this `form` element.
3. `Submit` this `form` element, from *submitter*.

DOM

`HTMLFormElement.reset`

Support in all current engines.

Firefox 1+ Safari 3+ Chrome 1+

Opera 8+ Edge 79+

Edge (Legacy) 12+ Internet Explorer 9+

Firefox Android 4+ Safari iOS 1+ Chrome Android 18+ Web View Android 1+ Samsung Internet 1.0+ Opera Android 10.1+

The `reset()` method, when invoked, must run the following steps:

1. If the `form` element is marked as `locked for reset`, then return.
2. Mark the `form` element as `locked for reset`.
3. `Reset` the `form` element.
4. Unmark the `form` element as `locked for reset`.

If the `checkValidity()` method is invoked, the user agent must `statically validate the constraints` of the `form` element, and return true if the constraint validation return a *positive* result, and false if it returned a *negative* result.

If the `reportValidity()` method is invoked, the user agent must `interactively validate the constraints` of the `form` element, and return true if the constraint validation return a *positive* result, and false if it returned a *negative* result.

Example

This example shows two search forms:

```
<form action="https://www.google.com/search" method="get">
  <label>Google: <input type="search" name="q"></label> <input type="submit" value="Search..."/>
</form>
<form action="https://www.bing.com/search" method="get">
  <label>Bing: <input type="search" name="q"></label> <input type="submit" value="Search..."/>
</form>
```

Tag omission in text/html:

Neither tag is omitable.

Content attributes:

Global attributes

`for` — Associates the label with form control

Accessibility considerations:

For authors

For implementers

DOM interface:

```
IDL([Exposed=Window])
interface HTMLLabelElement : HTMLElement {
  [HTMLConstructor] constructor();
}
```

```
readonly attribute HTMLFormElement? form;
```

```
[CSSEventSource] attribute DOMString htmlFor;
```

```
readonly attribute HTMLFormElement? htmlFor;
```

```
};
```

The `label` element **represents** a caption in a user interface. The caption can be associated with a specific form control, known as the `label` element's `labeled control`, either using the `for` attribute, or by putting the form control inside the `label` element itself.

Except where otherwise specified by the following rules, a `label` element has no `labeled control`.

The `for` attribute may be specified to indicate a form control with which the caption is to be associated. If the attribute is specified, the attribute's value must be the `ID` of a `labelable element` in the same `tree` as the `label` element. If the attribute is specified and there is an element in the `tree` whose `ID` is equal to the value of the `for` attribute, and the first such element in `tree order` is a `labelable element`, then that element is the `label` element's `labeled control`.

If the `for` attribute is not specified, but the `label` element has a `labelable element` descendant, then the first such descendant in `tree order` is the `label` element's `labeled control`.

The `label` element's exact default presentation and behavior, in particular what its `activation behavior` might be, if anything, should match the platform's label behavior. The `activation behavior` of a `label` element for events targeted at `interactive content` descendants of a `label` element, and any descendants of those `interactive content` descendants, must be to do nothing.

Note

Form-associated custom elements are `labelable elements`, so for user agents where the `label` element's `activation behavior` impacts the `labeled control`, both built-in and custom elements will be impacted.

Example

For example, on platforms where clicking a label activates the form control, clicking the `label` in the following snippet could trigger the user agent to [fire a click event](#) at the `input` element, as if the element itself had been triggered by the user:

```
<label><input type="checkbox" name="lost"> Lost</label>  
Similarly, assuming my-checkbox was declared as a form-associated custom element (like in this example), then the code  
<label><my-checkbox name="lost"></my-checkbox> Lost</label>  
would have the same behavior, firing a click event at the my-checkbox element.
```

On other platforms, the behavior in both cases might be just to focus the control, or to do nothing.

Example

The following example shows three form controls each with a label, two of which have small text showing the right format for users to use.

```
<p><label><input name="fn" value="Sam"> Format: First Last</label></p>  
<p><label><input name="age" type="number" min="0"> /label></p>  
<p><label><input name="pct" type="text" value="40.00"> Rate</label></p>
```

For web developers (non-normative)

`label .control`

Returns the form control that is associated with this element.

`label .form`

Returns the [form owner](#) of the form control that is associated with this element.

Returns null if there isn't one.

`labelable` elements and all `input` elements have a `live NodeList` object associated with them that represents the list of `label` elements, in `tree_order`, whose `labeled control` is the element in question. The `labels` IDL attribute of `labelable` elements that are not [form-associated custom elements](#), and the `label` IDL attribute of `input` elements, on getting, must return that `NodeList` object, and that same value must always be returned, unless this element is an `input` element whose `type` attribute is in the `Hidden` state, in which case it must instead return null.

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Example

```
This (non-conforming) example shows what happens to the NodeList and what label returns when an input element has its type attribute changed.

<doctype html>
<script>
<!-- input = document.querySelector('input') -->
const labels = input.labels;
console.assert(labels.length === 1);

input.type = 'hidden';
console.assert(labels.length === 0); // the input is no longer the label's labeled control
document.querySelector('input').labels === null;

input.type = 'checkbox';
console.assert(labels.length === 1); // the input is once again the label's labeled control
console.assert(input.labels === labels); // same value as returned originally
</script>
```

The `input` element [represents](#) a typed data field, usually with a form control to allow the user to edit the data.

The `type` attribute controls the data type (and associated control) of the element. It is an [enumerated attribute](#). The following table lists the keywords and states for the attribute — the keywords in the left column map to the states in the cell in the second column on the same row as the keyword.

Keyword	State	Data type	Control type
<code>hidden</code>	<code>Hidden</code>	An arbitrary string	n/a
<code>text</code>	<code>Text</code>	Text with no line breaks	A text control
<code>search</code>	<code>Search</code>	Text with no line breaks	Search control
<code>tel</code>	<code>Telephone</code>	Text with no line breaks	A text control
<code>url</code>	<code>URL</code>	An absolute URL	A text control
<code>email</code>	<code>E-mail</code>	An e-mail address or list of e-mail addresses	A text control that obscures data entry
<code>password</code>	<code>Password</code>	Text with no line breaks (sensitive information)	A text control
<code>date</code>	<code>Date</code>	A date (year, month, day) with no time zone	A date control
<code>month</code>	<code>Month</code>	A date consisting of a year and a month with no time zone	A month control
<code>week</code>	<code>Week</code>	A date consisting of a week-year number and a week number with no time zone	A week control
<code>time</code>	<code>Time</code>	A time (hour, minute, seconds, fractional seconds) with no time zone	A time control
<code>datetime-local</code>	<code>Local Date & Time</code>	A date and time (year, month, day, hour, minute, second, fraction of a second) with no time zone	A date and time control
<code>number</code>	<code>Number</code>	A numerical value	A text control or spinner control
<code>range</code>	<code>Range</code>	A numerical value, with the extra semantic that the exact value is not important	A slider control or similar
<code>color</code>	<code>Color</code>	An sRGB color with 8-bit red, green, and blue components	A color picker
<code>checkbox</code>	<code>Checkbox</code>	A set of zero or more values from a predefined list	A checkbox
<code>radio</code>	<code>Radio Button</code>	An enumerated value	A radio button
<code>file</code>	<code>File Upload</code>	Zero or more files each with a MIME type and optionally a file name	A label and a button
<code>submit</code>	<code>Submit Button</code>	An enumerated value, with the extra semantic that it must be the last value selected and initiates form submission	A button
<code>image</code>	<code>Image Button</code>	A coordinate, relative to a particular image's size, with the extra semantic that it must be the last value selected and initiates form submission	Either a clickable image, or a button
<code>reset</code>	<code>Reset Button</code>	n/a	A button
<code>button</code>	<code>Button</code>	n/a	A button

The [missing value default](#) and the [invalid value default](#) are the `Text` state.

Which of the `accept`, `alt`, `autocomplete`, `checked`, `dirname`, `formaction`, `formenctype`, `formmethod`, `formvalidate`, `height`, `list`, `max`, `minlength`, `multiple`, `pattern`, `placeholder`, `readonly`, `required`, `size`, `step`, and `width` content attributes, the `checked`, `files`, `valueAsNumber`, and `value` IDL attributes, the `selected`, `selectedEnd`, and `selectionRange` IDL attributes, the `getSelected` and `getSelectionRange` methods, and the `input` and `change` events apply to an `input` element depends on the state of its `type` attribute. The subsections that define each type also clearly define in normative "bookkeeping" sections which of these feature apply, and which do not apply, to each type. The behavior of these features depends on whether they apply or not, as defined in their various sections (q.v. for [content attributes](#), for [APIs](#) for [events](#)).

The following table is non-normative and summarizes which of those content attributes, IDL attributes, methods, and events [apply](#) to each state:

	<code>Hidden</code>	<code>Text</code>	<code>URL</code>	<code>E-mail</code>	<code>Password</code>	<code>Date</code>	<code>Month</code>	<code>Week</code>	<code>Local Date & Time</code>	<code>Number</code>	<code>Range</code>	<code>Color</code>	<code>Checkbox</code>	<code>Radio Button</code>	<code>File Upload</code>	<code>Submit Button</code>	<code>Image Button</code>	<code>Reset Button</code>	<code>Button</code>

† If the control has selectable text, the `select()` method results in a no-op, with no ["invalid state error"](#) thrown.

Some states of the `type` attribute define a [value sanitization algorithm](#).

Each `input` element has a `value`, which is exposed by the `value` IDL attribute. Some states define an [algorithm to convert a string to a number](#), an [algorithm to convert a number to a string](#), an [algorithm to convert a string to a `Date` object](#), and an [algorithm to convert a `Date` object to a string](#), which are used by `max`, `min`, `step`, `valueAsData`, `valueAsNumber`, and `step`.

An `input` element's `dirtyValueFlag` must be set to true whenever the user interacts with the control in a way that changes the `value`. (It is also set to true when the value is programmatically changed, as described in the definition of the `value` IDL attribute.)

The `value` content attribute gives the default `value` of the `input` element. When the `value` content attribute is added, set, or removed, if the control's `dirtyValueFlag` is false, the user agent must set the `value` of the element to the value of the `value` content attribute, if there is one, or the empty string otherwise, and then run the current [value sanitization algorithm](#), if one is defined.

Each `input` element has a `checkedness`, which is exposed by the `checked` IDL attribute.

Each `input` element has a boolean `dirtycheckednessFlag`. When it is true, the element is said to have a `dirty checkedness`. The `dirtycheckednessFlag` must be initially set to false when the element is created, and must be set to true whenever the user interacts with the control in a way that changes the `checkedness`.

The `checked` content attribute is a `boolean` attribute that gives the default `checkedness` of the `input` element. When the `checked` content attribute is added, if the control does not have `dirtycheckedness`, the user agent must set the `checkedness` of the element to true; when the `checked` content attribute is removed, if the control does not have `dirtycheckedness`, the user agent must set the `checkedness` of the element to false.

The `setAlgorithm` for `input` elements is to set the `dirtyValueFlag` and `dirtycheckednessFlag` back to false, set the `value` of the element to the value of the `value` content attribute, if there is one, or the empty string otherwise, set the `checkedness` of the element to true if the element has a `checked` content attribute and false if it does not, empty the list of `selectedFiles`, and then invoke the `value sanitization algorithm`, if the `type` attribute's current state defines one.

Each `input` element can be `mutable`. Except where otherwise specified, an `input` element is always `mutable`. Similarly, except where otherwise specified, the user agent should not allow the user to modify the element's `value` or `checkedness`.

When an `input` element is `disabled`, it is not `mutable`.

Note

The `readonly` attribute can also in some cases (e.g. for the `Date` state, but not the `Checkbox` state) stop an `input` element from being `mutable`.

The `cloning` step for `input` elements must propagate the `value`, `dirtyValueFlag`, `checkedness`, and `dirtycheckednessFlag` from the node being cloned to the copy.

The `activationBehavior` for `input` elements are these steps:

- If this element is not `mutable`, then return.
- Run this element's `input activation behavior`, if any, and do nothing otherwise.

The `legacy-pre-activation behavior` for `input` elements are these steps:

- If this element is not `mutable`, then return.
- If the element's `type` attribute is in the `Checkbox` state, then set this element's `checkedness` to its opposite value (i.e. true if it is false, false if it is true) and set this element's `indeterminate` IDL attribute to false.
- If this element's `type` attribute is in the `Radio Button` state, then get a reference to the element in this element's `radio button group` that has its `checkedness` set to true, if any, and then set this element's `checkedness` to true.

The `legacy-cancelled-activation behavior` for `input` elements are these steps:

- If the element is not `mutable`, then return.
- If the element's `type` attribute is in the `radio button group`, and the element's `checkedness` and the element's `indeterminate` IDL attribute back to the values they had before the `legacy-pre-activation behavior` was run.
- If this element's `type` attribute is in any mode other than the `value` mode, and the new state of the element's `type` attribute puts the `value` IDL attribute in either the `default` mode or the `defaultValue` mode, then set the element's `value` content attribute to the element's `value`.

When an `input` element's `type` attribute changes state, the user agent must run the following steps:

- If the previous state of the element's `type` attribute put the `value` IDL attribute in the `value` mode, and the element's `value` is not the empty string, and the new state of the element's `type` attribute puts the `value` IDL attribute in either the `default` mode or the `defaultValue` mode, then set the element's `value` content attribute to the element's `value`.
- Otherwise, if the previous state of the element's `type` attribute put the `value` IDL attribute in any mode other than the `value` mode, and the new state of the element's `type` attribute puts the `value` IDL attribute in the `value` mode, then set the `value` of the element to the value of the `value` content attribute, if there is one, or the empty string otherwise, and then set the control's `dirtyValueFlag`.
- Otherwise, if the previous state of the element's `type` attribute put the `value` IDL attribute in any mode other than the `filename` mode, and the new state of the element's `type` attribute puts the `value` IDL attribute in the `filename` mode, then set the `value` of the element to the empty string.

4. Unset the element's `content` and `behavior` to the new state.

5. Signal a type change for the element. (The `Radio Button` state uses this, in particular.)

6. Invoke the `value sanitization algorithm`, if one is defined for the `type` attribute's new state.

7. Let `previouslySelectable` be true if `setRangeText()` previously applied to the element, and false otherwise.

8. Let `nowSelectable` be true if `setRangeText()` now applies to the element, and false otherwise.

9. If `previouslySelectable` is false and `nowSelectable` is true, set the element's `textEntryCursorPosition` to the beginning of the text control, and `set its selection direction` to "none".

The `name` attribute represents the element's name. The `dirname` attribute controls how the element's `directionality` is submitted. The `disabled` attribute is used to make the control non-interactive and to prevent its value from being submitted. The `form` attribute is used to explicitly associate the `input` element with its `form owner`. The `autocomplete` attribute controls how the user agent provides autfill behavior.

The `indeterminate` IDL attribute must initially be set to false. On getting, it must return the last value it was set to. On setting, it must be set to the new value. It has no effect except for changing the appearance of `checkbox` controls.

[]

Source: [caniuse.com](#)

The `accept`, `alt`, `max`, `min`, `multiple`, `pattern`, `placeholder`, `required`, `size`, `src`, and `step` IDL attributes must `reflect` the respective content attributes of the same name. The `dirName` IDL attribute must `reflect` the `dirname` content attribute. The `readonly` IDL attribute must `reflect` the `readonly` content attribute. The `defaultChecked` IDL attribute must `reflect` the `checked` content attribute. The `defaultValue` IDL attribute must `reflect` the `value` content attribute.

The `type` IDL attribute must `reflect` the respective content attribute of the same name, `limited to only known values`. The `maxLength` IDL attribute must `reflect` the `maxlength` content attribute, `limited to only non-negative numbers`. The `minLength` IDL attribute must `reflect` the `minlength` content attribute, `limited to only non-negative numbers`.

The `IDL` attributes `width` and `height` must return the rendered width and height of the image, in `CSS pixels`, if an image is `being rendered`, and is being rendered to a visual medium; or else the `intrinsic width and height` of the image, in `CSS pixels`, if an image is `available` but not being rendered to a visual medium; or else 0, if no image is `available`. When the `input` element's `type` attribute is not in the `Image Button` state, then no image is `available` [CSS].

On setting, they must act as if they `reflect` the respective content attributes of the same name.

The `willValidate`, `validityMessage` IDL attributes, and the `checkValidity()`, `reportValidity()`, and `setCustomValidity()` methods, are part of the `constraint validation API`. The `label` IDL attribute provides a list of the element's `label`s. The `select()`, `selectionStart`, `selectionEnd`, `selectionDirection`, `setRangeText()`, and `setSelectionRange()` methods and IDL attributes expose the element's text selection. The `disabled`, `form`, and `name` IDL attributes are part of the element's forms API.

4.18.5.1 States of the `type` attribute

4.18.5.1.1 `Hidden` state (`type=hidden`)

[]

Element

Support in all current engines.

Firefox1+Safari1+Chrome1+

Opera2+Edge79+

Edge (Legacy)12+Internet ExplorerYes

Firefox Android4+Safari iOS8+Chrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

When an `input` element's `type` attribute is in the `Hidden` state, the rules in this section apply.

The `input` element `represents` a value that is not intended to be examined or manipulated by the user.

Constraint validation: If an `input` element's `type` attribute is in the `Hidden` state, it is `barred from constraint validation`.

If the `name` attribute is present and has a value that is a `case-sensitive` match for the string "`changes`", then the element's `value` attribute must be omitted.

The `autocomplete` content attribute `applies` to this element.

The `value` IDL attribute `applies` to this element and is in mode `default`.

The following content attributes must not be specified and `do not apply` to the element: `accept`, `alt`, `checked`, `dirname`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `list`, `maxlength`, `min`, `maxlength`, `multiple`, `pattern`, `placeholder`, `readonly`, `required`, `size`, `src`, `step`, and `width`.

The following IDL attributes and methods `do not apply` to the element: `checked`, `files`, `list`, `selectionStart`, `selectionEnd`, `selectionDirection`, `valueAsDate`, and `valueAsNumber` IDL attributes; `select()`, `setRangeText()`, `setSelectionRange()`, `stepDown()`, and `stepUp()` methods.

The `input` and `change` events `do not apply`.

4.18.5.1.2 `Text` (`type=text`) state and `Search` state (`type=search`)

[]

When an `input` element's `type` attribute is in the `Text` state or the `Search` state, the rules in this section apply.

The `input` element `represents` a one line plain text edit control for the element's `value`.

Note
The difference between the `Text` state and the `Search` state is primarily stylistic: on platforms where search controls are distinguished from regular text controls, the `Search` state might result in an appearance consistent with the platform's search controls rather than appearing like a regular text control.

If the element is `mutable`, its `value` should be editable by the user. User agents must not allow users to insert U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters into the element's `value`.

If the element is `mutable`, the user agent should allow the user to change the writing direction of the element, setting it either to a left-to-right writing direction, or a right-to-left writing direction. If the user does so, the user agent must then run the following steps:

1. Set the element's `dir` attribute to "`ltr`" if the user selected a left-to-right writing direction, and "`rtr`" if the user selected a right-to-left writing direction.

2. Queue an `interaction task` on the `user interaction task source` given the element to `fire an event` named `input` at the element, with the `bubbles` attribute initialized to true.

The `value` attribute, if specified, must have a value that contains no U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters.

The `value sanitization algorithm` is as follows: `Strip newlines` from the `value`.

The following common `input` element content attributes, IDL attributes, and methods `apply` to the element: `autocomplete`, `dirname`, `list`, `maxlength`, `minlength`, `pattern`, `placeholder`, `readonly`, `required`, and `size` content attributes; `list`, `selectionStart`, `selectionEnd`, `selectionDirection`, and `value` IDL attributes; `select()`, `setRangeText()`, and `getSelectionRange()` methods.

The `value` IDL attribute is in mode `value`.

The `input` and `change` events `apply`.

The following content attributes must not be specified and `do not apply` to the element: `accept`, `alt`, `checked`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `max`, `min`, `multiple`, `src`, `step`, and `width`.

The following IDL attributes and methods `do not apply` to the element: `checked`, `files`, `list`, `selectionStart`, `selectionEnd`, `selectionDirection`, `valueAsDate`, and `valueAsNumber` IDL attributes; `stepDown()` and `stepUp()` methods.

4.18.5.1.3 `Telephone` state (`type=tel`)

[]

When an `input` element's `type` attribute is in the `Telephone` state, the rules in this section apply.

The `input` element `represents` a control for editing a telephone number given in the element's `value`.

If the element is `mutable`, its `value` should be editable by the user. User agents may change the spacing and, with care, the punctuation of `values` that the user enters. User agents must not allow users to insert U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters into the element's `value`.

The `value` attribute, if specified, must have a value that contains no U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters.

The `value sanitization algorithm` is as follows: `Strip newlines` from the `value`.

Note
Unlike the `URL` and `E-mail` types, the `Telephone` type does not enforce a particular syntax. This is intentional; in practice, telephone number fields tend to be free-form fields, because there are a wide variety of valid phone numbers. Systems that need to enforce a particular format are encouraged to use the `pattern` attribute or the `setCustomValidity()` method to hook into the client-side validation mechanism.

The following common `input` element content attributes, IDL attributes, and methods `apply` to the element: `autocomplete`, `list`, `maxlength`, `minlength`, `pattern`, `placeholder`, `readonly`, `required`, and `size` content attributes; `list`, `selectionStart`, `selectionEnd`, `selectionDirection`, and `value` IDL attributes; `select()`, `setRangeText()`, and `getSelectionRange()` methods.

When an `input` element's `type` attribute is in the `Date` state, the rules in this section apply.The `input` element **represents** a control for setting the element's `value` to a string representing a specific `date`.If the element is `mutable`, the user agent should allow the user to change the `date` represented by its `value`, as obtained by `parsing a date` from it. User agents must not allow the user to set the `value` to a non-empty string that is not a `valid date string`. If the user agent provides a user interface for selecting a `date`, then the `value` must be set to a `valid date string` representing the user's selection. User agents should allow the user to set the `value` to the empty string.Constraint validation: While the user interface describes input that the user agent cannot convert to a `valid date string`, the control is `suffering from bad input`.**Note**See the [introduction section](#) for a discussion of the difference between the input format and submission format for date, time, and number form controls, and the [implementation notes](#) regarding localization of form controls.The `value` attribute, if specified and not empty, must have a value that is a `valid date string`.The **value sanitization algorithm** is as follows: If the `value` of the element is not a `valid date string`, then set it to the empty string instead.The `max` attribute, if specified, must have a value that is a `valid date string`. The `max` attribute, if specified, must have a value that is a `valid date string`.The `step` attribute is expressed in days. The `step-scale-factor` is 86,400,000 (which converts the days to milliseconds, as used in the other algorithms). The `default step` is 1 day.When the element is `suffering from a step mismatch`, the user agent may round the element's `value` to the nearest `date` for which the element would not `suffer from a step mismatch`.The **algorithm to convert a string to a number**, given a `string input`, is as follows: If `parsing a date` from `input` results in an error, then return an error; otherwise, return the number of milliseconds elapsed from midnight UTC on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00") to midnight UTC on the morning of the parsed `date`, ignoring leap seconds.The **algorithm to convert a number to a string**, given a `number input`, is as follows: Return a `valid date string` that represents the `date` in UTC, is current `input` milliseconds after midnight UTC on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00").The **algorithm to convert a string to a date object**, given a `string input`, is as follows: If `parsing a date` from `input` results in an error, then return an error; otherwise, return a `new Date object` representing midnight UTC on the morning of the parsed `date`.The **algorithm to convert a date object to a string**, given a `date object input`, is as follows: Return a `valid date string` that represents the `date` current at the time represented by `input` in the UTC time zone.**Note**The `Date` state (and other date- and time-related states described in subsequent sections) is not intended for the entry of values for which a precise date and time relative to the contemporary calendar cannot be established. For example, it would be inappropriate for the entry of times like "one millisecond after the big bang", "the early part of the Jurassic period", or "a winter around 250 BCE".For the input of dates before the introduction of the Gregorian calendar, authors are encouraged to not use the `Date` state (and the other date- and time-related states described in subsequent sections), as user agents are not required to support converting dates and times from earlier periods to the Gregorian calendar, and asking users to do so manually puts an undue burden on users. (This is complicated by the manner in which the Gregorian calendar was phased in, which occurred at different times in different countries, ranging from partway through the 16th century all the way to early in the 20th.) Instead, authors are encouraged to provide fine-grained input controls using the `select` element and `input` elements with the `Number` state.The following common `input` element content attributes, IDL attributes, and methods `apply` to the element: `autocomplete`, `list`, `max`, `min`, `readonly`, `required`, and `step` content attributes; `list`, `value`, `valueAsData`, and `valueAsNumber` IDL attributes; `select()`, `stepDown()`, and `stepUp()` methods.The `value` IDL attribute is in mode `value`.The `input` and `change` events `apply`.The following content attributes must not be specified and **do not apply** to the element: `accept`, `alt`, `checked`, `dirname`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `maxlength`, `minlength`, `multiple`, `pattern`, `placeholder`, `size`, `src`, and `width`.The following IDL attributes and methods **do not apply** to the element: `checkbox`, `files`, `list`, `selectionStart`, `selectionEnd`, and `selectionDirection` IDL attributes; `getRangeText()`, and `setSelectionRange()` methods.**4.10.5.1.8 Month state (type=month)****Element**

When an `input` element's `type` attribute is in the `Week` state, the rules in this section apply.

The `input` element **represents** a control for setting the element's `value` to a string representing a specific `week`.

If the element is `mutable`, the user agent should allow the user to change its `value`, as obtained by `parsing a week` from it. User agents must not allow the user to set the `value` to a non-empty string that is not a `valid week string`. If the user agent provides a user interface for selecting a `week`, then the `value` must be set to a `valid week string` representing the user's selection. User agents should allow the user to set the `value` to the empty string.

Constraint validation: While the user interface describes input that the user agent cannot convert to a `valid week string`, the control is `suffering from bad input`.

Note
See the [introduction section](#) for a discussion of the difference between the input format and submission format for date, time, and number form controls, and the [implementation notes](#) regarding localization of form controls.

The `value` attribute, if specified and not empty, must have a value that is a `valid week string`.

The value sanitization algorithm is as follows: If the `value` of the element is not a `valid week string`, then set it to the empty string instead.

The `max` attribute, if specified, must have a value that is a `valid week string`. The `min` attribute, if specified, must have a value that is a `valid week string`.

The `step` attribute is expressed in weeks. The `step scale factor` is 604,800,000 (which converts the weeks to milliseconds, as used in the other algorithms). The `default step` is 1 week. The `default step base` is -259,200,000 (the start of week 1970-W01).

When the element is `suffering from a step mismatch`, the user agent may round the element's `value` to the nearest `week` for which the element would not `suffer from a step mismatch`.

The algorithm to convert a string to a number, given a `string input`, is as follows: If `parsing a week` from `input` results in an error, then return an error; otherwise, return the number of milliseconds elapsed from midnight UTC on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0Z") to midnight UTC on the morning of the Monday of the parsed `week`, ignoring leap seconds.

The algorithm to convert a number to a string, given a `number input`, is as follows: Return a `valid week string` that represents the `week` that, in UTC, is current `input` milliseconds after midnight UTC on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0Z").

The algorithm to convert a string to a date object, given a `string input`, is as follows: If `parsing a week` from `input` results in an error, then return an error; otherwise, return a `new Date object` representing midnight UTC on the morning of the Monday of the parsed `week`.

The algorithm to convert a date object to a string, given a `date object input`, is as follows: Return a `valid week string` that represents the `week` current at the time represented by `input` in the UTC time zone.

The following common `input` element content attributes, IDL attributes, and methods `apply` to the element: `autocomplete`, `list`, `max`, `min`, `readonly`, `required`, and `step` content attributes; `list`, `value`, `valueAsData`, and `valueAsNumber` IDL attributes; `select()`, `stepDown()`, and `stepUp()` methods.

The `value` IDL attribute is in mode `value`.

The `input` and `change` events `apply`.

The following content attributes must not be specified and `do not apply` to the element: `accept`, `alt`, `checked`, `dirname`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `maxlength`, `minlength`, `multiple`, `pattern`, `placeholder`, `size`, `src`, and `width`.

The following IDL attributes and methods `do not apply` to the element: `checked`, `files`, `selectionStart`, `selectionEnd`, and `selectionDirection` IDL attributes; `setRangeText()`, and `setSelectionRange()` methods.

When an `input` element's `type` attribute is in the `Time` state, the rules in this section apply.

The `input` element **represents** a control for setting the element's `value` to a string representing a specific `time`.

If the element is `mutable`, the user agent should allow the user to change its `value`, as obtained by `parsing a time` from it. User agents must not allow the user to set the `value` to a non-empty string that is not a `valid time string`. If the user agent provides a user interface for selecting a `time`, then the `value` must be set to a `valid time string` representing the user's selection. User agents should allow the user to set the `value` to the empty string.

Constraint validation: While the user interface describes input that the user agent cannot convert to a `valid time string`, the control is `suffering from bad input`.

Note

See the [introduction section](#) for a discussion of the difference between the input format and submission format for date, time, and number form controls, and the [implementation notes](#) regarding localization of form controls.

The `value` attribute, if specified and not empty, must have a value that is a `valid time string`.

The value sanitization algorithm is as follows: If the `value` of the element is not a `valid time string`, then set it to the empty string instead.

The form control has a periodic domain.

The `max` attribute, if specified, must have a value that is a `valid time string`. The `min` attribute, if specified, must have a value that is a `valid time string`.

The `step` attribute is expressed in seconds. The `step scale factor` is 1000 (which converts the seconds to milliseconds, as used in the other algorithms). The `default step` is 60 seconds.

When the element is `suffering from a step mismatch`, the user agent may round the element's `value` to the nearest `time` for which the element would not `suffer from a step mismatch`.

The algorithm to convert a string to a number, given a `string input`, is as follows: If `parsing a time` from `input` results in an error, then return an error; otherwise, return the number of milliseconds elapsed from midnight to the parsed `time` on a day with no time changes.

The algorithm to convert a number to a string, given a `number input`, is as follows: Return a `valid time string` that represents the `time` that is `input` milliseconds after midnight on a day with no time changes.

The algorithm to convert a string to a date object, given a `string input`, is as follows: If `parsing a time` from `input` results in an error, then return an error; otherwise, return a `new Date object` representing the parsed `time` in UTC on 1970-01-01.

The algorithm to convert a date object to a string, given a `date object input`, is as follows: Return a `valid time string` that represents the UTC `time` component that is represented by `input`.

The following common `input` element content attributes, IDL attributes, and methods `apply` to the element: `autocomplete`, `list`, `max`, `min`, `readonly`, and `step` content attributes; `list`, `value`, `valueAsData`, and `valueAsNumber` IDL attributes; `select()`, `stepDown()`, and `stepUp()` methods.

The `value` IDL attribute is in mode `value`.

The `input` and `change` events `apply`.

The following content attributes must not be specified and `do not apply` to the element: `accept`, `alt`, `checked`, `dirname`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `maxlength`, `minlength`, `multiple`, `pattern`, `placeholder`, `size`, `src`, and `width`.

The following IDL attributes and methods `do not apply` to the element: `checked`, `files`, `selectionStart`, `selectionEnd`, and `selectionDirection` IDL attributes; `setRangeText()`, and `setSelectionRange()` methods.

4.18.5.1.10 Local Date and Time state (type=“datetime-local”)

MDN

[Element/input/datetime-local](#)

Support in all current engines.

Firefox NoSafari NoChrom20+

Opera 11+ Edge 79+

Edge (Legacy) 12+ Internet ExplorerNo

Firefox AndroidYes Safari iOSYes Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera Android11+

When an `input` element's `type` attribute is in the `Local Date and Time` state, the rules in this section apply.

The `input` element **represents** a control for setting the element's `value` to a string representing a `local date and time`, with no time-zone offset information.

If the element is `mutable`, the user agent should allow the user to change its `value`, as obtained by `parsing a date and time` from it. User agents must not allow the user to set the `value` to a non-empty string that is not a `valid normalized local date and time string`. If the user agent provides a user interface for selecting a `local date and time`, then the `value` must be set to a `valid normalized local date and time string` representing the user's selection. User agents should allow the user to set the `value` to the empty string.

Constraint validation: While the user interface describes input that the user agent cannot convert to a `valid normalized local date and time string`, the control is `suffering from bad input`.

Note

See the [introduction section](#) for a discussion of the difference between the input format and submission format for date, time, and number form controls, and the [implementation notes](#) regarding localization of form controls.

The `value` attribute, if specified and not empty, must have a value that is a `valid local date and time string`.

The value sanitization algorithm is as follows: If the `value` of the element is a `valid local date and time string`, then set it to a `valid normalized local date and time string` representing the same date and time; otherwise, set it to the empty string instead.

The `max` attribute, if specified, must have a value that is a `valid local date and time string`. The `min` attribute, if specified, must have a value that is a `valid local date and time string`.

The `step` attribute is expressed in seconds. The `step scale factor` is 1000 (which converts the seconds to milliseconds, as used in the other algorithms). The `default step` is 60 seconds.

When the element is `suffering from a step mismatch`, the user agent may round the element's `value` to the nearest `local date and time` for which the element would not `suffer from a step mismatch`.

The algorithm to convert a string to a number, given a `string input`, is as follows: If `parsing a date and time` from `input` results in an error, then return an error; otherwise, return the number of milliseconds elapsed from midnight on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0Z") to the parsed `local date and time`, ignoring leap seconds.

The algorithm to convert a number to a string, given a `number input`, is as follows: Return a `valid normalized local date and time string` that represents the date and time that is `input` milliseconds after midnight on the morning of 1970-01-01 (the time represented by the value "1970-01-01T00:00:00.0Z").

Note

See the [note on historical data](#) in the `Date` state section.

The following common `input` element content attributes, IDL attributes, and methods `apply` to the element: `autocomplete`, `list`, `max`, `min`, `readonly`, and `step` content attributes; `list`, `value`, and `valueAsNumber` IDL attributes; `select()`, `stepDown()`, and `stepUp()` methods.

The `value` IDL attribute is in mode `value`.

The `input` and `change` events `apply`.

The following content attributes must not be specified and `do not apply` to the element: `accept`, `alt`, `checked`, `dirname`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `maxlength`, `minlength`, `multiple`, `pattern`, `placeholder`, `size`, `src`, and `width`.

The following IDL attributes and methods `do not apply` to the element: `checked`, `files`, `selectionStart`, `selectionEnd`, and `selectionDirection` IDL attributes; `setRangeText()`, and `setSelectionRange()` methods.

Example

The following example shows part of a flight booking application. The application uses an `input` element with its `type` attribute set to `datetime-local`, and it then interprets the given date and time in the time zone of the selected airport.

```
<label>Destination</label>
<p><label>Airport: <input type="text" name="to" list="airports"></label><br/>
<input type="text" name="date" value="2019-01-01T12:00:00" /><br/>
<label>Flight: <input type="text" name="flight"></label><br/>
<input type="text" name="airline" value="Delta Air Lines" /><br/>
<input type="text" name="airline" value="American Airlines" /><br/>
<input type="text" name="airline" value="Frankfurt" /><br/>
</p>
```

When an `input` element's `type` attribute is in the `Number` state, the rules in this section apply.

The `input` element **represents** a control for setting the element's `value` to a string representing a number.

If the element is **mutable**, the user agent should allow the user to change the number represented by its `value`, as obtained from applying the `rules for parsing floating-point number values` to it. User agents must not allow the user to set the `value` to a non-empty string that is not a `valid floating-point number`. If the user agent provides a user interface for selecting a number, then the `value` must be set to the `best representation of the number representing the user's selection as a floating-point number`. User agents should allow the user to set the `value` to the empty string.

Constraint validation: While the user interface describes input that the user agent cannot convert to a `valid floating-point number`, the control is *suffering from bad input*.

Note

This specification does not define what user interface user agents are to use; user agent vendors are encouraged to consider what would best serve their users' needs. For example, a user agent in Persian or Arabic markets might support Persian and Arabic numeric input (converting it to the format required for submission as described above). Similarly, a user agent designed for Romans might display the value in Roman numerals rather than in decimal; or (more realistically) a user agent designed for the French market might display the value with apostrophes between thousands and commas before the decimals, and allow the user to enter a value in that manner, internally converting it to the submission format described above.

The `value` attribute, if specified and not empty, must have a value that is a `valid floating-point number`.

The value sanitization algorithm is as follows: If the `value` of the element is not a `valid floating-point number`, then set it to the empty string instead.

The `min` attribute, if specified, must have a value that is a `valid floating-point number`. The `max` attribute, if specified, must have a value that is a `valid floating-point number`.

The `step` scale factor is 1. The `default step` is 1 (allowing only integers to be selected by the user, unless the `step` base has a non-integer value).

When the element is *suffering from a step mismatch*, the user agent may round the element's `value` to the nearest number for which the element would not *suffer from a step mismatch*. If there are two such numbers, user agents are encouraged to pick the one nearest positive infinity.

The algorithm to convert a string to a number, given a string `input`, is as follows: If applying the `rules for parsing floating-point number values` to `input` results in an error, then return an error; otherwise, return the resulting number.

The algorithm to convert a number to a string, given a number `input`, is as follows: Return a `valid floating-point number` that represents `input`.

The following common `input` element content attributes, IDL attributes, and methods `apply` to the element: `autocomplete`, `list`, `max`, `placeholder`, `readonly`, `required`, and `step` content attributes; `list_value`, and `valueAsNumber` IDL attributes; `select()`, `stepDown()`, and `stepUp()` methods.

The `value` IDL attribute is in mode `value`.

The `input` and `change` events `apply`.

The following content attributes must not be specified and `do not apply` to the element: `accept`, `alt`, `checked`, `dirname`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `maxlength`, `minlength`, `multiple`, `pattern`, `size`, `src`, and `width`.

The following IDL attributes and methods `do not apply` to the element: `checked`, `files`, `selectionStart`, `selectionEnd`, `selectionDirection`, and `valueAsData` IDL attributes; `getRangeText()`, and `setSelectionRange()` methods.

Example

Here is an example of using a numeric input control:

```
<label>How much do you want to charge? <input type="number" min=0 step=0.01 name="price"></label>
```

As described above, a user agent might support numeric input in the user's local format, converting it to the format required for submission as described above. This might include handling grouping separators (as in "872,000,000.00") and various decimal separators (such as ".99" vs "3.99") or using local digits (such as those in Arabic, Devanagari, Persian, and Thai).

Note

The `type="number"` state is not appropriate for input that happens to only consist of numbers but isn't strictly speaking a number. For example, it would be inappropriate for credit card numbers or US postal codes. A simple way of determining whether to use `type="number"` is to consider whether it would make sense for the input control to have a spinbox interface (e.g. with "up" and "down" arrows). Getting a credit card number wrong by 1 in the last digit isn't a minor mistake; it's as wrong as getting every digit incorrect. So it would not make sense for the user to select a credit card number using "up" and "down" buttons. When a spinbox interface is not appropriate, `type="text"` is probably the right choice possibly with a `pattern` attribute).

A 4.0.1.1.1 Range state (`type="range"`)

Support: input-rangeChrome for Android 81+Chrome 4+iOS Safari 5.0+Safari 3.1+Firefox 23+Samsung Internet 4+Edge 12+UC Browser for Android 12.12+IE 10+Opera 9+Opera Mini NonFirefox for Android 68+

When an `input` element's `type` attribute is in the `Range` state, the rules in this section apply.

The `input` element **represents** a control for setting the element's `value` to a string representing a number, but with the caveat that the exact value is not important, letting UAs provide a simpler interface than they do for the `Number` state.

If the element is **mutable**, the user agent should allow the user to change number represented by its `value`, as obtained from applying the `rules for parsing floating-point number values` to it. User agents must not allow the user to set the `value` to a non-empty string that is not a `valid floating-point number`. If the user agent provides a user interface for selecting a number, then the `value` must be set to a `best representation of the number representing the user's selection as a floating-point number`. User agents must not allow the user to set the `value` to the empty string.

Constraint validation: While the user interface describes input that the user agent cannot convert to a `valid floating-point number`, the control is *suffering from bad input*.

The `value` attribute, if specified, must have a value that is a `valid floating-point number`.

The value sanitization algorithm is as follows: If the `value` of the element is not a `valid floating-point number`, then set it to the `best representation as a floating-point number` of the `default value`.

The `default value` is the `minimum` plus half the difference between the `minimum` and the `maximum`, unless the `maximum` is less than the `minimum`, in which case the `default value` is the `minimum`.

When the element is *suffering from an underflow*, the user agent must set the element's `value` to the `best representation as a floating-point number` of the `minimum`.

When the element is *suffering from an overflow*, the user agent must set the element's `value` to a `valid floating-point number` that represents the `maximum`.

When the element is *suffering from a step mismatch*, the user agent must round the element's `value` to the nearest number for which the element would not *suffer from a step mismatch* and which is greater than or equal to the `minimum` and, if the `maximum` is not less than the `minimum` which is less than or equal to the `maximum`, if there is a number that matches these constraints. If two numbers match these constraints, then user agents must use the one nearest to positive infinity.

Example

For example, the markup `<input type="range" min=0 max=100 step=20 value=50>` results in a range control whose initial value is 60.

Example

Here is an example of a range control using an autocomplete list with the `list` attribute. This could be useful if there are values along the full range of the control that are especially important, such as preconfigured light levels or typical speed limits in a range control used as a speed control. The following markup fragment:

```
<input type="range" min="-100" max="100" value="0" step="10" name="power" list="powers">
<datalist id="powers">
<option value="-100">
<option value="0">
<option value="30">
<option value="300">
<option value="++50">
</datalist>
```

...with the following style sheet applied:

```
cssinput { height: 75px; width: 49px; background: #D5CCBB; color: black; }
```

...might render as:

Note how the UA determined the orientation of the control from the ratio of the style-sheet-specified height and width properties. The colors were similarly derived from the style sheet. The tick marks, however, were derived from the markup. In particular, the `step` attribute has not affected the placement of tick marks, the UA deciding to only use the author-specified completion values and then adding longer tick marks at the extremes.

Note also how the invalid value `++50` was completely ignored.

Example

For another example, consider the following markup fragment:

```
<input name=x type="range" min=100 max=700 step=9.09090909 value=509.090909>
```

A user agent could display in a variety of ways, for instance:

Or, alternatively, for instance:

The user agent could pick which one to display based on the dimensions given in the style sheet. This would allow it to maintain the same resolution for the tick marks, despite the differences in width.

Example

Finally, here is an example of a range control with two labeled values:

```
<input type="range" name="a" list="a-values">
<datalist id="a-values">
<option value="10" label="Low">
<option value="100" label="High">
</datalist>
```

With styles that make the control draw vertically, it might look as follows:

Note
In this state, the range and step constraints are enforced even during user input, and there is no way to set the value to the empty string.

The `step` attribute, if specified, must have a value that is a [valid floating-point number](#). The `default minimum` is 0. The `step` attribute, if specified, must have a value that is a [valid floating-point number](#). The `default maximum` is 100.

The `step scale factor` is 1. The `default step` is 1 (allowing only integers, unless the `step` attribute has a non-integer value).

The **algorithm to convert a string to a number**, given a `string input`, is as follows: If applying the [rules for parsing floating-point number values](#) to `input` results in an error, then return an error; otherwise, return the resulting number.

The **algorithm to convert a number to a string**, given a `number input`, is as follows: Return the `best representation`, as a floating-point number, of `input`.

The following common `input` element content attributes, IDL attributes, and methods `apply` to the element: `autocomplete`, `list`, `max`, `min`, and `step` content attributes; `list`, `value`, and `valueAsNumber` IDL attributes; `stepDown()` and `stepUp()` methods.

The `value` IDL attribute is in mode `value`.

The `input` and `change` events apply.

The following content attributes must not be specified and [do not apply](#) to the element: `accept`, `alt`, `checked`, `dirname`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `max`, `maxlength`, `minlength`, `multiple`, `pattern`, `placeholder`, `readonly`, `required`, `size`, `src`, and `width`.

The following IDL attributes and methods [do not apply](#) to the element: `checked`, `files`, `selectionStart`, `selectionEnd`, `selectionDirection`, and `valueAsDate` IDL attributes; `select()`, `setRangeText()`, and `getSelectionRange()` methods.

4.10.5.1.14 Color state (type=“color”)

When an `input` element's `type` attribute is in the `Color` state, the rules in this section apply.

The `input` element **represents** a color well control, for setting the element's `value` to a string representing a [simple color](#).

Note

In this state, there is always a color picked, and there is no way to set the value to the empty string.

If the element is [mutable](#), the user agent should allow the user to change the color represented by its `value`, as obtained from applying the [rules for parsing simple color values](#) to it. User agents must not allow the user to set the `value` to a string that is not a [valid lowercase simple color](#). If the user agent provides a user interface for selecting a color, then the `value` must be set to the result of using the [rules for serializing simple color values](#) to the user's selection. User agents must not allow the user to set the `value` to the empty string.

Constraint validation: While the user interface describes input that the user agent cannot convert to a [valid lowercase simple color](#), the control is [suffering from bad input](#).

The `value` attribute, if specified and not empty, must have a value that is a [valid simple color](#).

The **value sanitization algorithm** is as follows: If the `value` of the element is a [valid simple color](#), then set it to the `value` of the element [converted to ASCII lowercase](#); otherwise, set it to the string "#000000".

The following common `input` element content attributes and IDL attributes `apply` to the element: `autocomplete` and `list` content attributes; `list` and `value` IDL attributes; `select()` method.

The `value` IDL attribute is in mode `value`.

The `input` and `change` events `apply`.

The following content attributes must not be specified and [do not apply](#) to the element: `accept`, `alt`, `checked`, `dirname`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `max`, `maxlength`, `min`, `minlength`, `multiple`, `pattern`, `placeholder`, `readonly`, `required`, `size`, `src`, `step`, and `width`.

The following IDL attributes and methods [do not apply](#) to the element: `checked`, `files`, `selectionStart`, `selectionEnd`, `selectionDirection`, `valueAsDate` and `valueAsNumber` IDL attributes; `getRangeText()`, `setSelectionRange()`, `stepDown()`, and `stepUp()` methods.

4.10.5.1.15 Checkbox state (type=“checkbox”)

MDN

Element

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy)12+Internet Explorer Yes

Firefox, Android 4+Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

When an `input` element's `type` attribute is in the `Checkbox` state, the rules in this section apply.

The `input` element **represents** a two-state control that represents the element's `checkedness` state. If the element's `checkedness` state is true, the control represents a positive selection, and if it is false, a negative selection. If the element's `indeterminate` IDL attribute is set to true, then the control's selection should be obscured as if the control was in a third, indeterminate, state.

Note

The control is never a true tri-state control, even if the element's `indeterminate` IDL attribute is set to true. The `indeterminate` IDL attribute only gives the appearance of a third state.

The `input activation behavior` is to [fire an event](#) named `input` at the element, with the `bubbles` attribute initialized to true, and then [fire an event](#) named `change` at the element, with the `bubbles` attribute initialized to true.

Constraint validation: If the element is `required` and its `checkedness` is false, then the element is [suffering from being missing](#).

For web developers (non-normative)

`input : indeterminate = value`

When set, overrides the rendering of `checkbox` controls so that the current value is not visible.

The following common `input` element content attributes and IDL attributes `apply` to the element: `checked`, and `required` content attributes; `checked` and `value` IDL attributes.

The `value` IDL attribute is in mode `defaultOn`.

The `input` and `change` events `apply`.

The following content attributes must not be specified and [do not apply](#) to the element: `accept`, `alt`, `autocomplete`, `dirname`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `list`, `max`, `maxlength`, `min`, `minlength`, `multiple`, `pattern`, `placeholder`, `readonly`, `size`, `src`, `step`, and `width`.

The following IDL attributes and methods [do not apply](#) to the element: `files`, `list`, `selectionStart`, `selectionEnd`, `selectionDirection`, `valueAsDate`, and `valueAsNumber` IDL attributes; `select()`, `setRangeText()`, `getSelectionRange()`, `stepDown()`, and `stepUp()` methods.

4.10.5.1.16 Radio Button state (type=“radio”)

MDN

Element

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy)12+Internet Explorer Yes

Firefox, Android 4+Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

When an `input` element's `type` attribute is in the `Radio Button` state, the rules in this section apply.

The `input` element **represents** a control that when used in conjunction with other `input` elements, forms a `radio button group` in which only one control can have its `checkedness` state set to true. If the element's `checkedness` state is true, the control represents the selected control in the group, and if it is false, it indicates a control in the group that is not selected. The `radio button group` that contains an `input` element *a* also contains all the other `input` elements *b* that fulfill all of the following conditions:

- The `input` element *b*'s `type` attribute is in the `Radio Button` state.
- Either *a* and *b* have the same `form owner`, or they both have no `form owner`.
- Both *a* and *b* are in the same `list`.
- They both have a `name` attribute, their `name` attributes are not empty, and the value of *a*'s `name` attribute equals the value of *b*'s `name` attribute.

`input` must not contain an `input` element whose `radio button group` contains only that element.

When any of the following phenomena occur, if the element's `checkedness` state is true after the occurrence, the `checkedness` state of all the other elements in the same `radio button group` must be set to false:

- The element's `checkedness` state is set to true (for whatever reason).
- The element's `name` attribute is set, changed, or removed.
- The element's `form owner` changes.
- A `pre-change` is signaled for the element.

The `input activation behavior` is to [fire an event](#) named `input` at the element, with the `bubbles` attribute initialized to true, and then [fire an event](#) named `change` at the element, with the `bubbles` attribute initialized to true.

Constraint validation: If an element in the `radio button group` is `required`, and all of the `input` elements in the `radio button group` have a `checkedness` that is false, then the element is [suffering from being missing](#).

Example

The following example, for some reason, has specified that puppers are both `required` and `disabled`:

```
<form><label><input type="radio" name="dog-type" value="pupper" required disabled> Pupper</label>
```

EXPAND

`</form>`
 If the user tries to submit this form without first selecting "Doggie", then both `input` elements will be [suffering from being missing](#), since an element in the `radio button group` is [required](#) (viz. the first element), and both of the elements in the radio button group have a false `checkedness`.
 On the other hand, if the user selects "Doggie" and then submits the form, then neither `input` element will be [suffering from being missing](#), since while one of them is [required](#), not all of them have a false `checkedness`.

Note
 If none of the radio buttons in a `radio button group` are checked, then they will all be initially unchecked in the interface, until such time as one of them is checked (either by the user or by script).

The following common `input` element content attributes and IDL attributes [apply](#) to the element: `checked` and `required` content attributes; `checked` and `value` IDL attributes.

The `value` IDL attribute is in mode `defaultOn`.

The `input` and `change` events [apply](#).

The following content attributes must not be specified and [do not apply](#) to the element: `accept`, `alt`, `autocomplete`, `dirname`, `formaction`, `formencType`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `list`, `max`, `maxlength`, `min`, `minlength`, `multiple`, `pattern`, `placeholder`, `readonly`, `size`, `src`, `step`, and `width`.

The following IDL attributes and methods [do not apply](#) to the element: `files`, `list`, `selectionStart`, `selectionEnd`, `selectionDirection`, `valueAsDate`, and `valueAsString` IDL attributes; `select()`, `setRangeText()`, `getSelectionRange()`, `stepDown()`, and `stepUp()` methods.

4.10.5.1.17 `File Upload state` (`type=files`)

MDN

[Element](#)

Support in all current engines.

Firefox 1+ Safari 1+ Chrome 1+

Opera 11+ Edge 79+

Edge (Legacy) 12+ Internet Explorer 10+

Firefox 40+ Safari iOS 8+ Chrome Android 4+ Samsung Internet 4+ Opera Android 11+

When an `input` element's `type` attribute is in the [File Upload](#) state, the rules in this section apply.

MDN

[File list](#)

Support in all current engines.

Firefox 3+ Safari 4+ Chrome 1+

Opera 11.1+ Edge 79+

Edge (Legacy) 12+ Internet Explorer 10+

Firefox Android 4+ Safari iOS 3.2+ Chrome Android 18+ WebView Android 1+ Samsung Internet 1.0+ Opera Android 11.1+

The `input` element [represents](#) a list of `selected files`, each file consisting of a file name, a file type, and a file body (the contents of the file).

File names must not contain `path components`, even in the case that a user has selected an entire directory hierarchy or multiple files with the same name from different directories. `Path components`, for the purposes of the [File Upload](#) state, are those parts of file names that are separated by U+005C REVERSE SOLIDUS character () characters.

Unless the `multiple` attribute is set, there must be no more than one file in the list of `selected files`.

The element's `input activation behavior` is to run the following steps:

1. If the algorithm is invoked when the element's `Window` object does not have `transient activation`, then return without doing anything else.
2. Run these steps in parallel:
 1. Optionally, wait until any prior execution of this algorithm has terminated.
 2. Display a prompt to the user requesting that the user specify some files. If the `multiple` attribute is not set, there must be no more than one file selected; otherwise, any number may be selected. Files can be from the filesystem or created on the fly, e.g., a picture taken from a camera connected to the user's device.
 3. Wait for the user to have made their selection.
4. [Queue an element task](#) on the `user interaction task source` given the `input` element and the following steps:
 1. Update the element's `selected files` so that it represents the user's selection.
 2. [Fire an event](#) named `input` at the `input` element, with the `bubbles` attribute initialized to true, and finally [fire an event](#) named `change` at the `input` element, with the `bubbles` attribute initialized to true.

If the element is `mutable`, the user agent should allow the user to change the files on the list in other ways also, e.g. adding or removing files by drag-and-drop. When the user does so, the user agent must [queue a task](#) to first update the element's `selected files` so that it represents the user's new selection, then [fire an event](#) named `input` at the `input` element, with the `bubbles` attribute initialized to true, and finally [fire an event](#) named `change` at the `input` element, with the `bubbles` attribute initialized to true.

If the element is not `mutable`, the user agent must not allow the user to change the element's selection.

Constraint validation: If the element is `required` and the list of `selected files` is empty, then the element is [suffering from being missing](#).

The `accept` attribute may be specified to provide user agents with a hint of what file types will be accepted.

Support: input-file-acceptChrome for Android (limited) 81+ Chrome 26+ iOS Safari (limited) 8+ Safari 11.1+ Firefox 37+ Samsung Internet (limited) 4+ Edge 79+ UC Browser for Android NonIE 10+ Opera 15+ Opera Mini NonFirefox for Android None

Source: [caniuse.com](#)

If specified, the attribute must consist of a [set of comma-separated tokens](#), each of which must be an [ASCII case-insensitive](#) match for one of the following:

The string "`audio/*`"

Indicates that sound files are accepted.

The string "`video/*`"

Indicates that video files are accepted.

The string "`image/*`"

Indicates that image files are accepted.

A [valid MIME type string with no parameters](#)

Indicates that files of the specified type are accepted.

A string whose first character is a U+002E FULL STOP character (.)

Indicates that files with the specified file extension are accepted.

The tokens must not be [ASCII case-insensitive](#) matches for any of the other tokens (i.e. duplicates are not allowed). To obtain the list of tokens from the attribute, the user agent must [split the attribute value on commas](#).

User agents may use the value of this attribute to display a more appropriate user interface than a generic file picker. For instance, given the value `image/*`, a user agent could offer the user the option of using a local camera or selecting a photograph from their photo collection; given the value `audio/*`, a user agent could offer the user the option of recording a clip using a headset microphone.

User agents should prevent the user from selecting files that are not accepted by one (or more) of these tokens.

Note

Authors are encouraged to specify both any MIME types and any corresponding extensions when looking for data in a specific format.

Example

For example, consider an application that converts Microsoft Word documents to Open Document Format files. Since Microsoft Word documents are described with a wide variety of MIME types and extensions, the site can list several, as follows:

```
<input type="file" accept=".doc,.docx,application/msword,application/vnd.openxmlformats-officedocument.wordprocessingml.document">
```

On platforms that only use file extensions to describe file types, the extensions listed here can be used to filter the allowed documents, while the MIME types can be used with the system's type registration table (mapping MIME types to extensions used by the system), if any, to determine any other extensions to allow. Similarly, on a system that does not have file names or extensions but labels documents with MIME types internally, the MIME types can be used to pick the allowed files, while the extensions can be used if the system has an extension registration table that maps known extensions to MIME types used by the system.

⚠ Warning!

Extensions tend to be ambiguous (e.g. there are an untold number of formats that use the ".dat" extension, and users can typically quite easily rename their files to have a ".doc" extension even if they are not Microsoft Word documents), and MIME types tend to be unreliable (e.g. many formats have no formally registered types, and many formats are in practice labeled using a number of different MIME types). Authors are reminded that, as usual, data received from a client should be treated with caution, as it may not be in an expected format even if the user is not hostile and the user agent fully obeyed the `accept` attribute's requirements.

MDN

[Element](#)

Example

For historical reasons, the `value` IDL attribute prefixes the file name with the string "`c:\fakepath\`". Some legacy user agents actually included the full path (which was a security vulnerability). As a result of this, obtaining the file name from the `value` IDL attribute in a backwards-compatible way is non-trivial. The following function extracts the file name in a suitably compatible manner:

```
function extractFilename(path) {
  let i = path.lastIndexOf('\'');
  return path.substring(i); // modern browser
  var x;
  if (x < 0) x = path.lastIndexOf('/');
  if (x >= 0) // Unix-based path
    return path.substring(x+1);
  if (x < 0) x = path.lastIndexOf('\\');
  if (x >= 0) // Windows-based path
    return path.substring(x+1);
  return path; // just the file name
}
```

This can be used as follows:

```
<p><input type="file" value="image changes="updateFilename(this.value)"></p>
<script>
  let file = document.querySelector('input');
  file.addEventListener('change', function() {
    var name = extractFilename(file.value);
    document.getElementById('filename').textContent = name;
  });
</script>
```

The following common `input` element content attributes and IDL attributes [apply](#) to the element: `accept`, `multiple`, and `required` content attributes; `files` and `value` IDL attributes; `select()` method.

The `value` IDL attribute is in mode `filename`.

The `input` and `change` events [apply](#).

The following content attributes must not be specified and [do not apply](#) to the element: `alt`, `autocomplete`, `checked`, `dirname`, `formaction`, `formencType`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `list`, `max`, `maxlength`, `min`, `minlength`, `multiple`, `pattern`, `placeholder`, `readonly`, `size`, `src`, `step`, and `width`.

The element's `value` attribute must be omitted.

The following IDL attributes and methods [do not apply](#) to the element: `checked`, `list`, `selectionStart`, `selectionEnd`, `selectionDirection`, `valueAsDate`, and `valueAsString` IDL attributes; `getRangeText()`, `getSelectionRange()`, `stepDown()`, and `stepUp()` methods.

4.10.5.1.18 `Submit button state` (`type=submit`)

Edge (Legacy) 12+|Internet Explorer Yes

Firefox Android 4+|Safari iOS|Yes|Chrome Android|Yes|WebView Android|Yes|Samsung Internet|Yes|Opera Android|Yes

When an `input` element's `type` attribute is in the `Submit Button` state, the rules in this section apply.The `input` element represents a button that, when activated, submits the form. If the element has a `value` attribute, the button's label must be the value of that attribute; otherwise, it must be an implementation-defined string that means "Submit" or some such. The element is a `button`, specifically a `submit button`.**Note**

Since the default label is implementation-defined, and the width of the button typically depends on the button's label, the button's width can leak a few bits of fingerprintable information. These bits are likely to be strongly correlated to the identity of the user agent and the user's locale.

The element's `input activation behavior` is as follows: if the element has a `form owner`, and the element's `node document` is `fully active`, submit the `form owner` from the `input` element; otherwise, do nothing.The `formaction`, `formenctype`, `formmethod`, `formnovalidate`, and `formtarget` attributes are `attributes for form submission`.**Note**The `formnovalidate` attribute can be used to make submit buttons that do not trigger the constraint validation.The following common `input` element content attributes and IDL attributes apply to the element: `formaction`, `formenctype`, `formmethod`, `formnovalidate`, and `formtarget`, content attributes; `value` IDL attribute.The `value` IDL attribute is in mode `default`.The following content attributes must not be specified and do not apply to the element: `accept`, `alt`, `autocomplete`, `checked`, `dirname`, `height`, `list`, `max`, `maxlength`, `min`, `minlength`, `multiple`, `pattern`, `placeholder`, `readonly`, `required`, `size`, `src`, `step`, and `width`.The following IDL attributes and methods do not apply to the element: `checked`, `files`, `list`, `selectionStart`, `selectionEnd`, `selectionDirection`, `valuesAsDate`, and `valuesAsNumber` IDL attributes; `select()`, `setRangeText()`, `setSelectionRange()`, `stepDown()`, and `stepUp()` methods.The `input` and `change` events do not apply.4.10.5.1.19 Image Button state (`type="image"`)**MDN****Element**

Firefox, Android 4+|Safari iOS|Yes|Chrome Android|Yes|WebView Android|Yes|Samsung Internet|Yes|Opera Android|Yes

When an `input` element's `type` attribute is in the `Image Button` state, the rules in this section apply.The `input` element represents either an image from which a user can select a coordinate and submit the form, or alternatively a button from which the user can submit the form. The element is a `button`, specifically a `submit button`.**Note**

The coordinate is sent to the server during form submission by sending two entries for the element, derived from the name of the control but with ".x" and ".y" appended to the name with the x and y components of the coordinate respectively.

The image is given by the `src` attribute. The `src` attribute must be present, and must contain a valid non-empty URL potentially surrounded by spaces referencing a non-interactive, optionally animated, image resource that is neither paged nor scripted.

When any of the these events occur

- The `input` element's `type` attribute is first set to the `Image Button` state (possibly when the element is first created), and the `src` attribute is present
- The `input` element's `type` attribute is changed back to the `Image Button` state, and the `src` attribute is present, and its value has changed since the last time the `type` attribute was in the `Image Button` state
- The `input` element's `type` attribute is in the `Image Button` state, and the `src` attribute is set or changed

then unless the user agent cannot support images, or its support for images has been disabled, or the user agent only fetches images on demand, or the `src` attribute's value is the empty string, the user agent must `parse` the value of the `src` attribute value, relative to the element's `node document`, and if that is successful, then:

1. Let `request` be a new `request` whose `url` is the `resulting URL record`, `client` is the element's `node document`'s `relevant settings object`, `destination` is "image", `credentials mode` is "include", and whose `use-URL-credentials flag` is set.
2. Fetch `request`.

Fetching the image must `delay the load event` of the element's `node document` until the `task` that is `queued` by the `networking task source` once the resource has been fetched (defined below) has been run.If the image was successfully obtained, with no network errors, and the image's type is a supported image type, and the image is a valid image of that type, then the image is said to be `available`. If this is true before the image is completely downloaded, each `task` that is `queued` by the `networking task source` while the image is being fetched must update the presentation of the image appropriately.The user agent should apply the `image sniffing rules` to determine the type of the image, with the image's `associated Content-Type headers` giving the `official type`. If these rules are not applied, then the type of the image must be the type given by the image's `associated Content-Type headers`.User agents must not support non-image resources with the `input` element. User agents must not run executable code embedded in the image resource. User agents must only display the first page of a multipage resource. User agents must not allow the resource to act in an interactive fashion, but should honor any animation in the resource.The `task` that is `queued` by the `networking task source` once the resource has been fetched, must, if the download was successful and the image is `available`, queue a task to fire an event named `load` at the `input` element; and otherwise, if the fetching process fails without a response from the remote server, or completes but the image is not a valid or supported image, queue a task to fire an event named `error` on the `input` element.The `alt` attribute provides the textual label for the button for users and user agents who cannot use the image. The `alt` attribute must be present, and must contain a non-empty string giving the label that would be appropriate for an equivalent button if the image was unavailable.The `input` element supports `dimension attributes`.If the `src` attribute is set, and the image is `mutable` and the user agent is configured to display that image, then: The element represents a control for selecting a `coordinate` from the image specified by the `src` attribute; if the element is `mutable`, the user agent should allow the user to select this `coordinate`, and the element's `input activation behavior` is as follows: if the element has a `form owner`, and the element's `node document` is `fully active`, take the user's selected `form owner` from the `input` element. If the user activates the control without explicitly selecting a coordinate, then the coordinate (0,0) must be assumed.Otherwise, the element represents a submit button whose label is given by the value of the `alt` attribute; the element's `input activation behavior` is as follows: if the element has a `form owner`, and the element's `node document` is `fully active`, set the `selected coordinate` to (0,0), and submit the `input` element's `form owner` from the `input` element.In either case, if the element has no `form owner` or the element's `node document` is not `fully active`, then its `input activation behavior` must be to do nothing.The `selected coordinate` must consist of an x-component and a y-component. The coordinates represent the position relative to the edge of the image, with the coordinate space having the positive x direction to the right, and the positive y direction downwards.The x-component must be a `valid integer` representing a number x in the range $-(\text{border}_left + \text{padding}_left) \leq x \leq \text{width} - \text{border}_right - \text{padding}_right$, where `width` is the rendered width of the image, `border_left` is the width of the border on the left of the image, `padding_left` is the width of the padding on the left of the image, `border_right` is the width of the border on the right of the image, and `padding_right` is the width of the padding on the right of the image, with all dimensions given in [CSS pixels](#).The y-component must be a `valid integer` representing a number y in the range $-(\text{border}_top + \text{padding}_top) \leq y \leq \text{height} - \text{border}_bottom - \text{padding}_bottom$, where `height` is the rendered height of the image, `border_top` is the width of the border above the image, `padding_top` is the width of the padding above the image, `border_bottom` is the width of the border below the image, and `padding_bottom` is the width of the padding below the image, with all dimensions given in [CSS pixels](#).Where a border or padding is missing, its width is zero [CSS pixels](#).The `formaction`, `formenctype`, `formmethod`, `formnovalidate`, and `formtarget` attributes are `attributes for form submission`.**For web developers (non-normative)**`image - width [= value]``image - height [= value]`

These attributes return the actual rendered dimensions of the image, or zero if the dimensions are not known.

They can be set, to change the corresponding content attributes.

The following common `input` element content attributes and IDL attributes apply to the element: `alt`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `src`, and `width` content attributes; `value` IDL attribute.The `value` IDL attribute is in mode `default`.The following content attributes must not be specified and do not apply to the element: `accept`, `autocomplete`, `checked`, `dirname`, `list`, `max`, `maxlength`, `min`, `minlength`, `multiple`, `pattern`, `placeholder`, `readonly`, `required`, `size`, and `step`.The element's `value` attribute must be omitted.The following IDL attributes and methods do not apply to the element: `checked`, `files`, `list`, `selectionStart`, `selectionEnd`, `selectionDirection`, `valuesAsDate`, and `valuesAsNumber` IDL attributes; `select()`, `setRangeText()`, `setSelectionRange()`, `stepDown()`, and `stepUp()` methods.The `input` and `change` events do not apply.**Note**Many aspects of this state's behavior are similar to the behavior of the `img` element. Readers are encouraged to read that section, where many of the same requirements are described in more detail.**Example**

Take the following form:

`<form action="process.cgi">
<input type="image" src="map.png" alt="Show location list" />
</form>`

If the user clicked on the image at coordinate (127,40) then the URL used to submit the form would be "process.cgi?where.x=127&where.y=40".

In this example, it's assumed that for users who don't see the map, and who instead just see a button labeled "Show location list", clicking the button will cause the server to show a list of locations to pick from instead of the map.)

4.10.5.1.20 Reset Button state (`type="reset"`)**MDN****Element**

Support in all current engines.

Firefox 1+|Safari 1+|Chrome 1+

Opera Yes|Edge 79+

Edge (Legacy) 12+|Internet Explorer Yes

Firefox, Android 4+|Safari iOS|Yes|Chrome Android|Yes|WebView Android|Yes|Samsung Internet|Yes|Opera Android|Yes

When an `input` element's `type` attribute is in the `Reset Button` state, the rules in this section apply.The `input` element represents a button that, when activated, resets the form. If the element has a `value` attribute, the button's label must be the value of that attribute; otherwise, it must be an implementation-defined string that means "Reset" or some such. The element is a `button`.

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Note
Since the default label is implementation-defined, and the width of the button typically depends on the button's label, the button's width can leak a few bits of fingerprintable information. These bits are likely to be strongly correlated to the identity of the user agent and the user's locale.

The element's `input.activationBehavior`, if the element has a `formOwner` and the element's `node.document` is `fullyActive`, is to `reset` the `formOwner`; otherwise, it is to do nothing.

Constraint validation: The element is `barred from constraint validation`.

The `value` IDL attribute `applies` to this element and is in mode `default`.

The following content attributes must not be specified and `do not apply` to the element: `accept-charset`, `autocomplete`, `checked`, `dirname`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `list`, `max`, `maxlength`, `min`, `multiple`, `pattern`, `placeholder`, `readonly`, `required`, `sizes`, `step`, and `width`.

The following IDL attributes and methods `do not apply` to the element: `checked`, `files`, `list`, `selectionStart`, `selectionEnd`, `selectionDirection`, `valueAsDate`, and `valueAsNumber`. IDL attributes: `select()`, `setRangeText()`, `setSelectionRange()`, `stepDown()`, and `stepUp()` methods.

The `input` and `change` events `do not apply`.

4.10.5.1.21 `button` state (`type=button`)

OMN

Element/`input/button`

Support in all current engines:

Firefox 1+|Safari 1+|Chrome 1+

Opera Yes|Edge 79+

Edge (Legacy) 12+|Internet Explorer Yes

Firefox Android 4+|Safari iOS|Yes|Chrome Android 18+|WebView Android|Yes|Samsung Internet 1.0+|Opera Android|Yes

When an `input` element's `type` attribute is in the `button` state, the rules in this section apply.

The `input` element `represents` a button with no default behavior. A label for the button must be provided in the `value` attribute, though it may be the empty string. If the element has a `value` attribute, the button's label must be the value of that attribute; otherwise, it must be the empty string. The element is a `button`.

The element has no `input activation behavior`.

Constraint validation: The element is `barred from constraint validation`.

The `value` IDL attribute `applies` to this element and is in mode `default`.

The following content attributes must not be specified and `do not apply` to the element: `accept-charset`, `autocomplete`, `checked`, `dirname`, `formaction`, `formenctype`, `formmethod`, `formnovalidate`, `formtarget`, `height`, `list`, `max`, `maxlength`, `min`, `multiple`, `pattern`, `placeholder`, `readonly`, `required`, `sizes`, `step`, and `width`.

The following IDL attributes and methods `do not apply` to the element: `checked`, `files`, `list`, `selectionStart`, `selectionEnd`, `selectionDirection`, `valueAsDate`, and `valueAsNumber`. IDL attributes: `select()`, `getRangeText()`, `getSelectionRange()`, `stepDown()`, and `stepUp()` methods.

The `input` and `change` events `do not apply`.

4.10.5.2 Implementation notes regarding localization of form controls

This section is non-normative.

The formats shown to the user in date, time, and number controls is independent of the format used for form submission.

Browsers are encouraged to use user interfaces that present dates, times, and numbers according to the conventions of either the locale implied by the `input` element's `language` or the user's preferred locale. Using the page's locale will ensure consistency with page-provided data.

Example

For example, it would be confusing to users if an American English page claimed that a Cirque Du Soleil show was going to be showing on 02/03, but their browser, configured to use the British English locale, only showed the date 03/02 in the ticket purchase date picker. Using the page's locale would at least ensure that the date was presented in the same format everywhere. (There's still a risk that the user would end up arriving a month late, of course, but there's only so much that can be done about such cultural differences...)

4.10.5.3 Common `input` element attributes

These attributes only `apply` to an `input` element if its `type` attribute is in a state whose definition declares that the attribute `applies`. When an attribute `does not apply` to an `input` element, user agents must `ignore` the attribute, regardless of the requirements and definitions below.

4.10.5.3.1 The `maxlength` and `minlength` attributes

Support: input-minLengthChrome for Android 81+|Chrome 40+|iOS Safari 10.3+Safari 10.1+|Firefox 51+|Samsung Internet 5.0+|Edge 17+|UC Browser for Android 12.12+|IE None|Opera 27+|Omnibar Mini|None|Firefox for Android 68+

Source: [caniuse.com](#)

The `maxlength` attribute, when it `applies`, is a `form control maxlength attribute`.

Support: maxLengthChrome for Android 81+|Chrome 4+|iOS Safari 9.0+Safari 5.1+|Firefox 4+|Samsung Internet 4+|Edge 12+|UC Browser for Android 12.12+|IE 10+|Opera 15+|Opera Mini (limited) all+|Firefox for Android 68+

Source: [caniuse.com](#)

The `minlength` attribute, when it `applies`, is a `form control minlength attribute`.

If the `input` element has a `maximum allowed value length`, then the `JavaScript string length` of the value of the element's `value` attribute must be equal to or less than the element's `maximum allowed value length`.

Example

The following extract shows how a messaging client's text entry could be arbitrarily restricted to a fixed number of characters, thus forcing any conversation through this medium to be terse and discouraging intelligent discourse.

```
<label>What are you doing? <input name=status maxlength=140></label>
```

Example

Here, a password is given a minimum length:

```
<pre><label>Username: <input name=username required></label>
<label>Password: <input name=password required minlength=12></label></pre>
```

4.10.5.3.2 The `size` attribute

The `size` attribute gives the number of characters that, in a visual rendering, the user agent is to allow the user to see while editing the element's `value`.

The `size` attribute, if specified, must have a value that is a `valid non-negative integer` greater than zero.

If the attribute is present, then its value must be parsed using the `rules for parsing non-negative integers`, and if the result is a number greater than zero, then the user agent should ensure that at least that many characters are visible.

The `size` IDL attribute is `limited to only non-negative numbers greater than zero` and has a default value of 20.

4.10.5.3.3 The `readonly` attribute

Support: readonly-attrChrome for Android 81+|Chrome 26+|iOS Safari 7.0+Safari 5.1+|Firefox 4+|Samsung Internet 4+|Edge 12+|UC Browser for Android 12.12+|IE 6+|Opera 15+|Opera Mini all+|Firefox for Android 68+

Source: [caniuse.com](#)

The `readonly` attribute is a `boolean attribute` that controls whether or not the user can edit the form control. When specified, the element is not `mutable`.

Constraint validation: If the `readonly` attribute is specified on an `input` element, the element is `barred from constraint validation`.

Note

The difference between `disabled` and `readonly` is that read-only controls can still function, whereas disabled controls generally do not function as controls until they are enabled. This is spelled out in more detail elsewhere in this specification with normative requirements that refer to the `disabled` concept (for example, the element's `activation behavior`, whether or not it is a `focusing area`, or when `constructing the entry list`). Any other behavior related to user interaction with disabled controls, such as whether text can be selected or copied, is not defined in this standard.

Only text controls can be made read-only, since for other controls (such as checkboxes and buttons) there is no useful distinction between being read-only and being disabled, so the `readonly` attribute `does not apply`.

Example

In the following example, the existing product identifiers cannot be modified, but they are still displayed as part of the form, for consistency with the row representing a new product (where the identifier is not yet filled in).

```
<form action="products.cgi" method="post" enctype="multipart/form-data">
  <tr> <td>Product ID <input type="text" name="id" value="HAL127">
    <td> <input type="text" name="1.pid" value="Floor lamp Ulka">
    <td> <input type="text" name="1.pname" value="1.pid">
    <td> <input type="text" name="1.pprice" value="49.99">
    <td> <input type="text" name="1.pdesc" value="A simple floor lamp with a single light fixture.">
  </tr>
  <tr> <td> <input type="text" name="2.pid" value="T22">
    <td> <input type="text" name="2.pname" value="Table lamp Ulka">
    <td> <input type="text" name="2.pid" value="2.pid">
    <td> <input type="text" name="2.pprice" value="24.99">
    <td> <input type="text" name="2.pdesc" value="A small table lamp with two light fixtures.">

    <td> <input type="text" name="
```

Example

For radio buttons, the `required` attribute is satisfied if any of the radio buttons in the `group` is selected. Thus, in the following example, any of the radio buttons can be checked, not just the one marked as required:

```
<form>
<legend>Did the movie pass the Bechdel test?</legend>
<p><label><input type="radio" name="bechdel" value="no-characters"> No, there are not even two female characters in the movie. </label>
<label><input type="radio" name="bechdel" value="no-topics"> No, the female characters never talk to each other. </label>
<label><input type="radio" name="bechdel" value="no-topic"> No, when female characters talk to each other it's always about a male character. </label>
<label><input type="radio" name="bechdel" value="yes" required> Yes. </label>
<label><input type="radio" name="bechdel" value="unknown"> I don't know. </label>
</form>
```

To avoid confusion as to whether a `radio button group` is required or not, authors are encouraged to specify the attribute on all the radio buttons in a group. Indeed, in general, authors are encouraged to avoid having radio button groups that do not have any initially checked controls in the first place, as this is a state that the user cannot return to, and is therefore generally considered a poor user interface.

4.10.5.3.5 The `multiple` attribute

The `multiple` attribute is a [boolean attribute](#) that indicates whether the user is to be allowed to specify more than one value.

Support: input-file-multiple Chrome for Android (limited) 81+Chrome 5+iOS Safari 6.0+Safari 4+Firefox 3.6+Samsung Internet (limited) 5.0+Edge 12+UC Browser for Android NonIE 10+Opera 10.6+Opera Mini NonFirefox for Android NonIE

Source: caniuse.com

Example

The following extract shows how an e-mail client's "To" field could accept multiple e-mail addresses.

```
<label>To: <input type="email" multiple name="to"></label>
<input type="button" value="Send" /> <input type="button" value="Save Now" /> <input type="button" value="Discard" />
To: spider@parker.example.net Spider-Man
scarlet@avengers.example.net Scarlet Witch
```

The page could also link in the user's contacts database from the site:

```
<label><input type="email" multiple name="to" list="contacts"></label>
<datalist id="contacts">
<option value="bob@example.com">
<option value="parker@example.com">
<option value="spider@example.com">
<option value="astrophys@ute.example">
<option value="astronomy@science.example.org">
</datalist>
```

Suppose the user had entered "bob@example.net" into this text control, and then started typing a second e-mail address starting with ". ". The user agent might show both the two friends mentioned earlier, as well as the "astrophys" and "astronomy" values given in the `datalist` element.

```
<label><input type="button" value="Send" /> <input type="button" value="Save Now" /> <input type="button" value="Discard" />
To: bob@example.net, <input type="text" value="Spider-Man" />
spider@avengers.example.net Scarlet Witch
astronomy@science.example.org
astrophys@ute.example
```

Example

The following extract shows how an e-mail client's "Attachments" field could accept multiple files for upload.

```
<label>Attachments: <input type="file" multiple name="att"></label>
```

4.10.5.3.6 The `pattern` attribute

Support: input-patternChrome for Android 81+Chrome 10+iOS Safari 10.3+Safari 10.1+Firefox 4+Samsung Internet 4+Edge 12+UC Browser for Android 12.12+IE 10+Opera 9.5+Opera Mini NonFirefox for Android 68+

Source: caniuse.com

The `pattern` attribute specifies a regular expression against which the control's `value`, or, when the `multiple` attribute [applies](#) and is set, the control's `values`, are to be checked.

If specified, the attribute's value must match the JavaScript [Pattern](#) production.

If an `input` element has a `pattern` attribute specified, and the attribute's value, when compiled as a JavaScript regular expression with only the `^$` flag specified, compiles successfully, then the resulting regular expression is the element's [compiled pattern regular expression](#). If the element has no such attribute, or if the value doesn't compile successfully, then the element has no [compiled pattern regular expression](#). [\[JAVASCRIPT\]](#)

Note

If the value doesn't compile successfully, user agents are encouraged to log this fact in a developer console, to aid debugging.

Constraint validation: If the element's `value` is not the empty string, and either the element's `multiple` attribute is not specified or it [does not apply](#) to the `input` element given its `type` attribute's current state, and the element has a [compiled pattern regular expression](#) but that regular expression does not match the entirety of the element's `value`, then the element is [suffering from a pattern mismatch](#).

Constraint validation: If the element's `value` is not the empty string, and the element's `multiple` attribute is specified and [applies](#) to the `input` element, and the element has a [compiled pattern regular expression](#) but that regular expression does not match the entirety of each of the element's `values`, then the element is [suffering from a pattern mismatch](#).

The [compiled pattern regular expression](#), when matched against a string, must have its start anchored to the start of the string and its end anchored to the end of the string.

Note

This implies that the regular expression language used for this attribute is the same as that used in JavaScript, except that the `pattern` attribute is matched against the entire value, not just any subset (somewhat as if it implied a `^(\.)` at the start of the pattern and a `\5` at the end).

When an `input` element has a `pattern` attribute specified, authors should include a `title` attribute to give a description of the pattern. User agents may use the contents of this attribute, if it is present, when informing the user that the pattern is not matched, or at any other suitable time, such as in a tooltip or read out by assistive technology when the control gains focus.

Example

For example, the following snippet:

```
<label>Part number:<br/>
<input pattern="^0-9{1,3}{1,3}" name="part" title="A part number is a digit followed by three uppercase letters." />
</label>
```

...could cause the UA to display an alert such as:

```
A part number is a digit followed by three uppercase letters.  
You cannot submit this form when the field is incorrect.
```

When a control has a `pattern` attribute, the `title` attribute, if used, must describe the pattern. Additional information could also be included, so long as it assists the user in filling in the control. Otherwise, assistive technology would be impaired.

Example

For instance, if the `title` attribute contained the caption of the control, assistive technology could end up saying something like `The text you have entered does not match the required pattern. Birthday, which is not useful.`

UAs may still show the `title` in non-error situations (for example, as a tooltip when hovering over the control), so authors should be careful not to word `title` as if an error has necessarily occurred.

4.10.5.3.7 The `min` and `max` attributes

Some form controls can have explicit constraints applied limiting the allowed range of values that the user can provide. Normally, such a range would be linear and continuous. A form control can have a *periodic domain*, however, in which case the form control's broadest possible range is finite, and authors can specify explicit ranges within it that span the boundaries.

Example

Specifically, the broadest range of a `timeinterval` control is midnight to midnight (24 hours), and authors can set both continuous linear ranges (such as 9pm to 11pm) and discontinuous ranges spanning midnight (such as 11pm to 1am).

The `min` and `max` attributes indicate the allowed range of values for the element.

Their syntax is defined by the section that defines the `type` attribute's current state.

If the element has a `min` attribute, and the result of applying the [algorithm to convert a string to a number](#) to the value of the `min` attribute is a number, then that number is the element's `minimum`; otherwise, if the `type` attribute's current state defines a `default minimum`, then that is the `minimum`; otherwise, the element has no `minimum`.

The `min` attribute also defines the `step-base`.

If the element has a `max` attribute, and the result of applying the [algorithm to convert a string to a number](#) to the value of the `max` attribute is a number, then that number is the element's `maximum`; otherwise, if the `type` attribute's current state defines a `default maximum`, then that is the `maximum`; otherwise, the element has no `maximum`.

If the element does not have a *periodic domain*, the `max` attribute's value (the `maximum`) must not be less than the `min` attribute's value (its `minimum`).

Note

If an element that does not have a *periodic domain* has a `maximum` that is less than its `minimum`, then so long as the element has a `value`, it will either be [suffering from an underflow](#) or [suffering from an overflow](#).

An element has a *reversed range* if it has a *periodic domain* and its `maximum` is less than its `minimum`.

An element has *range limitations* if it has a defined `minimum` or a defined `maximum`.

Constraint validation: When the element has a `minimum` and does not have a *reversed range*, and the result of applying the [algorithm to convert a string to a number](#) to the string given by the element's `value` is a number, and the number obtained from that algorithm is less than the `minimum`, the element is [suffering from an underflow](#).

Constraint validation: When the element has a `maximum` and does not have a *reversed range*, and the result of applying the [algorithm to convert a string to a number](#) to the string given by the element's `value` is a number, and the number obtained from that algorithm is more than the `maximum`, the element is [suffering from an overflow](#).

Constraint validation: When an element has a *reversed range*, and the result of applying the [algorithm to convert a string to a number](#) to the string given by the element's `value` is a number, and the number obtained from that algorithm is more than the `maximum` and less than the `minimum`, the element is simultaneously [suffering from an underflow](#) and [suffering from an overflow](#).

Example

The following date control limits input to dates that are before the 1980s:

```
<input name="bday" type="date" max="1979-12-31">
```

Example

The following number control limits input to whole numbers greater than zero:

```
<input name="quantity" required="" type="number" min="1" value="1">
```

Example

The following time control limits input to those minutes that occur between 9pm and 6am, defaulting to midnight:

```
<input name="sleepStart" type="time" min="21:00" max="06:00" step="60" value="00:00">
```

4.10.5.3.8 The `step` attribute

This attribute specifies the step size for the `number` and `range` controls. It is expected that the value of this attribute is a floating-point number. In floating-point notation, the value is rounded to the nearest integer, and in some cases the default step value, which are used in processing this attribute as described below.

EXPAND

The `step` attribute, if specified, must either have a value that is a [valid floating-point number](#) that [parses](#) to a number that is greater than zero, or must have a value that is an [ASCII case-insensitive](#) match for the string "any".

The attribute provides the [allowed value step](#) for the element, as follows:

- If the attribute is absent, then the [allowed value step](#) is multiplied by the [step scale factor](#).
- Otherwise, if the attribute's value is an [ASCII case-insensitive](#) match for the string "any", then there is no [allowed value step](#).
- Otherwise, if the [rules for parsing floating-point number values](#), when they are applied to the attribute's value, return an error, zero, or a number less than zero, then the [allowed value step](#) is the [default step](#) multiplied by the [step scale factor](#).
- Otherwise, the [allowed value step](#) is the number returned by the [rules for parsing floating-point number values](#) when they are applied to the attribute's value, multiplied by the [step scale factor](#).

The [step base](#) is the value returned by the following algorithm:

- If the element has a [min](#) content attribute, and the result of applying the [algorithm to convert a string to a number](#) to the value of the [min](#) content attribute is not an error, then return that result.
- If the element has a [max](#) content attribute, and the result of applying the [algorithm to convert a string to a number](#) to the value of the [max](#) content attribute is not an error, then return that result.
- If a [default step base](#) is defined for this element given its [type](#) attribute's state, then return it.
- Return zero.

Constraint validation: When the element has an [allowed value step](#), and the result of applying the [algorithm to convert a string to a number](#) to the string given by the element's [value](#) is a number, and that number subtracted from the [step base](#) is not an integral multiple of the [allowed value step](#), the element is [suffering from a step mismatch](#).

Example

The following range control only accepts values in the range 0.1, and allows 256 steps in that range:

```
<input name=opacity type=range min=0 max=1 step=0.00392156863>
```

Example

The following control allows any time in the day to be selected, with any accuracy (e.g. thousandths-of-a-second accuracy or more):

```
<input name=favtime type=time step=any>
```

Normally, time controls are limited to an accuracy of one minute.

4.10.5.3.9 The `list` attribute

The `list` attribute is used to identify an element that lists predefined options suggested to the user.

If present, its value must be the [ID](#) of a [datalist](#) element in the same [tree](#).

The [suggestions source element](#) is the first element in the [tree](#) in [tree order](#) to have an [ID](#) equal to the value of the [list](#) attribute, if that element is a [datalist](#) element. If there is no [list](#) attribute, or if there is no element with that [ID](#), or if the first element with that [ID](#) is not a [datalist](#) element, then there is no [suggestions source element](#).

If there is a [suggestions source element](#), then, when the user agent is allowing the user to edit the [input](#) element's [value](#), the user agent should offer the suggestions represented by the [suggestions source element](#) to the user in a manner suitable for the type of control used. If appropriate, the user agent should use the suggestion's [label](#) and [value](#) to identify the suggestion to the user.

User agents are encouraged to filter the suggestions represented by the [suggestions source element](#) when the number of suggestions is large, including only the most relevant ones (e.g. based on the user's input so far). No precise threshold is defined, but capping the list at four to seven values is reasonable. If filtering based on the user's input, user agents should use substring matching against both the suggestions' [label](#) and [value](#).

Example

This text field allows you to choose a type of JavaScript function.

```
<input type="text" list="function-types">
<datalist id="function-types">
<option value="function">function</option>
<option value="async function">async function</option>
<option value="generator function">generator function</option>
<option value="arrow function">arrow function</option>
<option value="=>">async arrow function</option>
<option value="async function">async generator function</option>
</datalist>
```

For user agents that follow the above suggestions, both the [label](#) and [value](#) would be shown:

function	function
async function	async function
function*	generator function
=>	arrow function
async =>	async arrow function
async function*	async generator function

Then, typing "arrow" or "=>" would filter the list to the entries with labels "arrow function" and "async arrow function". Typing "generator" or "function" would filter the list to the entries with labels "generator function" and "async generator function".

Note

As always, user agents are free to make user interface decisions which are appropriate for their particular requirements and for the user's particular circumstances. However, this has historically been an area of confusion for implementors, web developers, and users alike, so we've given some "should" suggestions above.

How user selections of suggestions are handled depends on whether the element is a control accepting a single value only, or whether it accepts multiple values:

If the element does not have a [multiple](#) attribute specified or if the [multiple](#) attribute [does not apply](#)

When the user selects a suggestion, the [input](#) element's [value](#) must be set to the selected suggestion's [value](#), as if the user had written that value themselves.

If the element's [type](#) attribute is in the [final](#) state and the element has a [multiple](#) attribute specified

When the user selects a suggestion, the user agent must either add a new entry to the [input](#) element's [values](#), whose value is the selected suggestion's [value](#), or change an existing entry in the [input](#) element's [values](#) to have the value given by the selected suggestion's [value](#), as if the user had themselves added an entry with that value, or edited an existing entry to be that value. Which behavior is to be applied depends on the user interface in a user-agent-defined manner.

If the [list](#) attribute [does not apply](#), there is no [suggestions source element](#).

Example

This URL field offers some suggestions.

```
<label>Homepage: <input name=hp type=url list=hpuris></label>
<option value="https://www.google.com/" label="Google">
<option value="https://www.reddit.com/" label="Reddit">
</datalist>
```

Other URLs from the user's history might show also; this is up to the user agent.

Example

This example demonstrates how to design a form that uses the autocomplete list feature while still degrading usefully in legacy user agents.

If the autocomplete list is merely an aid, and is not important to the content, then simply using a [datalist](#) element with children [option](#) elements is enough. To prevent the values from being rendered in legacy user agents, they need to be placed inside the [value](#) attribute instead of inline.

```
<label>
<input type="text" list="breeds" value="Burmese">
<datalist id="breeds">
<option value="Abyssinian">
<option value="Alpaca">
</option>
</datalist>
</label>
```

However, if the values need to be shown in legacy UAs, then fallback content can be placed inside the [datalist](#) element, as follows:

```
<label>
  Enter a breed:
  <input type="text" name="breed" list="breeds">
<datalist id="breeds">
<label> or select one from the list:
<input type="text" value="Burmese">
<option value=""> (none selected)
<option>AbyssinianAlpaca

```

The fallback content will only be shown in UAs that don't support [datalist](#). The options, on the other hand, will be detected by all UAs, even though they are not children of the [datalist](#) element.

Note that if an [option](#) element used in a [datalist](#) is [selected](#), it will be selected by default by legacy UAs (because it affects the [select](#)), but it will not have any effect on the [input](#) element in UAs that support [datalist](#).

4.10.5.3.10 The `placeholder` attribute

The `placeholder` attribute represents a *short hint* (a word or short phrase) intended to aid the user with data entry when the control has no value. A hint could be a sample value or a brief description of the expected format. The attribute, if specified, must have a value that contains no U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters.

...

Support: input-placeholderChrome for Android 81+Chrome 4+iOS Safari 5.2+Safari 5+Firefox 4+Samsung Internet 4+Edge 12+UC Browser for Android 12.12+IE 10+Opera 11.5+Opera Mini all+Firefox for Android 68+

Source: caniuse.com

The `placeholder` attribute should not be used as an alternative to a [label](#). For a longer hint or other advisory text, the [title](#) attribute is more appropriate.

Note

These mechanisms are very similar but subtly different: the hint given by the control's [label](#) is shown at all times; the short hint given in the `placeholder` attribute is shown before the user enters a value; and the hint in the [title](#) attribute is shown when the user requests further help.

User agents should present this hint to the user, after having [stripped newlines](#) from it, when the element's [value](#) is the empty string, especially if the control is not [focused](#).

If a user agent normally doesn't show this hint to the user when the control is [focused](#), then the user agent should nonetheless show the hint for the control if it was focused as a result of the [autofocus](#) attribute, since in that case the user will not have had an opportunity to examine the control before focusing it.

Example

Here is an example of a mail configuration user interface that uses the [placeholder](#) attribute:

```
<fields>
<!-- Mail Account /legend-->
<p><label>Mail Account /legend>
<input type="text" name="fullname" placeholder="John Ratzenberger"></label></p>
<p><label>Address: <input type="email" name="address" placeholder="john@example.net"></label></p>
<p><label>Password: <input type="password" name="password"></label></p>
<p><label>Description: <input type="text" name="desc" placeholder="My Email Account"></label></p>
</fields>
```

12. Set the `value` of the element to `value as string`.

The `list` IDL attribute must return the current `suggestions source element`, if any, or null otherwise.

4.10.5.5 Common event behaviors

When the `input` and `change` events `apply` (which is the case for all `input` controls other than `button` and those with the `type` attribute in the `Hidden` state), the events are fired to indicate that the user has interacted with the control. The `input` event fires whenever the user has modified the data of the control. The `change` event fires when the value is committed, if that makes sense for the control, or else when the control `loses focus`. In all cases, the `input` event comes before the corresponding `change` event (if any).

When an `input` element has a defined `input activation behavior`, the rules for dispatching these events, if they `apply`, are given in the section above that defines the `type` attribute's state. (This is the case for all `input` controls with the `type` attribute in the `Checkbox` state, the `Radio Button` state, or the `File Upload` state.)

For `input` elements without a defined `input activation behavior`, but to which these events `apply`, and for which the user interface involves both interactive manipulation and an explicit commit action, then when the user changes the element's `value`, the user agent must `queue a task to fire an event named` `input` at the `input` element, with the `bubbles` attribute initialized to true, and any time the user commits the change, the user agent must `queue a task to fire an event named` `change` at the `input` element, with the `bubbles` attribute initialized to true.

Example

An example of a user interface involving both interactive manipulation and a commit action would be a `Range` control that uses a slider, when manipulated using a pointing device. While the user is dragging the control's knob, `input` events would fire whenever the position changed, whereas the `change` event would only fire when the user let go of the knob, committing to a specific value.

For `input` elements without a defined `input activation behavior`, but to which these events `apply`, and for which the user interface involves an explicit commit action but no intermediate manipulation, then any time the user commits a change to the element's `value`, the user agent must `queue a task to first fire an event named` `input` at the `input` element, with the `bubbles` attribute initialized to true, and then `fire an event named` `change` at the `input` element, with the `bubbles` attribute initialized to true.

Example

An example of a user interface with a commit action would be a `Color` control that consists of a single button that brings up a color wheel: if the `value` only changes when the dialog is closed, then that would be the explicit commit action. On the other hand, if manipulating the control changes the color interactively, then there might be no commit action.

Example
Another example of a user interface with a commit action would be a `Date` control that allows both text-based user input and user selection from a drop-down calendar: while text input might not have an explicit commit step, selecting a date from the drop down calendar and then dismissing the drop down would be a commit action.

For `input` elements without a defined `input activation behavior`, but to which these events `apply`, any time the user causes the element's `value` to change without an explicit commit action, the user agent must `queue a task to fire an event named` `input` at the `input` element, with the `bubbles` attribute initialized to true. The corresponding `change` event, if any, will be fired when the control `loses focus`.

Example

Examples of a user changing the element's `value` would include the user typing into a text control, pasting a new value into the control, or undoing an edit in that control. Some user interactions do not cause changes to the value, e.g., hitting the "delete" key in an empty text control, or replacing some text in the control with text from the clipboard that happens to be exactly the same text.

Example
A `Range` control in the form of a slider that the user has `focused` and is interacting with using a keyboard would be another example of the user changing the element's `value` without a commit step.

In the case of `tasks` that just fire an `input` event, user agents may wait for a suitable break in the user's interaction before `queuing` the tasks; for example, a user agent could wait for the user to have not hit a key for 100ms, so as to only fire the event when the user pauses, instead of continuously for each keystroke.

When the user agent is to change an `input` element's `value` on behalf of the user (e.g. as part of a form prefilling feature), the user agent must `queue a task` to first update the `value` accordingly, then `fire an event named` `input` at the `input` element, with the `bubbles` attribute initialized to true, then `fire an event named` `change` at the `input` element, with the `bubbles` attribute initialized to true.

Note
These events are not fired in response to changes made to the values of form controls by scripts. (This is to make it easier to update the values of form controls in response to the user manipulating the controls, without having to then filter out the script's own changes to avoid an infinite loop.)

The `task source` for these `tasks` is the `user interaction task source`.

Categories:

- Flow content
- Phrasing content
- Interactive content
- Listed, labelable, submittable, and `autocomplete-inheriting` form-associated element
- Palpable content

Contexts in which this element can be used:

- Where phrasing content is expected.

Content model:

- Phrasing content, but there must be no `interactive content` descendant.

Tag omission in `text/html`:

- Neither tag is permissible.

Content attributes:

- Global attributes**
 - `disabled` — Whether the form control is disabled
 - `form` — Associates the element with a `form` element
 - `formaction` — URL to use for `form submission`
 - `formencoding` — Entry list encoding type to use for `form submission`
 - `formmethod` — Value to use for `form submission`
 - `formnovalidate` — Bypass form control validation for `form submission`
 - `formtarget` — Browsing context for `form submission`
 - `name` — Name of the element to use for `form submission` and in the `form.elements` API
 - `type` — Type of button
- `value` — Value to be used for `form submission`

Accessories and modifications:

- For authors
- For implementors

DOM interface:

```
IDL Exposed<Window>
interface HTMLButtonElement : HTMLElement {
  [Constructor] constructor();
  [Attr] boolean attribute disabled;
  [Attr] string attribute form;
  [Attr] USVString attribute formaction;
  [Attr] DOMString attribute formencoding;
  [Attr] DOMString attribute formmethod;
  [Attr] boolean attribute formnovalidate;
  [Attr] DOMString attribute formtarget;
  [Attr] string attribute type;
  [Attr] USVString attribute value;
  readonly attribute boolean willValidate;
  readonly attribute ValidityState validity;
  readonly attribute string validationMessage;
  boolean checkValidity();
  void setCustomValidity(DOMString error);
  readonly attribute NodeList labels;
}
```

The `button` element `represents` a button labeled by its contents.

The element is a `button`.

The `type` attribute controls the behavior of the button when it is activated. It is an [enumerated attribute](#). The following table lists the keywords and states for the attribute — the keywords in the left column map to the states in the cell in the second column on the same row as the keyword.

Keyword State Brief description

<code>submit</code>	<code>Submit</code>	Submits the form.
<code>reset</code>	<code>Reset Button</code>	Resets the form.
<code>button</code>	<code>Button</code>	Does nothing.

The `missing value default` and `invalid value default` are the `Submit` button state.

If the `type` attribute is in the `Submit` button state, the element is specifically a `submit` button.

Constraint validation: If the `type` attribute is in the `Reset Button` state or the `Button` state, the element is `barred from constraint validation`.

A `button` element's `activation behavior` is to run the steps defined in the following list for the current state of this element's `type` attribute, if this element is not `disabled`, and do nothing otherwise:

Submit Button

- If the element has a `form owner` and the element's `node document` is `fully active`, the element must `submit` the `form owner` from the `button` element.

Reset Button

- If the element has a `form owner` and the element's `node document` is `fully active`, the element must `reset` the `form owner`.

Button

- Do nothing.

The `form` attribute is used to explicitly associate the `button` element with its `form owner`. The `name` attribute represents the element's name. The `disabled` attribute is used to make the control non-interactive and to prevent its value from being submitted. The `formaction`, `formencoding`, `formmethod`, `formnovalidate`, and `formtarget` attributes are [attributes for form submission](#).

Note

The `formnovalidate` attribute can be used to make submit buttons that do not trigger the constraint validation.

The `formaction`, `formencoding`, `formmethod`, `formnovalidate`, and `formtarget` must not be specified if the element's `type` attribute is not in the `Submit` state.

The `value` attribute gives the element's value for the purposes of form submission. The element's `value` is the value of the element's `value` attribute, if there is one, or the empty string otherwise.

Note

A button (and its `value`) is only included in the form submission if the button itself was used to initiate the form submission.

The `value` IDL attribute must [reflect](#) the `content` attribute of the same name.

The `type` IDL attribute must [reflect](#) the `content` attribute of the same name, [limited to only known values](#).

The `willValidate`, `validity`, and `validationMessage` IDL attributes, and the `checkValidity()`, `reportValidity()`, and `setCustomValidity()` methods, are part of the [constraint validation API](#). The `labels` IDL attribute provides a list of the element's [labels](#). The `disabled`, `form`, and `name` IDL attributes are part of the element's forms API.

Example

The following button is labeled "Show hint" and pops up a dialog box when activated:

```
<button type="button"
        onclick="alert('This 15-20 minute piece was composed by George Gershwin.')">
    Show hint
</button>
```

  [ContentEventHandlers] attribute void remove(unsigned long index);
  [ContentEventHandlers] attribute void (unsigned long index, HTMLOptionElement? option);
  [SameObject] readonly attribute HTMLCollection selectedOptions;
  attribute long selectedIndex;
  attribute DOMString value;
  readonly attribute boolean willValidate;
  readonly attribute DOMString validationMessage;
  boolean checkValidity();
  boolean reportValidity();
  void setCustomValidity(DOMString error);
  readonly attribute NodeList labels;
}
```

The `select` element represents a control for selecting amongst a set of options.

The `multiple` attribute is a [boolean attribute](#). If the attribute is present, then the `select` element [represents](#) a control for selecting zero or more options from the [list of options](#). If the attribute is absent, then the `select` element [represents](#) a control for selecting a single option from the [list of options](#).

The `size` attribute gives the number of options to show to the user. The `size` attribute, if specified, must have a value that is a [valid non-negative integer](#) greater than zero.

The display size of a `select` element is the result of applying the [rules for parsing non-negative integers](#) to the value of element's `size` attribute, if it has one and parsing it is successful. If applying those rules to the attribute's value is not successful, or if the `size` attribute is absent, then the element's `display size` is 4 if the element's `multiple` content attribute is present, and 1 otherwise.

The [list of options](#) for a `select` element consists of all the `option` element children of the `select` element, and all the `option` element children of all the `optgroup` element children of the `select` element, in [tree order](#).

The `required` attribute is a [boolean attribute](#). When specified, the user will be required to select a value before submitting the form.

If a `select` element has a `optgroup` attribute specified, does not have a `multiple` attribute specified, and has a `display size` of 1; and if the `value` of the first `option` element in the `select` element's [list of options](#) (if any) is the empty string, and that `option` element's parent node is the `select` element (and not an `optgroup` element), then that `option` is the `select` element's [placeholder label option](#).

If a `select` element has a `required` attribute specified, does not have a `multiple` attribute specified, and has a `display size` of 1, then the `select` element must have a `placeholder label option`.

Note

In practice, the requirement stated in the paragraph above can only apply when a `select` element does not have a `size` attribute with a value greater than 1.

Constraint validation: If the element has its `required` attribute specified, and either none of the `option` elements in the `select` element's [list of options](#) have their `selectedness` set to true, or the only `option` element in the `select` element's [list of options](#) with its `selectedness` set to true is the `placeholder label option`, then the element is [suffering from being muted](#).

If the `multiple` attribute is absent, and the element is not `disabled`, then the user agent should allow the user to pick an `option` element in its [list of options](#) that is itself not `disabled`. Upon such an element being `picked` (either through a click, or through unfocusing the element after changing its value, or through a `menu command`, or through any other mechanism), and before the relevant user interaction event is queued (e.g. before the `click` event), the user agent must set the `selectedness` of the picked `option` element to true, set its `dirty` to true, and then `send select update notifications`.

If the `multiple` attribute is absent, whenever an `option` element in the `select` element's [list of options](#) has its `selectedness` set to true, and whenever an `option` element with its `selectedness` set to true is added to the `select` element's [list of options](#), the user agent must set the `selectedness` of all the other `option` elements in its [list of options](#) to false.

If the `multiple` attribute is absent and the element's `display size` is greater than 1, then the user agent should also allow the user to request that the `option` whose `selectedness` is true, if any, be unselected. Upon this request being conveyed to the user agent, and before the relevant user interaction event is queued (e.g. before the `click` event), the user agent must set the `selectedness` of the `option` element to false, set its `dirty` to true, and then `send select update notifications`.

If codes are inserted or removed causing the `list of options` to gain or lose one or more `option` elements, or if an `option` element in the `list of options` asks for a reset, then, if the `select` element's `multiple` attribute is absent, the user agent must run the first applicable set of steps from the following list:

If the `select` element's `display size` is 1, and no `option` elements in the `select` element's [list of options](#) have their `selectedness` set to true

Set the `selectedness` of the first `option` element in the `list of options` in [tree order](#) that is not `disabled`, if any, to true.

If two or more `option` elements in the `select` element's [list of options](#) have their `selectedness` set to true

Set the `selectedness` of all but the last `option` element with its `selectedness` set to true in the `list of options` in [tree order](#) to false.

If the `multiple` attribute is present, and the element is not `disabled`, then the user agent should allow the user to toggle the `selectedness` of the `option` elements in its `list of options` that are themselves not `disabled`. Upon such an element being `toggled` (either through a click, or through a `menu command`, or any other mechanism), and before the relevant user interaction event is queued (e.g. before a related `click` event), the `selectedness` of the `option` element must be changed (from true to false or false to true), the `dirty` of the element must be set to true, and the user agent must `send select update notifications`.

When the user agent is to `send select update notifications`, `queue a task`, using the `user interaction task source`, to run these steps:

- Fire an event named `input` at the `select` element, with the `bubbles` attribute initialized to true.

- Fire an event named `change` at the `select` element, with the `bubbles` attribute initialized to true.

The `reset` attribute for `select` elements is to go through all the `option` elements in the element's `list of options`, set their `selectedness` to true if the `option` element has a `selected` attribute, and false otherwise, set their `dirty` to false, and then have the `option` elements ask for a reset.

The `form` attribute is used to explicitly associate the `select` element with its `form owner`. The `name` attribute represents the element's name. The `disabled` attribute is used to make the control non-interactive and to prevent its value from being submitted. The `autocomplete` attribute controls how the user agent provides autofill behavior.

A `select` element that is not `disabled` is [mutable](#).

For web developers (non-normative)

```
select ::-moz-selection
```

Returns "select-multiple" if the element has a `multiple` attribute, and "select-one" otherwise.

```
select::option
```

Returns an `HTMLCollection` of the `list of options`.

```
select::length [= value]
```

Returns the number of elements in the `list of options`.

When set to a smaller number, truncates the number of `option` elements in the `select`.

```
element = select . item(index)
select(index)

    Returns the item with index index from the list of options. The items are sorted in tree order.
element = select . namedItem(name)

    Returns the first item with ID or name from the list of options.
    Returns null if no element with that ID could be found.

select . add(element [, before ])

    Inserts element before the node given by before.
    The before argument can be a number, in which case element is inserted before the item with that number, or an element from the list of options, in which case element is inserted before that element.
    If before is omitted, null, or a number out of range, then element will be added at the end of the list.
    This method will throw a "HierarchyRequestError" DOMException if element is an ancestor of the element into which it is to be inserted.

select . selectedOptions

    Returns an HTMLCollection of the list of options that are selected.

select . selectedIndex [= value]

    Returns the index of the first selected item, if any, or -1 if there is no selected item.
    Can be set, to change the selection.

select . value [= value]

    Returns the value of the first selected item, if any, or the empty string if there is no selected item.
    Can be set, to change the selection.
```

Firefox Android26+Safari iOS6+Chrome Android25+WebView Android37+Samsung Internet1.5+Opera Android10.1+

The `selectedOptions` IDL attribute must return an [HTMLCollection](#) rooted at the `select` node, whose filter matches the elements in the [list of options](#) that have their `selectedness` set to true.

MDN[HTMLSelectElement/selectedIndex](#)

Support in all current engines.

FirefoxYesSafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet Explorer?

Firefox AndroidYesSafari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

The `selectedIndex` IDL attribute, on getting, must return the `index` of the first `option` element in the [list of options](#) in `tree order` that has its `selectedness` set to true, if any. If there isn't one, then it must return `-1`.

On setting, the `selectedIndex` attribute must set the `selectedness` of all the `option` elements in the [list of options](#) to false, and then the `option` element in the [list of options](#) whose `index` is the given new value, if any, must have its `selectedness` set to true and its `dirtness` set to true.

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

This can result in no element having a `selectedness` set to true even in the case of the `select` element having no `multiple` attribute and a `display size` of 1.

The `value` IDL attribute, on getting, must return the `value` of the first `option` element in the `list` of `options` in `tree order` that has its `selectedness` set to true, if any. If there isn't one, then it must return the empty string.

On setting, the `value` attribute must set the `selectedness` of all the `option` elements in the `list` of `options` to false, and then the first `option` element in the `list` of `options`, in `tree order`, whose `value` is equal to the given new value, if any, must have its `selectedness` set to true and its `dirty`ness set to true.

Note

This can result in no element having a `selectedness` set to true even in the case of the `select` element having no `multiple` attribute and a `display size` of 1.

The `multiple`, `required`, and `size` IDL attributes must reflect the respective content attributes of the same name. The `size` IDL attribute has a default value of zero.

Note

For historical reasons, the default value of the `size` IDL attribute does not return the actual size used, which, in the absence of the `size` content attribute, is either 1 or 4 depending on the presence of the `multiple` attribute.

The `willValidate`, `validity`, and `validationMessage` IDL attributes, and the `checkValidity()`, `reportValidity()`, and `setCustomValidity()` methods, are part of the `constraint validation API`. The `label` IDL attribute provides a list of the element's `label`s. The `disabled`, `form`, and `name` IDL attributes are part of the element's forms API.

Example

The following example shows how a `select` element can be used to offer the user with a set of options from which the user can select a single option. The default option is preselected.

```
<label for="unit-type">Select unit type</label>
<select id="unit-type" name="unit-type">
  <option value="1"> Miner </option>
  <option value="2"> Puffer </option>
  <option value="3"> Snipey </option>
  <option value="4"> Max </option>
  <option value="5"> Firebot </option>
</select>
</div>
```

When there is no default option, a placeholder can be used instead:

```
<select name="unit-type" required>
  <option value=""> Select unit type </option>
  <option value="1"> Miner </option>
  <option value="2"> Puffer </option>
  <option value="3"> Snipey </option>
  <option value="4"> Max </option>
  <option value="5"> Firebot </option>
</select>
```

Example

Here, the user is offered a set of options from which they can select any number. By default, all five options are selected.

```
<label for="allowedunits">Select unit types to enable on this map:</label>
<select id="allowedunits" name="allowedunits" multiple>
  <option value="1" selected> Miner </option>
  <option value="2" selected> Puffer </option>
  <option value="3" selected> Snipey </option>
  <option value="4" selected> Max </option>
  <option value="5" selected> Firebot </option>
</select>
```

Example

Sometimes, a user has to select one or more items. This example shows such an interface.

```
<label>
  Select the songs from that you would like on your Act II Mix Tape:
<select multiple required name="act2">
  <option value="1">The Best of Both Worlds (Reprise)
  <option value="2">There Is Life Outside Your Apartment
  <option value="3">The More You Ruv Someone
  <option value="4">I'm Gonna Be (Weird)
  <option value="5">I Wish I Could Go Back to College
  <option value="6">The Money Song
  <option value="7">I'm Gonna Be (Weird)
  <option value="8">I'm Gonna Be (Weird)
  <option value="9">The Money Song (Reprise)
  <option value="10">There's a Fine, Fine Line (Reprise)
  <option value="11">What Do You Do With a B.A. in English? (Reprise)
  <option value="12">For Now
</select>
</label>
```

interface HTMListElement : HTMLElement {
  [HTMLConstructor] Constructor();
  [SameObject] readonly attribute HTMLCollection options;
};
```

The `datalist` element represents a set of `option` elements that represent predefined options for other controls. In the rendering, the `datalist` element `represents` nothing and it, along with its children, should be hidden.

The `datalist` element can be used in two ways. In the simplest case, the `datalist` element has just `option` element children.

Example

```
<label>
  Sex:
  <input name="sex" list="sexes">
</label>
<input id="sexes" list="sexes">
<label>
  <select from the list:
  <option name="sex"></option>
  <option value="">Female</option>
  <option value="Male">Male</option>
  </select>
</label>
</datalist>
```

In the more elaborate case, the `datalist` element can be given contents that are to be displayed for down-level clients that don't support `datalist`. In this case, the `option` elements are provided inside a `select` element inside the `datalist` element.

Example

```
<label>
  Sex:
  <input name="sex" list="sexes">
</label>
<input id="sexes" list="sexes">
<label>
  <select from the list:
  <option name="sex"></option>
  <option value="">Female</option>
  <option value="Male">Male</option>
  </select>
</label>
</datalist>
```

The `datalist` element is hooked up to an `input` element using the `list` attribute on the `input` element.

Each `option` element that is a descendant of the `datalist` element, that is not `disabled`, and whose `value` is a string that isn't the empty string, represents a suggestion. Each suggestion has a `value` and a `label`.

For web developers (non-normative)

datalist, options

Returns an `HTMLCollection` of the `option` elements of the `datalist` element.

The `options` IDL attribute must return an `HTMLCollection` rooted at the `datalist` node, whose filter matches `option` elements.

Constraint validation: If an element has a `datalist` element ancestor, it is `banned from constraint validation`.

Contexts in which this element can be used:
As a child of a `<select>` element.
Content mode:
Zero or more `<option>` and `<script-supporting>` elements.
Tag content in text mode:
An `<option>` element's `end tag` can be omitted if the `<optgroup>` element is immediately followed by another `<optgroup>` element, or if there is no more content in the parent element.
Content attributes:
`Global attributes`
`disabled` — Whether the form control is disabled
`label` — User-visible label
Accessibilit `aria-labelledby`
For authors
For implementers
DOM interface

```
IDL([Exposed=Window]
interface HTMLOptGroupElement : HTMLElement {
  [HTMLConstructor] constructor();
  (CReactions) attribute boolean disabled;
  (CReactions) attribute DOMString label;
};
```

The `<optgroup>` element represents a group of `<option>` elements with a common label. The element's group of `<option>` elements consists of the `<option>` elements that are children of the `<optgroup>` element. When showing `<option>` elements in `<select>` elements, user agents should show the `<option>` elements of such groups as being related to each other and separate from other `<option>` elements. The `disabled` attribute is a `boolean attribute` and can be used to disable a group of `<option>` elements together. The `label` attribute must be specified. Its value gives the name of the group, for the purposes of the user interface. User agents should use this attribute's value when labeling the group of `<option>` elements in a `<select>` element. The `disabled` and `label` attributes must reflect the respective content attributes of the same name.

Note
There is no way to select a `<optgroup>` element. Only `<option>` elements can be selected. An `<optgroup>` element merely provides a label for a group of `<option>` elements.

Example

The following snippet shows how a set of lessons from three courses could be offered in a `<select>` drop-down widget:

```
<form action="courseselector.dll" method="get">
<p>Which course would you like to watch today?</p>
<p><label>Course:</label><br/></p>
<select>
  <optgroup label="8.01 Physics I: Classical Mechanics">
    <option value="8.01.1">Lecture 01: Units and Vectors
    <option value="8.01.2">Lecture 02: 1D Kinematics
    <option value="8.01.3">Lecture 03: Vectors
  </optgroup>
  <optgroup label="8.02 Electricity and Magnetism">
    <option value="8.02.1">Lecture 01: What holds our world together?
    <option value="8.02.2">Lecture 02: Electric Field
    <option value="8.02.3">Lecture 03: Currents and Circuits
  </optgroup>
  <optgroup label="8.03 Physics III: Vibrations and Waves">
    <option value="8.03.1">Lecture 01: Periodic Phenomenon
    <option value="8.03.2">Lecture 02: Beats
    <option value="8.03.3">Lecture 03: Forced Oscillations with Damping
  </optgroup>
</select>
</form>
<p><input type="submit" value="▶ Play"></p>
</form>
```

As a child of a `<datalist>` element.
As a child of a `<optgroup>` element.

Content attributes:
If the element has a `label` attribute and a `value` attribute: `Nothing`.
If the element has a `label` attribute but no `value` attribute: `Text`.
If the element has no `label` attribute and is not a child of a `<label>` element: `Text` that is not `inter-element whitespace`.
If the element has no `label` attribute and is a child of a `<label>` element: `Text`.

Tag omission in text/html:
An `<option>` element's `<end tag>` can be omitted if the `<option>` element is immediately followed by another `<option>` element, or if it is immediately followed by an `<optgroup>` element, or if there is no more content in the parent element.

Content attributes:
Global attributes
`disabled` — Whether the form control is disabled.
`label` — User-visible label.
`selected` — Whether the option is selected by default.
`value` — Value to be used for form submission.

Accessibility considerations:
For authors
For implementers

DOM interface:

```
IDL Exposed=Window, NameOfConstructor="<option>"; optional DOMString text = "", optional DOMString value, optional boolean defaultSelected = false, optional boolean selected = false);
interface HTMLFormElement : HTMLElement {
    [Constructable] constructor();
    [Event] attribute boolean disabled;
    readonly attribute HTMLFormElement? form;
    attribute DOMString label;
    attribute boolean selected;
    attribute boolean selected;
    [Event] attribute DOMString value;
    [Event] attribute DOMString text;
    readonly attribute long index;
};
```

The `option` element represents an option in a `select` element or as part of a list of suggestions in a `datalist` element.

In certain circumstances described in the definition of the `select` element, an `option` element can be a `select` element's placeholder label option. A placeholder label option does not represent an actual option, but instead represents a label for the `select` control.

The `disabled` attribute is a **boolean attribute**. An `option` element is *disabled* if its `disabled` attribute is present or if it is a child of an `optgroup` element whose `disabled` attribute is present.

An `option` element that is `disabled` must prevent any `click` events that are `queued` on the user interaction task source from being dispatched on the element.

The `label` attribute provides a label for element. The `label` of an `option` element is the value of the `label` content attribute, if there is one and its value is not the empty string, or, otherwise, the value of the element's `text` IDL attribute.

The `label` content attribute, if specified, must not be empty.

The `value` content attribute, if specified, must not be empty.

The `selected` attribute is a boolean attribute. It represents the default selectedness of the element.

The `dirty` attribute is a [boolean attribute](#). It represents the default [correctness](#) of the element.

The `dirty` state of an [option](#) element is a boolean state, initially false. It controls whether adding or

► THIS IS A REVIEW

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION

EXPAND

The `selectedness` of an `option` element is a boolean state, initially false. Except where otherwise specified, when the element is created, its `selectedness` must be set to true if the element has a `selected` attribute. Whenever an `option` element's `selected` attribute is added, if its `dirtness` is false, its `selectedness` must be set to true. Whenever an `option` element's `selected` attribute is removed, if its `dirtness` is false, its `selectedness` must be set to false.

Note

The `option` constructor, when called with three or fewer arguments, overrides the initial state of the `selectedness` state to always be false even if the third argument is true (implying that a `selected` attribute is to be set). The fourth argument can be used to explicitly set the initial `selectedness` state when using the constructor.

A `select` element whose `multiple` attribute is not specified must have more than one descendant `option` element with its `selected` attribute set.

An `option` element's `index` is the number of `option` elements that are in the same `list` but that come before it in `tree order`. If the `option` element is not in a `list`, then the `option` element's `index` is zero.

For web developers (non-normative)

`option.selected`

Returns true if the element is selected, and false otherwise.

Can be set, to override the current state of the element.

`option.index`

Returns the index of the element in its `select` element's `options` list.

`option.form`

Returns the element's `form` element, if any, or null otherwise.

`option.text`

Same as `textContent`, except that spaces are collapsed and `script` elements are skipped.

`option = new Option({ text [, value [, defaultSelected [, selected]]})`

Returns a new `option` element.

The `text` argument sets the contents of the element.

The `value` argument sets the `value` attribute.

The `defaultSelected` argument sets the `selected` attribute.

The `selected` argument sets whether or not the element is selected. If it is omitted, even if the `defaultSelected` argument is true, the element is not selected.

The `disabled` IDL attribute must `reflect` the `content` attribute of the same name. The `defaultSelected` IDL attribute must `reflect` the `selected` content attribute.

The `label` IDL attribute, on getting, if there is a `label` content attribute, must return that attribute's value; otherwise, it must return the element's `label`. On setting, the element's `label` content attribute must be set to the new value.

The `value` IDL attribute, on getting, must return the element's `value`. On setting, the element's `value` content attribute must be set to the new value.

The `selected` IDL attribute, on getting, must return true if the element's `selectedness` is true, and false otherwise. On setting, it must set the element's `selectedness` to the new value, set its `dirtness` to true, and then cause the element to `ask for a reset`.

The `index` IDL attribute must return the element's `index`.

The `text` IDL attribute, on getting, must return the result of `stripping and collapsing ASCII whitespace` from the concatenation of `data` of all the `text` node descendants of the `option` element, in `tree order`, excluding any that are descendants of descendants of the `option` element that are themselves `script` or `SVG script` elements.

The `text` attribute's setter must `string.replace_all` with the given value within this element.

The `form` IDL attribute's behavior depends on whether the `option` element is in a `select` element or not. If the `option` has a `select` element as its parent, or has an `optgroup` element as its parent and that `optgroup` element has a `select` element as its parent, then the `form` IDL attribute must return the same value as the `form` IDL attribute on that `select` element. Otherwise, it must return null.

A constructor is provided for creating `HTMLOptionElement` objects (in addition to the factory methods from DOM such as `createElement()`: `Option(text, value, defaultSelected, selected)`). When invoked, the constructor must perform the following steps:

1. Let `document` be the `currentGlobal`'s `associatedDocument`.

2. Let `option` be the result of `creating an element` given `document`, `option`, and the `HTML namespace`.

3. If `text` is not the empty string, then append to `option` a new `Text` node whose data is `text`.

4. If `value` is given, then `set an attribute value` for `option` using `"value"` and `value`.

5. If `defaultSelected` is true, then `set an attribute value` for `option` using `"selected"` and the empty string.

6. If `selected` is true, then set `option's selectedness` to true; otherwise set its `selectedness` to false (even if `defaultSelected` is true).

7. Return `option`.

Content model:

`Text`

Tag omission in `text/html`:

Neither tag is omission.

Content attributes:

Global attributes

- `autocorrect` — Hint for form autofill feature
- `cols` — Maximum number of characters per line
- `dirname` — Name of form control to use for sending the element's `directionality` in `form submission`
- `disabled` — Whether the form control is disabled
- `form` — Associates the element with a `form` element
- `maxlength` — Maximum length of value
- `name` — Name of the element to use for `form submission` and in the `form.elements` API
- `placeholder` — User-visible label to be placed within the form control
- `readonly` — Whether to allow the value to be edited by the user
- `required` — Whether the control is required for `form submission`
- `rows` — Number of lines to show
- `step` — How the value of the form control is to be wrapped for `form submission`

Accessibility considerations:

For authors

For implementers

DOM interface

```
IDL Exposed<Window>
interface HTMLTextAreaElement : HTMLElement {
  [HTMLConstructor] HTMLTextAreaElement();
  [CSSProperties] attribute DOMString autoComplete;
  attribute unsigned long autoComplete;
  [CSSProperties] attribute DOMString dirName;
  [CSSProperties] attribute boolean disabled;
  readonly attribute DOMString form;
  [CSSProperties] attribute long maxLength;
  [CSSProperties] attribute DOMString name;
  [CSSProperties] attribute DOMString placeholder;
  [CSSProperties] attribute boolean required;

  readonly attribute boolean willValidate;
  readonly attribute DOMString validationMessage;
  readonly attribute DOMString validationMessage;
  boolean checkValidity();
  boolean reportValidity();
  void setCustomValidity(DOMString error);
  void setHTMLValidity(DOMString error);
  readonly attribute NodeList labels;
  void select();
  attribute unsigned long selectionStart;
  attribute unsigned long selectionEnd;
  attribute DOMString selectionDirection;
  void setSelectionRange(DOMString replacement);
  void setSelectionRange(unsigned long start, unsigned long end, optional SelectionMode selectionMode = "preserve");
}
;
```

The `textarea` element represents a multiline plain text edit control for the element's `raw value`. The contents of the control represent the control's default value.

Note
This element has rendering requirements involving the bidirectional algorithm.

The `readonly` attribute is a `boolean` attribute used to control whether the text can be edited by the user or not.

Example

In this example, a text control is marked read-only because it represents a read-only file:

```
filename: <code>/etc/hush.hushrc</code>
<textarea name="buffer" readonly>
# System-wide .hushrc file for interactive bash(1) shells.
# To enable the settings / commands in this file for login shells as well,
# this file has to be sourced in /etc/profile.
# If not running interactively, don't do anything
[ -z "$PS1" ] & rm -f & return
</textarea>
```

Constraint validation: If the `readonly` attribute is specified on a `textarea` element, the element is [barred from constraint validation](#).

A `textarea` element is `mutable` if it is neither `disabled` nor has a `readonly` attribute specified.

When a `textarea` is `mutable`, its `rawValue` should be edible by the user: the user agent should allow the user to edit, insert, and remove text, and to insert and remove line breaks in the form of U+000A LINE FEED (LF) characters. Any time the user causes the element's `rawValue` to change, the user agent must [queue a task to fire an event](#) named `input` at the `textarea` element, with the `bubbles` attribute initialized to true. User agents may wait for a suitable break in the user's interaction before queuing the task; for example, a user agent could wait for the user to have not hit a key for 100ms, so as to only fire the event when the user pauses, instead of continuously for each keystroke.

A `textarea` element's `dirtyValueFlag` must be set to true whenever the user interacts with the control in a way that changes the `rawValue`.

The [cloning steps](#) for `textarea` elements must propagate the `rawValue` and `dirtyValueFlag` from the node being cloned to the copy.

The [children changed steps](#) for `textarea` elements must, if the element's `dirtyValueFlag` is false, set the element's `rawValue` to its `childTextContent`.

The [reset algorithm](#) for `textarea` elements is to set the `dirtyValueFlag` back to false, and set the `rawValue` of element to its `childTextContent`.

When a `textarea` element is popped off the [stack of open elements](#) of an `HTMLParser` or `XMLParser`, then the user agent must invoke the element's [reset algorithm](#).

If the element is `mutable`, the user agent should allow the user to change the writing direction of the element, setting it either to a left-to-right writing direction or a right-to-left writing direction. If the user does so, the user agent must then run the following steps:

1. Set the element's `dir` attribute to "`ltr`" if the user selected a left-to-right writing direction, and "`rtl`" if the user selected a right-to-left writing direction.

2. [Queue an element task](#) on the [user interaction task source](#) given the `textarea` element to [fire an event](#) named `input` at the `textarea` element, with the `bubbles` attribute initialized to true.

The `cols` attribute specifies the expected maximum number of characters per line. If the `cols` attribute is specified, its value must be a [valid non-negative integer](#) greater than zero. If applying the [rules for parsing non-negative integers](#) to the attribute's value results in a number greater than zero, then the element's `characterWidth` is that value; otherwise, it is 20.

The user agent may use the `textarea` element's `characterWidth` as a hint to the user as to how many characters the server prefers per line (e.g. for visual user agents by making the width of the control be that many characters). In visual renderings, the user agent should wrap the user's input in the rendering so that each line is no wider than this number of characters.

The `rows` attribute specifies the number of lines to show. If the `rows` attribute is specified, its value must be a [valid non-negative integer](#) greater than zero. If applying the [rules for parsing non-negative integers](#) to the attribute's value results in a number greater than zero, then the element's `characterHeight` is that value; otherwise, it is 2.

Visual user agents should set the height of the control to the number of lines given by `characterHeight`.

The `wrap` attribute is an [enumerated attribute](#) with two keywords and states: the `soft` keyword which maps to the `Soft` state, and the `hard` keyword which maps to the `Hard` state. The `missingValueDefault` and `invalidValueDefault` are the `Soft` state.

The `Soft` state indicates that the text in the `textarea` is not to be wrapped when it is submitted (though it can still be wrapped in the rendering).

The `Hard` state indicates that the text in the `textarea` is to have newlines added by the user agent so that the text is wrapped when it is submitted.

If the element's `wrap` attribute is in the `Hard` state, the `cols` attribute must be specified.

For historical reasons, the element's value is normalized in three different ways for three different purposes. The `rawValue` is the value as it was originally set. It is not normalized. The `API value` is the value used in the `value` IDL attribute, `textLength` IDL attribute, and by the `maxLength` and `minLength` content attributes. It is normalized so that line breaks use U+000A LINE FEED (LF) characters. Finally, there is the `value`, as used in form submission and other processing models in this specification. It is normalized so that line breaks use U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pairs, and in addition, if necessary given the element's `wrap` attribute, additional line breaks are inserted to wrap the text at the given width.

The algorithm for obtaining the element's `API value` is to return the element's `rawValue`, with [newlines normalized](#).

The element's `value` is defined to be the element's `rawValue` with the [textarea wrapping transformation](#) applied. The [textarea wrapping transformation](#) is the following algorithm, as applied to a string:

1. Replace every occurrence of a U+000D CARRIAGE RETURN (CR) character not followed by a U+000A LINE FEED (LF) character, and every occurrence of a U+000A LINE FEED (LF) character not preceded by a U+000D CARRIAGE RETURN (CR) character, by a two-character string consisting of a U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair.
2. If the element's `wrap` attribute is in the `Hard` state, insert U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pairs into the string using a UA-defined algorithm so that each line has no more than `characterWidth` characters. For the purposes of this requirement, lines are delimited by the start of the string, the end of the string, and U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pairs.

The `maxLength` attribute is a [form control maxLength attribute](#).

If the `textarea` element has a `maximum allowed value length`, then the element's children must be such that the `JavaScript string length` of the value of the element's `descendantTextContent` with [newlines normalized](#) is equal to or less than the element's `maximum allowed value length`.

The `minLength` attribute is a [form control minLength attribute](#).

The `required` attribute is a `boolean` attribute. When specified, the user will be required to enter a value before submitting the form.

Constraint validation: If the element has its `required` attribute specified, and the element is `mutable`, and the element's `value` is the empty string, then the element is [suffering from being missing](#).

The `placeholder` attribute represents a `short hint` (a word or short phrase) intended to aid the user with data entry when the control has no value. A hint could be a sample value or a brief description of the expected format.

The `placeholder` attribute should not be used as an alternative to a `label`. For a longer hint or other advisory text, the `title` attribute is more appropriate.

Note

These mechanisms are very similar but subtly different: the hint given by the control's `label` is shown at all times; the short hint given in the `placeholder` attribute is shown before the user enters a value; and the hint in the `title` attribute is shown when the user requests further help.

User agents should present this hint to the user when the element's `value` is the empty string and the control is [focused](#) (e.g. by displaying it inside a blank unfocused control). All U+000D CARRIAGE RETURN U+000A LINE FEED character pairs (CRLF) in the hint, as well as all other U+000D CARRIAGE RETURN (CR) and U+000A LINE FEED (LF) characters in the hint, must be treated as line breaks when rendering the hint.

The `name` attribute represents the element's name. The `name` attribute controls how the element's `directionality` is submitted. The `disabled` attribute is used to make the control non-interactive and to prevent its value from being submitted. The `form` attribute is used to explicitly associate the `textarea` element with its `form owner`. The `autocomplete` attribute controls how the user agent provides autofill behavior.

For web developers (non-normative)

`textarea : type`

Returns the string "`textarea`".

`textarea : value`

Returns the current value of the element.

Can be set, to change the value.

The `cols`, `placeholder`, `required`, `rows`, and `wrap` IDL attributes must [reflect](#) the respective content attributes of the same name. The `cols` and `rows` attributes are [limited to only non-negative numbers greater than zero with fallback](#). The `cols` IDL attribute's default value is 20. The `rows` IDL attribute's default value is 2. The `dirName` IDL attribute must [reflect](#) the `dirName` content attribute. The `maxLength` IDL attribute must [reflect](#) the `maxLength` content attribute, [limited to only non-negative numbers](#). The `minLength` IDL attribute must [reflect](#) the `minLength` content attribute, [limited to only non-negative numbers](#). The `readonly` IDL attribute must [reflect](#) the `readonly` content attribute.

The `type` IDL attribute must return the value "`textarea`".

The `defaultValue` attribute's getter must return the element's `childTextContent`.

The `defaultValue` attribute's setter must `stringReplaceAll` with the given value within this element.

The `value` IDL attribute must, on getting, return the element's `API value`. On setting, it must perform the following steps:

1. Let `oldAPIValue` be this element's `API value`.
2. Set this element's `rawValue` to the new value.
3. Set this element's `dirtyValueFlag` to true.
4. If the new `API value` is different from `oldAPIValue`, then move the `textEntryCursorPosition` to the end of the text control, unselecting any selected text and [resetting the selection direction](#) to "`none`".

The `textLength` IDL attribute must return the `JavaScript string length` of the element's `API value`.

The `willValidate`, `validityMessage` IDL attributes, and the `checkValidity()`, `reportValidity()`, and `getCustomValidity()` methods, are part of the [constraint validation API](#). The `labels` IDL attribute provides a list of the element's `labels`. The `select()`, `selectionStart`, `selectionEnd`, `selectionDirection`, `setRangeText()`, and `setSelectionRange()` methods and IDL attributes expose the element's text selection. The `disabled`, `form`, and `name` IDL attributes are part of the element's forms API.

Example

Here is an example of a `textarea` being used for unrestricted free-form text input in a form:

```
<p>If you have any comments, please let us know: <textarea cols=80 name=comments></textarea></p>
```

To specify a maximum length for the comments, one can use the `maxLength` attribute:

```
<p>If you have any short comments, please let us know: <textarea cols=80 name=comments maxLength=200></textarea></p>
```

To give a default value, text can be included inside the element:

```
<p>If you have any comments, please let us know: <textarea cols=80 name=comments>You rock!</textarea></p>
```

You can also give a minimum length. Here, a letter needs to be filled out by the user; a template (which is shorter than the minimum length) is provided, but is insufficient to submit the form:

```
<textarea required minLength=5>Dear Madam Speaker,
```

Regarding your letter dated ...

...

Yours Sincerely,

...</textarea>

A placeholder can be given as well, to suggest the basic form to the user, without providing an explicit template:

```
<textarea placeholder="Dear Francine,"
```

They closed the parks this week, so we won't be able to

meet you there. Should we just have dinner?

Love,

Daddy"></textarea>

To have the browser submit the `directionality` of the element along with the value, the `dirname` attribute can be specified:

```
<p>If you have any comments, please let us know (you may use either English or Hebrew for your comments):
```

```
<textarea cols=80 name=comments dirname="dir"></textarea>
```

Content attributes:

Global attributes

`for` — Specifies controls from which the output was calculated`form` — Associates the element with a [form](#) element`name` — Name of the element to use in the [form.elements](#) API.**Accessibility (aria-labelledby):**

For authors.

For implementers.

DOM interface:

```
IDL(Exposed=Window)
interface HTMLOutputElement : HTMLElement {
  constructor();
  constructor(label);
  [SameObject, PutForwards=using] readonly attribute DOMTokenList htmlFor;
  readonly attribute HTMLFormElement? form;
  [Useragent] attribute DOMString value;
  readonly attribute DOMString type;
  [Useragent] attribute DOMString defaultValue;
  [Useragent] attribute DOMString value;
  readonly attribute boolean willValidate;
  readonly attribute DOMString validationMessage;
  readonly attribute DOMString validationMessage;
  boolean checkValidity();
  boolean reportValidity();
  void setCustomValidity(DOMString error);
  readonly attribute NodeList labels;
}
```

The `output` element represents the result of a calculation performed by the application, or the result of a user action.**Note**This element can be contrasted with the `span` element, which is the appropriate element for quoting the output of other programs run previously.The `form` content attribute allows an explicit relationship to be made between the result of a calculation and the elements that represent the values that went into the calculation or that otherwise influence the calculation. The `for` attribute, if specified, must contain a string consisting of an [unordered set of unique space-separated tokens](#) that are [case-sensitive](#), each of which must have the value of an `ID` of an element in the same `tree`.The `form` attribute is used to explicitly associate the `output` element with its `form owner`. The `name` attribute represents the element's name. The `output` element is associated with a form so that it can be easily [referenced](#) from the event handlers of form controls; the element's value itself is not submitted when the form is submitted.The element has a `default value override` (null or a string). Initially it must be null.The element's `default value` is determined by the following steps:

- If this element's `default value override` is non-null, then return it.
- Return this element's `descendant text content`.

The `reset algorithm` for `output` elements is to run these steps:

- `String replaceAll` with this element's `default value` within this element.
- Set this element's `default value override` to null.

For web developers (non-normative)`output.value [= value]`

Returns the element's current value.

Can be set, to change the value.

`output.defaultValue [= value]`

Returns the element's current default value.

Can be set, to change the default value.

`output.type`

Returns the string "output".

The `value` attribute's getter must return this element's `descendant text content`.The `value` attribute's setter must run these steps:

- Set this element's `default value override` to its `default value`.
- `String replaceAll` with the given value within this element.

The `defaultValue` attribute's getter must return the result of running this element's `default value`.The `defaultValue` attribute's setter must run these steps:

- If this element's `default value override` is null, then `String replaceAll` with the given value within this element and return.
- Set this element's `default value override` to the given value.

The `type` attribute's getter must return "output".The `name` for IDL attribute must [reflect](#) the `for` content attribute.The `willValidate`, `validity`, and `validationMessage` IDL attributes, and the `checkValidity()`, `reportValidity()`, and `setCustomValidity()` methods, are part of the [constraint validation API](#). The `label` IDL attribute provides a list of the element's `labels`. The `form` and `name` IDL attributes are part of the element's forms API.**Example**A simple calculator could use `output` for its display of calculated results:

```
<form onsubmit="return false"><input>.value = a.valueAsNumber + b.valueAsNumber</input>
<input id="a" type="number" step="any">
<input id="b" type="number" step="any">
<output id="c" for="a b"></output>
</form>
```

ExampleIn this example, an `output` element is used to report the results of a calculation performed by a remote server, as they come in:

```
<output id="result"></output>
<script>
var primeSource = new WebSocket('ws://primes.example.net/');
primeSource.onmessage = function (event) {
  document.getElementById('result').value = event.data;
}</script>
```

4.10.13 The progress element

Labelable element

Parsable content

Contexts in which this element can be used:

Where phrasing content is expected.

Content model:Phrasing content, but there must be no `progress` element descendants.**Tag omission in text/html:**

Neither tag ismissible.

Content attributes:**Global attributes**`value` — Current value of the element`max` — Upper bound of range**Accessibility considerations:**

For authors

For implementors

DOM interface:

```
IDL Exposed=Window
interface HTMLProgressElement : HTMLElement {
  [HTMLConstructor] constructor();
  [CSSProperties] attribute double value;
  [CSSProperties] attribute double max;
  [CSSProperties] attribute double low;
  [CSSProperties] attribute double high;
  [CSSProperties] attribute double optimum;
  readonly attribute NodeList labels;
}
```

The `progress` element represents the completion progress of a task. The progress is either indeterminate, indicating that progress is being made but that it is not clear how much more work remains to be done before the task is complete (e.g. because the task is waiting for a remote host to respond), or the progress is a number in the range zero to a maximum, giving the fraction of work that has so far been completed.

There are two attributes that determine the current task completion represented by the element. The `value` attribute specifies how much of the task has been completed, and the `max` attribute specifies how much work the task requires in total. The units are arbitrary and not specified.

Note

To make a determinate progress bar, add a `value` attribute with the current progress (either a number from 0.0 to 1.0, or, if the `max` attribute is specified, a number from 0 to the value of the `max` attribute). To make an indeterminate progress bar, remove the `value` attribute.

Authors are encouraged to also include the current value and the maximum value inline as text inside the element, so that the progress is made available to users of legacy user agents.

Example

Here is a snippet of a Web application that shows the progress of some automated task:

```
<section>
<h2>Update Progress</h2>
<p><progress id="p" max=100><span>%</span></progress></p>
<script>
var progressBar = document.getElementById('p');
function updateProgress(newValue) {
  progressBar.value = newValue;
  progressBar.getElementsByTagName('span')[0].textContent = newValue;
}</script>
</section>
```

(The `updateProgress()` method in this example would be called by some other code on the page to update the actual progress bar as the task progressed.)

The `value` and `max` attributes, when present, must have values that are [valid floating-point numbers](#). The `value` attribute, if present, must have a value equal to or greater than zero, and less than or equal to the value of the `max` attribute, if present, or 1.0, otherwise. The `max` attribute, if present, must have a value greater than zero.

Note

The `progress` element is the wrong element to use for something that is just a gauge, as opposed to task progress. For instance, indicating disk space usage using `progress` would be inappropriate. Instead, the `meter` element is available for such use cases.

User agent requirements: If the `value` attribute is omitted, then the progress bar is an indeterminate progress bar. Otherwise, it is a determinate progress bar.

If the progress bar is a determinate progress bar and the element has a `max` attribute, the user agent must parse the `max` attribute's value according to the [rules for parsing floating-point number values](#). If this does not result in an error, and if the parsed value is greater than zero, then the `maximum` value of the progress bar is that value. Otherwise, if the element has no `max` attribute, or if it has one but parsing it resulted in an error, or if the parsed value was less than or equal to zero, then the `maximum` value of the progress bar is 1.0.

If the progress bar is a determinate progress bar, user agents must parse the `value` attribute's value according to the [rules for parsing floating-point number values](#). If this does not result in an error and the parsed value is greater than zero, then the `value` of the progress bar is that parsed value. Otherwise, if parsing the `value` attribute's value resulted in an error or a number less than or equal to zero, then the `value` of the progress bar is zero.

If the progress bar is a determinate progress bar, then the `current_value` is the `maximum_value`, if `value` is greater than the `maximum_value`, and `value` otherwise.

UA requirements for showing the progress bar: When representing a `progress` element to the user, the UA should indicate whether it is a determinate or indeterminate progress bar, and in the former case, should indicate the relative position of the `current_value` relative to the `maximum_value`.

For web developers (non-normative)

`progress . position`

For a determinate progress bar (one with known current and maximum values), returns the result of dividing the current value by the maximum value.

For an indeterminate progress bar, returns -1.

If the progress bar is an indeterminate progress bar, then the `position` IDL attribute must return -1. Otherwise, it must return the result of dividing the `current_value` by the `maximum_value`.

If the progress bar is an indeterminate progress bar, then the `value` IDL attribute, on getting, must return 0. Otherwise, it must return the `current_value`. On setting, the given value must be converted to the [best representation of the number as a floating-point number](#) and then the `value` content attribute must be set to that string.

Note

Setting the `value` IDL attribute to itself when the corresponding content attribute is absent would change the progress bar from an indeterminate progress bar to a determinate progress bar with no progress.

The `max` IDL attribute must [reflect](#) the content attribute of the same name, [limited to numbers greater than zero](#). The default value for `max` is 1.0.

The `label` IDL attribute provides a list of the element's `labels`.

4.10.14 The `meter` element

...

Contexts in which this element can be used:

Where phrasing content is expected.

Content model:Phrasing content, but there must be no `meter` element descendants.**Tag omission in text/html:**

Neither tag ismissible.

Content attributes:**Global attributes**`value` — Current value of the element`min` — Lower bound of range`max` — Upper bound of range`low` — High limit of low range`high` — Low limit of high range`optimum` — Optimum value in gauge**Accessibility considerations:**

For authors

For implementors

DOM interface:

```
IDL Exposed=Window
interface HTMLMeterElement : HTMLElement {
  [HTMLConstructor] constructor();
  [CSSProperties] attribute double value;
  [CSSProperties] attribute double min;
  [CSSProperties] attribute double max;
  [CSSProperties] attribute double low;
  [CSSProperties] attribute double high;
  [CSSProperties] attribute double optimum;
  readonly attribute NodeList labels;
}
```

This is a review draft of the standard and a W3C candidate recommendation.

[EXPAND](#)

This is also known as a gauge.

The `<meter>` element should not be used to indicate progress (as in a progress bar). For that role, HTML provides a separate `<progress>` element.

Note

The `<meter>` element also does not represent a scalar value of arbitrary range — for example, it would be wrong to use this to report a weight, or height, unless there is a known maximum value.

There are six attributes that determine the semantics of the gauge represented by the element.

The `min` attribute specifies the lower bound of the range, and the `max` attribute specifies the upper bound. The `value` attribute specifies the value to have the gauge indicate as the "measured" value.

The other three attributes can be used to segment the gauge's range into "low", "medium", and "high" parts, and to indicate which part of the gauge is the "optimum" part. The `low` attribute specifies the range that is considered to be the "low" part, and the `high` attribute specifies the range that is considered to be the "high" part. The `optimum` attribute gives the position that is "optimum"; if that is higher than the "high" value then this indicates that the higher the value, the better; if it's lower than the "low" mark then it indicates that lower values are better, and naturally if it is in between then it indicates that neither high nor low values are good.

Authoring requirements The `value` attribute must be specified. The `value`, `min`, `low`, `high`, and `optimum` attributes, when present, must have values that are [valid floating-point numbers](#).

In addition, the attributes' values are further constrained:

If `value` is the `value` attribute's number.

If the `min` attribute is specified, then let `minimum` be that attribute's value; otherwise, let it be zero.

If the `max` attribute is specified, then let `maximum` be that attribute's value; otherwise, let it be 1.0.

The following inequalities must hold, as applicable:

- $\text{minimum} \leq \text{value} \leq \text{maximum}$
- $\text{minimum} \leq \text{low} \leq \text{maximum}$ (if `low` is specified)
- $\text{minimum} \leq \text{high} \leq \text{maximum}$ (if `high` is specified)
- $\text{minimum} \leq \text{optimum} \leq \text{maximum}$ (if `optimum` is specified)
- $\text{low} \leq \text{high}$ (if both `low` and `high` are specified)

Note

If no `minimum` or `maximum` is specified, then the `range` is assumed to be 0..1, and the `value` thus has to be within that range.

Authors are encouraged to include a textual representation of the gauge's state in the element's contents, for users of user agents that do not support the `<meter>` element.

When used with `<microdata>`, the `<meter>` element's `value` attribute provides the element's machine-readable value.

Example

The following examples show three gauges that would all be three-quarters full:

```
Storage space usage: <meter value="6.8" max="8">8 blocks used (out of 8 total)</meter>
Tickets sold: <meter min="0" max="10" value="7.5">7.5

```

The following example is incorrect use of the element, because it doesn't give a range (and since the default maximum is 1, both of the gauges would end up looking maxed out):

```
<p>The grapefruit pie had a radius of <meter value="12.2" max="12.2">12.2cm</meter>
```

and a height of meter value="2.2" max="2.2" value="2.2" style="border: 1px solid black; width: 100%; height: 100%; display: inline-block; vertical-align: middle; font-size: 0.8em;">BAD!

Instead, we could either not include the meter element, or use the meter element with a defined range to give the dimensions in context compared to other pies:

```
<p>The grapefruit pie had a radius of 12cm and a height of 2cm.</p>
<div>
  <dt>Radius: <dd><meter min="0" max="20" value="12">12cm</meter></dd>
  <dt>Height: <dd><meter min="0" max="10" value="2">2cm</meter></dd>
</div>
```

There is no explicit way to specify units in the `<meter>` element, but the units may be specified in the `title` attribute in free-form text.

Example

The example above could be extended to mention the units:

```
<div>
  <dt>Radius: <dd><meter min="0" max="20" value="12" title="centimeters">12cm</meter></dd>
  <dt>Height: <dd><meter min="0" max="10" value="2" title="centimeters">2cm</meter></dd>
</div>
```

User agent requirements: User agents must parse the `min`, `max`, `value`, `low`, `high`, and `optimum` attributes using the rules for parsing floating-point number values.

User agents must then use all these numbers to obtain values for six points on the gauge, as follows. (The order in which these are evaluated is important, as some of the values refer to earlier ones.)

The `minimum` value

If the `min` attribute is specified and a value could be parsed out of it, then the minimum value is that value. Otherwise, the minimum value is zero.

The `maximum` value

If the `max` attribute is specified and a value could be parsed out of it, then the candidate maximum value is that value. Otherwise, the candidate maximum value is 1.0.

If the candidate maximum value is greater than or equal to the minimum value, then the maximum value is the candidate maximum value. Otherwise, the maximum value is the same as the minimum value.

The `actual` value

If the `value` attribute is specified and a value could be parsed out of it, then that value is the candidate actual value. Otherwise, the candidate actual value is zero.

If the candidate actual value is less than the minimum value, then the actual value is the minimum value.

Otherwise, if the candidate actual value is greater than the maximum value, then the actual value is the maximum value.

Otherwise, the actual value is the candidate actual value.

The `low` boundary

If the `low` attribute is specified and a value could be parsed out of it, then the candidate low boundary is that value. Otherwise, the candidate low boundary is the same as the minimum value.

If the candidate low boundary is less than the minimum value, then the low boundary is the minimum value.

Otherwise, if the candidate low boundary is greater than the maximum value, then the low boundary is the maximum value.

Otherwise, the low boundary is the candidate low boundary.

The `high` boundary

If the `high` attribute is specified and a value could be parsed out of it, then the candidate high boundary is that value. Otherwise, the candidate high boundary is the same as the maximum value.

If the candidate high boundary is less than the low boundary, then the high boundary is the low boundary.

Otherwise, if the candidate high boundary is greater than the maximum value, then the high boundary is the maximum value.

Otherwise, the high boundary is the candidate high boundary.

The `optimum` point

If the `optimum` attribute is specified and a value could be parsed out of it, then the candidate optimum point is that value. Otherwise, the candidate optimum point is the midpoint between the minimum value and the maximum value.

If the candidate optimum point is less than the minimum value, then the optimum point is the minimum value.

Otherwise, if the candidate optimum point is greater than the maximum value, then the optimum point is the maximum value.

Otherwise, the optimum point is the candidate optimum point.

All of which will result in the following inequalities all being true:

- $\text{minimum} \leq \text{actual} \leq \text{maximum}$
- $\text{minimum} \leq \text{low} \leq \text{high} \leq \text{maximum}$
- $\text{minimum} \leq \text{optimum} \leq \text{maximum}$

UA requirements for regions of the gauge: If the optimum point is equal to the low boundary or the high boundary, or anywhere in between them, then the region between the low and high boundaries of the gauge must be treated as the optimum region, and the low and high parts, if any, must be treated as suboptimal. Otherwise, if the optimum point is less than the low boundary, then the region between minimum value and the low boundary must be treated as the optimum region, the region from the low boundary up to the high boundary must be treated as a suboptimal region, and the remaining region must be treated as an even less good region. Finally, if the optimum point is higher than the high boundary, then the region is reversed: the region between the high boundary and the maximum value must be treated as the optimum region, the region from the high boundary down to the low boundary must be treated as a suboptimal region, and the remaining region must be treated as an even less good region.

UA requirements for showing the gauge: When representing a `<meter>` element to the user, the UA should indicate the relative position of the actual value to the minimum and maximum values, and the relationship between the actual value and the three regions of the gauge.

Example

The following markup:

```
<div>
  <h3>Suggested groups</h3>
  <ul>
    <li><a href="#" onclick="hideSuggestedGroups()">Hide suggested groups</a></li>
    <li><a href="#">View suggested groups</a></li>
    <li><a href="#">Join</a></li>
    <li><a href="#">Subscribe</a></li>
  </ul>
  <hr>
  <ul>
    <li><a href="#">View group</a></li>
    <li><a href="#">Join group</a></li>

  <hr>
  <ul
```

Example

For example, the following snippet:

```
<meter min=0 max=60 value=23.2 title="seconds">/</meter>
```

...might cause the user agent to display a gauge with a tooltip saying "Value: 23.2 out of 60." on one line and "seconds" on a second line.

The `value` IDL attribute, on getting, must return the [actual value](#). On setting, the given value must be converted to the [best representation of the number as a floating-point number](#) and then the `value` content attribute must be set to that string. The `min` IDL attribute, on getting, must return the [minimum value](#). On setting, the given value must be converted to the [best representation of the number as a floating-point number](#) and then the `min` content attribute must be set to that string. The `max` IDL attribute, on getting, must return the [maximum value](#). On setting, the given value must be converted to the [best representation of the number as a floating-point number](#) and then the `max` content attribute must be set to that string. The `low` IDL attribute, on getting, must return the [low boundary](#). On setting, the given value must be converted to the [best representation of the number as a floating-point number](#) and then the `low` content attribute must be set to that string. The `high` IDL attribute, on getting, must return the [high boundary](#). On setting, the given value must be converted to the [best representation of the number as a floating-point number](#) and then the `high` content attribute must be set to that string. The `optimum` IDL attribute, on getting, must return the [optimum value](#). On setting, the given value must be converted to the [best representation of the number as a floating-point number](#) and then the `optimum` content attribute must be set to that string. The `label` IDL attribute provides a list of the element's [label](#)s.

Example

The following example shows how a gauge could fall back to localized or pretty-printed text.

```
<p>Disk usage: <meter min=0 value=170261928 max=233257824></meter></p>
out of 233257824 bytes available</meter></p>
```

Flow content

Sectioning root

Form and [aria-form-associated](#), [inheriting form-associated element](#).

Palpable content

Contexts in which this element can be used:

Where [flow content](#) is expected.

Content model:

Optionally a [legend](#) element, followed by [flow content](#).

Tag omission in XML:

Neither tag ismissible.

Content attributes:

[Global attributes](#)

[disabled](#) — Whether the descendant form controls, except any inside [legend](#), are disabled

[form](#) — Associates the element with a [form](#) element

[name](#) — Name of the element to use in the [form.elements](#) API.

Accessibility considerations:

For authors

For implementers

DOM interface:

```
IDL:<Exposed> interface HTMLFieldSetElement : HTMLElement {
  [HTMLConstructor] constructor();
  [REActions] attribute boolean disabled;
  readonly attribute HTMLFormElement? form;
  [REActions] attribute DOMString name;
  readonly attribute DOMString type;
  [SameObject] readonly attribute HTMLCollection elements;
  readonly attribute boolean willValidate;
  [SameObject] readonly attribute ValidationState validity;
  readonly attribute DOMString validationMessage;
  boolean reportValidity();
  void setCustomValidity(DOMString error);
};
```

The `fieldset` element represents a set of form controls (or other content) grouped together, optionally with a caption. The caption is given by the first `legend` element that is a child of the `fieldset` element, if any. The remainder of the descendants form the group.

The `disabled` attribute, when specified, causes all the form control descendants of the `fieldset` element, excluding those that are descendants of the `fieldset` element's first `legend` element child, if any, to be `disabled`.

...

Support: fieldset-disabled.Chrome for Android 81+Chrome 20+iOS Safari 6.0+Safari 6+Firefox 4+Samsung Internet 4+Edge 12+UC Browser for Android 12.12+IE (limited) 6+Opera 10.0+Opera Mini (limited) all+Firefox for Android 68+

Source: [caniuse.com](#)

A `fieldset` element is a *disabled fieldset* if it matches any of the following conditions:

- Its `disabled` attribute is specified
- It is a descendant of another `fieldset` element whose `disabled` attribute is specified, and is *not* a descendant of that `fieldset` element's first `legend` element child, if any.

The `form` attribute is used to explicitly associate the `fieldset` element with its `form.owner`. The `name` attribute represents the element's name.

For web developers (non-normative)

`fieldset .type`

Returns the string "fieldset".

`fieldset .elements`

Returns an [HTMLCollection](#) of the form controls in the element.

The `disabled` IDL attribute must reflect the content attribute of the same name.

The `type` IDL attribute must return the string "fieldset".

The `elements` IDL attribute must return an [HTMLCollection](#) rooted at the `fieldset` element, whose filter matches [listed elements](#).

The `willValidate`, `validity`, and `validationMessage` attributes, and the `checkValidity()`, `reportValidity()`, and `setCustomValidity()` methods, are part of the [constraint validation API](#). The `form` and `name` IDL attributes are part of the element's forms API.

Example

This example shows a `fieldset` element being used to group a set of related controls:

```
<fieldset>
  <legend>Display</legend>
  <input type="radio" name="value" checked="" value="white"/> White
  <input type="radio" name="value" value="black"/> Black
  <input type="checkbox" name="checkbox" checked="" value="true"/> True
  <input type="checkbox" name="checkbox" value="false"/> False
  <input type="range" name="contrast" value="100" min="0" max="100" step="1"/>
  <option label="Normal value">
  <option label="Maximum value">100</option>
</input>
</fieldset>
```

Example

The following snippet shows a `fieldset` with a checkbox in the legend that controls whether or not the `fieldset` is enabled. The contents of the `fieldset` consist of two required text controls and an optional year/month control.

```
<fieldset name="clubfields" disabled>
  <legend>Club</legend>
  <input type="checkbox" name="club" onchange="form.clubfields.disabled = !checked">
  <p>Use Club Card</p>
  <input type="text" name="cardnumber" required="required" pattern="[\d-]{1-9}[\d-]{1-9}[\d-]{1-9}[\d-]{1-9}">
  <input type="radio" checked="" name="clubexp" value="0" checked="checked" /> My card has numbers on it
  <input type="radio" checked="" name="clubexp" value="1" checked="checked" /> My card is a credit card
  <input type="radio" checked="" name="clubexp" value="2" checked="checked" /> My card is a debit card
  <input type="radio" checked="" name="clubexp" value="3" checked="checked" /> My card is a gift card
</fieldset>
```

Example

You can also nest `fieldset` elements. Here is an example expanding on the previous one that does so:

```
<fieldset name="clubfields" disabled>
  <label>Club</label>
  <input type="checkbox" name="club" checked="" value="1" checked="checked" /> Use Club Card
  <input type="text" name="cardnumber" required="required" pattern="[\d-]{1-9}[\d-]{1-9}[\d-]{1-9}[\d-]{1-9}">
  <input type="radio" checked="" name="clubexp" value="0" checked="checked" /> My card has numbers on it
  <input type="radio" checked="" name="clubexp" value="1" checked="checked" /> My card is a credit card
  <input type="radio" checked="" name="clubexp" value="2" checked="checked" /> My card is a debit card
  <input type="radio" checked="" name="clubexp" value="3" checked="checked" /> My card is a gift card
</fieldset>
```

```
<input type="radio" name="clubtype" onchange="form.letfields.disabled = !checked">
  My card has letters on it
</label> </legend>
</div><div id="c"><input type="text" value="Card code: <input name="clublet" required pattern="^A-Za-z+$"/>"></div>
</fieldset>
```

In this example, if the outer "Use Club Card" checkbox is not checked, everything inside the outer `fieldset`, including the two radio buttons in the legends of the two nested `fieldsets`, will be disabled. However, if the checkbox is checked, then the radio buttons will both be enabled and will let you select which of the two inner `fieldsets` is to be enabled.

None.

Contexts in which this element can be used:

As the first child of a `fieldset` element.

Content model:

Phrasing content.

Text omission in `text/html`.

Content attributes:

Global attributes

Accessibility considerations:

For authors

For implementers

DOM interface

```
interface HTMLEmbedElement : HTMLElement {
  [HTMLConstructor] constructor();
  readonly attribute HTMLFormElement? form;
  // also has obsolete members
}
```

The `legend` element represents a caption for the rest of the contents of the `legend` element's parent `fieldset` element, if any.

For web developers (non-normative)

`legend form`

Returns the element's `form` element, if any, or null otherwise.

The `form` IDL attribute's behavior depends on whether the `legend` element is in a `fieldset` element or not. If the `legend` has a `fieldset` element as its parent, then the `form` IDL attribute must return the same value as the `form` IDL attribute on that `fieldset` element. Otherwise, it must return null.

4.10.17 Form control infrastructure

4.10.17.1 A form control's value

Most form controls have a *value* and a *checkedness*. (The latter is only used by `input` elements.) These are used to describe how the user interacts with the control.

A control's *value* is its internal state. As such, it might not match the user's current input.

Note

For instance, if a user enters the word "three" into a `numeric` field that expects digits, the user's input would be the string "three" but the control's *value* would remain unchanged. Or, if a user enters the email address " awesome@example.com" (with leading whitespace) into an `email` field, the user's input would be the string " awesome@example.com" but the browser's UI for email fields might translate that into a value of "awesome@example.com" (without the leading whitespace).

`input` and `textarea` elements have a *dirty value flag*. This is used to track the interaction between the *value* and default value. If it is false, *value* mirrors the default value. If it is true, the default value is ignored.

To define the behavior of constraint validation in the face of the `input` element's `multiple` attribute, `input` elements can also have separately defined *values*.

To define the behavior of the `maxlength` and `minlength` attributes, as well as other APIs specific to the `textarea` element, all form control with a *value* also have an algorithm for obtaining an *API value*. By default this algorithm is to simply return the control's *value*.

The `select` element does not have a *value*; the *selectedness* of its `option` elements is what is used instead.

4.10.17.2 Mutability

A form control can be designated as *mutable*.

Note

This determines (by means of definitions and requirements in this specification that rely on whether an element is so designated) whether or not the user can modify the *value* or *checkedness* of a form control, or whether or not a control can be automatically prefilled.

4.10.17.3 Association of controls and forms

A `form-associated element` can have a relationship with a `form` element, which is called the element's *form owner*. If a `form-associated element` is not associated with a `form` element, its *form owner* is said to be null.

A `form-associated element` has an associated *parser inserted flag*.

A `form-associated element` is, by default, associated with its nearest ancestor `form` element (as described below), but, if it is `listed`, may have a `form` attribute specified to override this.

...

Support: form-attributeChrome for Android 8.1+Chrome 10+iOS Safari 5.0+Safari 5.1+Firefox 4+Samsung Internet 4+Edge 16+UC Browser for Android 12.12+IE NoneOpera 9.5+Opera Mini all+Firefox for Android 68+

Source: [caniuse.com](#)

Note

This feature allows authors to work around the lack of support for nested `form` elements.

If a `listed form-associated element` has a `form` attribute specified, then that attribute's value must be the `ID` of a `form` element in the element's `tree`.

Note

The rules in this section are complicated by the fact that although conforming documents or `trees` will never contain nested `form` elements, it is quite possible (e.g., using a script that performs DOM manipulation) to generate `trees` that have such nested elements. They are also complicated by rules in the HTML parser that, for historical reasons, can result in a `form-associated element` being associated with a `form` element that is not its ancestor.

When a `form-associated element` is created, its *form owner* must be initialized to null (no owner).

When a `form-associated element` is to be associated with a form, its *form owner* must be set to that form.

When a `form-associated element` or one of its ancestors is `inserted`, then:

1. If the `form-associated element's parser inserted flag` is set, then return.
2. Reset the form owner of the `form-associated element`.

When a `form-associated element` or one of its ancestors is `removed`, then:

1. If the `form-associated element` has a `form owner` and the `form-associated element` and its `form owner` are no longer in the same `tree`, then reset the form owner of the `form-associated element`.

When a `listed form-associated element's form` attribute is set, changed, or removed, then the user agent must reset the form owner of that element.

When a `listed form-associated element` has a `form` attribute and the `ID` of any of the elements in the `tree` changes, then the user agent must reset the form owner of that `form-associated element`.

When a `listed form-associated element` has a `form` attribute and an element with an `ID` is `inserted into` or `removed from` the `document`, then the user agent must reset the form owner of that `form-associated element`.

When the user agent is to reset the form owner of a `form-associated element`, it must run the following steps:

1. Unset element's *parser inserted flag*.
2. If all of the following conditions are true
 - element's `form owner` is not null
 - element is not `listed` or its `form` content attribute is not present
 - element's `form owner` is its nearest `form` element ancestor after the change to the ancestor chain
- then do nothing, and return.
3. Set element's `form owner` to null.
4. If element is `listed`, has a `form` content attribute, and is `connected`, then
 1. If the first element in element's `tree`, in `tree order`, to have an `ID` that is `case-sensitively` equal to element's `form` content attribute's value, is a `form` element, then associate the element with that `form` element.
5. Otherwise, if element has an ancestor `form` element, then associate element with the nearest such ancestor `form` element.

Example

In the following non-conforming snippet:

```
<form id="a">
  <div id="b"></div>
</form>
<script>
  document.getElementById('b').innerHTML =
    '<table><tr><td><div><form id="c"><input id="d"></form></div></td></tr></table>';
  <input id="e">';
</script>
```

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Attributes for form submission can be specified both on `form` elements and on `submit` buttons (elements that represent buttons that submit forms, e.g. an `input` element whose `type` attribute is in the `Submit Button` state).

Support: form-submit-attributesChrome for Android 81+Chrome 15+iOS Safari 5.0+Safari 5.1+Firefox 4+Samsung Internet 4+Edge 12+UC Browser for Android 12.12+IE 10+Opera 10.6+Opera Mini all+Firefox for Android 68+

Source: [caniuse.com](#)

The `attributes for form submission` that may be specified on `form` elements are `action`, `enctype`, `method`, `novalidate`, and `target`.

The corresponding `attributes for form submission` that may be specified on `submit` buttons are `formaction`, `formenctype`, `formmethod`, `formnovalidate`, and `formtarget`. When omitted, they default to the values given on the corresponding attributes on the `form` element.

The `action` and `formaction` content attributes, if specified, must have a value that is a valid non-empty URL potentially surrounded by spaces.

The `action` of an element is the value of the element's `formaction` attribute, if the element is a `submit` button and has such an attribute, or the value of its `form owner`'s `action` attribute, if it has one, or else the empty string.

The `method` and `formmethod` content attributes are `enumerated attributes` with the following keywords and states:

- The keyword `get`, mapping to the state `GET`, indicating the HTTP GET method.
- The keyword `post`, mapping to the state `POST`, indicating the HTTP POST method.
- The keyword `dialog`, mapping to the state `dialog`, indicating that submitting the `form` is intended to close the `dialog` box in which the form finds itself, if any, and otherwise not submit.

The `invalid value default` for these attributes is the `GET` state. The `missing value default` for the `method` attribute is also the `GET` state. (There is no `missing value default` or `invalid value default` for the `formmethod` attribute.)

The `method` of an element is one of those states. If the element is a `submit` button and has a `formmethod` attribute, then the element's `method` is that attribute's state; otherwise, it is the `form owner`'s `method` attribute's state.

Example

Here the `method` attribute is used to explicitly specify the default value, "`get`", so that the search query is submitted in the URL:

```
<form method="get" action="/search.cgi">
<p><label>Search terms: <input type="search" name="q"></label></p>
<p><input type="submit" value="Submit search"></p>
</form>
```

Example

On the other hand, here the `method` attribute is used to specify the value "`post`", so that the user's message is submitted in the HTTP request's body:

```
<form method="post" action="post-message.cgi">
<p><label>Message: <input type="text" name="msg"></label></p>
<p><input type="submit" value="Submit message"></p>
</form>
```

Example

In this example, a `form` is used with a `dialog`. The `method` attribute's "`dialog`" keyword is used to have the dialog automatically close when the form is submitted.

```
<dialog id="ship">
<form method="dialog">
<p>A ship has arrived in the harbour.</p>
<p><input type="submit" value="board">Board the ship</button>
<button type="submit" value="call">Call to the captain</button>
</form>
</dialog>
<script>
var ship = document.getElementById('ship');
ship.onclose = function (event) {
  if (ship.returnValue == 'board') {
    event.preventDefault();
  }
}
</script>
```

The `enctype` and `formenctype` content attributes are `enumerated attributes` with the following keywords and states:

- The `application/x-www-form-urlencoded` keyword and corresponding state.
- The `multipart/form-data` keyword and corresponding state.
- The `text/plain` keyword and corresponding state.

The `invalid value default` for these attributes is the `application/x-www-form-urlencoded` state. The `missing value default` for the `enctype` attribute is also the `application/x-www-form-urlencoded` state. (There is no `missing value default` for the `formenctype` attribute.)

The `enctype` of an element is one of those three states. If the element is a `submit` button and has a `formenctype` attribute, then the element's `enctype` is that attribute's state; otherwise, it is the `form owner`'s `enctype` attribute's state.

The `target` and `formtarget` content attributes, if specified, must have values that are `valid browsing context names or keywords`.

The `novalidate` and `formnovalidate` content attributes are `boolean attributes`. If present, they indicate that the form is not to be validated during submission.

The `no-validate` state of an element is true if the element is a `submit` button and the element's `formnovalidate` attribute is present, or if the element's `form owner`'s `novalidate` attribute is present, and false otherwise.

Example

This attribute is useful to include "save" buttons on forms that have validation constraints, to allow users to save their progress even though they haven't fully entered the data in the form. The following example shows a simple form that has two required fields. There are three buttons: one to submit the form, which requires both fields to be filled in; one to save the form so that the user can come back and fill it in later; and one to cancel the form altogether.

```
<form action="editor.cgi" method="post">
<p><label>Name: <input required name="fn"></label></p>
<p><label>Essay: <textarea required name="essay"></textarea></label></p>
<p><input type="submit" name="submit" value="Submit essay"></p>
<p><input type="button" name="validate" value="Validate essay"></p>
<p><input type="button" name="cancel" value="Cancel" formnovalidate></p>
</form>
```

Opera Yes Edge 79+

Edge (Legacy) No Internet Explorer No

Firefox, Android Yes Safari iOS/Chrome Android 66+WebView Android 66+Samsung Internet 9.0+Opera Android Yes

There are two ways this attribute is used. When wearing the `autofill expectation mantle`, the `autocomplete` attribute describes what input is expected from users. When wearing the `autofill anchor mantle`, the `autocomplete` attribute describes the meaning of the given value.

On an `input` element whose `type` attribute is in the `Hidden` state, the `autocomplete` attribute wears the `autofill anchor mantle`. In all other cases, it wears the `autofill expectation mantle`.

When wearing the `autofill expectation mantle`, the `autocomplete` attribute, if specified, must have a value that is an ordered `set of space-separated tokens` consisting of either a single token that is an `ASCII case-insensitive` match for the string "`off`", or a single token that is an `ASCII case-insensitive` match for the string "`on`", or `autofill detail tokens`.

When wearing the `autofill anchor mantle`, the `autocomplete` attribute, if specified, must have a value that is an ordered `set of space-separated tokens` consisting of just `autofill detail tokens` (i.e. the "`on`" and "`off`" keywords are not allowed).

`Autofill detail tokens` are the following, in the order given below:

1. Optionally, a token whose first eight characters are an `ASCII case-insensitive` match for the string "`section-`", meaning that the field belongs to the named group.

Example

For example, if there are two shipping addresses in the form, then they could be marked up as:

```
<fieldset>
<legend>Send the blue gift to...</legend>
<p><label>Address:</label> <textarea name=ba autocomplete="section-blue shipping street-address"></textarea> </label>
<p><label>City:</label> <input type="text" name=bc autocomplete="section-blue shipping address-level2"> </label>
<p><label>Postal Code:</label> <input type="text" name=bp autocomplete="section-blue shipping postal-code"> </label>
</fieldset>
<fieldset>
<legend>Ship the red gift to...</legend>
<p><label>Address:</label> <textarea name=ra autocomplete="section-red shipping street-address"></textarea> </label>
<p><label>City:</label> <input type="text" name=rc autocomplete="section-red shipping address-level2"> </label>
<p><label>Postal Code:</label> <input type="text" name=rp autocomplete="section-red shipping postal-code"> </label>
</fieldset>
```

2. Optionally, a token that is an `ASCII case-insensitive` match for one of the following strings:

- "`shipping`", meaning the field is part of the shipping address or contact information
- "`billing`", meaning the field is part of the billing address or contact information

3. Either of the following two options:

- A token that is an `ASCII case-insensitive` match for one of the following `autofill field` names, excluding those that are `inappropriate for the control`:

```
"name"
"nonrific-prefix"
"given-name"
"additional-name"
"family-name"
"nonrific-suffix"
"nickname"
"username"
"password"
"current-password"
"one-time-code"
"organization-title"
"organization"
"organization"
"address-line1"
"address-line2"
"address-line3"
"address-line4"
"address-line5"
"address-line6"
"country"
"country-name"
"postal-code"
"city"
"region"
"region-name"
"co-additional-name"
"co-family-name"
"co-number"
"co-type"
"transaction"
"transaction-currency"
"transaction-amount"
"transaction"
"day"
"day-day"
"day-month"
"day-year"
"month"
"year"
"unit"
"short"
```

(See the table below for descriptions of these values.)

- The following, in the given order:

1. Optionally, a token that is an `ASCII case-insensitive` match for one of the following strings:

- "`home`", meaning the field is for contacting someone at their residence
- "`work`", meaning the field is for contacting someone at their workplace
- "`mob`", meaning the field is for contacting someone regardless of location
- "`fax`", meaning the field describes a fax or a person's contact details
- "`page`", meaning the field describes a page or a beeper's contact details

2. A token that is an `ASCII case-insensitive` match for one of the following `autofill field` names, excluding those that are `inappropriate for the control`:

```
"tel"
"tel-country-code"
"tel-national"
"tel-area-code"
"tel-local"
"tel-local-prefix"
"tel-local-suffix"
"tel-extension"
"email"
"impp"
```

(See the table below for descriptions of these values.)

As noted earlier, the meaning of the attribute and its keywords depends on the mantle that the attribute is wearing.

When wearing the `autofill expectation mantle`...

The "`on`" keyword indicates either that the control's input data is particularly sensitive (for example the activation code for a nuclear weapon), or that it is a value that will never be reused (for example a one-time-key for a bank login) and the user will therefore have to explicitly enter the data each time, instead of being able to rely on the UA to prefill the value for them; or that the document provides its own autocomplete mechanism and does not want the user agent to provide autocomplete values.

The "`on`" keyword indicates that the user agent is allowed to provide the user with autocomplete values, but does not provide any further information about what kind of data the user might be expected to enter. User agents would have to use heuristics to decide what autocomplete values to suggest.

The `autofill field` listed above indicate that the user agent is allowed to provide the user with autocomplete values, and specifies what kind of value is expected. The meaning of each such keyword is described in the table below.

If the `autocomplete` attribute is omitted, the default value corresponding to the state of the element's `form-owner`'s `autocomplete` attribute is used instead (either "`on`" or "`off`"). If there is no `form-owner`, then the value "`on`" is used.

When wearing the `autofill anchor mantle`...

The `autofill field` listed above indicate that the value of the particular kind of value specified is that value provided for this element. The meaning of each such keyword is described in the table below.

Example

In this example the page has explicitly specified the currency and amount of the transaction. The form requests a credit card and other billing details. The user agent could use this information to suggest a credit card that it knows has sufficient balance and that supports the relevant currency.

```
<form method="post" action="http://example.com/submit">
<input type="hidden" autocomplete="transaction-currency" value="CHF">
<input type="hidden" autocomplete="transaction-amount" value="15.00">
<p><label>Credit card number:</label> <input type="text" name=cc-number autocomplete="cc-number"> </label>
<p><label>Expiry date:</label> <input type="text" name=cc-exp autocomplete="cc-exp"> </label>
</p>
</form>
```

The `autofill field` keywords relate to each other as described in the table below. Each field name listed on a row of this table corresponds to the meaning given in the cell for that row in the column labeled "Meaning". Some fields correspond to subparts of other fields; for example, a credit card expiry date can be expressed as one field giving both the month and year of expiry ("`cc-exp`"), or as two fields, one giving the month ("`cc-exp-month`") and one the year ("`cc-exp-year`"). In such cases, the names of the broader fields cover multiple rows, in which the narrower fields are defined.

Note	Generally, authors are encouraged to use the broader fields rather than the narrower fields, as the narrower fields tend to expose Western biases. For example, while it is common in some Western cultures to have a given name and a family name, in that order (and thus often referred to as a <i>first name</i> and a <i>surname</i>), many cultures put the family name first and the given name second, and many others simply have one name (<i>a mononym</i>). Having a single field is therefore more flexible.
------	--

Some fields are only appropriate for certain form controls. An `autofill field` name is `inappropriate for a control` if the control does not belong to the group listed for that `autofill field` in the fifth column of the first row describing that `autofill field` in the table below. What controls fall into each group is described below the table.

Field name	Meaning	Canonical Format	Canonical Format Example	Control group
"name"	Full name	Free-form text, no newlines	Sir Tim John Berners-Lee, OM, KBE, FRS, FREng,	Text
"nonrific-prefix"	Prefix or title (e.g. "Mr.", "Ms.", "Dr.", "Mlle")	Free-form text, no newlines	FRSA	
"given-name"	Given name (in some Western cultures, also known as the <i>first name</i>)	Free-form text, no newlines	Sir	
"additional-name"	Additional names (in some Western cultures, also known as <i>middle names</i> , forenames other than the first name)	Free-form text, no newlines	Timothy	
"family-name"	Family name (in some Western cultures, also known as the <i>last name or surname</i>)	Free-form text, no newlines	John	
"nonrific-suffix"	Suffix (e.g. "Jr.", "B.Sc.", "MBASW", "II")	Free-form text, no newlines	Berners-Lee	
"nickname"	Nickname, screen name, handle; a typically short name used instead of the full name	Free-form text, no newlines	OM, KBE, FRS, FREng, FRSA	
"organization"	Job title (e.g. "Software Engineer", "Senior Vice President", "Deputy Managing Director")	Free-form text, no newlines	Tim	
"title"	A title	Free-form text, no newlines	Professor	
"username"	A username	Free-form text, no newlines	timbl	
"new-password"	A new password (e.g. when creating an account or changing a password)	Free-form text, no newlines	GUMfXbadyrS3	Text
"current-password"	The current password for the account identified by the <code>username</code> field (e.g. when logging in)	Free-form text, no newlines	qwerty	Text
"one-time-code"	One-time code used for verifying user identity	Free-form text, no newlines	123456	Text
"organization"	Company name corresponding to the person, address, or contact information in the other fields associated with this field	Free-form text, no newlines	World Wide Web Consortium	Multiline
"street-address"	Street address (multiple lines, newlines preserved)	Free-form text	32 Vassar Street	
"address-line1"	Street address (one line per field)	Free-form text, no newlines	MIT Room 32-G524	
			32 Vassar Street	
			Text	

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Field name	Meaning	Canonical Format	Canonical Format Example	Control group
"address-level3"	The most fine-grained administrative level, in addresses with four administrative levels	Free-form text, no newlines		Text
"address-level4"	The third administrative level, in addresses with three or more administrative levels	Free-form text, no newlines		Text
"address-level5"	The second administrative level, in addresses with two or more administrative levels; in the countries with two administrative levels, this would typically be the city, town, village, or other locality within which the relevant street address is found	Free-form text, no newlines	Cambridge	Text
"address-level6"	The broadest administrative level in the address, i.e. the province within which the locality is found; for example, in the US, this would be the state; in Switzerland it would be the canton in the UK, the post town	Free-form text, no newlines	MA	Text
"country"	Country code	Free-form text, no newlines	US	Text
"country-name"	Country name	Free-form text, no newlines	US	Text
"postal-code"	Postal code, ZIP code, CEDEX code (if CEDEX, append "CEDEX", and the arrondissement, if relevant, to the <code>address-level2</code> field)	Free-form text, no newlines	02139	Text
"cc-name"	Full name as given on the payment instrument	Free-form text, no newlines	Tim Berners-Lee	Text
"cc-given-name"	Given name as given on the payment instrument (in some Western cultures, also known as the <i>first name</i>)	Free-form text, no newlines	Tim	Text
"cc-additional-name"	Additional names given on the payment instrument (in some Western cultures, also known as <i>middle names</i> , forenames other than the first name)	Free-form text, no newlines		Text
"cc-family-name"	Name given on the payment instrument (in some Western cultures, also known as the <i>last name or surname</i>)	Free-form text, no newlines	Berners-Lee	Text
"cc-cnumbers"	Code identifying the payment instrument (e.g. the credit card number)	ASCII digits	4114360123456785	Text
"cc-exp"	Expiration date of the payment instrument	Valid month string	2014-12	Month
"cc-exp-month"	Month component of the expiration date of the payment instrument	Valid integer in the range 1..12	12	Numeric
"cc-exp-year"	Year component of the expiration date of the payment instrument	Valid integer greater than zero	2014	Numeric
"cc-eu2"	Security code for the payment instrument (also known as the card security code (CSC), card validation code (CVC), card verification value (CVV), signature panel code (SPC), credit card ID (CCID), etc)	ASCII digits	419	Text
"cc-type"	Type of payment instrument	Free-form text, no newlines	Visa	Text
"transaction-currency"	The currency that the user would prefer the transaction to use	ISO 4217 currency code [ISO4217]	GBP	Text
"transaction-amount"	The amount that the user would like for the transaction (e.g. when entering a bid or sale price)	Valid floating-point number	401.00	Numeric
"language"	Preferred language	Valid BCP 47 language tag [BCP47]	en	Text
"day"	Birthday	Valid date string	1955-06-08	Date
"day-of-day"	Day component of birthday	Valid integer in the range 1..31	8	Numeric
"day-of-month"	Month component of birthday	Valid integer in the range 1..12	6	Numeric
"day-of-year"	Year component of birthday	Valid integer greater than zero	1955	Numeric
"gender"	Gender identity (e.g. Female, F/a/fine)	Free-form text, no newlines	Male	Text
"url"	Home page or other Web page corresponding to the company, person, address, or contact information in the other fields associated with this field	Valid URL string	https://www.w3.org/People/Berners-Lee/	URL
"photo"	Photograph, icon, or other image corresponding to the company, person, address, or contact information in the other fields associated with this field	Valid URL string	https://www.w3.org/Stock/Berners-Lee/2001-europeancighth.jpg	URL
"tel"	Full telephone number, including country code	ASCII digits and U+0020 SPACE characters, prefixed by a U+002B PLUS SIGN character (+)	+1 6125 5702	Tel
"tel-country-code"	Country code component of the telephone number	ASCII digits prefixed by a U+002B PLUS SIGN character (+)	+1	Text
"tel-national"	Telephone number without the country code component, with a country-internal prefix applied if applicable	ASCII digits and U+0020 SPACE characters	6125 5702	Text
"tel-area-code"	Area code component of the telephone number, with a country-internal prefix applied if applicable	ASCII digits	617	Text
"tel-local"	Telephone number without the country code and area code components	ASCII digits	2535702	Text
"tel-local-prefix"	First part of the component of the telephone number that follows the area code, when that component is split into two components	ASCII digits	253	Text
"tel-local-suffix"	Second part of the component of the telephone number that follows the area code, when that component is split into two components	ASCII digits	5702	Text
"tel-extension"	Telephone number internal extension code	ASCII digits	1000	Text
"email"	E-mail address	Valid e-mail address	timbl@w3.org	E-mail
"impp"	URL representing an instant messaging protocol endpoint (for example, " <code>sim:go!m?screenname@example</code> " or " <code>xmpp:fred@example.net</code> ")	Valid URL string	irc://example.com/timblisuser	URL

 elements

Address levels: The `"address-level1"` – `"address-level5"` fields are used to describe the locality of the street address. Different locales have different numbers of levels. For example, the US uses two levels (state and town), the UK uses one or two depending on the address (the post town, and in some cases the locality), and China can use three (province, city, district). The `"address-level1"` field represents the widest administrative division. Different locales order the fields in different ways; for example, in the US the town (level 2) precedes the state (level 1); while in Japan the prefecture (level 1) precedes the city (level 2) which precedes the district (level 3). Authors are encouraged to provide forms that are presented in a way that matches the country's conventions (hiding, showing, and rearranging fields accordingly as the user changes the country).

4.18.1.7.2 Processing model

Each `input` element to which the `autocomplete` attribute applies, each `select` element, and each `textarea` element, has an `autofill hint set`, an `autofill scope`, an `autofill field name`, and an `IDL-exposed autofill value`.

The `autofill field name` specifies the specific kind of data expected in the field, e.g. `"street-address"` or `"cc-exp"`.

The `autofill hint set` identifies what address or contact information type the user agent is to look at, e.g. `"shipping fax"` or `"billing"`.

The `autofill scope` identifies the group of fields whose information concerns the same subject, and consists of the `autofill hint set` with, if applicable, the `section-` prefix, e.g. `"billing"`, `"section-parent shipping"`, or `"section-child shipping home"`.

These values are defined as the result of running the following algorithm:

- If the element has no `autocomplete` attribute, then jump to the step labeled `default`.
- Let `tokens` be the result of `splitting the attribute's value on ASCII whitespace`.
- If `tokens` is empty, then jump to the step labeled `default`.
- Let `index` be the index of the last token in `tokens`.
- If the `index` token in `tokens` is not an `ASCII case-insensitive` match for one of the tokens given in the first column of the following table, or if the number of tokens in `tokens` is greater than the maximum number given in the cell in the second column of that token's row, then jump to the step labeled `default`. Otherwise, let `field` be the string given in the cell of the first column of the matching row, and let `category` be the value of the cell in the third column of that same row.

6. If category is Off or Automatic but the element's `autocomplete` attribute is wearing the `autofill_anchor_mantle`, then jump to the step labeled `default`.

7. If category is Off, let the element's `autofill_field_name` be the string "`off`", let its `autofill_hint_set` be empty, and let its `IDL_exposed_autofill_value` be the string "`off`". Then, return.

8. If category is Automatic, let the element's `autofill_field_name` be the string "`on`", let its `autofill_hint_set` be empty, and let its `IDL_exposed_autofill_value` be the string "`on`". Then, return.

9. Let `scope tokens` be an empty list.

10. Let `hint tokens` be an empty set.

11. Let `IDL value` have the same value as `field`.

12. If the `indexeth` token in `tokens` is the first entry, then skip to the step labeled `done`.

13. Decrement `index` by one.

14. If category is Contact and the `indexeth` token in `tokens` is an `ASCII_case-insensitive` match for one of the strings in the following list, then run the substeps that follow:

- o "name"
- o "work"
- o "home"
- o "fax"
- o "pager"

The substeps are:

1. Let `contact` be the matching string from the list above.

2. Insert `contact` at the start of `scope tokens`.

3. Add `contact` to `hint tokens`.

4. Let `IDL value` be the concatenation of `contact`, a U+0020 SPACE character, and the previous value of `IDL value` (which at this point will always be `field`).

5. If the `indexeth` entry in `tokens` is the first entry, then skip to the step labeled `done`.

6. Decrement `index` by one.

15. If the `indexeth` token in `tokens` is an `ASCII_case-insensitive` match for one of the strings in the following list, then run the substeps that follow:

- o "shipping"
- o "billing"

The substeps are:

1. Let `mode` be the matching string from the list above.

2. Insert `mode` at the start of `scope tokens`.

3. Add `mode` to `hint tokens`.

4. Let `IDL value` be the concatenation of `mode`, a U+0020 SPACE character, and the previous value of `IDL value` (which at this point will either be `field` or the concatenation of `contact`, a space, and `field`).

5. If the `indexeth` entry in `tokens` is the first entry, then skip to the step labeled `done`.

6. Decrement `index` by one.

16. If the `indexeth` entry in `tokens` is not the first entry, then jump to the step labeled `default`.

17. If the first eight characters of the `indexeth` token in `tokens` are not an `ASCII_case-insensitive` match for the string "`section`", then jump to the step labeled `default`.

18. Let `section` be the `indexeth` token in `tokens`, `converted_to_ASCII_lowcase`.

19. Insert `section` at the start of `scope tokens`.

20. Let `IDL value` be the concatenation of `section`, a U+0020 SPACE character, and the previous value of `IDL value`.

21. `Done`: Let the element's `autofill_hint_set` be `hint tokens`.

22. Let the element's `autofill_scope` be `scope tokens`.

23. Let the element's `autofill_field_name` be `field`.

24. Let the element's `IDL_exposed_autofill_value` be `IDL value`.

25. Return.

26. `Default`: Let the element's `IDL_exposed_autofill_value` be the empty string, and its `autofill_hint_set` and `autofill_scope` be empty.

27. If the element's `autocomplete` attribute is wearing the `autofill_anchor_mantle`, then let the element's `autofill_field_name` be the empty string and return.

28. Let `form` be the element's `form_owner`, if any, or null otherwise.

29. If `form` is not null and `form`'s `autocomplete` attribute is in the `off` state, then let the element's `autofill_field_name` be "`off`".

Otherwise, let the element's `autofill_field_name` be "`on`".

For the purposes of autofill, a `control's data` depends on the kind of control:

An `input` element with its `type` attribute in the `Email` state and with the `multiple` attribute specified
The element's `value`.

Any other `input` element

A `text` element

The element's `value`

A `select` element with its `multiple` attribute specified

The `option` elements in the `select` element's `list` of options that have their `selectedness` set to true.

Any other `select` element

The `option` element in the `select` element's `list` of options that has its `selectedness` set to true.

How to process the `autofill_hint_set`, `autofill_scope`, and `autofill_field_name` depends on the mantle that the `autocomplete` attribute is wearing.

When wearing the `autofill_expectation_mantle`...

When an element's `autofill_field_name` is "`off`", the user agent should not remember the `control's data`, and should not offer past values to the user.

Note

In addition, when an element's `autofill_field_name` is "`off`", values are reset when traversing the history.

Example

Banks frequently do not want UAs to prefill login information:

```
<p><label>account: <input type="text" name="ac" autocomplete="off"></label></p>
<p><label>password: <input type="password" name="pin" autocomplete="off"></label></p>
```

When an element's `autofill_field_name` is not "`off`", the user agent may store the `control's data`, and may offer previously stored values to the user.

Example

```
<select name="country">
<option>Afghanistan
<option>Albania
<option>Algeria
<option>Andorra
<option>Angola
<option>Anguilla and Barbuda
<option>Argentina
<option>Armenia
<option>Aruba
<option>Yemen
<option>Zambia
<option>Zimbabwe
</select>
```

This might render as follows:

Suppose that on the first visit to this page, the user selects "Zambia". On the second visit, the user agent could duplicate the entry for Zambia at the top of the list, so that the interface instead looks like this:

When the `autocomplete="on"`, the user agent should attempt to use heuristics to determine the most appropriate values to offer the user, e.g. based on the element's `name` value, the position of the element in its `tree`, what other fields exist in the form, and so forth.

When the `autocomplete="on"` is one of the names of the `autofill fields` described above, the user agent should provide suggestions that match the meaning of the field name as given in the table earlier in this section. The `autofill hint set` should be used to select amongst multiple possible suggestions.

Example
For example, if a user once entered one address into fields that used the `"shipping"` keyword, and another address into fields that used the `"billing"` keyword, then in subsequent forms only the first address would be suggested for form controls whose `autofill hint set` contains the keyword `"shipping"`. Both addresses might be suggested, however, for address-related form controls whose `autofill hint set` does not contain either keyword.

When wearing the `autofill anchor mantle`...

When the `autofill field name` is not the empty string, then the user agent must act as if the user had specified the `control's data` for the given `autofill hint set`, `autofill scope`, and `autofill field name` combination.

When the user agent `autofills form controls`, elements with the same `form owner` and the same `autofill scope` must use data relating to the same person, address, payment instrument, and contact details. When a user agent autofills `"country"` and `"country-name"` fields with the same `form owner` and `autofill scope`, and the user agent has a value for the `country` field(s), then the `"country-name"` field(s) must be filled using a human-readable name for the same country. When a user agent fills in multiple fields at once, all fields with the same `autofill field name`, `form owner` and `autofill scope` must be filled with the same value.

Example
Suppose a user agent knows of two phone numbers, +1 555 123 1234 and +1 555 666 7777. It would not be conforming for the user agent to fill a field with `autocomplete="shipping tel-local-prefix"` with the value "123" and another field in the same form with `autocomplete="shipping tel-local-suffix"` with the value "7777". The only valid prefilled values given the aforementioned information would be "123" and "1234", or "666" and "7777", respectively.

Example
Similarly, if a form for some reason contained both a `<cc-exp-addr>` field and a `<cc-exp-month>` field, and the user agent prefilled the form, then the month component of the former would have to match the latter.

Example

This requirement interacts with the `autofill anchor mantle` also. Consider the following markup snippet:

```
<form>
<input type=hidden autocomplete="nickname" value="TreePlate">
<input type=text autocomplete="nickname">
</form>
```

The only value that a conforming user agent could suggest in the text control is "TreePlate", the value given by the hidden `input` element.

The `<section>` tokens in the `autofill scope` are opaque; user agents must not attempt to derive meaning from the precise values of these tokens.

Example
For example, it would not be conforming if the user agent decided that it should offer the address it knows to be the user's daughter's address for `"section-child"` and the addresses it knows to be the user's spouses' addresses for `"section-spouse"`.

The autocompletion mechanism must be implemented by the user agent acting as if the user had modified the `control's data`, and must be done at a time where the element is `mutable` (e.g. just after the element has been inserted into the document, or when the user agent `stops parsing`). User agents must only prefill controls using values that the user could have entered.

Example
For example, if a `select` element only has `option` elements with values "Steve" and "Rebecca", "Jay", and "Bob", and has an `autofill field name` `"given-name"`, but the user agent's only idea for what to prefill the field with is "Evan", then the user agent cannot prefill the field. It would not be conforming to somehow set the `select` element to the value "Evan", since the user could not have done so themselves.

A user agent prefilling a form control must not discriminate between form controls that are `in a document tree` and those that are `connected`; that is, it is not conforming to make the decision on whether or not to autofill based on whether the element's `root` is a `shadow root` versus a `document`.

A user agent preferring a form control's `value` must not cause that control to `suffer from a type mismatch`, `suffer from being too long`, `suffer from being too short`, `suffer from an underflow`, `suffer from an overflow`, or `suffer from a step mismatch`. A user agent prefiling a form control's `value` must not cause that control to `suffer from a pattern mismatch` either. Where possible given the control's constraints, user agents must use the format given as canonical in the aforementioned table. Where it's not possible for the canonical format to be used, user agents should use heuristics to attempt to convert values so that they can be used.

Example

For example, if the user agent knows that the user's middle name is "Ines", and attempts to prefill a form control that looks like this:

```
<input name=middle>initial maxlength=1 autocomplete="additional-name">
```

...then the user agent could convert "Ines" to "I" and prefill it that way.

Example

A more elaborate example would be with month values. If the user agent knows that the user's birthday is the 27th of July 2012, then it might try to prefill all of the following controls with slightly different values, all driven from this information:

```
<input name=b type=month autocomplete="bday"> 2012-07 The day is dropped since the Month state only accepts a month/year combination. (Note that this example is non-conforming, because the autofill field name bday is not allowed with the Month state.)
```

```
<select type=month> autocomplete="bday">
<option>Jan
<option>Feb
...
<option>Jul
<option>Aug
...
</select>
```

July The user agent picks the month from the listed options, either by noticing there are twelve options and picking the 7th, or by recognizing that one of the strings (three characters "Jul" followed by a newline and a space) is a close match for the name of the month (July) in one of the user agent's supported languages, or through some other similar mechanism.

```
<input name=a type=number min=1 max=12 autocomplete="bday-month"> 7      User agent converts "July" to a month number in the range 1..12, like the field.
```

```
<input name=a type=number min=0 max=11 autocomplete="bday-month"> 6      User agent converts "July" to a month number in the range 0..11, like the field.
```

```
<input name=a type=number min=0 max=11 autocomplete="bday-month">      User agent doesn't fill in the field, since it can't make a good guess as to what the form expects.
```

A user agent may allow the user to override an element's `autofill field name`, e.g. to change it from `"_id"` to `"_id"` to allow values to be remembered and prefilled despite the page author's objections, or to always `"_id"`, never remembering values.

More specifically, user agents may in particular consider replacing the `autofill field name` of form controls that match the description given in the first column of the following table, when their `autofill field name` is either `"_id"` or `"_id"`, with the value given in the second cell of that row. If this table is used, the replacements must be done in `tree_order`, since all but the first row references the `autofill field name` of earlier elements. When the descriptions below refer to controls being preceded or followed by others, they mean in the list of `list-item` elements that share the same `form owner`.

Form control	New <code>autofill field name</code>
<code>input</code> element whose <code>type</code> attribute is in the <code>Text</code> state that is followed by an <code>input</code> element whose <code>type</code> attribute is in the <code>Password</code> state	<code>"_password"</code>
<code>input</code> element whose <code>type</code> attribute is in the <code>Password</code> state that is preceded by an <code>input</code> element whose <code>autofill field name</code> is <code>"username"</code>	<code>"current-password"</code>
<code>input</code> element whose <code>type</code> attribute is in the <code>Password</code> state that is preceded by an <code>input</code> element whose <code>autofill field name</code> is <code>"current-password"</code>	<code>"new-password"</code>
<code>input</code> element whose <code>type</code> attribute is in the <code>Password</code> state that is preceded by an <code>input</code> element whose <code>autofill field name</code> is <code>"new-password"</code>	<code>"old-password"</code>

The `autocomplete` IDL attribute, on getting, must return the element's `IDL-exposed autofill value`, and on setting, must reflect the content attribute of the same name.

4.10.19 APIs for the text control selections

The `input` and `textarea` elements define several attributes and methods for handling their selection. Their shared algorithms are defined here.

For web developers (non-normative)

`element.select()`

Selects everything in the text control.

`element.selectionStart = value`

Returns the offset to the start of the selection.

Can be set, to change the start of the selection.

`element.selectionEnd = value`

Returns the offset to the end of the selection.

Can be set, to change the end of the selection.

`element.selectionDirection = value`

Returns the current direction of the selection.

Can be set, to change the direction of the selection.

The possible values are `"forward"`, `"backward"`, and `"none"`.

`element.setSelectionRange(start, end, direction)`

Changes the selection to cover the given substring in the given direction. If the direction is omitted, it will be reset to be the platform default (none or forward).

`element.setRangeText(replacement [, start, end [, selectionMode]])`

Replaces a range of text with the new text. If the `start` and `end` arguments are not provided, the range is assumed to be the selection.

The final argument determines how the selection will be set after the text has been replaced. The possible values are:

Selects the newly inserted text.
 "start"
 Moves the selection to just before the inserted text.
 "end"
 Moves the selection to just after the selected text.
 "preserve"
 Attempts to preserve the selection. This is the default.

All `input` elements to which these APIs apply, and all `textareas` elements, have either a `selection` or a `text entry cursor position` at all times (even for elements that are not being rendered). The initial state must consist of a `text entry cursor` at the beginning of the control.

For `input` elements, these APIs must operate on the element's `value`. For `textareas` elements, these APIs must operate on the element's `API value`. In the below algorithms, we call the value string being operated on the `relevant value`.

Example

The use of `API value` instead of `raw value` for `textareas` elements means that U+000D (CR) characters are normalized away. For example,

```
<textarea id="demo"></textarea>
<script>
demo.value = "\r\n\r\n";
demo.setRangeText("replaced", 0, 2);
assert(demo.value === "replaced");
</script>
```

If we had operated on the `raw value` of "\r\n\r\n", then we would have replaced the characters "\r\n", ending up with a result of "replaced\n". But since we used the `API value` of "\r\n\r\n", we replaced the characters "\r\n", giving "replaced".

Whenever the `relevant value` changes for an element to which these APIs apply, run these steps:

1. If the element has a `selection`:
 1. If the start of the selection is now past the end of the `relevant value`, set it to the end of the `relevant value`.
 2. If the end of the selection is now past the end of the `relevant value`, set it to the end of the `relevant value`.
 3. If the user agent does not support empty selection, and both the start and end of the selection are now pointing to the end of the `relevant value`, then instead set the element's `text entry cursor position` to the end of the `relevant value`, removing any selection.
2. Otherwise, the element must have a `text entry cursor position`. If it is now past the end of the `relevant value`, set it to the end of the `relevant value`.

Note

In some cases where the `relevant value` changes, other parts of the specification will also modify the `text entry cursor position`, beyond just the clamping steps above. For example, see the `value` setter for `textareas`.

Characters with no visible rendering, such as U+200D ZERO WIDTH JOINER, still count as characters. Thus, for instance, the selection can include just an invisible character, and the text insertion cursor can be placed to one side or another of such a character.

Where possible, user interface features for changing the `text selection` in `input` and `textareas` elements must be implemented using the `set the selection range` algorithm so that, e.g., all the same events fire.

The `selections` of `input` and `textareas` elements have a `selection direction`, which is either "forward", "backward", or "none". The exact meaning of the selection direction depends on the platform. This direction is set when the user manipulates the selection. The initial `selection direction` must be "none" if the platform supports that direction, or "forward" otherwise.

To set the `selection direction` of an element to a given direction, update the element's `selection direction` to the given direction, unless the direction is "none" and the platform does not support that direction; in that case, update the element's `selection direction` to "forward".

Note

On Windows, the direction indicates the position of the caret relative to the selection: a "forward" selection has the caret at the end of the selection and a "backward" selection has the caret at the start of the selection. Windows has no "none" direction.

On Mac, the direction indicates which end of the selection is affected when the user adjusts the size of the selection using the arrow keys with the Shift modifier: the "forward" direction means the end of the selection is modified, and the "backward" direction means the start of the selection is modified. The "none" direction is the default on Mac, it indicates that no particular direction has yet been selected. The user sets the direction implicitly when first adjusting the selection, based on which directional arrow key was used.

MDN

HTMLInputElement/select

The `select()` method, when invoked, must run the following steps:

1. If this element is an `input` element, and either `selection` `does not apply` to this element or the corresponding control has no selectable text, return.
2. Set the `selection range` with 0 and infinity.

The `selectionStart` attribute's getter must run the following steps:

1. If this element is an `input` element, and `selectionStart` `does not apply` to this element, return null.
2. If there is no `selection`, return the offset (in logical order) within the `relevant value` to the character that immediately follows the `text entry cursor`.
3. Return the offset (in logical order) within the `relevant value` to the character that immediately follows the start of the `selection`.

The `selectionStart` attribute's setter must run the following steps:

1. If this element is an `input` element, and `selectionStart` `does not apply` to this element, throw an `"invalidStateError"` `DOMException`.
2. Let `end` be the value of this element's `selectionEnd` attribute.
3. If `end` is less than the given value, set `end` to the given value.
4. Set the `selection range` with the given value, `end`, and the value of this element's `selectionDirection` attribute.

The `selectionEnd` attribute's getter must run the following steps:

1. If this element is an `input` element, and `selectionEnd` `does not apply` to this element, return null.
2. If there is no `selection`, return the offset (in logical order) within the `relevant value` to the character that immediately follows the `text entry cursor`.
3. Return the offset (in logical order) within the `relevant value` to the character that immediately follows the end of the `selection`.

The `selectionEnd` attribute's setter must run the following steps:

1. If this element is an `input` element, and `selectionEnd` `does not apply` to this element, throw an `"invalidStateError"` `DOMException`.
2. Set the `selection range` with the value of this element's `selectionStart` attribute, the value of this element's `selectionEnd` attribute, and the given value.

MDN

HTMLInputElement/setSelectionRange

Support in all current engines.

Firefox 1+Safari 3+Chrome 1+

Opera 8+Edge 79+

Edge (Legacy) 12+Internet Explorer 9+

Firefox Android 4+Safari iOS 1+Chrome Android 18+WebView Android 1+Samsung Internet 1.0+Opera Android 10.1+

The `setSelectionRange(start, end, direction)` method, when invoked, must run the following steps:

Support: input-selectionChrome for Android 81+Chrome 4+iOS Safari 4.0+Firefox 2+Samsung Internet 4+Edge 12+UC Browser for Android 12.12+IE 9+Opera 10.6+Opera Mini NoneFirefox for Android 68+

Source: caniuse.com

1. If this element is an `input` element, and `setSelectionRange()` `does not apply` to this element, throw an `"invalidStateError"` `DOMException`.
2. Set the `selection range` with `start`, `end`, and `direction`.

To set the `selection range` with an integer or null `start`, an integer or null or the special value `infinity` `end`, and optionally a string `direction`, run the following steps:

1. If `start` is null, let `start` be zero.
2. If `end` is null, let `end` be zero.
3. Set the `selection` of the text control to the sequence of characters within the `relevant value` starting with the character at the `start` position (in logical order) and ending with the character at the `(end-1)` position. Arguments greater than the length of the `relevant value` of the text control (including the special value `infinity`) must be treated as pointing at the end of the text control. If `end` is less than or equal to `start` then the start of the selection and the end of the selection must both be placed immediately before the character with offset `end`. In UAs where there is no concept of an empty selection, this must set the cursor to be just before the character with offset `end`.
4. If `direction` is not a `case-sensitive` match for either the string "backward" or "forward", or if the `direction` argument was omitted, set `direction` to "none".
5. Set the `selection direction` of the text control to `direction`.
6. If the previous steps caused the `selection` of the text control to be modified (in either extent or `direction`), then queue a task, using the `user interaction task source`, to fire an event named `select` at the element, with the `bubbles` attribute initialized to true.

MDN

HTMLInputElement/setRangeText

Support in all current engines.

Firefox 27+Safari 1+Chrome 24+

OperaYesEdge 79+

Edge (Legacy)NoInternet Explorer No

Firefox AndroidYesSafari iOS7+Chrome Android 25+WebView AndroidYesSamsung InternetYesOpera AndroidYes

The `setRangeText(replacement, start, end, selectMode)` method, when invoked, must run the following steps:

1. If this element is an `input` element, and `setRangeText()` `does not apply` to this element, throw an `"invalidStateError"` `DOMException`.
2. Set this element's `dirtyValue flag` to true.
3. If the method has only one argument, then let `start` and `end` have the values of the `selectionStart` attribute and the `selectionEnd` attribute respectively.

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Otherwise, let *start*, *end* have the values of the second and third arguments respectively.

4. If *start* is greater than *end*, then throw an `"IndexSizeError"` `DOMException`.
5. If *start* is greater than the length of the `relevantValue` of the text control, then set it to the length of the `relevantValue` of the text control.
6. If *end* is greater than the length of the `relevantValue` of the text control, then set it to the length of the `relevantValue` of the text control.
7. Let `selection start` be the current value of the `selectionStart` attribute.
8. Let `selection end` be the current value of the `selectionEnd` attribute.
9. If *start* is less than *end*, delete the sequence of characters within the element's `relevantValue` starting with the character at the *start*th position (in logical order) and ending with the character at the *(end-1)*th position.
10. Insert the value of the first argument into the text of the `relevantValue` of the text control, immediately before the *start* character.
11. Let *new length* be the length of the value of the first argument.
12. Let *new end* be the sum of *start* and *new length*.
13. Run the appropriate set of substeps from the following list:

If the fourth argument's value is `"select"`

Let `selection start` be *start*.

Let `selection end` be *new end*.

If the fourth argument's value is `"start"`

Let `selection start` and `selection end` be *start*.

If the fourth argument's value is `"end"`

Let `selection start` and `selection end` be *new end*.

If the fourth argument's value is `"preserve"`

If the method has only one argument:

1. Let *old length* be *end* minus *start*.

2. Let *delta* be *new length* minus *old length*.

3. If `selection start` is greater than *end*, then increment it by *delta*. (If *delta* is negative, i.e. the new text is shorter than the old text, then this will decrease the value of `selection start`.)

Otherwise: if `selection start` is greater than *start*, then set it to *start*. (This snaps the start of the selection to the start of the new text if it was in the middle of the text that it replaced.)

4. If `selection end` is greater than *end*, then increment it by *delta* in the same way.

Otherwise: if `selection end` is greater than *start*, then set it to *new end*. (This snaps the end of the selection to the end of the new text if it was in the middle of the text that it replaced.)

14. Set the selection range with selection start and selection end.

The `setRangeText()` method uses the following enumeration:

```
enum SelectionMode {
  "Select",
  "SelectAll",
  "None",
  "Preserve" // default
};
```

Example

To obtain the currently selected text, the following JavaScript suffices:

```
var selectionText = control.value.substring(control.selectionStart, control.selectionEnd);
...where control is the input or textarea element;
```

Example

To add some text at the start of a text control, while maintaining the text selection, the three attributes must be preserved:

```
var oldStart = control.selectionStart;
var oldEnd = control.selectionEnd;
var oldDirection = control.selectionDirection;
var prefix = "http://";
control.value = prefix + control.value;
control.setSelectionRange(oldStart + prefix.length, oldEnd + prefix.length, oldDirection);
...where control is the input or textarea element.
```

4.10.20 Constraints

4.10.20.1 Definitions

A `submittable element` is a candidate for constraint validation except when a condition has barred the element from constraint validation. (For example, an element is `banned from constraint validation` if it is an `object` element.)

An element can have a `custom validity error message` defined. Initially, an element must have its `customValidity.errorMessage` set to the empty string. When its value is not the empty string, the element is `suffering from a custom error`. It can be set using the `getCustomValidity()` method, except for `form-associated custom elements`. Form-associated custom elements can have a `custom validity error message` set via their `ElementInternals`'s `setValidity()` method. The user agent should use the `customValidity.errorMessage` when alerting the user to the problem with the control.

An element can be constrained in various ways. The following is the list of `validity` states that a form control can be in, making the control invalid for the purposes of constraint validation. (The definitions below are non-normative; other parts of this specification define more precisely when each state applies or does not.)

Suffering from being missing

When a control has no `value` but has a `required` attribute (`input required`, `textarea required`); or, more complicated rules for `select` elements and controls in `radio button groups`, as specified in their sections.

When the `getValidity()` method sets `valueMissing` flag to true for a `form-associated custom element`.

Suffering from a type mismatch

When a control that allows arbitrary user input has a `value` that is not in the correct syntax (`E-mail`, `URL`).

When the `getValidity()` method sets `typeMismatch` flag to true for a `form-associated custom element`.

Suffering from a pattern mismatch

When a control has a `value` that doesn't satisfy the `pattern` attribute.

When the `getValidity()` method sets `patternMismatch` flag to true for a `form-associated custom element`.

Suffering from being too long

When a control has a `value` that is too long for the `form control maxlen attribute` (`input maxlength`, `textarea maxlength`).

When the `getValidity()` method sets `tooLong` flag to true for a `form-associated custom element`.

Suffering from being too short

When a control has a `value` that is too short for the `form control minlength attribute` (`input minlength`, `textarea minlength`).

When the `getValidity()` method sets `tooShort` flag to true for a `form-associated custom element`.

Suffering from an underflow

When a control has a `value` that is not the empty string and is too low for the `min` attribute.

When the `getValidity()` method sets `rangeUnderflow` flag to true for a `form-associated custom element`.

Suffering from a step mismatch

When a control has a `value` that doesn't fit the rules given by the `step` attribute.

When the `getValidity()` method sets `stepMismatch` flag to true for a `form-associated custom element`.

Suffering from bad input

When a control has incomplete input and the user agent does not think the user ought to be able to submit the form in its current state.

When the `getValidity()` method sets `badInput` flag to true for a `form-associated custom element`.

Suffering from a custom error

When a control's `customValidity.errorMessage` (as set by the element's `setCustomValidity()` method or `ElementInternals`'s `setValidity()` method) is not the empty string.

Note

An element can still suffer from these states even when the element is `disabled`; thus these states can be represented in the DOM even if validating the form during submission wouldn't indicate a problem to the user.

An element satisfies its constraints if it is not suffering from any of the above `validity states`.

4.10.20.2 Constraint validation

When the user agent is required to statically validate the constraints of `form` element `form`, it must run the following steps, which return either a `positive result` (all the controls in the form are valid) or a `negative result` (there are invalid controls) along with a (possibly empty) list of elements that are invalid and for which no script has claimed responsibility:

1. Let `controls` be a list of all the `submittable elements` whose `form owner` is `form`, in `tree order`.

2. Let `invalid controls` be an initially empty list of elements.

3. For each element `field` in `controls`, in `tree order`:

1. If `field` is not a `candidate for constraint validation`, then move on to the next element.

2. Otherwise, if `field satisfies its constraints`, then move on to the next element.

3. Otherwise, add `field` to `invalid controls`.

4. If `invalid controls` is empty, then return a `positive result`.

5. Let `unhandled invalid controls` be an initially empty list of elements.

1. Let `notCanceled` be the result of [firing an event](#) named `invalid` at `field`, with the `cancelable` attribute initialized to true.
 2. If `notCanceled` is true, then add `field` to `unhandled invalid controls`.
 7. Return a *negative* result with the list of elements in the `unhandled invalid controls` list.

If a user agent is to [interactively validate the constraints](#) of `form`, then the user agent must run the following steps:

1. [Statically validate the constraints](#) of `form` and let `unhandled invalid controls` be the list of elements returned if the result was *negative*.
2. If the result was *positive*, then return that result.
3. Report the problem with the constraints of at least one of the elements given in `unhandled invalid controls` to the user.
 - User agents may focus one of those elements in the process, by running the [focusing steps](#) for that element, and may change the scrolling position of the document, or perform some other action that brings the element to the user's attention. For elements that are [form-associated custom elements](#), user agents should use their [validation anchor](#) instead, for the purposes of these actions.
 - User agents may report more than one constraint violation.
 - User agents may coalesce related constraint violation reports if appropriate (e.g. if multiple radio buttons in a `group` are marked as required, only one error need be reported).
 - If one of the controls is not [being rendered](#) (e.g. it has the `hidden` attribute set) then user agents may report a script error.
4. Return a *negative* result.

4.10.20.3 The constraint validation API

For web developers (non-normative)

`element.willValidate`

Returns true if the element will be validated when the form is submitted; false otherwise.

`element.setCustomValidity(message)`

Sets a custom error, so that the element would fail to validate. The given message is the message to be shown to the user when reporting the problem to the user.

If the argument is the empty string, clears the custom error.

`element.validity.valueMissing`

Returns true if the element has no value but is a required field; false otherwise.

`element.validity.typeMismatch`

Returns true if the element's value is not in the correct syntax; false otherwise.

`element.validity.patternMismatch`

Returns true if the element's value doesn't match the provided pattern; false otherwise.

`element.validity.tooLong`

Returns true if the element's value is longer than the provided maximum length; false otherwise.

`element.validity.tooShort`

Returns true if the element's value, if it is not the empty string, is shorter than the provided minimum length; false otherwise.

`element.validity.rangeUnderflow`

Returns true if the element's value is lower than the provided minimum; false otherwise.

`element.validity.rangeOverflow`

Returns true if the element's value is higher than the provided maximum; false otherwise.

`element.validity.stepMismatch`Returns true if the element's value doesn't fit the rules given by the `step` attribute; false otherwise.`element.validity.badInput`

Returns true if the user has provided input in the user interface that the user agent is unable to convert to a value; false otherwise.

`element.validity.customError`

Returns true if the element has a custom error; false otherwise.

`element.validity.valid`

Returns true if the element's value has no validity problems; false otherwise.

`valid = element.checkValidity()`Returns true if the element's value has no validity problems; false otherwise. Fires an `invalid` event at the element in the latter case.`valid = element.reportValidity()`Returns true if the element's value has no validity problems; otherwise, returns false, fires an `invalid` event at the element, and (if the event isn't canceled) reports the problem to the user.`element.validationMessage`

Returns the error message that would be shown to the user if the element was to be checked for validity.

The `setCustomValidity(message)` method, when invoked, must set the `custom validity error message` to message.**Example**In the following example, a script checks the value of a form control each time it is edited, and whenever it is not a valid value, uses the `setCustomValidity()` method to set an appropriate message.

```
<label>Feeling: <input name=f type="text" oninput="check(this)"></label>
function check(input) {
  if (input.value == "good" || input.value == "great") {
    input.value = "tired";
    input.setCustomValidity("'" + input.value + "' is not a feeling.");
  } else {
    // input is fine - reset the error message
    input.setCustomValidity("");
  }
}
```

Firefox, Android 44+, Safari, iOS, Chrome, Android 46+, WebView, Android 46+, Samsung Internet 5.0+, Opera, Android Yes

The `validationMessage` attribute's getter must run these steps:

1. If this element is not a [candidate for constraint validation](#) or if this element [satisfies its constraints](#), then return the empty string.
2. Return a suitably localized message that the user agent would show the user if this were the only form control with a validity constraint problem. If the user agent would not actually show a textual message in such a situation (e.g., it would show a graphical cue instead), then return a suitably localized message that expresses (one or more of) the validity constraint(s) that the control does not satisfy. If the element is a [candidate for constraint validation](#) and is [suffering from a custom error](#), then the `customValidityError message` should be present in the return value.

4.10.20.4 Security

Servers should not rely on client-side validation. Client-side validation can be intentionally bypassed by hostile users, and unintentionally bypassed by users of older user agents or automated tools that do not implement these features. The constraint validation features are only intended to improve the user experience, not to provide any kind of security mechanism.

4.10.21 Form submission

4.10.21.1 Introduction

This section is [non-normative](#).

When a form is submitted, the data in the form is converted into the structure specified by the `enctype`, and then sent to the destination specified by the `action` using the given `method`.

For example, take the following form:

```
<form action="/find.cgi" method="get">
<input type="text" name="t">
<input type="search" name="q">
<input type="submit">
</form>
```

If the user types "in*ts" in the first field and "fur" in the second, and then hits the submit button, then the user agent will load `/find.cgi?t=ts&q=fur`.

On the other hand, consider this form:

```
<form action="/find.cgi" method="post" enctype="multipart/form-data">
<input type="text" name="t">
<input type="search" name="q">
<input type="submit">
</form>
```

Given the same user input, the result on submission is quite different: the user agent instead does an HTTP POST to the given URL, with as the entity body something like the following text:

```
-----KYPFd4jMJBgCavE
Content-Disposition: form-data; name="t"
cats
-----KYPFd4jMJBgCavE
Content-Disposition: form-data; name="q"
fur
-----KYPFd4jMJBgCavE--
```

4.10.21.2 Implicit submission

A `form` element's `default button` is the first `submit button` in `tree order` whose `form owner` is that `form` element.

If the user agent supports letting the user submit a form implicitly (for example, on some platforms hitting the "enter" key while a text control is [focused](#) implicitly submits the form), then doing so for a form, whose `default button` has [activation behavior](#) and is not [disabled](#), must cause the user agent to [fire a click event](#) at that `default button`.

Note

There are pages on the Web that are only usable if there is a way to implicitly submit forms, so user agents are strongly encouraged to support this.

If the form has no `submit button`, then the implicit submission mechanism must do nothing if the form has more than one *field that blocks implicit submission*, and must `submit` the `form` element from the `form` element itself otherwise.

For the purpose of the previous paragraph, an element is a *field that blocks implicit submission* of a `form` element if it is an `input` element whose `form owner` is that `form` element and whose `type` attribute is in one of the following states: [Text](#), [Search](#), [URL](#), [Telephoning](#), [E-mail](#), [Password](#), [Date](#), [Month](#), [Week](#), [Time](#), [Local Date and Time](#), [Number](#).

4.10.21.3 Form submission algorithm

Each `form` element has a `constructing entry list` boolean, initially false.

Each `form` element has a `firing submission events` boolean, initially false.

When a `form` element is `submitted` from an element `submitter` (typically a button), optionally with a `submitted from` `submitter()` method flag set, the user agent must run the following steps:

1. If `form` [cannot navigate](#), then return.
2. If `form`'s `constructing entry list` is true, then return.
3. Let `form document` be `form`'s `node document`.
4. If `form document`'s `active sandboxing flag` set its `sandboxed forms browsing context flag` set, then return.
5. Let `form browsing context` be the `browsing context` of `form document`.
6. If `submitted from` `submitter()` method flag is not set, then:
 1. If `form`'s `firing submission events` is true, then return.
 2. Set `form`'s `firing submission events` to true.
 3. If the `submitter` element's `no-validate state` is false, then [interactively validate the constraints](#) of `form` and examine the result. If the result is negative (i.e., the constraint validation concluded that there were invalid fields and probably informed the user of this), then:
 1. [Fire an event](#) named `invalid` at the `form` element.
 2. Set `form`'s `firing submission events` to false.
 3. Return.
4. Let `submitterButton` be null if `submitter` is `form`. Otherwise, let `submitterButton` be `submitter`.

5. Let `continue` be the result of [firing an event](#) named `submit` at `form` using `submitter`, with the `submitter` attribute initialized to `submitterButton`, the `bubbles` attribute initialized to true, and the `cancelable` attribute initialized to true.

6. Set `form`'s `firing submission events` to false.

7. If `continue` is false, then return.

8. If `form` [cannot navigate](#), then return.

Note
Cannot navigate is run again as dispatching the `submit` event in `constructing the entry list` could have changed the outcome.

7. Let `encoding` be the result of [picking an encoding for the form](#).

8. Let `entry list` be the result of [constructing the entry list](#) with `form`, `submitter`, and `encoding`.

9. If `form` [cannot navigate](#), then return.

Note
Cannot navigate is run again as dispatching the `formdata` event in `constructing the entry list` could have changed the outcome.

10. Let `action` be the `submitter` element's `action`.

11. If `action` is the empty string, let `action` be the `URL` of the `form document`.

12. [Parse the URL](#), `action`, relative to the `submitter` element's `node document`. If this fails, return.

13. Let `parsed action` be the `resulting URL record`.

15. Let `enctype` be the `submitter` element's `enctype`.
16. Let `method` be the `submitter` element's `method`.
17. Let `target` be the `submitter` element's `formtarget` attribute value, if the element is a `submit` button and has such an attribute. Otherwise, let it be the result of `getting an element's target` given `submitter`'s `form owner`.
18. Let `noreferrer` be the result of `getting an element's noreferrer` with `form` and `targetAttributeValue`.
19. Let `target browsing context` and `replace` be the result of applying the [rules for choosing a browsing context](#) using `target`, `form browsing context`, and `noreferrer`.
20. If `target browsing context` is null, then return.
21. If `form` document has not yet `completely loaded` and the `submitted from` `submit()` method flag is set, then set `replace` to true.
22. If the value of `method` is `dialog` then jump to the `submit_dialog` steps.

Otherwise, select the appropriate row in the table below based on the value of `scheme` as given by the first cell of each row. Then, select the appropriate cell on that row based on the value of `method` as given in the first cell of each column. Then, jump to the steps named in that cell and defined below the table.

<code>GET</code>	<code>POST</code>
<code>http</code>	Mutate action URL: Submit as entity body
<code>https</code>	Mutate action URL: Submit as entity body
<code>ftp</code>	Get action URL: Get action URL
<code>javascript</code>	Get action URL: Get action URL
<code>data</code>	Mutate action URL: Get action URL
<code>mailto</code>	Mail with headers: Mail as body

If `scheme` is not one of those listed in this table, then the behavior is not defined by this specification. User agents should, in the absence of another specification defining this, act in a manner analogous to that defined in this specification for similar schemes.

Each `form` element has a `planned navigation`, which is either null or a `task`; when the `form` is first created, its `planned navigation` must be set to null. In the behaviors described below, when the user agent is required to `plan to navigate` to a particular resource `destination`, it must run the following steps:

1. If `destination` is not a `request`, then set `destination` to a new `request` whose `URL` is `destination`.
2. If the `form` element's `link types` include the `noreferrer` keyword, then set `destination`'s `referrer` to "no-referrer".
3. If the `form` has a non-null `planned navigation`, remove it from its `task queue`.
4. Queue an element task on the DOM manipulation task source given the `form` element and the following steps:

1. Set the `form`'s `planned navigation` to null.
2. Navigate target browsing context to `destination`. If `replace` is true, then `target browsing context` must be navigated with `replacement enabled`.

For the purposes of this task, `target browsing context` and `replace` are the variables that were set up when the overall form submission algorithm was run, with their values as they stood when this `planned navigation` was queued.

5. Set the `form`'s `planned navigation` to the just-queued `task`.

The behaviors are as follows:

Mutate action URL

Let `query` be the result of running the `application/x-www-form-urlencoded serializer` with `entry list` and `encoding`.

Set `parsed action's query` component to `query`.

[Plan to navigate](#) to `parsed action`.

Submit as entity body

Switch on `enctype`:

`application/x-www-form-urlencoded`

Let `body` be the result of running the `application/x-www-form-urlencoded serializer` with `entry list` and `encoding`.

Set `body` to the result of `encoding` `body`.

Let `MIME type` be "`application/x-www-form-urlencoded`".

`multipart/form-data`

Let `body` be the result of running the `multipart/form-data encoding algorithm` with `entry list` and `encoding`.

Let `MIME type` be the concatenation of the string "`multipart/form-data`", a U+0020 SPACE character, the string "`boundary`", and the `multipart/form-data boundary` string generated by the `multipart/form-data encoding algorithm`.

`text/plain`

Let `body` be the result of running the `text/plain encoding algorithm` with `entry list`.

Set `body` to the result of `encoding` `body` using `encoding`.

Let `MIME type` be "`text/plain`".

[Plan to navigate](#) to a new `request` whose `url` is `parsed action`, `method` is `method`, `header list` consists of "`Content-Type`/`MIME type`", and `body` is `body`.

Get action URL

[Plan to navigate](#) to `parsed action`.

Note

`entry list` is discarded.

Mail with headers

Let `headers` be the result of running the `application/x-www-form-urlencoded serializer` with `entry list` and `encoding`.

Replace occurrences of U+002B PLUS SIGN characters (+) in `headers` with the string "%20".

Set `parsed action's query` to `headers`.

[Plan to navigate](#) to `parsed action`.

Mail as body

Switch on `enctype`:

`text/plain`

Let `body` be the result of running the `text/plain encoding algorithm` with `entry list`.

Set `body` to the result of concatenating the result of `UTF-8 percent encoding` each code point in `body`, using the `default encode set` [URL].

Otherwise

Let `body` be the result of running the `application/x-www-form-urlencoded serializer` with `entry list` and `encoding`.

If `parsed action's query` is null, then set it to the empty string.

If `parsed action's query` is not the empty string, then append a single U+0026 AMPERSAND character (&) to it.

Append "`body`" to `parsed action's query`.

Append `body` to `parsed action's query`.

[Plan to navigate](#) to `parsed action`.

Submit dialog

Let `subject` be the nearest ancestor `dialog` element of `form`, if any.

If there isn't one, or if it does not have an `open` attribute, do nothing. Otherwise, proceed as follows:

If `submitter` is an `input` element whose `type` attribute is in the `Image Button` state, then let `result` be the string formed by concatenating the `selected coordinate`'s `x`-component, expressed as a base-ten number using `ASCII digits`, a U+002C COMMA character (,), and the `selected coordinate`'s `y`-component, expressed in the same way as the `x`-component.

Otherwise, if `submitter` has a `value`, then let `result` be that `value`.

Otherwise, there is no `result`.

Then, `close the dialog` `subject`. If there is a `result`, let that be the return value.

4.10.21.4 Constructing the entry list

The algorithm to construct the `entry list` given a `form`, an optional `submitter`, and an optional `encoding`, is as follows. If not specified otherwise, `submitter` is null.

1. If `form`'s `constructing entry list` is true, then return null.
2. Set `form`'s `constructing entry list` to true.
3. Let `controls` be a list of all the `submittable elements` whose `form owner` is `form`, in `tree order`.
4. Let `entry list` be a new empty `list` of `entries`.
5. For each element `field` in `controls`, in `tree order`:

1. If any of the following is true:
 - The `field` element has a `submit` element ancestor.
 - The `field` element is `disabled`.
 - The `field` element is a `button` but it is not `submitter`.
 - The `field` element is an `input` element whose `type` attribute is in the `Checkbox` state and whose `checkedness` is false.
 - The `field` element is an `input` element whose `type` attribute is in the `Radio Button` state and whose `checkedness` is false.
 - The `field` element is an `object` element that is not using a `plugin`.

Then continue.

2. If the `field` element is an `input` element whose `type` attribute is in the `Image Button` state, then:
 1. If the `field` element has a `name` attribute specified and its value is not the empty string, let `name` be that value followed by a single U+002E FULL STOP character (.). Otherwise, let `name` be the empty string.
 2. Let `namex` be the string consisting of the concatenation of `name` and a single U+0078 LATIN SMALL LETTER X character (x).
 3. Let `namey` be the string consisting of the concatenation of `name` and a single U+0079 LATIN SMALL LETTER Y character (y).

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

5. [Append an entry](#) to `entry list` with `namex` and `x`.
6. [Append an entry](#) to `entry list` with `namey` and `y`.
7. Continue.
3. If the `field` is a [form-associated custom element](#), then perform the [entry construction algorithm](#) given `field` and `entry list`, then [continue](#).
4. If either the `field` element does not have a `name` attribute specified, or its `name` attribute's value is the empty string, then [continue](#).
5. Let `name` be the value of the `field` element's `name` attribute.
6. If the `field` element is a `select` element, then for each `option` element in the `select` element's `list of options` whose `selectedness` is true and that is not `disabled`, [append an entry](#) to `entry list` with `name` and the `value` of the `option` element.
7. Otherwise, if the `field` element is an `input` element whose `type` attribute is in the `Checkbox` state or the `Radio Button` state, then:
 1. If the `field` element has a `value` attribute specified, then let `value` be the value of that attribute; otherwise, let `value` be the string "`on`".
 2. [Append an entry](#) to `entry list` with `name` and `value`.
8. Otherwise, if the `field` element is an `input` element whose `type` attribute is in the `File Upload` state, then:
 1. If there are no `selected files`, then [append an entry](#) to `entry list` with `name` and a new `File` object with an empty name, `application/octet-stream` as type, and an empty body.
 2. Otherwise, for each file in `selected files`, [append an entry](#) to `entry list` with `name` and a `File` object representing the file.
9. Otherwise, if the `field` element is an `object` element: try to obtain a form submission value from the `value`, and if that is successful, [append an entry](#) to `entry list` with `name` and the returned form submission value.
10. Otherwise, if the `field` element is an `input` element whose `type` attribute is in the `Hidden` state and `name` is "`charset`".
 1. Let `charset` be the `name` of `encoding` if `encoding` is given, and "`UTF-8`" otherwise.
 2. [Append an entry](#) to `entry list` with `name` and `charset`.
11. Otherwise, if the `field` element is a `textarea` element, [append an entry](#) to `entry list` with `name` and the `value` of the `field` element, and the `prevent line break normalization flag` set.

Note
In the case of the `value` of `textarea` elements, the line break normalization is already performed during the conversion of the control's `raw value` into the control's `value` (which also performs any necessary line wrapping).
12. Otherwise, [append an entry](#) to `entry list` with `name` and the `value` of the `field` element.
13. If the element has a `dirname` attribute, and that attribute's value is not the empty string, then:
 1. Let `dirname` be the value of the element's `dirname` attribute.
 2. Let `dir` be the string "`ltr`" if the `directionality` of the element is "`ltr`", and "`rtl`" otherwise (i.e., when the `directionality` of the element is "`rl`").
 3. [Append an entry](#) to `entry list` with `dirname` and `dir`.

Note
An element can only have a `dirname` attribute if it is a `textarea` element or an `input` element whose `type` attribute is in either the `Text` state or the `Search` state.

6. Let `form data` be a new `FormData` object associated with `entry list`.

7. [Fire an event](#) named `formdata` at `form` using `FormDataEvent`, with the `formData` attribute initialized to `form data` and the `bubbles` attribute initialized to true.

8. Set `form`'s `constructingEntryList` to false.

9. Return a `clone` of `entry list`.

To append an entry to `entry list`, given `name`, `value`, and optional `prevent line break normalization flag`, run these steps:

1. For `name`, replace every occurrence of U+000D (CR) not followed by U+000A (LF), and every occurrence of U+000A (LF) not preceded by U+000D (CR), by a string consisting of a U+000D (CR) and U+000A (LF).
2. Replace `name` with the result of [converting to a sequence of Unicode scalar values](#).
3. If `value` is not a `File` object, then:
 1. If the `prevent line break normalization flag` is unset, then replace every occurrence of U+000D (CR) not followed by U+000A (LF), and every occurrence of U+000A (LF) not preceded by U+000D (CR) in `value`, by a string consisting of a U+000D (CR) and U+000A (LF).
 2. Replace `value` with the result of [converting to a sequence of Unicode scalar values](#).
4. [Create an entry](#) with `name` and `value`, and [append](#) it to `entry list`.

4.10.21.5 Selecting a form submission encoding

If the user agent is to [pick an encoding](#) for a `form`, it must run the following steps:

1. Let `encoding` be the `document's character encoding`.
2. If the `form` element has an `accept-charset` attribute, set `encoding` to the return value of running these substeps:
 1. Let `input` be the value of the `form` element's `accept-charset` attribute.
 2. Let `candidate encoding labels` be the result of [splitting input on ASCII whitespace](#).
 3. Let `candidate encodings` be an empty list of `character encodings`.
 4. For each token in `candidate encoding labels` in turn (in the order in which they were found in `input`), [get an encoding](#) for the token and, if this does not result in failure, append the `encoding` to `candidate encodings`.
 5. If `candidate encoding` is empty, return `UTF-8`.
 6. Return the first encoding in `candidate encodings`.
3. Return the result of [getting an output encoding](#) from `encoding`.

4.10.21.6 URL-encoded form data

See `URL` for details on [application/x-www-form-urlencoded](#) [URL].

4.10.21.7 Multipart form data

The `multipart/form-data` encoding algorithm, given an `entry list` and `encoding`, is as follows:

1. Let `result` be the empty string.
2. For each `entry` in `entry list`:
 1. For each character in the entry's `name` and `value` that cannot be expressed using the selected character encoding, replace the character by a string consisting of a U+0026 AMPERSAND character (&), a U+0023 NUMBER SIGN character (#), one or more `ASCII digits` representing the code point of the character in base ten, and finally a U+003B (.)
3. Encode the (now mutated) `entry list` using the rules described by RFC 7578, *Returning Values from Forms: multipart/form-data*, and return the resulting byte stream. [RFC7578]

Each entry in `entry list` is a `field`, the name of the entry is the `field name` and the value of the entry is the `field value`.

The order of parts must be the same as the order of fields in `entry list`. Multiple entries with the same name must be treated as distinct fields.

The parts of the generated `multipart/form-data` resource that correspond to non-file fields must not have a `Content-Type` header specified. Their names and values must be encoded using the character encoding selected above.

File names included in the generated `multipart/form-data` resource (as part of file fields) must use the character encoding selected above, though the precise name may be approximated if necessary (e.g. newlines could be removed from file names, quotes could be changed to "%22", and characters not expressible in the selected character encoding could be replaced by other characters).

The boundary used by the user agent in generating the return value of this algorithm is the `multipart/form-data boundary string`. (This value is used to generate the MIME type of the form submission payload generated by this algorithm.)

For details on how to interpret `multipart/form-data` payloads, see RFC 7578. [RFC7578]

4.10.21.8 Plain text form data

The `text/plain` encoding algorithm, given an `entry list`, is as follows:

1. Let `result` be the empty string.
2. For each `entry` in `entry list`:
 1. If the entry's value is a `File` object, then set its value to the `file` object's `name`.
 2. Append the entry's name to `result`.
 3. Append a single U+003D EQUALS SIGN character (=) to `result`.
 4. Append the entry's value to `result`.
 5. Append a U+000D CARRIAGE RETURN (CR) U+000A LINE FEED (LF) character pair to `result`.
3. Return `result`.

Payloads using the `text/plain` format are intended to be human readable. They are not reliably interpretable by computer, as the format is ambiguous (for example, there is no way to distinguish a literal newline in a value from the newline at the end of the value).

4.10.21.9 The `submitEvent` interface

Categories:[Flow content](#)[Sectioning root](#)[Interactive content](#)[Pointable content](#)**Content where this element can be used:**Where [flow content](#) is expected.**Content model:**One [summary](#) element followed by [flow content](#).**Tax omission in text/html:**The `</>` tag is omitted.**Content attributes:**[Global attributes](#)`open` — Whether the details are visible**Accessibility considerations:**[For authors](#)[For implementers](#)[DOM interface](#)

```
IDL([Exposed=Window])  
interface HTMLOpenDetailsElement : HTMLElement {  
  [HTMLConstruction] constructor();  
  [CRActions] attribute boolean open;  
};
```

The `details` element [represents](#) a disclosure widget from which the user can obtain additional information or controls.**Note**The `details` element is not appropriate for footnotes. Please see the [section on footnotes](#) for details on how to mark up footnotes.The first `summary` element child of the element, if any, [represents](#) the summary or legend of the details. If there is no child `summary` element, the user agent should provide its own legend (e.g. "Details").The rest of the element's contents [represents](#) the additional information or controls.The `open` content attribute is a [boolean attribute](#). If present, it indicates that both the summary and the additional information is to be shown to the user. If the attribute is absent, only the summary is to be shown.

When the element is created, if the attribute is absent, the additional information should be hidden; if the attribute is present, that information should be shown. Subsequently, if the attribute is removed, then the information should be hidden; if the attribute is added, the information should be shown.

The user agent should allow the user to request that the additional information be shown or hidden. To honor a request for the details to be shown, the user agent must [set](#) the `open` attribute on the element to the empty string. To honor a request for the information to be hidden, the user agent must [remove](#) the `open` attribute from the element.**Note**
This ability to request that additional information be shown or hidden may simply be the [activation behavior](#) of the appropriate `summary` element, in the case such an element exists. However, if no such element exists, user agents can still provide this ability through some other user interface affordance.

1. If another `task` has been `queued` to run the `details notification task steps` for this `details` element, then return.

Note

When the `open` attribute is toggled several times in succession, these steps essentially get coalesced so that only one event is fired.

2. **Fire an event** named `popup` at the `details` element.

The `task source` for this task must be the `DOM manipulation task source`.

The `open` IDL attribute must `reflect` the `open` content attribute.

Example

The following example shows the `details` element being used to hide technical details in a progress report.

```
<section class="progress window">
<h1>Copying "Really Achieving Your Childhood Dreams"</h1>
<summary>Copying... <progress max="375505392" value="97543282">25%</summary>
<div>
  <dt><Transfer state></dt> <dd>512KB/s</dd>
  <dt><Local filename></dt> <dd>/home/rpausch/raycd.m4v</dd>
  <dt><Remote filename></dt> <dd>/www/lectures/raycd.m4v</dd>
  <dt><Duration></dt> <dd>00:01:18.275</dd>
  <dt><Color profile></dt> <dd>SD (6=1)</dd>
  <dt><Dimensions></dt> <dd>320x240</dd>
</div>
</details>
</section>
```

Example

The following shows how a `details` element can be used to hide some controls by default:

```
<details>
  <summary><label for="fnName & Extension"></label></summary>
  <input type="text" id="fn" value="Pillar Magazine.pdf">
  <label><input type="checkbox" name="ext checked"> Hide extension</label>
</details>
```

One could use this in conjunction with other `details` in a list to allow the user to collapse a set of fields down to a small set of headings, with the ability to open each one.

In these examples, the summary really just summarizes what the controls can change, and not the actual values, which is less than ideal.

Example

Because the `open` attribute is added and removed automatically as the user interacts with the control, it can be used in CSS to style the element differently based on its state. Here, a style sheet is used to animate the color of the summary when the element is opened or closed:

```
<style>
  details > summary { transition: color 1s; color: black; }
  details[open] > summary { color: red; }
</style>
<details>
  <summary>Automated Status: Operational</summary>
  <p>Velocity: 12m/s</p>
  <p>Location: North</p>
</details>
```

4.11.2 The `summary` element**MDN****Element/summary**

Categories:

Contexts in which this element can be used:

As the first child of a `details` element.

Content model:

Either: `phrasing content`.

Or: one element of `heading content`.

Tag omission in text/html:

The `summary` tag is omitted.

Content attributes:

Global attributes:

For authors:

For implementers:

DOM interface:

Uses `HTMLElement`.

The `summary` element **represents** a summary, caption, or legend for the rest of the contents of the `summary` element's parent `details` element, if any.

A `summary` element is a *summary for its parent details* if the following algorithm returns true:

- If this `summary` element has no parent, then return false.
- Let `parent` be this `summary` element's parent.
- If `parent` is not a `details` element, then return false.
- If `parent`'s first `summary` element child is not this `summary` element, then return false.
- Return true.

The **activation behavior** of `summary` elements is to run the following steps:

- If this `summary` element is not the `summary for its parent details`, then return.
- Let `parent` be this `summary` element's parent.
- If the `open` attribute is present on `parent`, then `remove` it. Otherwise, set `parent`'s `open` attribute to the empty string.

Note

This will then run the `details notification task steps`.

4.11.3 Commands**4.11.3.1 Facts**

A **command** is the abstraction behind menu items, buttons, and links. Once a command is defined, other parts of the interface can refer to the same command, allowing many access points to a single feature to share facets such as the `Disabled State`.

Commands are defined to have the following *facets*:

Label

The name of the command as seen by the user.

Access Key

A key combination selected by the user agent that triggers the command. A command might not have an Access Key.

Hidden State

Whether the command is hidden or not (basically, whether it should be shown in menus).

Disabled State

Whether the command is relevant and can be triggered or not.

Action

The actual effect that triggering the command will have. This could be a scripted event handler, a `URL`, to which to `navigate`, or a form submission.

User agents may expose the `commands` that match the following criteria:

• The `hidden` facet is false (visible)

• THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

- Neither the element nor any of its ancestors has a `hidden` attribute specified.

User agents are encouraged to do this especially for commands that have [Access Keys](#), as a way to advertise those keys to the user.

Example

For example, such commands could be listed in the user agent's menu bar.

4.11.3.2 Using the `a` element to define a command

An `a` element with an `href` attribute [defines a command](#).

The [Label](#) of the command is the element's [descendant text content](#).

The [Access Key](#) of the command is the element's [assigned access key](#), if any.

The [Hidden State](#) of the command is true (hidden) if the element has a `hidden` attribute, and false otherwise.

The [Disabled State](#) facet of the command is true if the element or one of its ancestors is `inert`, and false otherwise.

The [Action](#) of the command is to [fire a click event](#) at the element.

4.11.3.3 Using the `button` element to define a command

A `button` element always [defines a command](#).

The [Label](#), [Access Key](#), [Hidden State](#), and [Action](#) facets of the command are determined [as for a elements](#) (see the previous section).

The [Disabled State](#) of the command is true if the element or one of its ancestors is `inert`, or if the element's `disabled` state is set, and false otherwise.

4.11.3.4 Using the `input` element to define a command

An `input` element whose `type` attribute is in one of the `Submit Button`, `Reset Button`, `Image Button`, `Button`, `Radio Button`, or `Checkbox` states [defines a command](#).

The [Label](#) of the command is determined as follows:

- If the `type` attribute is in one of the `Submit Button`, `Reset Button`, `Image Button`, or `Button` states, then the [Label](#) is the string given by the `value` attribute, if any, and a UA-dependent, locale-dependent value that the UA uses to label the button itself if the attribute is absent.
- Otherwise, if the element is a [labeled control](#), then the [Label](#) is the [descendant text content](#) of the first `label` element in `tree order` whose [labeled control](#) is the element in question. (In JavaScript terms, this is given by `element.labels[0].textContent`.)
- Otherwise, if the `value` attribute is present, then the [Label](#) is the value of that attribute.
- Otherwise, the [Label](#) is the empty string.

Note

Even though the `value` attribute on `input` elements in the `Image Button` state is non-conformant, the attribute can still contribute to the [Label](#) determination, if it is present and the `Image Button`'s `alt` attribute is missing.

The [Access Key](#) of the command is the element's [assigned access key](#), if any.

The [Hidden State](#) of the command is true (hidden) if the element has a `hidden` attribute, and false otherwise.

The [Disabled State](#) of the command is true if the element or one of its ancestors is `inert`, or if the element's `disabled` state is set, and false otherwise.

The [Action](#) of the command is to [fire a click event](#) at the element.

4.11.3.5 Using the `option` element to define a command

An `option` element with an ancestor `select` element and either no `value` attribute or a `value` attribute that is not the empty string [defines a command](#).

The [Label](#) of the command is the value of the `option` element's `label` attribute, if there is one, or else the `option` element's [descendant text content](#), with ASCII whitespace stripped and collapsed.

The [Access Key](#) of the command is the element's [assigned access key](#), if any.

The [Hidden State](#) of the command is true (hidden) if the element has a `hidden` attribute, and false otherwise.

The [Disabled State](#) of the command is true if the element is `disabled`, or if its nearest ancestor `select` element is `disabled`, or if it or one of its ancestors is `inert`, and false otherwise.

If the `option`'s nearest ancestor `select` element has a `multiple` attribute, the [Action](#) of the command is to [toggle](#) the `option` element. Otherwise, the [Action](#) is to [pick](#) the `option` element.

4.11.3.6 Using the `accesskey` attribute on a `legend` element to define a command

A `legend` element [defines a command](#) if all of the following are true:

- It has an [assigned access key](#).
- It is a child of a [fieldset](#) element.
- Its parent has a descendant that [defines a command](#) that is neither a `label` element nor a `legend` element. This element, if it exists, is the `legend` element's [accesskey delegatee](#).

The [Label](#) of the command is the element's [descendant text content](#).

The [Access Key](#) of the command is the element's [assigned access key](#).

The [Hidden State](#), [Disabled State](#), and [Action](#) facets of the command are the same as the respective facets of the `legend` element's [accesskey delegatee](#).

Example

In this example, the `legend` element specifies an `accesskey`, which, when activated, will delegate to the `input` element inside the `legend` element.

```
<fieldset>
  <legend accesskey='p'>
    I want input name=pizza type=number step=1 value=1 min=0
    <input name=toppings value=pizza>
    <input name=toppings value=cheese>
    <input name=toppings value=ham>
    <input name=toppings value=cheese checked> Cheese</label>
    <input name=toppings value=ham checked> Ham</label>
    <input name=toppings value=pineapple checked> Pineapple</label>
  </legend>
</fieldset>
```

4.11.3.7 Using the `accesskey` attribute to define a command on other elements

An element that has an [assigned access key defines a command](#).

If one of the earlier sections that define elements that [define commands](#) define that this element [defines a command](#), then that section applies to this element, and this section does not. Otherwise, this section applies to that element.

The [Label](#) of the command depends on the element. If the element is a [labeled control](#), the [descendant text content](#) of the first `label` element in `tree order` whose [labeled control](#) is the element in question is the [Label](#) (in JavaScript terms, this is given by `element.labels[0].textContent`). Otherwise, the [Label](#) is the element's [descendant text content](#).

The [Access Key](#) of the command is the element's [assigned access key](#).

The [Hidden State](#) of the command is true (hidden) if the element has a `hidden` attribute, and false otherwise.

The [Disabled State](#) of the command is true if the element or one of its ancestors is `inert`, and false otherwise.

The [Action](#) of the command is to run the following steps:

- Run the [focusing step](#) for the element.
- [Fire a click event](#) at the element.

4.11.4 The `dialog` element

For authors

For implementers

DOM interface

```
IDLExposedWindow
interface HTMLDialogElement : HTMLElement
  [HTMLConstructor] constructor();
  attribute boolean open;
```

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

```
[CBReactions] void showModal()
[CBReactions] void close(optional DOMString returnValue)

```

The `dialog` element represents a part of an application that a user interacts with to perform a task, for example a dialog box, inspector, or window.

The `open` attribute is a [boolean attribute](#). When specified, it indicates that the `dialog` element is active and that the user can interact with it.

A `dialog` element without an `open` attribute specified should not be shown to the user. This requirement may be implemented indirectly through the style layer. For example, user agents that [support the suggested default rendering](#) implement this requirement using the CSS rules described in the [rendering section](#).

Note

Removing the `open` attribute will usually hide the dialog. However, doing so has a number of strange additional consequences:

- The `close` event will not be fired.
- The `close()` method, and any [user-agent provided cancellation interface](#), will no longer be able to close the dialog.
- If the dialog was shown using its `showModal()` method, the `document` will still be [blocked](#).

For these reasons, it is generally better to never remove the `open` attribute manually. Instead, use the `close()` method to close the dialog, or the `hidden` attribute to hide it.

The `tabindex` attribute must not be specified on `dialog` elements.

For web developers (non-normative)

`dialog.show()`

Displays the `dialog` element.

`dialog.showModal()`

Displays the `dialog` element and makes it the top-most modal dialog.

This method honors the `autofocus` attribute.

`dialog.close(result)`

Closes the `dialog` element.

The argument, if provided, provides a return value.

`dialog.returnValue [= result]`

Returns the `dialog`'s return value.

Can be set, to update the return value.

MDN

[HTMLDialogElement/show](#)

Firefox 53+ Safari No Chrome 37+

Opera Yes Edge 79+

Edge (Legacy) No Internet Explorer No

Firefox Android 53+ Safari iOS No Chrome Android No WebView Android No Samsung Internet No Opera Android No

When the `show()` method is invoked, the user agent must run the following steps:

1. If the element already has an `open` attribute, then return.
2. Add an `open` attribute to the `dialog` element, whose value is the empty string.
3. Set the `dialog` to the [normal alignment mode](#).
4. Run the [dialog focusing steps](#) for the `dialog` element.

MDN

[HTMLDialogElement/showModal](#)

Firefox 53+ Safari No Chrome 37+

Opera Yes Edge 79+

Edge (Legacy) No Internet Explorer No

Firefox Android 53+ Safari iOS No Chrome Android No WebView Android No Samsung Internet No Opera Android No

When the `showModal()` method is invoked, the user agent must run the following steps:

1. Let `subject` be the `dialog` element on which the method was invoked.
2. If `subject` already has an `open` attribute, then throw an "`InvalidStateError`" `DOMException`.
3. If `subject` is not [connected](#), then throw an "`InvalidStateError`" `DOMException`.
4. Add an `open` attribute to `subject`, whose value is the empty string.
5. Set the `dialog` to the [centered alignment mode](#).
6. Let `subject's node document` be [blocked by the modal dialog subject](#).
7. If `subject's node document's top layer` does not already [contain](#) `subject`, then [add subject to subject's node document's top layer](#).
8. Run the [dialog focusing steps](#) for `subject`.

The [dialog focusing steps](#) for a `dialog` element `subject` are as follows:

1. If `subject` is [inert](#), return.
2. Let `control` be the first descendant element of `subject`, in [tree order](#), that is not [inert](#) and has the `autofocus` attribute specified.
- If there isn't one, then let `control` be the first non-[inert](#) descendant element of `subject`, in tree order.
- If there isn't one of those either, then let `control` be `subject`.
3. Run the [focusing steps](#) for `control`.
4. Let `topDocument` be the [active document](#) of `control's node document's browsing context's top-level browsing context`.
5. If `control's node document's origin` is not the [same](#) as the `origin` of `topDocument`, then return.
6. [Empty topDocument's autofocus candidates](#).
7. Set `topDocument's autofocus processed flag` to true.

If at any time a `dialog` element is [removed from a document](#), then if that `dialog` is in that `document's top layer`, it must be [removed](#) from it.

MDN

[HTMLDialogElement/close](#)

Firefox 53+ Safari No Chrome 37+

Opera Yes Edge 79+

Edge (Legacy) No Internet Explorer No

Firefox Android 53+ Safari iOS No Chrome Android No WebView Android No Samsung Internet No Opera Android No

When the `close()` method is invoked, the user agent must [close the dialog](#) that the method was invoked on. If the method was invoked with an argument, that argument must be used as the return value; otherwise, there is no return value.

When a `dialog` element `subject` is to be [closed](#), optionally with a return value `result`, the user agent must run the following steps:

1. If `subject` does not have an `open` attribute, then return.
2. Remove `subject's open` attribute.
3. If the argument `result` was provided, then set the `returnValue` attribute to the value of `result`.
4. If `subject` is in its `document's top layer`, then [remove](#) it.
5. [Queue a task to fire an event named close at subject](#).

MDN

[HTMLDialogElement/returnValue](#)

Firefox 53+ Safari No Chrome 37+

Opera Yes Edge 79+

Edge (Legacy) No Internet Explorer No

Firefox Android 53+ Safari iOS No Chrome Android No WebView Android No Samsung Internet No Opera Android No

The `returnValue` IDL attribute, on getting, must return the last value to which it was set. On setting, it must be set to the new value. When the element is created, it must be set to the empty string.

Cancelling dialogs: When `document` is [blocked by a modal dialog dialog](#), user agents may provide a user interface that, upon activation, [queues a task](#) to run these steps:

1. Let `close` be the result of [firing an event named cancel at dialog](#), with the `cancelable` attribute initialized to true.
2. If `close` is true and `dialog` has an `open` attribute, then [close the dialog](#) with no return value.

Note

An example of such a UI mechanism would be the user pressing the "Escape" key.

A `dialog` element is in one of two modes: [normal alignment](#) or [centered alignment](#). When a `dialog` element is created, it must be placed in the [normal alignment mode](#). In this mode, normal CSS requirements apply to the element. The [centered alignment mode](#) is only used for `dialog` elements that are in the `top layer`. [\[FULLSCREEN\] \(CSS\)](#)

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

`'bottom' or 'left')`, is the value that would place the element's `margin-edge` on the side that corresponds to `subject`'s parent's `block-start` side as far from the same-side edge of the `viewport` as the element's opposing side `margin-edge` from that same-side edge of the `viewport`; if the element's dimension (`width` or `height`) in `subject`'s parent's `block-flow direction` is the same-axis dimension of the `viewport`, and otherwise is the value that would place the element's `margin-edge` on the side that corresponds to `subject`'s parent's `block-start` side at the same-side edge of the `viewport`.

If there is a `dialog` element with `centered alignment` and that is `being rendered` when its `browsing context` changes `viewport` dimensions (as measured in `CSS pixels`), or when this `dialog` element's parent changes `block flow direction`, then the user agent must recreate the element's boxes, recalculating its edge that corresponds to this `dialog` element's parent's `block-start` edge as in the previous paragraph.

This static position of a `dialog` element's edge with `centered alignment` must remain the element's static position of that edge until its boxes are recreated. (The element's static position is only used in calculating the `used value` of the appropriate box offset property (`top`, `right`, `bottom`, or `left`) in certain situations; it's not used, for instance, to position the element if its `position` property is set to `static`.)

User agents in visual interactive media should allow the user to pan the `viewport` to access all parts of a `dialog` element's `border box`, even if the element is larger than the `viewport` and the `viewport` would otherwise not have a scroll mechanism (e.g. because the `viewport`'s `overflow` property is set to `hidden`).

MDN

[HTMLDialogElement/open](#)

Firefox 53+ Safari/Chrome 37+

Opera/Edge 79+

Edge (Legacy) No Internet Explorer No

Firefox/Android 44+ Safari/iOS Chrome Android No WebView Android No Samsung Internet No Opera Android No

The `open` IDL attribute must `reflect` the `open` content attribute.

Example

This dialog box has some small print. The `strong` element is used to draw the user's attention to the more important part.

```
<dialog>
  <h1>Add to Wallet</h1>
  <p><strong>Label for</strong> How many gold coins do you want to add to your wallet?</label></p>
  <p><input id="coins" name="coins" type="number" min="0" step="1" value="100"/></p>
  <p><input type="checkbox" checked="" value="true"/> Add your own coins</p>
  <p><label><input name="round" type="checkbox"> Only add perfectly round coins </label></p>
  <p><input type="button" onclick="submit()" value="Add Coins"></p>
</dialog>
```

4.12 Scripting

Scripts allow authors to add interactivity to their documents.

Authors are encouraged to use declarative alternatives to scripting where possible, as declarative mechanisms are often more maintainable, and many users disable scripting.

Example

For example, instead of using script to show or hide a section to show more details, the `details` element could be used.

Authors are also encouraged to make their applications degrade gracefully in the absence of scripting support.

Example

For example, if an author provides a link in a table header to dynamically resort the table, the link could also be made to function without scripts by requesting the sorted table from the server.

For authors

For implementers

[DOM interface:](#)

```
IDL Exposed=Window
interface HTMLScriptElement : HTMLElement {
  constructor();
  constructor(script);
}
```

`[also has obsolete members]`

`}`

The `script` element allows authors to include dynamic script and data blocks in their documents. The element does not [present](#) content for the user.

The `type` attribute allows customization of the type of script represented.

`script`

Support: es6-moduleChrome for Android 81+Chrome 61+iOS Safari 11.0+Firefox 60+Samsung Internet 8.2+Edge 16+UC Browser for Android NonIE NoneOpera 48+Opera Mini NoneFirefox for Android 68+

Source: [caniuse.com](#)

- Omitting the attribute, setting it to the empty string, or setting it to a [JavaScript MIME type essence match](#), means that the script is a [classic script](#), to be interpreted according to the JavaScript [Script](#) top-level production. Classic scripts are affected by the `async` and `defer` attributes, but only when the `src` attribute is set. Authors should omit the `type` attribute instead of redundantly setting it.
- Setting the attribute to an ASCII case-insensitive match for the string `"module"` means that the script is a [module script](#), to be interpreted according to the JavaScript [Module](#) top-level production. Module scripts are not affected by the `defer` attribute, but are affected by the `async` attribute (regardless of the state of the `src` attribute).
- Setting the attribute to any other value means that the script is a [data block](#), which is not processed. None of the `script` attributes (except `type` itself) have any effect on data blocks. Authors must use a [valid MIME type string](#) that is not a [JavaScript MIME type essence match](#) to denote data blocks.

[Note](#)

The requirement that `data blocks` must be denoted using a [valid MIME type string](#) is in place to avoid potential future collisions. If this specification ever adds additional types of `script`, they will be triggered by setting the `type` attribute to something which is not a MIME type, like how the `"module"` value denotes [module scripts](#). By using a valid MIME type string now, you ensure that your data block will not ever be reinterpreted as a different script type, even in future user agents.

[Classic script](#) and [module script](#) can be embedded inline, or be imported from an external file using the `src` attribute, which if specified gives the [URL](#) of the external script resource to use. If `src` is specified, it must be a [valid non-empty URL potentially surrounded by spaces](#). The contents of inline `script` elements, or the external script resource, must conform with the requirements of the JavaScript specification's [Script](#) or [Module](#) productions, for [classic scripts](#) and [module scripts](#) respectively. [\[JAVASCRIPT\]](#)

When used to include `data blocks`, the data must be embedded inline, the format of the data must be given using the `type` attribute, and the contents of the `script` element must conform to the requirements defined for the format used. The `src`, `async`, `nonModule`, `defer`, `processOnLoad`, `integrity`, and `referrerpolicy` attributes must not be specified.

The `nonModule` attribute is a [boolean attribute](#) that prevents a script from being executed in user agents that support [module scripts](#). This allows selective execution of [module scripts](#) in modern user agents and [classic scripts](#) in older user agents, as shown below. The `nonModule` attribute must not be specified on [module scripts](#) (and will be ignored if it is).

The `async` and `defer` attributes are [boolean attributes](#) that indicate how the script should be evaluated. [Classic scripts](#) may specify `defer` or `async`, but must not specify either unless the `src` attribute is present. [Module scripts](#) may specify the `async` attribute, but must not specify the `defer` attribute.

`script`

Support: script-deferChrome for Android 81+Chrome 8+iOS Safari 5.0+Safari 5+Firefox 3.5+Samsung Internet 4+Edge 12+UC Browser for Android 12.12+IE 10+Opera 15+Opera Mini NoneFirefox for Android 68+

Source: [caniuse.com](#)

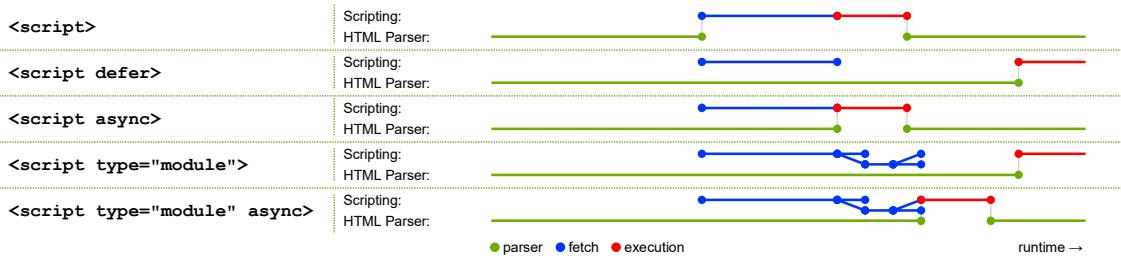

Support: script-asyncChrome for Android 81+Chrome 8+iOS Safari 5.0+Safari 5.1+Firefox 3.6+Samsung Internet 4+Edge 12+UC Browser for Android 12.12+IE 10+Opera 15+Opera Mini NoneFirefox for Android 68+

Source: [caniuse.com](#)

There are several possible modes that can be selected using these attributes, and depending on the script's type.

For `module scripts`, if the `async` attribute is present, then the module script and all its dependencies will be fetched `in parallel` to parsing, and the module script will be evaluated as soon as it is available (potentially before parsing completes). Otherwise, the module script and its dependencies will be fetched `in parallel` to parsing and evaluated when the page has finished parsing. (The `defer` attribute has no effect on module scripts.)

This is all summarized in the following schematic diagram:

Note
The exact processing details for these attributes are, for mostly historical reasons, somewhat non-trivial, involving a number of aspects of HTML. The implementation requirements are therefore by necessity scattered throughout the specification. The algorithms below (in this section) describe the core of this processing, but these algorithms reference and are referred by the parsing rules for `<script>` start and end tags in HTML, in foreign content, and in XML, the rules for the `document.write()` method, the handling of `scripting`, etc.

The `defer` attribute may be specified even if the `async` attribute is specified, to cause legacy Web browsers that only support `defer` (and not `async`) to fall back to the `defer` behavior instead of the blocking behavior that is the default.

The `crossorigin` attribute is a CORS settings attribute. For classic scripts, it controls whether error information will be exposed, when the script is obtained from other origins. For module scripts, it controls the `credentials mode` used for cross-origin requests.

Note

Unlike classic scripts, module scripts require the use of the CORS protocol for cross-origin fetching.

The `integrity` attribute represents the integrity metadata for requests which this element is responsible for. The value is text. The `integrity` attribute must not be specified when the `src` attribute is not specified. [SRI]

The `referrerpolicy` attribute is a referer policy attribute. Its purpose is to set the `referrer policy` used when fetching the script, as well as any scripts imported from it. [REFERRERPOLICY]

Example

An example of a `<script>` element's referer policy being used when fetching imported scripts but not other subresources:

```
<script referrerpolicy="origin">
  import("http://myorigin.com/a.js") // is fetched with <script>'s referer policy ("origin" in this case)
  import("./utils.mjs") // is fetched with <script>'s referer policy ("origin" in this case)
</script>
```

Changing the `src-type`, `nonModule`, `async`, `defer`, `crossorigin`, `integrity`, and `referrerpolicy` attributes dynamically has no direct effect; these attributes are only used at specific times described below.

The IDL attributes `src`, `type`, `defer`, and `integrity`, must each `reflect` the respective content attributes of the same name.

MDN

[HTML ScriptElement/referrerPolicy](#)

Firefox65+ SafariNoChrome70+

OperaYesEdge79+

Edge (Legacy)NoInternet ExplorerNo

FoxAndroid65+Safari iOSNoChrome Android70+WebView Android70+Samsung Internet10.0+Opera AndroidYes

The `referrerPolicy` IDL attribute must `reflect` the `referrerpolicy` content attribute, limited to only known values.

The `crossorigin` IDL attribute must `reflect` the `crossorigin` content attribute, limited to only known values.

The `nonModule` IDL attribute must `reflect` the `nonModule` content attribute.

The `async` IDL attribute controls whether the element will execute asynchronously or not. If the element's "non-blocking" flag is set, then, on getting, the `async` IDL attribute must return true, and on setting, the "non-blocking" flag must first be unset, and then the content attribute must be removed if the IDL attribute's new value is false, and must be set to the empty string if the IDL attribute's new value is true. If the element's "non-blocking" flag is not set, the IDL attribute must `reflect` the `async` content attribute.

For web developers (non-normative)

`script.text = value`

Returns the `childTextContent` of the element.

Can be set to replace the element's children with the given value.

The `text` attribute's getter must return this `<script>` element's `childTextContent`.

The `text` attribute's setter must `stringReplaceAll` with the given value within this `<script>` element.

Note

When inserted using the `document.write()` method, `script` elements usually execute (typically blocking further script execution or HTML parsing). When inserted using the `innerHTML` and `outerHTML` attributes, they do not execute at all.

Example

In this example, two `<script>` elements are used. One embeds an external `classic script`, and the other includes some data as a `data block`.

```
<script src="game-engine.js"></script>
<script type="text/x-game-map">
  .....
  U.....
  o.....
  A.....
  .
  .
  J.A...A...AA...A...
</script>
```

The data in this case might be used by the script to generate the map of a video game. The data doesn't have to be used that way, though; maybe the map data is actually embedded in other parts of the page's markup, and the data block here is just used by the site's search engine to help users who are looking for particular features in their game maps.

Example

The following sample shows how a `<script>` element can be used to define a function that is then used by other parts of the document, as part of a `classic script`. It also shows how a `<script>` element can be used to invoke script while the document is being parsed, in this case to initialize the form's output.

```
<script>
function calculate(form) {
  var price = 52000;
  if (form.elements.brakes.checked)
    price += 1000;
  if (form.elements.radio.checked)
    price += 5000;
  if (form.elements.turbo.checked)
    price += 5000;
  if (form.elements.sticker.checked)
    price += 250;
  form.elements.result.value = price;
}
</script>
<form name="priceCalc" onsubmit="return false" onchange="calculate(this)">
<fieldset>
<legend>Work out the price of your car</legend>
<p>Select additional options:</p>
<ul>
<li><label><input type="checkbox" name="brakes"> Ceramic brakes (<input type="radio" value="10000"/>)</label></li>
<li><label><input type="checkbox" name="radio"> Satellite radio (<input type="radio" value="5000"/>)</label></li>
<li><label><input type="checkbox" name="turbo"> Turbo charger (<input type="radio" value="5000"/>)</label></li>
<li><label><input type="checkbox" name="sticker"> "KZ" sticker (<input type="radio" value="250"/>)</label></li>
</ul>
<output name="result"></output>
</fieldset>
<script>
update(document.forms.priceCalc);
</script>
</form>
```

Example

The following sample shows how a `<script>` element can be used to include an external `module script`.

```
<script type="module" src="app.mjs"></script>
```

This module, and all its dependencies (expressed through JavaScript `import` statements in the source file), will be fetched. Once the entire resulting module graph has been imported, and the document has finished parsing, the contents of `app.mjs` will be evaluated.

Additionally, if code from another `<script>` element in the same `Window` imports the module from `app.mjs` (e.g. via `import "./app.mjs"`), then the same `module script` created by the former `<script>` element will be imported.

Example

This example shows how to include a `module script` for modern user agents, and a `classic script` for older user agents:

```
<script type="module" src="app.mjs"></script>
<script nomodule defer src="classic-app-bundle.js"></script>
```

In modern user agents that support `module scripts`, the `<script>` element with the `nomodule` attribute will be ignored, and the `<script>` element with a `type` of "`module`" will be fetched and evaluated (as a `module script`). Conversely, older user agents will ignore the `<script>` element with a `type` of "`module`", as that is an unknown script type for them—but they will have no problem fetching and evaluating the other `<script>` element (as a `classic script`), since they do not implement the `nomodule` attribute.

Example

The following sample shows how a `<script>` element can be used to write an inline `module script` that performs a number of substitutions on the document's text, in order to make for a more interesting reading experience (e.g. on a news site): [XKCD1288]

```
<script type="module">
import { walkAllTextNodesDescendants } from './dom-utils.mjs';

const substitutions = new Map([
  ["winchester", "these dudes I know"],
  ["dredd", "the Judge"],
  ["new study", "Tumblr post"],
  ["rebuilt", "avenged"],
  ["old school", "classic"],
  ["Google glass", "Virtual Boy"],
  ["electric", "atomic"],
  ["Senator", "El-Lord"],
  ["car", "carz"]
]);
```

▶ THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

```
/*Homestar security*, "Homestar Ruusma"]*
["could not be reached for comment", "is guilty and everyone knows it"]
};

function substitute(textNode) {
  for (const [before, after] of substitutions.entries()) {
    textNode.data = textNode.data.replace(new RegExp(`\\b${before}\\b`, "ig"), after);
  }
}

walkAllTextNodesDescendants(document.body, substitute);
</script>
```

Some notable features gained by using a module script include the ability to import functions from other JavaScript modules, strict mode by default, and how top-level declarations do not introduce new properties onto the `global object`. Also note that no matter where this `<script>` element appears in the document, it will not be evaluated until both document parsing has complete and its dependency (`dom-utils.mjs`) has been fetched and evaluated.

4.12.1.1 Processing model

A `<script>` element has several associated pieces of state.

A `<script>` element has a flag indicating whether or not it has been “already started”. Initially, `<script>` elements must have this flag unset (script blocks, when created, are not “already started”). The `cloning steps` for `<script>` elements must set the “already started” flag on the copy if it is set on the element being cloned.

A `<script>` element has a `parser document`, which is either `null` or a `Document`. Initially, its value must be `null`. It is set by the `HTML parser` and the `XML parser` on `<script>` elements they insert, and affects the processing of those elements. `<script>` elements with non-null `parser documents` are known as “parser-inserted”.

A `<script>` element has a flag indicating whether the element will be “non-blocking”. Initially, `<script>` elements must have this flag set. It is unset by the `HTML parser` and the `XML parser` on `<script>` elements they insert. In addition, whenever a `<script>` element whose “non-blocking” flag is set has an `async` content attribute added, the element’s “non-blocking” flag must be unset.

A `<script>` element has a flag indicating whether or not the script block is “ready to be parser-executed”. Initially, `<script>` elements must have this flag unset (script blocks, when created, are not “ready to be parser-executed”). This flag is used only for elements that are also “parser-inserted”, to let the parser know when to execute the script.

The `script’s type` for a `<script>` element is either “classic” or “module”. It is determined when the script is `prepared`, based on the `type` attribute of the element at that time.

A `<script>` element has a `preparation-time document`, which is a `Document` determined near the beginning of the `prepare a script` algorithm. It is used to prevent scripts that move between documents during `preparation` from `executing`.

A `<script>` element has a flag indicating whether or not the script is `from an external file`. It is determined when the script is `prepared`, based on the `src` attribute of the element at that time.

The `script’s script` for a `<script>` element is either `null` or a `<script>` resulting from `preparing` the element. This is set asynchronously after the classic script or module graph is fetched. Once it is set, either to a `<script>` in the case of success or to `null` in the case of failure, the fetching algorithms will note that `the script is ready`, which can trigger other actions. The user agent must `delay the load event` of the element’s `node document` until the `script is ready`.

When a `<script>` element that is not “parser-inserted” experiences one of the events listed in the following list, the user agent must `immediately prepreg the <script> element`:

- The `<script>` element becomes `connected`.
- The `<script>` element is `connected` and a mode or document fragment is `inserted` into the `<script>` element, after any `<script>` elements `inserted` at that time.
- The `<script>` element is `connected` and has a `src` attribute set where previously the element had no such attribute.

To prepare a script, the user agent must act as follows:

1. If the `<script>` element is marked as having “already started”, then return. The script is not executed.
2. Let `parser document` be the element’s `parser document`.

3. Set the element’s `parser document` to `null`.

Note

This is done so that if `parser-inserted` `<script>` elements fail to run when the parser tries to run them, e.g. because they are empty or specify an unsupported scripting language, another script can later mutate them and cause them to run again.

4. If `parser document` is non-null and the element does not have an `async` attribute, then set the element’s “non-blocking” flag to true.

Note

This is done so that if a parser-inserted `<script>` element fails to run when the parser tries to run it, but it is later executed after a script dynamically updates it, it will execute in a non-blocking fashion even if the `async` attribute isn’t set.

5. Let `source text` be the element’s `child text content`.

6. If the element has no `src` attribute, and `source text` is the empty string, then return. The script is not executed.

7. If the element is not `connected`, then return. The script is not executed.

8. If either:

- The `<script>` element has a `type` attribute and its value is the empty string, or
- The `<script>` element has no `type` attribute but it has a `language` attribute and `that` attribute’s value is the empty string, or
- The `<script>` element has neither a `type` attribute nor a `language` attribute, then

`_let the script block’s type string for this <script> element be “text/javascript”.`

Otherwise, if the `<script>` element has a `type` attribute, let `the script block’s type string for this <script> element` be the value of that attribute with `leading and trailing ASCII whitespace stripped`.

Otherwise, the element has a non-empty `language` attribute; let `the script block’s type string for this <script> element` be the concatenation of the string “`text/`” followed by the value of the `language` attribute.

Note

The `language` attribute is never conforming, and is always ignored if there is a `type` attribute present.

Determine the `script’s type` as follows:

- If `the script block’s type string is a JavaScript MIME type essence match`, `the script’s type` is “classic”.
- If `the script block’s type string is an ASCII case-insensitive match for the string “module”`, `the script’s type` is “module”.
- If neither of the above conditions are true, then return. No script is executed.

9. If `parser document` is non-null, then set the element’s `parser document` back to `parser document` and set the element’s “non-blocking” flag to false.

10. Set the element’s “already started” flag.

11. Set the element’s `preparation-time document` to its `node document`.

12. If `parser document` is non-null, and `parser document` is not equal to the element’s `preparation-time document`, then return.

This step is not interoperable and is under debate; see [issue #2137](#).

13. If `scripting is disabled` for the `<script>` element, then return. The script is not executed.

Note

The definition of `scripting is disabled` means that, amongst others, the following scripts will not execute: scripts in `XMLEHttpRequest’s responseXML` documents, scripts in `DOMParser`-created documents, scripts in documents created by `XSLTProcessor’s transformToDocument` feature, and scripts that are first inserted by a script into a `document` that was created using the `createDocument` API. [XHR][DOMPARSING][XSLT][DOM]

14. If the `<script>` element has a `nomodule` content attribute and `the script’s type` is “classic”, then return. The script is not executed.

Note

This means specifying `nomodule` on a `module script` has no effect; the algorithm continues onward.

15. If the `<script>` element does not have a `src` content attribute, and the `Should element’s inline behavior be blocked by Content Security Policy?` algorithm returns “`blocked`” when executed upon the `<script>` element, “`script`”, and `source text`, then return. The script is not executed. [CSP]

16. If the `<script>` element has an `event` attribute and a `for` attribute, and `the script’s type` is “classic”, then:

1. Let `for` be the value of the `for` attribute.

2. Let `event` be the value of the `event` attribute.

3. `Strip leading and trailing ASCII whitespace` from `event` and `for`.

4. If `for` is not an ASCII case-insensitive match for the string “`window`”, then return. The script is not executed.

5. If `event` is not an ASCII case-insensitive match for either the string “`onload`” or the string “`onload()`”, then return. The script is not executed.

17. If the `<script>` element has a `charset` attribute, then let `encoding` be the result of `getting an encoding` from the value of the `charset` attribute.

If the `<script>` element does not have a `charset` attribute, or if `getting an encoding` failed, let `encoding` be the same as `the encoding` of the `<script>` element’s `node document`.

Note

If `the script’s type` is “`module`”, this encoding will be ignored.

18. Let `classic script CORS setting` be the current state of the element’s `crossorigin` content attribute.

19. Let `module script credentials mode` be the element’s `crossorigin` content attribute.

20. Let `cryptographic nonce` be the element’s `[ICryptographicNonce]` internal slot’s value.

21. If the `<script>` element has an `integrity` attribute, then let `integrity metadata` be that attribute’s value.

Otherwise, let `integrity metadata` be the empty string.

22. Let `referrer policy` be the current state of the element’s `referrerPolicy` content attribute.

23. Let `parser metadata` be “`parser-inserted`” if the `<script>` element is “`parser-inserted`”, and “`not-parser-inserted`” otherwise.

24. Let `options` be a `script fetch options` whose `cryptographic nonce` is `cryptographic nonce`, `integrity metadata`, `parser metadata`, `credentials mode` is `module script credentials mode`, and `referrer policy` is `referrer policy`.

25. Let `settings object` be the element’s `node document’s relevant settings object`.

26. If the element has a `src` content attribute, then:

1. Let `src` be the value of the element’s `src` attribute.

2. If `src` is the empty string, `queue a task to fire an event` named `error` at the element, and return.

3. Set the element’s `from an external file` flag.

4. `Parse` `src` relative to the element’s `node document`.

5. If the previous step failed, `queue a task to fire an event` named `error` at the element, and return. Otherwise, let `url` be the `resulting URL record`.

6. Switch on `the script’s type`:

“classic”

`Fetch a classic script` given `url`, `settings object`, `options`, `classic script CORS setting`, and `encoding`.

“module”

`Fetch an external module script graph` given `url`, `settings object`, and `options`.

When the chosen algorithm asynchronously completes, set `the script’s script` to the result. At that time, `the script is ready`.

For performance reasons, user agents may start fetching the classic script or module graph (as defined above) as soon as the `src` attribute is set, instead, in the hope that the element will be inserted into the document (and that the `crossorigin` attribute won’t change value in the meantime). Either way, once the element is `inserted into the document`, the load must have started as described in this step. If the UA performs such prefetching, but the element is never inserted in the document, or the `src` attribute is dynamically changed, or the `crossorigin` attribute is dynamically changed, then the user agent will not execute the script so obtained, and the fetching process will have been effectively wasted.

1. Let `base URL` be the `script` element's `node document's document base URL`.

2. Switch on `the script's type`:

- "classic"
 1. Let `script` be the result of [creating a classic script](#) using `source text`, `settings object`, `base URL`, and `options`.
 2. Set `the script's script` to `script`.
 3. `The script is ready`.
- "module"
 1. [Fetch an inline module script](#), given `source text`, `base URL`, `settings object`, and `options`. When this asynchronously completes, set `the script's script` to the result. At that time, `the script is ready`.

28. Then, follow the first of the following options that describes the situation:

If `the script's type` is "classic", and the element has a `src` attribute, and the element is `"parser-inserted"`, and the element does not have an `async` attribute
 If `the script's type` is "classic", and the element is `"ready"`, and the element does not have an `async` attribute

Add the element to the end of the `list of scripts that will execute when the document has finished parsing` associated with the `document` of the parser that created the element.

When `the script is ready`, set the element's `"ready to be parser-executed"` flag. The parser will handle executing the script.

If `the script's type` is "classic", and the element has a `src` attribute, and the element is `"parse-inserted"`, and the element does not have an `async` attribute

The element is the `pending-parsing-blocking script` of the `document` of the parser that created the element. (There can only be one such script per `document` at a time.)

When `the script is ready`, set the element's `"ready to be parser-executed"` flag. The parser will handle executing the script.

If `the script's type` is "classic", and the element has a `src` attribute, and the element does not have an `async` attribute and the element does not have the `"non-blocking"` flag set
 If `the script's type` is "module", and the element does not have an `async` attribute and the element does not have the `"non-blocking"` flag set

Add the element to the end of the `list of scripts that will execute in order as soon as possible` associated with the element's `preparation-time document`.

When `the script is ready`, run the following steps:

1. If the element is not now the first element in the `list of scripts that will execute in order as soon as possible` to which it was added above, then mark the element as ready but return without executing the script yet.
2. **Execution:** Execute the `script block` corresponding to the first script element in this `list of scripts that will execute in order as soon as possible`.
3. Remove the first element from this `list of scripts that will execute in order as soon as possible`.
4. If this `list of scripts that will execute in order as soon as possible` is still not empty and the first entry has already been marked as ready, then jump back to the step labeled `execution`.

If `the script's type` is "classic", and the element has a `src` attribute
 If `the script's type` is "module"

The element must be added to the `set of scripts that will execute as soon as possible` of the element's `preparation-time document`.

When `the script is ready`, execute the `script block` and then remove the element from the `set of scripts that will execute as soon as possible`.

If the element does not have a `src` attribute, and the element is `"parser-inserted"`, and either the `script` is an `XML parser` or it's an `HTML parser` whose `script nesting level` is not greater than one, and the element's `parser document` has a style sheet that is blocking scripts

The element is the `pending-parsing-blocking script` of its `parser document`. (There can only be one such script per `document` at a time.)

Set the element's `"ready to be parser-executed"` flag. The parser will handle executing the script.

Otherwise

[Immediately execute the script block](#), even if other scripts are already executing.

The `pending parsing-blocking script` of a `document` is used by the `document's` parsers.

Note
 If a `script` element that blocks a parser gets moved to another `document` before it would normally have stopped blocking that parser, it nonetheless continues blocking that parser until the condition that causes it to be blocking the parser no longer applies (e.g., if the script is a `pending-parsing-blocking script` because the original `document` has a style sheet that is blocking scripts when it was parsed, but then the script is moved to another `document` before the blocking style sheet(s) loaded, the script still blocks the parser until the style sheets are all loaded, at which time the script executes and the parser is unblocked).

To execute a script block given a `script` element `scriptElement`:

1. Let `document` be `scriptElement's node document`.
2. If `scriptElement's parser document` is non-null, and `scriptElement's parser document` is not equal to `document`, then return.

This step is not interoperable and is under debate; see [issue #2137](#).

3. If `the script's script` is null for `scriptElement`, then [fire an event](#) named `readystatechange` at `scriptElement`, and return.
4. If `scriptElement` is [from an external file](#), or the `script's type` for `scriptElement` is "module", then increment `document's ignore-destructive-writes counter`.
5. Switch on `the script's type` for `scriptElement`:

- "classic"
 1. Let `oldCurrentScript` be the value to which `document's currentScript` object was most recently set.
 2. If `scriptElement's root` is not a `shadow root`, then set `document's currentScript` attribute to `scriptElement`. Otherwise, set it to null.

Note
 [This does not use the `in a document tree` check, as `scriptElement` could have been removed from the document prior to execution, and in that scenario `currentScript` still needs to point to it.]

 3. [Run the classic script](#) given by `the script's script` for `scriptElement`.
 4. Set `document's currentScript` attribute to `oldCurrentScript`.
- "module"
 1. Assert: `document's currentScript` attribute is null.
 2. [Run the module script](#) given by `the script's script` for `scriptElement`.

6. Decrement the `ignore-destructive-writes counter` of `document`, if it was incremented in the earlier step.

7. If `scriptElement` is [from an external file](#), then [fire an event](#) named `load` at `scriptElement`.

4.12.1.2 Scripting languages

User agents are not required to support JavaScript. This standard needs to be updated if a language other than JavaScript comes along and gets similar wide adoption by web browsers. Until such a time, implementing other languages is in conflict with this standard, given the processing model defined for the `script` element.

Servers should use `text/javascript` for JavaScript resources. Servers should not use other `JavaScript MIME types` for JavaScript resources, and must not use non-`JavaScript MIME types`.

For external JavaScript resources, MIME type parameters in `content-type` headers are generally ignored. (In some cases the `charset` parameter has an effect.) However, for the `script` element's `type` attribute they are significant; it uses the `JavaScript MIME type essence match` concept.

Note
 For example, scripts with their `type` attribute set to `"text/javascript; charset=utf-8"` will not be evaluated, even though that is a valid `JavaScript MIME type` when parsed.

Furthermore, again for external JavaScript resources, special considerations apply around `content-type` header processing as detailed in the `prepare a script` algorithm and `Fetch (IFETCH)`.

4.12.1.3 Restrictions on contents of `script` elements

Note
 The easiest and safest way to avoid the rather strange restrictions described in this section is to always escape an ASCII case-insensitive match for "`<!--`" as "`<\!--`", "`<script>`" as "`<\>script`", and "`</script>`" as "`<\>/script`" when these sequences appear in literals in scripts (e.g. in strings, regular expressions, or comments), and to avoid writing code that uses such constructs in expressions. Doing so avoids the pitfalls that the restrictions in this section are prone to triggering, namely, that, for historical reasons, parsing of `script` blocks in HTML is a strange and exotic practice that acts unintuitively in the face of these sequences.

The `script` element's `descendant text content` must match the `script` production in the following ABNF. The character set for which is Unicode. (ABNF)

```

script      = outer *( comment-open inner comment-close outer )
outer      = < any string that doesn't contain a substring that matches not-in-outer >
not-in-outer = comment-open
inner      = < any string that doesn't contain a substring that matches not-in-inner >
not-in-inner = < any string that matches not-in-outer /> script-open
comment-open = "<!--"
comment-close = "-->"
script-open = "<*>" s c r i p t t a g - e n d
s           = U+0020 ; 0+0033 LATIN CAPITAL LETTER S
a           = U+0073 ; 0+0033 LATIN SMALL LETTER S
c           = U+0043 ; 0+0033 LATIN CAPITAL LETTER C
r           = U+0072 ; 0+0033 LATIN SMALL LETTER R
i           = U+0049 ; 0+0033 LATIN CAPITAL LETTER I
r           = U+0069 ; 0+0033 LATIN SMALL LETTER I
p           = U+0070 ; 0+0033 LATIN CAPITAL LETTER P
r           = U+0070 ; 0+0033 LATIN SMALL LETTER P
t           = U+0074 ; 0+0033 LATIN CAPITAL LETTER T
e           = U+0074 ; 0+0033 LATIN SMALL LETTER T
tag-end    = U+0009 ; 0+0009 CHARACTER TABULATION (tab)
tag-end    = U+000A ; 0+000A LINE FEED (LF)
tag-end    = U+000D ; 0+000C FORM FEED (FF)
tag-end    = U+000B ; 0+000B CARRIAGE RETURN (CR)
tag-end    = U+002F ; 0+002F SOLIDUS (/)
tag-end    = U+003E ; 0+003E GREATER-THAN SIGN (>)
  
```

When a `script` element contains `script documentation`, there are further restrictions on the contents of the element, as described in the section below.

Example

The following script illustrates this issue. Suppose you have a script that contains a string, as in:

```

var example = 'Consider this string:<!--<script>';
console.log(example);
  
```

If one were to put this string directly in a `script` block, it would violate the restrictions above:

```

<script>
  var example = 'Consider this string:<!--<script>';
  console.log(example);
</script>
  
```

The bigger problem, though, and the reason why it would violate those restrictions, is that actually the script would get parsed weirdly: `the script block above is not terminated`. That is, what looks like a `</script>` end tag in this snippet is actually still part of the `script` block. The script doesn't execute (since it's not terminated); if it somehow were to execute, as it might if the markup looked as follows, it would fail because the script (highlighted here) is not valid JavaScript:

```

<script>
  var example = 'Consider this string:<!--<script>';
  console.log(example);
</script>
  // Despite appearances, this is actually part of the script still! -->
  
```

What is going on here is that for legacy reasons, "<!--" and "<script" strings in `<script>` elements in HTML need to be balanced in order for the parser to consider closing the block.

By escaping the problematic strings as mentioned at the top of this section, the problem is avoided entirely:

```
// Note: '\` is an escape sequence for '`.
var example = `Consider this string: <\`t-- <script>`;
example.log(example);
<script>

<script>
// this is a new script block
</script>
It is possible for these sequences to naturally occur in script expressions, as in the following examples:
if (x!>y) { ... }
if (player<script> { ... }
In such cases the characters cannot be escaped, but the expressions can be rewritten so that the sequences don't occur, as in:
if (x < !y) { ... }
if (!y > x) { ... }
if (x < !y)
if (player < script> { ... }
if (script > player) { ... }
Doing this also avoids a different pitfall as well: for related historical reasons, the string "<!--" in <classic scripts> is actually treated as a line comment start, just like "/".
```

4.12.1.4 Inline documentation for external script

If a `<script>` element's `src` attribute is specified, then the contents of the `<script>` element, if any, must be such that the value of the `text` IDL attribute, which is derived from the element's contents, matches the `documentation` production in the following ABNF, the character set for which is Unicode: [\[ABNF\]](#)

```
documentation = *( space / tab / comment ) [line-comment] newline
comment = slash-star *not-star / star not-slash *star slash
newline = slash slash "not-newline"
; characters
tab = %x0009 ; U+0009 CHARACTER TABULATION (tab)
newline = %x000A ; U+000A LINE FEED (LF)
space = %x0020 ; U+0020 SPACE
star = %x002A ; U+002A ASTERISK (*)
slash = %x002F ; U+002F SOLIDUS (/)
not-newline = %x000D-0009 / %x000B-10FFFF
            ; a scalar value other than U+000A LINE FEED (LF)
not-star = %x002A-002B / %x002A-002A ASTERISK (*)
not-slash = %x002F-002E / %x002F-10FFFF
            ; a scalar value other than U+002F SOLIDUS (/)
```

Note

This corresponds to putting the contents of the element in JavaScript comments.

Note

This requirement is in addition to the earlier restrictions on the syntax of contents of `<script>` elements.

Example

This allows authors to include documentation, such as license information or API information, inside their documents while still referring to external script files. The syntax is constrained so that authors don't accidentally include what looks like valid script while also providing a `src` attribute.

```
<script src="cool-effects.js">
  // create new instances using
  //   var a = new Effect();
  // start a project using .play, stop using .stop:
  //   a.play();
  //   a.stop();
</script>
```

4.12.1.5 Interaction of `<script>` elements and XSLT

This section is non-normative.

This specification does not define how XSLT interacts with the `<script>` element. However, in the absence of another specification actually defining this, here are some guidelines for implementers, based on existing implementations:

- When an XSLT transformation program is triggered by an `<xsl:stylesheet>` processing instruction and the browser implements a direct-to-DOM transformation, `<script>` elements created by the XSLT processor need to have its `parser_document` set correctly, and run in document order (modulo scripts marked `defer` or `asynchronous`), **immediately**, as the transformation is occurring.
- The `XSLTProcessor.transformToDocument()` method adds elements to a `Document` object with a null `browsing_context`, and, accordingly, any `<script>` elements they create need to have their `"already_started"` flag set in the `prepare_a_script` algorithm and never get executed (`scripting_is_disabled`). Such `<script>` elements still need to have their `parser_document` set, though, such that their `async` content attribute.
- The `XSLTProcessor.transformToFragment()` method needs to create a fragment that is equivalent to one built manually by creating the elements using `document.createElementNS()`. For instance, it needs to create `<script>` elements with null `parser_document` and that don't have their `"already_started"` flag set, so that they will execute when the fragment is inserted into a document.

The main distinction between the first two cases and the last case is that the first two operate on `Documents` and the last operates on a fragment.

4.12.2 The `<noscript>` element

MDN

Element: `<noscript>`

Support in all current engines.

Firefox+|Safari|Yes|Chrome|Yes

Opera|Yes|Edge|Yes

Edge (Legacy)|12+|Internet Explorer|Yes

Firefox|Android|4+|Safari|iOS|Chrome|Android|Yes|WebView|Android|Yes|Samsung|Internet|Yes|Opera|Android|Yes

Categories

Metadata content

Flow content

Phrasing content

Comments in which this element can be used:

In a `head` element of an `HTML_document`, if there are no ancestor `<noscript>` elements.

Where `phrasing_content` is expected in `HTML_documents`, if there are no ancestor `<noscript>` elements.

Content model:

`noscript` is disabled, in a `head` element: in any order, zero or more `link` elements, zero or more `meta` elements, and zero or more `meta` elements.

When `scripting` is disabled, not in a `head` element: `transparent`; but there must be no `<noscript>` element descendants.

Otherwise: text that conforms to the requirements given in the prose.

Tag omission in text/html:

Neither tag ismissible.

Content attributes

`content`

Accessibility considerations:

For authors

For implementors

DOM interface

Uses `HTMLElement`.

The `<noscript>` element `represents` nothing if `scripting` is enabled, and `represents` its children if `scripting` is disabled. It is used to present different markup to user agents that support scripting and those that don't support scripting, by affecting how the document is parsed.

When used in `HTML_documents`, the allowed content model is as follows:

In a `head` element, if `scripting` is disabled for the `<noscript>` element

The `<noscript>` element must contain only `link`, `style`, and `meta` elements.

In a `head` element, if `scripting` is enabled for the `<noscript>` element

The `<noscript>` element must contain only text, except that invoking the `HTML_fragment_parsing_algorithm` with the `<noscript>` element as the `context` element and the text contents as the `input` must result in a list of nodes that consists only of `link`, `style`, and `meta` elements that would be conforming if they were children of the `<noscript>` element, and no `parse_error`.

Outside of `head` elements, if `scripting` is disabled for the `<noscript>` element

The `<noscript>` element's content model is `transparent`, with the additional restriction that a `<noscript>` element must not have a `<noscript>` element as an ancestor (that is, `<noscript>` can't be nested).

Outside of `head` elements, if `scripting` is enabled for the `<noscript>` element

The `<noscript>` element must contain only text, except that the text must be such that running the following algorithm results in a conforming document with no `<noscript>` elements and no `<script>` elements, and such that no step in the algorithm throws an exception or causes an `HTML_parser` to flag a `parse_error`:

1. Remove every `<script>` element from the document.
2. Make a list of every `<noscript>` element in the document. For every `<noscript>` element in that list, perform the following steps:
 1. Let `s` be the child `text_content` of the `<noscript>` element.
 2. Set the `data_value` attribute of the `<noscript>` element to the value of `s`. (This, as a side-effect, causes the `<noscript>` element to be removed from the document.) **[DOMPARSING]**

Note

All these contortions are required because, for historical reasons, the `<noscript>` element is handled differently by the `HTML_parser` based on whether `scripting` was enabled or not when the parser was invoked.

The `<noscript>` element must not be used in `XML_documents`.

Note

The `<noscript>` element is only effective in the `HTML_syntax`; it has no effect in the `XML_syntax`. This is because the way it works is by essentially "turning off" the parser when scripts are enabled, so that the contents of the element are treated as pure text and not as real elements. XML does not define a mechanism by which to do this.

The `<noscript>` element has no other requirements. In particular, children of the `<noscript>` element are not exempt from `form_submission`, scripting, and so forth, even when `scripting` is enabled for the element.

Example

In the following example, a `<noscript>` element is used to provide fallback for a script.

```
<form action="calcdsquare.php">
  <label for="xNumber">Label:</label>
  <input id="x" name="x" type="number">
  <script>
    var x = document.getElementById('x');
    x.oninput = function () { return false; }
    x.addEventListener('input', function () {
      var v = x.valueAsNumber;
      output.textContent = v + ' squared is ' + v * v;
    });
  </script>
  <noscript>
    <input type="submit" value="Calculate Square">
  </noscript>
```

When script is disabled, a button appears to do the calculation on the server side. When script is enabled, the value is computed on-the-fly instead.

```
<script action="calcSquare.php">
<form>
<label for=x>Number</label>
<input id="x" name="x" type="number">
</form>
<input id="submit" type="submit" value="Calculate Square">
<script>
var x = document.getElementById('x');
var output = document.createElement('p');
output.textContent = 'You entered a number! It will be squared right then!';
x.form.appendChild(output);
x.form.onsubmit = function () { return false; }
var v = x.valueAsNumber;
output.textContent = v + ' squared is ' + v * v;
var submit = document.getElementById('submit');
x.form.parentNode.removeChild(submit);
</script>
</form>
```

The above technique is also useful in XML documents, since `script` is not allowed there.

4.12.3 The `template` element

[Categories:](#)

[Metadata content](#)

[Flow content](#)

[Phrasing content](#)

[Content categories in which this element can be used:](#)

Where [metadata content](#) is expected.

Where [phrasing content](#) is expected.

Where [script-supporting elements](#) are expected.

As a child of a [colgroup](#) element that doesn't have a `span` attribute.

[Content model:](#)

No child (for clarification, see [example](#)).

[Tag omission in text/html:](#)

Neither tag is omitted.

[Content attributes:](#)

[Global attributes](#)

[Access key considerations:](#)

For authors

For implementers

[DOM interface](#)

`IDLExposedWindow`

`interface HTMLTemplateElement : HTMLElement`

`{<constructor> constructor();`

`readonly attribute DocumentFragment context;`

`}`

The `template` element is used to declare fragments of HTML that can be cloned and inserted in the document by script.

In a rendering, the `template` element [represents](#) nothing.

The `template contents` of a `template` element are [not children](#) of the element itself.

Note

It is also possible, as a result of DOM manipulation, for a `template` element to contain `text` nodes and element nodes; however, having any is a violation of the `template` element's content model, since its content model is defined as [nothing](#).

[Example](#)

For example, consider the following document:

```
<!doctype html>
<html lang="en">
<head>
<title>Homework</title>
<script>
let num = 3;
const fragment = document.createElement('template').content.cloneNode(true);
while (num-- > 1) {
    fragment.firstChild.insertBefore(fragment.firstChild.cloneNode(true));
    fragment.firstChild.textContent += fragment.lastChild.textContent;
}
document.body.appendChild(fragment);
</script>
</html>
```

The `g` element in the `template` is not a child of the `template` in the DOM; it is a child of the `DocumentFragment` returned by the `template` element's `context` IDL attribute.

If the script were to call `appendChild` on the `template` element, that would add a child to the `template` element (as for any other element); however, doing so is a violation of the `template` element's content model.

[For web developers \(non-normative\)](#)

`template : context`

Returns the `template contents` (a `DocumentFragment`).

Each `template` element has an associated `DocumentFragment` object that is its `template contents`. The `template contents` have [no conformance requirements](#). When a `template` element is created, the user agent must run the following steps to establish the `template contents`:

1. Let `doc` be the `template` element's `node document's appropriate template contents owner document`.
2. Create a `DocumentFragment` object whose `node document` is `doc` and `host` is the `template` element.
3. Set the `template` element's `template contents` to the newly created `DocumentFragment` object.

A `Document doc's appropriate template contents owner document` is the `Document` returned by the following algorithm:

1. If `doc` is not a `Document` created by this algorithm, then:
 1. If `doc` does not yet have an `associated inert template document`, then:
 1. Let `new doc` be a new `Document` (whose `browsing context` is null). This is a `Document` created by this algorithm* for the purposes of the step above.
 2. If `doc` is an `HTML document`, mark `new doc` as an `HTML document` also.
 3. Let `doc's associated inert template document` be `new doc`.
 2. Set `doc` to `doc's associated inert template document`.

Note

Each `Document` not created by this algorithm thus gets a single `Document` to act as its proxy for owning the `template contents` of all its `template` elements, so that they aren't in a `browsing context` and thus remain inert (e.g. scripts do not run). Meanwhile, `template` elements inside `Document` objects that are created by this algorithm just reuse the same `Document` owner for their contents.

2. Return `doc`.

The `adopting steps` (with `node` and `oldDocument` as parameters) for `template` elements are the following:

1. Let `doc` be `node's node document's appropriate template contents owner document`.

`node's node document` is the `Document` object that `node` was just adopted into.

2. `AddNode(node's template contents (a DocumentFragment object)) into doc`.

MDN

[HTMLTemplateElement/context](#)

Support in all current engines.

Firefox22+Safari8+Chrome26+

Opera15+Edge79+

Edge (Legacy)13+Internet ExplorerNo

Firefox Android22+Safari iOS8+Chrome Android26+WebView AndroidYesSamsung Internet 5+Opera AndroidYes
 The `content` IDL attribute must return the `template` element's `template contents`.

The `cloning steps` for a `template` element node being cloned to a copy `copy` must run the following steps:

1. If the `clone children` flag is not set in the calling `clone` algorithm, return.
2. Let `copied contents` be the result of `cloning` all the children of `node's template contents`, with `document` set to `copy's template contents's node document`, and with the `clone children` flag set.
3. Append `copied contents` to `copy's template contents`.

Example

In this example, a script populates a table four-column with data from a data structure, using a `template` to provide the element structure instead of manually generating the structure from markup.

```
<!DOCTYPE html>
<html lang="en">
<head><title>Cat Data</title>
<script>
var data = [
  { name: 'Bella', color: 'Ticked Tabby', sex: 'Female (neutered)', legs: 3 },
  { name: 'Hedra', color: 'Tuxedo', sex: 'Male (neutered)', legs: 4 },
];
</script>
<table>
<thead>
<tr>
<th>Name </th><th>Color </th><th>Sex </th><th>Legs </th>
</tr>
</thead>
<tbody>
<template id="row">
<tr><td></td><td></td><td></td><td></td>
</tr>
</template>
</tbody>
</table>
<script>
var template = document.querySelector('#row');
for (var i = 0; i < data.length; i++) {
  var cat = data[i];
  var clone = template.cloneNode(true);
  var cells = clone.querySelectorAll('td');
  cells[0].textContent = cat.name;
  cells[1].textContent = cat.color;
  cells[2].textContent = cat.sex;
  cells[3].textContent = cat.legs;
  template.parentNode.appendChild(clone);
}
</script>
```

This example uses `cloneNode(true)` on the `template`'s contents; it could equivalently have used `document.importNode(true)`, which does the same thing. The only difference between these two APIs is when the `node document` is updated: with `cloneNode(true)` it is updated when the nodes are appended with `appendChild()`, with `document.importNode(true)` it is updated when the nodes are cloned.

4.12.3.1 Interaction of `template` elements with XSLT and XPath

This section is non-normative.

This specification does not define how XSLT and XPath interact with the `template` element. However, in the absence of another specification actually defining this, here are some guidelines for implementers, which are intended to be consistent with other processing described in this specification:

- An XSLT processor based on an XML parser that acts as described in this specification needs to act as if `template` elements contain as descendants their `template contents` for the purposes of the transform.
- An XSLT processor that outputs a DOM needs to ensure that nodes that would go into a `template` element are instead placed into the element's `template contents`.
- XPath evaluation using the XPath DOM API when applied to a `document` parsed using the `HTML parser` or the `XML parser` described in this specification needs to ignore `template contents`.

4.12.4 The `slot` element

Phrasing content

Content in which this element can be used:

Where phrasing content is expected.

Content mode:

Transparent

Tag content in `shadow-root`:

Neither tag ismissible.

Content attributes:

Global attributes

`name` — Name of shadow tree slot

Accessibility considerations:

For implementers.

DOM interface:

```
IDL Exposed<Window>
interface HTMLSlotElement : HTMLElement {
  [HTMLConstructor] constructor();
}
```

```
[CustomEvent("slotchange", {bubbles: true, composed: true, detail: {}})]
attribute DOMString name;
sequence<Element> assignedNodes(optional AssignedNodesOptions options = ());
sequence<Element> assignedElements(optional AssignedNodesOptions options = ());

```

```
dictionary AssignedNodesOptions {
  boolean flatten = false;
}
```

The `slot` element defines a `slot`. It is typically used in a `shadow tree`. A `slot` element represents its `assigned nodes`, if any, and its contents otherwise.

The `name` content attribute may contain any string value. It represents a `slot's name`.

Note

The `name` attribute is used to assign slots to other elements: a `slot` element with a `name` attribute creates a named `slot` to which any element is `assigned` if that element has a `slot` attribute whose value matches that `name` attribute's value, and the `slot` element is a child of the `shadow tree` whose root's `host` has that corresponding `slot` attribute value.

For web developers (non-normative)

`slot` `name`

Can be used to get and set `slot's name`.

`slot.assignedNodes()`

Returns `slot's assigned nodes`.

`slot.assignedNodes({ flatten: true })`

Returns `slot's assigned nodes`, if any, and `slot's children` otherwise, and does the same for any `slot` elements encountered therein, recursively, until there are no `slot` elements left.

`slot.assignedElements()`

Returns `slot's assigned nodes`, limited to elements.

`slot.assignedElements({ flatten: true })`

Returns the same as `slot.assignedNodes({ flatten: true })`, limited to elements.

Neither tag is omitted.

Content attributes:`Global attributes``width` — Horizontal dimension`height` — Vertical dimension**Accessibility considerations:**

For authors

For implementers

DOM interface:

```
IDLTypeDef<CanvasRenderingContext2D> or ImageBitmapRenderingContext or WebGLRenderingContext or WebGL2RenderingContext RenderingContext;
[Exposed=Window]
interface HTMLCanvasElement : HTMLElement {
  [HTMLConstructor] constructor();
  [CSSAnimations] attribute unsigned long width;
  [CSSAnimations] attribute unsigned long height;
  [RenderingContext] getRenderingContext(DOMString contextId, optional any options = null);
  USVString? readURL(optional DOMString type = "image/png", optional any quality);
  void setReadURL(DOMString url, optional DOMString type = "image/png", optional any quality);
  offscreenCanvas? transferControlToOffscreen();
};

callback BlobCallback = void (Blob? blob);
```

The `canvas` element provides scripts with a rendering-dependent bitmap canvas, which can be used for rendering graphs, game graphics, art, or other visual images on the fly.Authors should not use the `canvas` element in a document when a more suitable element is available. For example, it is inappropriate to use a `canvas` element to render a page heading: if the desired presentation of the heading is graphically intense, it should be marked up using appropriate elements (typically `h1`) and then styled using CSS and supporting technologies such as `shadow trees`.When authors use the `canvas` element, they must also provide content that, when presented to the user, conveys essentially the same function or purpose as the `canvas`'s bitmap. This content may be placed as content of the `canvas` element. The contents of the `canvas` element, if any, are the element's `fallback content`.In interactive visual media, if `scripting` is enabled for the `canvas` element, and if support for `canvas` elements has been enabled, then the `canvas` element `represents embedded content` consisting of a dynamically created image, the element's bitmap.In non-interactive, static, visual media, if the `canvas` element has been previously associated with a rendering context (e.g. if the page was viewed in an interactive visual medium and is now being printed, or if some script ran during the page layout process painted on the element), then the `canvas` element `represents embedded content` with the element's current bitmap and size. Otherwise, the element represents its `fallback content` instead.In non-visual media, and in visual media if `scripting` is disabled for the `canvas` element or if support for `canvas` elements has been disabled, the `canvas` element `represents its fallback content` instead.When a `canvas` element `represents embedded content`, the user can still focus descendants of the `canvas` element (in the `fallback content`). When an element is `focused`, it is the target of keyboard interaction events (even though the element itself is not visible). This allows authors to make an interactive canvas keyboard-accessible: authors should have a one-to-one mapping of interactive regions to `focussable areas` in the `fallback content`. (Focus has no effect on mouse interaction events.) [\[UIEVENTS\]](#)An element whose nearest `canvas` element ancestor is `being rendered` and `represents embedded content` is an element that is *being used as relevant canvas fallback content*.[HTML CanvasElement/width](#)

Opera9+Edge79+

Edge (Legacy)12+Internet Explorer9+

Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android10.1+

The `canvas` element has two attributes to control the size of the element's bitmap: `width` and `height`. These attributes, when specified, must have values that are `valid non-negative integers`. The `rules for parsing non-negative integers` must be used to obtain their numeric values. If an attribute is missing, or if parsing its value returns an error, then the default value must be used instead. The `width` attribute defaults to 300, and the `height` attribute defaults to 150.When setting the value of the `width` or `height` attribute, if the `context mode` of the `canvas` element is set to `placeholder`, the user agent must throw an `"invalidStateError"` `SyntaxException` and leave the attribute's value unchanged.The `intrinsic dimensions` of the `canvas` element when it `represents embedded content` are equal to the dimensions of the element's bitmap.The user agent must use a square pixel density consisting of one pixel of image data per coordinate space unit for the bitmaps of a `canvas` and its rendering contexts.**Note**A `canvas` element can be sized arbitrarily by a style sheet; its bitmap is then subject to the `object-fit` CSS property.The bitmaps of `canvas` elements, the bitmaps of `ImageBitmap` objects, as well as some of the bitmaps of rendering contexts, such as those described in the sections on the `CanvasRenderingContext2D` and `ImageBitmapRenderingContext` objects below, have an `origin-clean` flag, which can be set to true or false. Initially, when the `canvas` element or `ImageBitmap` object is created, its bitmap's `origin-clean` flag must be set to true.A `canvas` element can have a rendering context bound to it. Initially, it does not have a bound rendering context. To keep track of whether it has a rendering context or not, and what kind of rendering context it is, a `canvas` also has a `canvas context mode`, which is initially `none` but can be changed to either `placeholder`, `2d`, `bitmaprenderer`, `webgl`, or `webgl2` by algorithms defined in this specification.When its `canvas context mode` is `none`, a `canvas` element has no rendering context, and its bitmap must be `transparent black` with an `intrinsic width` equal to the `numeric value` of the element's `width` attribute and an `intrinsic height` equal to the `numeric value` of the element's `height` attribute, those values being interpreted in `CSS pixels`, and being updated as the attributes are set, changed, or removed.When its `canvas context mode` is `placeholder`, a `canvas` element has no rendering context. It serves as a placeholder for an `OffscreenCanvas` object, and the content of the `canvas` element is updated by calling the `commit()` method of the `OffscreenCanvas` object's rendering context.When a `canvas` element represents `embedded content`, it provides a `paint source` whose width is the element's `intrinsic width`, whose height is the element's `intrinsic height`, and whose appearance is the element's bitmap.Whenever the `width` and `height` content attributes are set, removed, changed, or redundantly set to the value they already have, then the user agent must perform the action from the row of the following table that corresponds to the `canvas` element's `context mode`.**Context Mode****Action**2d Follow the steps to `get bitmap dimensions to the numeric values` of the `width` and `height` content attributes.webgl or webgl2 Follow the behavior defined in the WebGL specifications. [\[WEBGL\]](#)

Context Mode

Action

placeholder Do nothing.**none** Do nothing.The `width` and `height` IDL attributes must reflect the respective content attributes of the same name, with the same defaults.

For web developers (non-normative)

`context = canvas.getcontext(contextId [, options])`Returns an object that exposes an API for drawing on the canvas. `contextId` specifies the desired API: `2d`, `bitmaprenderer`, `webgl`, or `webl2`. `options` is handled by that API.This specification defines the `2d` and `bitmaprenderer` contexts below. The WebGL specifications define the `webgl` and `webl2` contexts. [WEBGL]Returns null if `contextId` is not supported, or if the canvas has already been initialized with another context type (e.g., trying to get a `2d` context after getting a `webgl` context).

Firefox, Android 4+ Safari iOS 1+ Chrome, Android 18+ WebView, Android 1+ Samsung Internet 1.0+ Opera, Android 10.1+

The `getContext(contextId, options)` method of the `canvas` element, when invoked, must run these steps:1. If `options` is not an `object`, then set `options` to null.2. Set `options` to the result of `converting options` to a JavaScript value.3. Run the steps in the cell of the following table whose column header matches this `canvas` element's `canvas context mode` and whose row header matches `contextId`.

<code>none</code>	<code>2d</code>	<code>bitmaprenderer</code>	<code>webgl</code> or <code>webl2</code>	<code>placeholder</code>
" <code>2d</code> "	Follow the 2D context creation algorithm defined in the section below, passing it this <code>canvas</code> element and <code>options</code> , to obtain a <code>CanvasRenderingContext2D</code> object; if this does not throw an exception, then set this <code>canvas</code> element's <code>context mode</code> to <code>2d</code> , and return the <code>CanvasRenderingContext2D</code> object.	2d	Return the same object as was returned the last time the method was invoked with this same first argument.	Throw an <code>"InvalidStateError"</code> <code>DOMException</code> .
" <code>bitmaprenderer</code> "	Follow the ImageBitmapRenderingContext creation algorithm defined in the section below, passing it this <code>canvas</code> element and <code>options</code> , to obtain an <code>ImageBitmapRenderingContext</code> object; then set this <code>canvas</code> element's <code>context mode</code> to <code>bitmaprenderer</code> , and return the <code>ImageBitmapRenderingContext</code> object.	Return null.	Return null.	Throw an <code>"InvalidStateError"</code> <code>DOMException</code> .
" <code>webgl</code> " or " <code>webl2</code> ", if the user agent supports the WebGL feature in its current configuration	Follow the instructions given in the WebGL specifications' Context Creation sections to obtain a <code>WebGLRenderingContext</code> , <code>WebGL2RenderingContext</code> , or null; if the returned value is null, then return null; otherwise, set this <code>canvas</code> element's <code>context mode</code> to <code>webgl</code> or <code>webl2</code> , and return the <code>WebGLRenderingContext</code> or <code>WebGL2RenderingContext</code> object. [WEBGL]	Return null.	Return null.	Throw an <code>"InvalidStateError"</code> <code>DOMException</code> .
An unsupported value*	Return null.	Return null.	Return null.	Throw an <code>"InvalidStateError"</code> <code>DOMException</code> .

* For example, the "`webgl`" or "`webl2`" value in the case of a user agent having exhausted the graphics hardware's abilities and having no software fallback implementation.

For web developers (non-normative)

`url = canvas.toDataURL([type [, quality]])`Returns a `data: URL` for the image in the canvas.The first argument, if provided, controls the type of the image to be returned (e.g. PNG or JPEG). The default is `"image/png"`; that type is also used if the given type isn't supported. The second argument applies if the type is an image format that supports variable quality (such as `"image/jpeg"`), and is a number in the range 0.0 to 1.0 inclusive indicating the desired quality level for the resulting image.When trying to use types other than `"image/png"`, authors can check if the image was really returned in the requested format by checking to see if the returned string starts with one of the exact strings `"data:image/png,"` or `"data:image/png;"`. If it does, the image is PNG, and thus the requested type was not supported. (The one exception to this is if the canvas has either no height or no width, in which case the result might simply be `"data:,"`)`canvas.toBlob(callback [, type [, quality]])`Creates a `Blob` object representing a file containing the image in the canvas, and invokes a callback with a handle to that object.The second argument, if provided, controls the type of the image to be returned (e.g. PNG or JPEG). The default is `"image/png"`; that type is also used if the given type isn't supported. The third argument applies if the type is an image format that supports variable quality (such as `"image/jpeg"`), and is a number in the range 0.0 to 1.0 inclusive indicating the desired quality level for the resulting image.`canvas.transferControlToOffscreen()`Returns a newly created `OffscreenCanvas` object that uses the `canvas` element as a placeholder. Once the `canvas` element has become a placeholder for an `OffscreenCanvas` object, its intrinsic size can no longer be changed, and it cannot have a rendering context. The content of the placeholder canvas is updated by calling the `commit()` method of the `OffscreenCanvas` object's rendering context.

- If this `canvas` element's bitmap's `origin-clean` flag is set to false, then throw a `"SecurityError"` `DOMException`.
- Let `result` be null.
- If this `canvas` element's bitmap has pixels (i.e., neither its horizontal dimension nor its vertical dimension is zero), then set `result` to a copy of this `canvas` element's bitmap.
- Run these steps in parallel:
 - If `result` is non-null, then set `result` to a [serialization of result as a file](#) with `type` and `quality` if given.
 - [Queue a task](#) to run these steps:
 - If `result` is non-null, then set `result` to a new `Blob` object, created in the [relevant Realm](#) of this `canvas` element, representing `result`. [FILEAPI]
 - [Invoke](#) `callback` with `result`.

The `task source` for this task is the `canvas blob serialization task source`.

MDN

[HTML.CanvasElement.transferControlToOffscreen](#)

Firefox 44+ Safari No Chrome 69+

Opera No Edge 79+

Edge (Legacy) No Internet Explorer No

Firefox, Android 44+ Safari iOS No Chrome, Android 69+ WebView, Android No Samsung Internet 10.0+ Opera, Android No

The `transferControlToOffscreen()` method, when invoked, must run these steps:

- If this `canvas` element's `context mode` is not set to `none`, throw an `"InvalidStateError"` `DOMException`.
- Let `offscreenCanvas` be a new `OffscreenCanvas` object with its width and height equal to the values of the `width` and `height` content attributes of this `canvas` element.
- Set the `placeholder canvas element` of `offscreenCanvas` to be a weak reference to this `canvas` element.
- Set this `canvas` element's `context mode` to `placeholder`.
- Return `offscreenCanvas`.

4.1.2.1 The 2D rendering context

```

void scrollPathIntoView();
void scrollPathIntoView(Path2D path);
}

interface mixin CanvasText {

```

Note
To maintain compatibility with existing Web content, user agents need to enumerate methods defined in [CanvasRenderingContext2D](#) immediately after the `stroke()` method on [CanvasRenderingContext2D](#) objects.

For web developers (non-normative)
`context = canvas.getContext('2d', { [if alpha: true], [if desynchronized: false] })`

Returns a [CanvasRenderingContext2D](#) object that is permanently bound to a particular `canvas` element.

If the `alpha` member is false, then the context is forced to always be opaque.

If the `desynchronized` member is true, then the context might be `desynchronized`.

`context.canvas`

Returns the `canvas` element.

`attributes = canvas.getContextAttributes()`

Returns an object whose:

- `alpha` member is true if the context has an alpha channel, or false if it was forced to be opaque.
- `desynchronized` member is true if the context can be `desynchronized`.

A [CanvasRenderingContext2D](#) object has an `output bitmap` that is initialized when the object is created.

The `output bitmap` has an `opaque` flag, which can be set to true or false. Initially, when one of these bitmaps is created, its `opaque` flag must be set to true.

The [CanvasRenderingContext2D](#) object also has an `alpha` boolean. When a [CanvasRenderingContext2D](#) object's `alpha` is false, then its alpha channel must be fixed to 1.0 (fully opaque) for all pixels, and attempts to change the alpha component of any pixel must be silently ignored.

Note

Thus, the bitmap of such a context starts off as `opaque black`, instead of `transparent black`; `clearRect()` always results in `opaque black` pixels, every fourth byte from `getTexImage()` is always 255, the `putImageData()` method effectively ignores every fourth byte in its input, and so on. However, the alpha component of styles and images drawn onto the canvas are still honoured up to the point where they would impact the `output bitmap`'s alpha channel; for instance, drawing a 50% transparent white square on a freshly created `output bitmap` with its `alpha` set to false will result in a fully-transparent gray square.

The [CanvasRenderingContext2D](#) object also has a `desynchronized` boolean. When a [CanvasRenderingContext2D](#) object's `desynchronized` is true, then the user agent may optimize the rendering of the canvas to reduce the latency, as measured from input events to rasterization, by desynchronizing the canvas paint cycle from the event loop, bypassing the ordinary user agent rendering algorithm, or both. Insofar as this mode involves bypassing the usual paint mechanisms, rasterization, or both, it might introduce visible tearing artifacts.

Note

The `desynchronized` boolean can be useful when implementing certain kinds of applications, such as drawing applications, where the latency between input and rasterization is critical.

The `getContextAttributes()` method, when invoked, must return a `CanvasRenderingContext2DSettings` dictionary containing the following members:

- `alpha`, set to this context's `alpha`.
- `desynchronized`, set to this context's `desynchronized`.

The `CanvasRenderingContext2D` 2D rendering context represents a flat linear Cartesian surface whose origin (0,0) is at the top left corner, with the coordinate space having x values increasing when going right, and y values increasing when going down. The x-coordinate of the right-most edge is equal to the width of the rendering context's `output bitmap` in `CSS pixels`; similarly, the y-coordinate of the bottom-most edge is equal to the height of the rendering context's `output bitmap` in `CSS pixels`.

The size of the coordinate space does not necessarily represent the size of the actual bitmaps that the user agent will use internally or during rendering. On high-definition displays, for instance, the user agent may internally use bitmaps with four device pixels per unit in the coordinate space, so that the rendering remains at high quality throughout. Anti-aliasing can similarly be implemented using oversampling with bitmaps of a higher resolution than the final image on the display.

Example

Using `CSS pixels` to describe the size of a rendering context's `output bitmap` does not mean that when rendered the canvas will cover an equivalent area in `CSS pixels`. `CSS pixels` are reused for ease of integration with CSS features, such as text layout.

In other words, the `canvas` element below's rendering context has a 200x200 `output bitmap` (which internally uses `CSS pixels` as a unit for ease of integration with CSS) and is rendered as 100x100 `CSS pixels`:

```
<canvas width=200 height=200 style="width:100px; height:100px">
```

The 2D context creation algorithm, which is passed a target (a `canvas` element) and options, consists of running these steps:

1. Let settings be the result of `converting` options to the dictionary type `CanvasRenderingContext2DSettings`. (This can throw an exception).
2. Let context be a new `CanvasRenderingContext2D` object.
3. Initialize context's `canvas` attribute to point to target.
4. Set context's `output bitmap` to the same bitmap as target's bitmap (so that they are shared).
5. Set bitmap dimensions to the numeric values of target's `width` and `height` content attributes.

7. Set `context's desynchronized` to `settings's desynchronized`.
 8. Return `context`.

When the user agent is to set `bitmap dimensions to width and height`, it must run these steps:

1. [Reset the rendering context to its default state](#).
2. Resize the `output bitmap` to the new `width` and `height` and clear it to `transparent black`.
3. Let `canvas` be the `canvas` element to which the rendering context's `canvas` attribute was initialized.
4. If the numeric value of `canvas's width` content attribute differs from `width`, then set `canvas's width` content attribute to the shortest possible string representing `width` as a `valid non-negative integer`.
5. If the numeric value of `canvas's height` content attribute differs from `height`, then set `canvas's height` content attribute to the shortest possible string representing `height` as a `valid non-negative integer`.

Example

Only one square appears to be drawn in the following example:

```
// canvas is a reference to a <canvas> element
var context = canvas.getContext('2d');
context.fillRect(0, 0, 50, 50);
// clears the canvas
context.fillStyle = 'black';
context.fillRect(0, 100, 50, 50);
// clears the canvas
context.fillRect(100, 0, 50, 50); // only this square remains
```

MDN

Opera Yes
Android Yes

The `canvas` attribute must return the value it was initialized to when the object was created.

The `CanvasFillRule` enumeration is used to select the `fill rule` algorithm by which to determine if a point is inside or outside a path.

The value "`nonzero`" value indicates the nonzero winding rule, wherein a point is considered to be outside a shape if the number of times a half-infinite straight line drawn from that point crosses the shape's path going in one direction is equal to the number of times it crosses the path going in the other direction.

The "`evenodd`" value indicates the even-odd rule, wherein a point is considered to be outside a shape if the number of times a half-infinite straight line drawn from that point crosses the shape's path is even.

If a point is not outside a shape, it is inside the shape.

The `ImageSmoothingQuality` enumeration is used to express a preference for the interpolation quality to use when smoothing images.

The "`low`" value indicates a preference for a low level of image interpolation quality. Low-quality image interpolation may be more computationally efficient than higher settings.

The "`medium`" value indicates a preference for a medium level of image interpolation quality.

The "`high`" value indicates a preference for a high level of image interpolation quality. High-quality image interpolation may be more computationally expensive than lower settings.

Note
Bilinear scaling is an example of a relatively fast, lower-quality image-smoothing algorithm. Bicubic or Lanczos scaling are examples of image-smoothing algorithms that produce higher-quality output. This specification does not mandate that specific interpolation algorithms be used.

4.12.5.1 Implementation notes

This section is non-normative.

The `output bitmap`, when it is not directly displayed by the user agent, implementations can, instead of updating this bitmap, merely remember the sequence of drawing operations that have been applied to it until such time as the bitmap's actual data is needed (for example because of a call to `drawImage()`, or the `createImageBitmap()` factory method). In many cases, this will be more memory efficient.

The bitmap of a `canvas` element is the one bitmap that's pretty much always going to be needed in practice. The `output bitmap` of a rendering context, when it has one, is always just an alias to a `canvas` element's bitmap.

Additional bitmaps are sometimes needed, e.g. to enable fast drawing when the canvas is being painted at a different size than its `intrinsic size`, or to enable double buffering so that graphics updates, like page scrolling for example, can be processed concurrently while canvas draw commands are being executed.

4.12.5.1.2 The canvas state

Objects that implement the `CanvasState` interface maintain a stack of drawing states. *Drawing states* consist of:

- The current `imageSmoothingMatrix`.
- The current `clippingRegion`.
- The current values of the following attributes: `strokeStyle`, `fillStyle`, `globalAlpha`, `lineWidth`, `lineCap`, `lineJoin`, `miterLimit`, `lineDashOffset`, `shadowOffsetX`, `shadowOffsetY`, `shadowBlur`, `shadowColor`, `filter`, `globalCompositeOperation`, `font`, `textAlign`, `textBaseline`, `direction`, `imageSmoothingEnabled`, `imageSmoothingQuality`.
- The current `dashList`.

Note

The `currentDefaultPath` and the rendering context's bitmaps are not part of the drawing state. The `currentDefaultPath` is persistent, and can only be reset using the `beginPath()` method. The bitmaps depend on whether and how the rendering context is bound to a `canvas` element.

For web developers (non-normative)

`context.push()`

Pushes the current state onto the stack.

`context.restore()`

Pops the top state on the stack, restoring the context to that state.

MDN

[CanvasRenderingContext2D.save](#)

The `restore()` method, when invoked, must pop the top entry in the drawing state stack, and reset the drawing state it describes. If there is no saved state, then the method must do nothing.

When the user agent is to *reset the rendering context to its default state*, it must clear the drawing state stack and everything that `drawingState` consists of to initial values.

4.12.5.1.3 Line styles

For web developers (non-normative)

`context.lineWidth [= value]`

`style.lineWidth [= value]`

Returns the current line width.

Can be set, to change the line width.

The possible line width values are "0", "1", "2", ..., "1000". Other values are ignored.

`context.lineCap [= value]`

`style.lineCap [= value]`

Returns the current line cap style.

Can be set, to change the line cap style.

The possible line cap styles are "butt", "round", and "square". Other values are ignored.

`context.lineJoin [= value]`

`style.lineJoin [= value]`

Returns the current line join style.

Can be set, to change the line join style.

The possible line join styles are "bevel", "round", and "miter". Other values are ignored.

`context.miterLimit [= value]`

`style.miterLimit [= value]`

Returns the current miter limit ratio.

Can be set, to change the miter limit ratio. Values that are not finite values greater than zero are ignored.

`context.getLineDash(segments)`

`style.lineDash(segments)`

Sets the current line dash pattern (as used when stroking). The argument is a list of distances for which to alternately have the line on and the line off.

`segments = styles.lineDash()`
 Returns a copy of the current line dash pattern. The array returned will always have an even number of entries (i.e. the pattern is normalized).

`context.lineDashOffset
style.lineDashOffset`
 Returns the phase offset (in the same units as the line dash pattern).
 Can be set, to change the phase offset. Values that are not finite values are ignored.

Objects that implement the `CanvasPathDrawingStyles` interface have attributes and methods (defined in this section) that control how lines are treated by the object.

MDN

`CanvasRenderingContext2D.lineWidth`

Support in all current engines.

Firefox, Android 4+ Safari iOS Yes Chrome Android Yes WebView, Android Yes Samsung Internet Yes Opera, Android Yes

The `lineCap` attribute defines the type of endings that UAs will place on the end of lines. The three valid values are "butt", "round", and "square".

On getting, it must return the current value. On setting, the current value must be changed to the new value.

When the object implementing the `CanvasPathDrawingStyles` interface is created, the `lineCap` attribute must initially have the value "butt".

MDN

`CanvasRenderingContext2D.lineJoin`

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox, Android 4+ Safari iOS Yes Chrome Android Yes WebView, Android Yes Samsung Internet Yes Opera, Android Yes

The `lineJoin` attribute defines the type of corners that UAs will place where two lines meet. The three valid values are "bevel", "round", and "miter".

On getting, it must return the current value. On setting, the current value must be changed to the new value.

When the object implementing the `CanvasPathDrawingStyles` interface is created, the `lineJoin` attribute must initially have the value "miter".

MDN

`CanvasRenderingContext2D.miterLimit`

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox, Android 4+ Safari iOS Yes Chrome Android Yes WebView, Android Yes Samsung Internet Yes Opera, Android Yes

When the `lineJoin` attribute has the value "miter", strokes use the miter limit ratio to decide how to render joins. The miter limit ratio can be explicitly set using the `miterLimit` attribute. On getting, it must return the current value. On setting, zero, negative, infinite, and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the `CanvasPathDrawingStyles` interface is created, the `miterLimit` attribute must initially have the value 10.0.

Each `CanvasPathDrawingStyles` object has a `dash` list, which is either empty or consists of an even number of non-negative numbers. Initially, the `dash` list must be empty.

MDN

`CanvasRenderingContext2D.setLineDash`

Support in all current engines.

Firefox 2.7+ Safari 6.1+ Chrome 23+

Opera 15+ Edge 79+

Edge (Legacy) 12+ Internet Explorer 11

Firefox, Android 2.7+ Safari iOS+ Chrome, Android 2.5+ WebView, Android 3.7+ Samsung Internet 1.5+ Opera, Android 14+

The `setLineDash()` method, when invoked, must run these steps:

1. Let a be the argument.
2. If any value in a is not finite (e.g. an Infinity or a NaN value), or if any value is negative (less than zero), then return (without throwing an exception; user agents could show a message on a developer console, though, as that would be helpful for debugging).
3. If the number of elements in a is odd, then let a be the concatenation of two copies of a .
4. Let the object's `dash` list be a .

`CanvasRenderingContext2D.getLineDash`

Support in all current engines.

Firefox 2.7+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer 11

Firefox, Android 2.7+ Safari iOS Yes Chrome, Android Yes WebView, Android Yes Samsung Internet Yes Opera, Android Yes

When the `getLineDash()` method is invoked, it must return a sequence whose values are the values of the object's `dash` list, in the same order.

MDN

`CanvasRenderingContext2D.lineDashOffset`

Support in all current engines.

Firefox 2.7+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer 11

Firefox, Android 2.7+ Safari iOS Yes Chrome, Android Yes WebView, Android Yes Samsung Internet Yes Opera, Android Yes

It is sometimes useful to change the "phase" of the dash pattern, e.g. to achieve a "marching ants" effect. The phase can be set using the `lineDashOffset` attribute. On getting, it must return the current value. On setting, infinite and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the `CanvasPathDrawingStyles` interface is created, the `lineDashOffset` attribute must initially have the value 0.0.

When a user agent is to *trace a path*, given an object `style` that implements the `CanvasPathDrawingStyles` interface, it must run the following algorithm. This algorithm returns a new `path`.

1. Let $path$ be a copy of the path being traced.
2. Prune all zero-length `lineSegments` from $path$.
3. Remove from $path$ any subpaths containing no lines (i.e. subpaths with just one point).
4. Replace each point in each subpath of $path$ other than the first point and the last point of each subpath by a `join` that joins the line leading to that point to the line leading out of that point, such that the subpaths all consist of two points (a starting point with a line leading out of it, and an ending point with a line leading into it), one or more lines (connecting the points and the joins), and zero or more joins (each connecting one line to another), connected together such that each subpath is a series of one or more lines with a join between each one and a point on each end.
5. Add a straight closing line to each closed subpath in $path$ connecting the last point and the first point of that subpath; change the last point to a join (from the previously last line to the newly added closing line), and change the first point to a join (from the newly added closing line to the first line).
6. If `style's dash` list is empty, then jump to the step labeled *convert*.
7. Let `pattern width` be the concatenation of all the entries of `style's dash` list, in coordinate space units.
8. For each subpath `subpath` in $path$, run the following substeps. These substeps mutate the subpaths in $path$ *in vivo*.

2. Let `offset` be the value of `style's lineDashOffset`, in coordinate space units.
 3. While `offset` is greater than `pattern width`, decrement it by `pattern width`.
 While `offset` is less than zero, increment it by `pattern width`.
 4. Define `L` to be a linear coordinate line defined along all lines in `subpath`, such that the start of the first line in the `subpath` is defined as coordinate 0, and the end of the last line in the `subpath` is defined as coordinate `subpath width`.
 5. Let `position` be zero minus `offset`.
 6. Let `index` be 0.
 7. Let `current state` be `off` (the other states being `on` and `zero-on`).
 8. `Dash on:` Let `segment length` be the value of `style's dash list`'s `index` entry.
 9. Increment `position` by `segment length`.
 10. If `position` is greater than `subpath width`, then end these substeps for this `subpath` and start them again for the next `subpath`; if there are no more `subpaths`, then jump to the step labeled `convert` instead.
 11. If `segment length` is nonzero, then let `current state` be `on`.
 12. Increment `index` by one.
 13. `Dash off:` Let `segment length` be the value of `style's dash list`'s `index` entry.
 14. Let `start` be the offset `position` on `L`.
 15. Increment `position` by `segment length`.
 16. If `position` is less than zero, then jump to the step labeled `post-cut`.
 17. If `start` is less than zero, then let `start` be zero.
 18. If `position` is greater than `subpath width`, then let `end` be the offset `subpath width` on `L`. Otherwise, let `end` be the offset `position` on `L`.
 19. Jump to the first appropriate step:
 If `segment length` is zero and `current state` is `off`
 Do nothing, just continue to the next step.
 If `current state` is `off`
 Cut the line on which `end` finds itself short at `end` and place a point there, cutting in two the `subpath` that it was in; remove all line segments, joins, points, and `subpaths` that are between `start` and `end`; and finally place a single point at `start` with no lines connecting to it.
 The point has a *directionality* for the purposes of drawing line caps (see below). The directionality is the direction that the original line had at that point (i.e. when `L` was defined above).
 Otherwise
 Cut the line on which `start` finds itself into two at `start` and place a point there, cutting in two the `subpath` that it was in, and similarly cut the line on which `end` finds itself short at `end` and place a point there, cutting in two the `subpath` that it was in, and then remove all line segments, joins, points, and `subpaths` that are between `start` and `end`.
 If `start` and `end` are the same point, then this results in just the line being cut in two and two points being inserted there, with nothing being removed, unless a join also happens to be at that point, in which case the join must be removed.
 20. `Post-cut:` If `position` is greater than `subpath width`, then jump to the step labeled `convert`.
 21. If `segment length` is greater than zero, then let `positioned-at-on-dash` be false.
 22. Increment `index` by one. If it is equal to the number of entries in `style's dash list`, then let `index` be 0.
 23. Return to the step labeled `dash on`.

9. `Convert:` This is the step that converts the path to a new path that represents its stroke.

Create a new `path` that describes the edge of the areas that would be covered if a straight line of length equal to `style's lineWidth` was swept along each `subpath` in `path` while being kept at an angle such that the line is orthogonal to the path being swept, replacing each point with the end cap necessary to satisfy `style's lineCap` attribute as described previously and elaborated below, and replacing each join with the join necessary to satisfy `style's lineJoin` type, as defined below.

Caps: Each point has a flat edge perpendicular to the direction of the line coming out of it. This is then augmented according to the value of `style's lineCap`. The "butⁿ" value means that no additional line cap is added. The "round" value means that a semi-circle with the diameter equal to `style's lineWidth` width must additionally be placed on to the line coming out of each point. The "square" value means that a rectangle with the length of `style's lineWidth` and the width of half `style's lineWidth` width, placed flat against the edge perpendicular to the direction of the line coming out of the point, must be added at each point.

Points with no lines coming out of them must have two caps placed back-to-back as if it was really two points connected to each other by an infinitesimally short straight line in the direction of the point's *directionality* (as defined above).

Joins: In addition to the point where a `join` occurs, two additional points are relevant to each `join`, one for each line: the two corners found half the line width away from the join point, one perpendicular to each line, each on the side furthest from the other line.

A triangle connecting these two opposite corners with a straight line, with the third point of the triangle being the join point, must be added at all `joins`. The `lineJoin` attribute controls whether anything else is rendered. The aforementioned values have the following meanings:

The "bevel" value means that this is all that is rendered at `joins`.

The "round" value means that an arc connecting the two aforementioned corners of the `join`, abutting (and not overlapping) the aforementioned triangle, with the diameter equal to the line width and the origin at the point of the `join`, must be added at `joins`.

The "miter" value means that a second triangle must (if it can give the miter length) be added at the `join`, with one line being the line between the two aforementioned corners, abutting the first triangle, and the other two being continuations of the outside edges of the two joining lines, as long as required to intersect without going over the miter length. The miter length is the distance from the point where the `join` occurs to the intersection of the line edges on the outside of the `join`. The miter limit ratio is the maximum allowed ratio of the miter length to half the line width. If the miter length would cause the miter limit ratio (as set by `style's miterLimit` attribute) to be exceeded, then this second triangle must not be added.

The subpaths in the newly created path must be oriented such that for any point, the number of times a half-infinite straight line drawn from that point crosses a `subpath` is even if and only if the number of times a half-infinite straight line drawn from that same point crosses a `subpath` going in one direction is equal to the number of times it crosses a `subpath` going in the other direction.

10. Return the newly created path.

4.12.5.1.4 Text styles

For web developers (non-normative)

`context : font [= value]`

`style : font [= value]`

Returns the current font settings.

Can be set, to change the font. The syntax is the same as for the CSS `font` property; values that cannot be parsed as CSS font values are ignored.

Relative keywords and lengths are computed relative to the font of the `canvas` element.

`context : textAlign [= value]`

`style : textAlign [= value]`

Returns the current text alignment settings.

Can be set, to change the alignment. The possible values are and their meanings are given below. Other values are ignored. The default is "start".

`context : textBaseline [= value]`

`style : textBaseline [= value]`

Returns the current baseline alignment settings.

Can be set, to change the baseline alignment. The possible values and their meanings are given below. Other values are ignored. The default is "`alphabetic`".

`context : direction [= value]`

`style : direction [= value]`

Returns the current directionality.

Can be set, to change the directionality. The possible values and their meanings are given below. Other values are ignored. The default is "`inherit`".

Objects that implement the `CanvasTextDrawingStyle` interface have attributes (defined in this section) that control how text is laid out (rasterized or outlined) by the object. Such objects can also have a `font style source object`. For `CanvasRenderingContext2D` objects, this is the `associated offscreenCanvas object`.

Font resolution for the `font style source object` requires a `font source`. This is determined for a given `object` implementing `CanvasTextDrawingStyle` by the following steps: [CSSFONTLOAD]

1. If `object's font style source object` is a `canvas` element, return the element's `node document`.

2. Otherwise, `object's font style source object` is an `OffscreenCanvas` object:

1. Let `global` be `object's relevant global object`.

2. If `global` is a `Window` object, then return `global's associated Document`.

3. Assert: `global` implements `WorkerGlobalScope`.

4. Return `global`.

Example

This is an example of font resolution with a regular `canvas` element with ID `c1`.

```
const font = new FontFace("MyCanvasFont", "url(mycanvasfont.ttf)");
document.fonts.add(font);

const context = document.getElementById("c1").getContext("2d");
context.font = "64px MyCanvasFont";
context.fillText("Hello", 0, 0);
});
```

In this example, the canvas will display text using `mycanvasfont.ttf` as its font.

Example

This is an example of how font resolution can happen using `OffscreenCanvas`. Assuming a `canvas` element with ID `c2` which is transferred to a worker like so:

```
const offscreenCanvas = document.createElementById("c2").transferControlToOffscreen();
worker.postMessage(offscreenCanvas, [offscreenCanvas]);
```

Then, in the worker:

```
self.onmessage = function(e) {
  const transferredCanvas = e.data;
  const context = transferredCanvas.getContext("2d");
  const font = new FontFace("MyFont", "url(myfont.ttf)");
  self.fonts.ready.then(function() {
    context.font = "64px MyFont";
    context.fillText("Hello", 0, 0);
  });
};
```

In this example, the canvas will display a text using `myfont.ttf`. Notice that the font is only loaded inside the worker, and not in the document context.

[CanvasRenderingContext2D.font](#)

Support in all current engines.

Firefox 3.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer 9+

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `font` IDL attribute, on setting, must be [parsed as a CSS value](#) (but without supporting property-independent style sheet syntax like 'inherit'), and the resulting font must be assigned to the context, with the `line-height` component forced to 'normal', with the `font-size` component converted to `CSS pixels`, and with system fonts being computed to explicit values. If the new value is syntactically incorrect (including using property-independent style sheet syntax like 'inherit' or 'initial'), then it must be ignored, without assigning a new font value. [\[CSS\]](#)

Font family names must be interpreted in the context of the `font-style source object` when the font is to be used; any fonts embedded using `#font-face` or loaded using `FontFace` objects that are visible to the `font-style source object` must therefore be available once they are loaded. (Each `font-style source object` has a `font source`, which determines what fonts are available.) If a font is used before it is fully loaded, or if the `font-style source object` does not have that font in scope at the time the font is to be used, then it must be treated as if it was an unknown font, falling back to another as described by the relevant CSS specifications. [\[CSSFONTS\]](#) [\[CSSFONTLOAD\]](#)

On getting, the `font` attribute must return the [serialized form](#) of the current font of the context (with no `line-height` component). [\[CSSOM\]](#)

Example

For example, after the following statement:

```
context.font = "italic 400 12px/2 Unknown Font, sans-serif";
```

`_the expression context.font would evaluate to the string "italic 12px \"Unknown Font\", sans-serif". The "400" font-weight doesn't appear because that is the default value. The line-height doesn't appear because it is forced to "normal", the default value.`

When the object implementing the `CanvasTextDrawingStyles` interface is created, the font of the context must be set to 10px sans-serif. When the `font-size` component is set to lengths using percentages, `em` or `ex` units, or the 'larger' or 'smaller' keywords, these must be interpreted relative to the `computed value` of the `font-size` property of the `font-style source object` at the time that the attribute is set, if it is an element. When the `font-weight` component is set to the relative values 'bolder' and 'lighter', these must be interpreted relative to the `computed value` of the `font-weight` property of the `font-style source object` at the time that the attribute is set, if it is an element. If the `computed values` are undefined for a particular case (e.g. because the `font-style source object` is not an element or is not `bolder`/`lighter`), then the relative keywords must be interpreted relative to the normal-weight 10px sans-serif default.

MDN[CanvasRenderingContext2D.textAlign](#)

Support in all current engines.

Firefox 3.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `textAlign` IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the `CanvasTextDrawingStyles` interface is created, the `textAlign` attribute must initially have the value `start`.

MDN[CanvasRenderingContext2D.textBaseline](#)

Support in all current engines.

Firefox 3.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer 9+

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `textBaseline` IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the `CanvasTextDrawingStyles` interface is created, the `textBaseline` attribute must initially have the value `alphabetic`.

MDN[CanvasRenderingContext2D.direction](#)

Firefox No Safari Yes Chrome Yes

Opera No Edge Yes

Edge (Legacy) No Internet Explorer No

Firefox Android No Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `direction` IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the `CanvasTextDrawingStyles` interface is created, the `direction` attribute must initially have the value `ltr`.

The `textAlign` attribute's allowed keywords are as follows:

`start`

Align to the start edge of the text (left side in left-to-right text, right side in right-to-left text).

`end`

Align to the end edge of the text (right side in left-to-right text, left side in right-to-left text).

`left`

Align to the left.

`right`

Align to the right.

`center`

Align to the center.

The `textBaseline` attribute's allowed keywords correspond to alignment points in the font:

The keywords map to these alignment points as follows:

`top`

The top of the em square

`hanging`

The hanging baseline

`middle`

The middle of the em square

`alphabetic`

The alphabetic baseline

`ideographic`

The ideographic baseline

`bottom`

The bottom of the em square

The `direction` attribute's allowed keywords are as follows:

`ltr`

Treat input to the `text-preparation algorithm` as left-to-right text.

`rtl`

Treat input to the `text-preparation algorithm` as right-to-left text.

`inherit`

Default to the directionality of the `canvas` element or `document` as appropriate.

The `text-preparation algorithm` is as follows. It takes as input a string `text`, a `CanvasTextDrawingStyles` object `target`, and an optional length `maxWidth`. It returns an array of glyph shapes, each positioned on a common coordinate space, a `physical alignment` whose value is one of `left`, `right`, and `center`, and an `inline box`. (Most callers of this algorithm ignore the `physical alignment` and the `inline box`.)

1. If `maxWidth` was provided but is less than or equal to zero or equal to NaN, then return an empty array.

2. Replace all `ASCII whitespace` in `text` with U+0020 SPACE characters.

3. Let `font` be the current font of `target`, as given by that object's `font` attribute.

4. Apply the appropriate step from the following list to determine the value of `direction`:

If the `target` object's `direction` attribute has the value "`ltr`"

 Let `direction` be "`ltr`".

If the `target` object's `direction` attribute has the value "`rl`"

 Let `direction` be "`rl`".

If the `target` object's `font-style source object` is an element

 Let `direction` be the `directionality` of the target object's `font-style source object`.

If the `target` object's `font-style source object` is a `Document`, with a non-null `documentElement`

 Let `direction` be the `directionality` of the target object's `font-style source object`'s `documentElement`.

Otherwise

 Let `direction` be "`ltr`".

5. Form a hypothetical infinitely wide CSS `line box` containing a single `inline box` containing the text `text`, with all the properties at their initial values except the `font` property of the `inline box` set to `font`, the `direction` property of the `inline box` set to `direction`, and the `white-space` property set to `'pre'`. [\[CSS\]](#)

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

7. The *anchor point* is a point on the *inline box*, and the *physical alignment* is one of the values *left*, *right*, and *center*. These variables are determined by the *textAlign* and *textBaseline* values as follows:

Horizontal position:

```
If textAlign is left  
If textBaseline is top, and direction is ltr  
If textBaseline is bottom and direction is rtl  
    Let the anchor point's horizontal position be the left edge of the inline box, and let physical alignment be left.  
If textAlign is right  
If textBaseline is top and direction is rtl  
If textBaseline is bottom and direction is rtl  
    Let the anchor point's horizontal position be the right edge of the inline box, and let physical alignment be right.  
If textAlign is center  
    Let the anchor point's horizontal position be half way between the left and right edges of the inline box, and let physical alignment be center.
```

Vertical position:

```
If textBaseline is top  
    Let the anchor point's vertical position be the top of the em box of the first available font of the inline box.  
If textBaseline is hangding  
    Let the anchor point's vertical position be the hanging baseline of the first available font of the inline box.  
If textBaseline is middle  
    Let the anchor point's vertical position be half way between the bottom and the top of the em box of the first available font of the inline box.  
If textBaseline is alphabetic  
    Let the anchor point's vertical position be the alphabetic baseline of the first available font of the inline box.  
If textBaseline is ideographic  
    Let the anchor point's vertical position be the ideographic baseline of the first available font of the inline box.  
If textBaseline is bottom  
    Let the anchor point's vertical position be the bottom of the em box of the first available font of the inline box.
```

8. Let *result* be an array constructed by iterating over each glyph in the *inline box* from left to right (if any), adding to the array, for each glyph, the shape of the glyph as it is in the *inline box*, positioned on a coordinate space using *CSS pixels* with its origin at the *anchor point*.

9. Return *result*, *physical alignment*, and the *inline box*.

4.12.5.1.5 Building paths

Objects that implement the `CanvasPath` interface have a `path`. A path has a list of zero or more subpaths. Each subpath consists of a list of one or more points, connected by straight or curved *line segments*, and a flag indicating whether the subpath is closed or not. A closed subpath is one where the last point of the subpath is connected to the first point of the subpath by a straight line. Subpaths with only one point are ignored when painting the path.

`Paths` have a *need new subpath* flag. When this flag is set, certain APIs create a new subpath rather than extending the previous one. When a `path` is created, its `need new subpath` flag must be set.

When an object implementing the `CanvasPath` interface is created, its `path` must be initialized to zero subpaths.

For web developers (non-normative)

```
context.moveTo(x, y)  
path.moveTo(x, y)
```

Creates a new subpath with the given point.

```
context.closePath()  
path.closePath()
```

Marks the current subpath as closed, and starts a new subpath with a point the same as the start and end of the newly closed subpath.

```
context.lineTo(x, y)  
path.lineTo(x, y)
```

Adds the given point to the current subpath, connected to the previous one by a straight line.

```
context.quadraticCurveTo(cpx, cpy, x, y)  
path.quadraticCurveTo(cpx, cpy, x, y)
```

Adds the given point to the current subpath, connected to the previous one by a quadratic Bézier curve with the given control point.

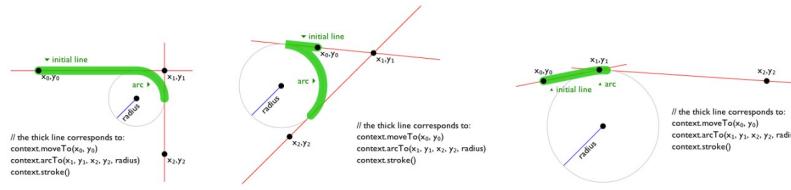

```
context.bezierCurveTo(cp1x, cp1y, cp2x, cp2y, x, y)  
path.bezierCurveTo(cp1x, cp1y, cp2x, cp2y, x, y)
```

Adds the given point to the current subpath, connected to the previous one by a cubic Bézier curve with the given control points.

```
context.arc(x1, y1, x2, y2, radius)  
path.arc(x1, y1, x2, y2, radius)
```

Adds an arc with the given control points and radius to the current subpath, connected to the previous point by a straight line.

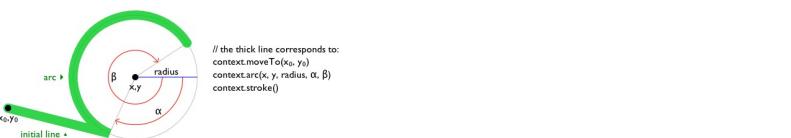

Throws an "`IndexSizeError`" `DOMException` if the given radius is negative.

```
context.arc(x, y, radius, startAngle, endAngle [, anticlockwise ])  
path.arc(x, y, radius, startAngle, endAngle [, anticlockwise ])
```

Adds points to the subpath such that are described by the circumference of the circle described by the arguments, starting at the given start angle and ending at the given end angle, going in the given direction (defaulting to clockwise), is added to the path, connected to the previous point by a straight line.

Throws an "`IndexSizeError`" `DOMException` if the given radius is negative.

```
context.ellipse(x, y, radiusX, radiusY, rotation, startAngle, endAngle [, anticlockwise ])  
path.ellipse(x, y, radiusX, radiusY, rotation, startAngle, endAngle [, anticlockwise ])
```

Adds points to the subpath such that are described by the circumference of the ellipse described by the arguments, starting at the given start angle and ending at the given end angle, going in the given direction (defaulting to clockwise), is added to the path, connected to the previous point by a straight line.

Throws an "`IndexSizeError`" `DOMException` if the given radius is negative.

```
context.rect(x, y, w, h)  
path.rect(x, y, w, h)
```

Adds a new closed subpath to the path, representing the given rectangle.

The following methods allow authors to manipulate the `path` of objects implementing the `CanvasPath` interface.

For objects implementing the `CanvasDrawPath` and `CanvasTransform` interfaces, the points passed to the methods, and the resulting lines added to `current default path` by these methods, must be transformed according to the `current transformation matrix` before being added to the path.

MDN

CanvasRenderingContext2D#moveTo

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `moveTo(x, y)` method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.
 2. Create a new subpath with the specified point as its first (and only) point.
- When the user agent is to *ensure there is a subpath* for a coordinate (x, y) on a `path`, the user agent must check to see if the `path` has its `need new subpath` flag set. If it does, then the user agent must create a new subpath with the point (x, y) as its first (and only) point, as if the `moveTo()` method had been called, and must then unset the `path`'s `need new subpath` flag.

MDN

CanvasRenderingContext2D#closePath

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `closePath()` method, when invoked, must do nothing if the object's path has no subpaths. Otherwise, it must mark the last subpath as closed, create a new subpath whose first point is the same as the previous subpath's first point, and finally add this new subpath to the path.

If the last subpath had more than one point in its list of points, then this is equivalent to adding a straight line connecting the last point back to the first point of the last subpath, thus "closing" the subpath.

New points and the lines connecting them are added to subpaths using the methods described below. In all cases, the methods only modify the last subpath in the object's path.

[CanvasRenderingContext2D.lineTo](#)

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `bezierCurveTo(cp1x, cp1y, cp2x, cp2y, x, y)` method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. [Ensure there is a subpath](#) for $(cp1x, cp1y)$.
3. Connect the last point in the subpath to the given point (x, y) using a cubic Bézier curve with control points $(cp1x, cp1y)$ and $(cp2x, cp2y)$. [\[BEZIER\]](#)
4. Add the point (x, y) to the subpath.

[CanvasRenderingContext2D.arcTo](#)

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `arcTo(x1, y1, x2, y2, radius)` method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. [Ensure there is a subpath](#) for $(x1, y1)$.
3. If `radius` is negative, then throw a "[IndexSizeError](#)" `DOMException`.
4. Let the point $(x0, y0)$ be the last point in the subpath, transformed by the inverse of the [current transformation matrix](#) (so that it is in the same coordinate system as the points passed to the method).
5. If the point $(x0, y0)$ is equal to the point $(x1, y1)$, or if the point $(x1, y1)$ is equal to the point $(x2, y2)$, or if `radius` is zero, then add the point $(x1, y1)$ to the subpath, and connect that point to the previous point $(x0, y0)$ by a straight line.
6. Otherwise, if the points $(x0, y0)$, $(x1, y1)$, and $(x2, y2)$ all lie on a single straight line, then add the point $(x1, y1)$ to the subpath, and connect that point to the previous point $(x0, y0)$ by a straight line.
7. Otherwise, let *The Arc* be the shortest arc given by circumference of the circle that has `radius` `radius`, and that has one point tangent to the half-infinite line that crosses the point $(x0, y0)$ and ends at the point $(x1, y1)$, and that has a different point tangent to the half-infinite line that ends at the point $(x1, y1)$ and crosses the point $(x2, y2)$. The points at which this circle touches these two lines are called the start and end tangent points respectively. Connect the point $(x0, y0)$ to the start tangent point by a straight line, adding the start tangent point to the subpath, and then connect the start tangent point to the end tangent point by *The Arc*, adding the end tangent point to the subpath.

[CanvasRenderingContext2D.arc](#)

Support in all current engines.

Firefox 1.5+ Safari 3+ Chrome 1+

Opera 11.6+ Edge 79+

The `arc(x, y, radius, startAngle, endAngle, anticlockwise)` method, when invoked, must run the [ellipse method steps](#) with this, $x, y, radius, radius, 0, startAngle, endAngle$, and `anticlockwise`.

This makes it equivalent to `ellipse()` except that both radii are equal and `rotation` is 0.

[CanvasRenderingContext2D.clip](#)

Support in all current engines.

Firefox 48+ Safari 9+ Chrome 31+

Opera 18+ Edge 79+

Edge (Legacy) 13+ Internet Explorer No

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android No Samsung Internet Yes Opera Android No

The `ellipse(x, y, radiusX, radiusY, rotation, startAngle, endAngle, anticlockwise)` method, when invoked, must run the [ellipse method steps](#) with this, $x, y, radiusX, radiusY, rotation, startAngle, endAngle$, and `anticlockwise`.

The `ellipse` method steps, given `canvasPath`, $x, y, radiusX, radiusY, rotation, startAngle, endAngle$, and `anticlockwise`:

1. If any of the arguments are infinite or NaN, then return.
2. If either `radiusX` or `radiusY` are negative, then throw a "[IndexSizeError](#)" `DOMException`.
3. If `canvasPath`'s path has any subpaths, then add a straight line from the last point in the subpath to the start point of the arc.

4. Add the start and end points of the arc to the subpath, and connect them with an arc. The arc and its start and end points are defined as follows:

Consider an ellipse that has its origin at (x, y) , that has a major-axis radius `radiusX` and a minor-axis radius `radiusY`, and that is rotated about its origin such that its semi-major axis is inclined `rotation` radians clockwise from the x-axis.

If `anticlockwise` is false and `endAngle - startAngle` is equal to or greater than 2π , or, if `anticlockwise` is true and `startAngle - endAngle` is equal to or greater than 2π , then the arc is the whole circumference of this ellipse, and the point at `startAngle` along this circle's circumference, measured in radians clockwise from the ellipse's semi-major axis, acts as both the start point and the end point.

Otherwise, the points at `startAngle` and `endAngle` along this circle's circumference, measured in radians clockwise from the ellipse's semi-major axis, are the start and end points respectively, and the arc is the path along the circumference of this ellipse from the start point to the end point, going anti-clockwise if `anticlockwise` is true, and clockwise otherwise. Since the points are on the ellipse, as opposed to being simply angles from zero, the arc can never cover an angle greater than 2π radians.

Even if the arc covers the entire circumference of the ellipse and there are no other points in the subpath, the path is not closed unless the `closePath()` method is appropriately invoked.

[CanvasRenderingContext2D.reset](#)

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Path2D

Support in all current engines.

Firefox3+Safari10+ChromeYes

OperaYesEdgeYes

Edge (Legacy)NoInternet Explorer?

Firefox Android31+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

`Path2D` objects can be used to declare paths that are then later used on objects implementing the `CanvasDrawPath` interface. In addition to many of the APIs described in earlier sections, `Path2D` objects have methods to combine paths, and to add text to paths.

For web developers (non-normative)

`path = new Path2D()`

Creates a new empty `Path2D` object.

`path = new Path2D(path)`

When `path` is a `Path2D` object, returns a copy.

When `path` is a string, creates the path described by the argument, interpreted as SVG path data. [SVG]

`path.addPath(path [, transform])`

Adds to the path the path given by the argument.

MDN

Path2DPath2D

Support in all current engines.

Firefox3+Safari10+ChromeYes

OperaYesEdgeYes

Edge (Legacy)NoInternet Explorer?

Firefox Android31+Safari iOSYesChrome Android42+WebView AndroidNoSamsung Internet4.0+Opera AndroidYes

The `Path2D(path)` constructor, when invoked, must run these steps:

1. Let `output` be a new `Path2D` object.
2. If `path` is not given, then return `output`.
3. If `path` is a `Path2D` object, then add all subpaths of `path` to `output` and return `output`. (In other words, it returns a copy of the argument.)
4. Let `svgPath` be the result of parsing and interpreting `path` according to SVG 2's rules for path data. [SVG]

Note
The resulting path could be empty. SVG defines error handling rules for parsing and applying path data.

5. Let (x, y) be the last point in `svgPath`.
6. Add all the subpaths, if any, from `svgPath` to `output`.
7. Create a new subpath in `output` with (x, y) as the only point in the subpath.
8. Return `output`.

The `addPath(b, transform)` method, when invoked on a `Path2D` object `a`, must run these steps:

1. If the `Path2D` object `b` has no subpaths, then return.
2. If `matrix` is the result of `creating a 2D matrix from the 2D dictionary transform`.
3. If one or more of `matrix.m11 element`, `m12 element`, `m21 element`, `m22 element`, `m41 element`, or `m42 element` are infinite or NaN, then return.
4. Create a copy of all the subpaths in `b`. Let this copy be known as `c`.
5. Transform all the coordinates and lines in `c` by the transform matrix `matrix`.
6. Let (x, y) be the last point in the last subpath of `c`.
7. Add all the subpaths in `c` to `a`.
8. Create a new subpath in `a` with (x, y) as the only point in the subpath.

4.12.5.1.7 Transformations

Objects that implement the `CanvasTransform` interface have a *current transformation matrix*, as well as methods (described in this section) to manipulate it. When an object implementing the `CanvasTransform` interface is created, its transformation matrix must be initialized to the identity matrix.

The `current transformation matrix` is applied to coordinates when creating the `currentDefaultPath`, and when painting text, shapes, and `Path2D` objects, on objects implementing the `CanvasTransform` interface.

The transformations must be performed in reverse order.

Note

For instance, if a scale transformation that doubles the width is applied to the canvas, followed by a rotation transformation that rotates drawing operations by a quarter turn, and a rectangle twice as wide as it is tall is then drawn on the canvas, the actual result will be a square.

For web developers (non-normative)

`context.translate(x, y)`

Changes the `current transformation matrix` to apply a scaling transformation with the given characteristics.

`context.rotate(angle)`

Changes the `current transformation matrix` to apply a rotation transformation with the given characteristics. The angle is in radians.

`context.translate(x, y)`

Changes the `current transformation matrix` to apply a translation transformation with the given characteristics.

`context.transform(a, b, c, d, e, f)`

Changes the `current transformation matrix` to apply the matrix given by the arguments as described below.

`matrix = context.getTransform()`

Returns a copy of the `current transformation matrix`, as a newly created `DOMMatrix` object.

`context.setTransform(a, b, c, d, e, f)`

Changes the `current transformation matrix` to the matrix given by the arguments as described below.

`context.resetTransform()`

Changes the `current transformation matrix` to the identity matrix.

The `resetTransform()` method, when invoked, must reset the [current transformation matrix](#) to the identity matrix.

Note

Given a matrix of the form created by the `transform` and `getTransform` methods, i.e.,

$$\begin{pmatrix} a & c & e \\ b & d & f \\ 0 & 0 & 1 \end{pmatrix}$$

the resulting transformed coordinates after transform matrix multiplication will be

$$\begin{aligned} x_{\text{new}} &= ax + cy + e \\ y_{\text{new}} &= bx + dy + f \end{aligned}$$

4.12.5.1.8 Image sources for 2D rendering contexts

Some methods on the [CanvasRawImage](#) and [CanvasFillStrokeStyles](#) interfaces take the union type [CanvasImageSource](#) as an argument.

This union type allows objects implementing any of the following interfaces to be used as image sources:

- `HTMLOrSVGImageElement` (`img` or `SVGImage` elements)
- `HTMLVideoElement` (`video` elements)
- `HTMLCanvasElement` (`canvas` elements)
- `ImageBitmap`

Note
Although not formally specified as such, `SVGImage` elements are expected to be implemented nearly identical to `img` elements. That is, `SVGImage` elements share the fundamental concepts and features of `img` elements.

Note
The `ImageBitmap` interface can be created from a number of other image-representing types, including `ImageData`.

1. Switch on `image`:`HTMLElementOrSVGImageElement`If `image`'s `currentRequest.state` is `broken`, then throw an `"invalidStateError"` `DOMException`.If `image` is not `fullyDecodable`, then return `bad`.If `image` has an `intrinsicWidth` or `intrinsicHeight` (or both) equal to zero, then return `bad`.`HTMLVideoElement`If `image`'s `readyState` attribute is either `HAVE NOTHING` or `HAVE_METADATA`, then return `bad`.`HTMLCanvasElement``OffscreenCanvas`If `image` has either a horizontal dimension or a vertical dimension equal to zero, then throw an `"invalidStateError"` `DOMException`.`ImageBitmap`If `image`'s `[IDetached]` internal slot value is set to true, then throw an `"invalidStateError"` `DOMException`.2. Return `good`.When a `CanvasImageSource` object represents an `HTMLElement`, the element's image must be used as the source image.Specifically, when a `CanvasImageSource` object represents an animated image in an `HTMLElement`, the user agent must use the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation, when rendering the image for `CanvasRenderingContext2D` APIs.When a `CanvasImageSource` object represents an `HTMLVideoElement`, then the frame at the `currentPlaybackPosition` when the method with the argument is invoked must be used as the source image when rendering the image for `CanvasRenderingContext2D` APIs, and the source image's dimensions must be the `intrinsicWidth` and `intrinsicHeight` of the `mediaSource` (i.e. after any aspect-ratio correction has been applied).When a `CanvasImageSource` object represents an `HTMLCanvasElement`, the element's bitmap must be used as the source image.When a `CanvasImageSource` object represents an element that is `beingRendered` and that element has been resized, the original image data of the source image must be used, not the image as it is rendered (e.g. `width` and `height` attributes on the source element have no effect on how the object is interpreted when rendering the image for `CanvasRenderingContext2D` APIs).When a `CanvasImageSource` object represents an `ImageBitmap`, the object's bitmap image data must be used as the source image.An object `image` is *not origin-clean* if, switching on `image`:`HTMLElementOrSVGImageElement``HTMLVideoElement`Image's `origin` is not `sameOrigin` with `entrySettings.object's origin`.`HTMLCanvasElement``ImageBitmap`Image's bitmap's `origin-clean` flag is false.

4.12.5.1.9 Fill and stroke styles

For web developers (non-normative)

`context.fillStyle [= value]`

Returns the current style used for filling shapes.

Can be set, to change the fill style.

The style can be either a string containing a CSS color, or a `CanvasGradient` or `CanvasPattern` object. Invalid values are ignored.`context.strokeStyle [= value]`

Returns the current style used for stroking shapes.

Can be set, to change the stroke style.

The style can be either a string containing a CSS color, or a `CanvasGradient` or `CanvasPattern` object. Invalid values are ignored.Objects that implement the `CanvasFillStrokeStyles` interface have attributes and methods (defined in this section) that control how shapes are treated by the object.

MDN

`CanvasRenderingContext2D.fillStyle`

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

`CanvasRenderingContext2D.strokeStyle`

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `fillStyle` attribute represents the color or style to use inside shapes, and the `strokeStyle` attribute represents the color or style to use for the lines around the shapes.Both attributes can be either strings, `CanvasGradients`, or `CanvasPatterns`. On setting, strings must be `parsed` with this `canvas` element and the color assigned, and `CanvasGradient` and `CanvasPattern` objects must be assigned themselves. If parsing the value results in failure, then it must be ignored, and the attribute must retain its previous value. If the new value is a `CanvasPattern` object that is marked as `notOriginClean`, then the `CanvasRenderingContext2D's originClean` flag must be set to false.When set to a `CanvasPattern` or `CanvasGradient` object, the assignment is `live`, meaning that changes made to the object after the assignment do affect subsequent stroking or filling of shapes.On getting, if the value is a color, then the `serialization` of the `color` must be returned. Otherwise, if it is not a color but a `CanvasGradient` or `CanvasPattern`, then the respective object must be returned. (Such objects are opaque and therefore only useful for assigning to other attributes or for comparison to other gradients or patterns.)The `serialization` of a color for a color value is a string, computed as follows: if it has alpha equal to 1.0, then the string is a lowercase six-digit hex value, prefixed with a `#` character (U+0023 NUMBER SIGN), with the first two digits representing the red component, the next two digits representing the green component, and the last two digits representing the blue component, the digits being `ASCII digits`. Otherwise, the color value has alpha less than 1.0, and the string is the color value in the CSS `rgba()` functional-notation format: the literal string `rgba` (U+0072 U+0067 U+0062 U+0061) followed by a U+0028 LEFT PARENTHESIS, a base-ten integer in the range 0-255 representing the red component (using `ASCII digits` in the shortest form possible), a literal U+002C COMMA and U+0020 SPACE, an integer for the green component, a comma and a space, an integer for the blue component, another comma and space, a U+0030 DIGIT ZERO, if the alpha value is greater than zero then a U+002E FULL STOP (representing the decimal point), if the alpha value is zero then one or more `ASCII digits` representing the fractional part of the alpha, and finally a U+0029 RIGHT PARENTHESIS. User agents must express the fractional part of the alpha value, if any, with the level of precision necessary for the alpha value, when reparsed, to be interpreted as the same alpha value.When the context is created, the `fillStyle` and `strokeStyle` attributes must initially have the string value `#000000`.

When the value is a color, it must not be affected by the transformation matrix when used to draw on bitmaps.

There are two types of gradients, linear gradients and radial gradients, both represented by objects implementing the opaque `CanvasGradient` interface.Once a gradient has been created (see below), stops are placed along it to define how the colors are distributed along the gradient. The color of the gradient at each stop is the color specified for that stop. Between each such stop, the colors and the alpha component must be linearly interpolated over the RGBA space without premultiplying the alpha value to find the color to use at that offset. Before the first stop, the color must be the color of the first stop. After the last stop, the color must be the color of the last stop. When there are no stops, the gradient is `transparent black`.

For web developers (non-normative)

`gradient.addColorStop(offset, color)`

Adds a color stop with the given color to the gradient at the given offset. 0.0 is the offset at one end of the gradient, 1.0 is the offset at the other end.

Throws an `"IndexSizeError"` `DOMException` if the offset is out of range. Throws a `"SyntaxError"` `DOMException` if the color cannot be parsed.`gradient = context.createLinearGradient(x0, y0, x1, y1)`Returns a `CanvasGradient` object that represents a linear gradient that paints along the line given by the coordinates represented by the arguments.`gradient = context.createRadialGradient(x0, y0, r0, x1, y1, r1)`Returns a `CanvasGradient` object that represents a radial gradient that paints along the cone given by the circles represented by the arguments.If either of the radii are negative, throws an `"IndexSizeError"` `DOMException`.

MDN

`CanvasGradient.addColorStop`

Support in all current engines.

Firefox 3+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `addColorStop(offset, color)` method on the `CanvasGradient`, when invoked, must run these steps:1. If the offset is less than 0 or greater than 1, then throw an `"IndexSizeError"` `DOMException`.2. Let `parsed color` be the result of `parsing color`.

Note

No element is passed to the parser because `CanvasGradient` objects are `canvas-neutral` — a `CanvasGradient` object created by one `canvas` can be used by another, and there is therefore no way to know which is the "element in question" at the time that the color is specified.3. If `parsed color` is failure, throw a `"SyntaxError"` `DOMException`.4. Place a new stop on the gradient, at offset `offset` relative to the whole gradient, and with the color `parsed color`.

If multiple stops are added at the same offset on a gradient, then they must be placed in the order added, with the first one closest to the start of the gradient, and each subsequent one infinitesimally further along towards the end point (in effect causing all but the first and last stop added at each point to be ignored).

MDN

`CanvasRenderingContext2D.createLinearGradient`

Firefox 1.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `createLinearGradient(x0, y0, x1, y1)` method takes four arguments that represent the start point ($x0, y0$) and end point ($x1, y1$) of the gradient. The method, when invoked, must return a linear `CanvasGradient` initialized with the specified line.

Linear gradients must be rendered such that all points on a line perpendicular to the line that crosses the start and end points have the color at the point where those two lines cross (with the colors coming from the [interpolation and extrapolation](#) described above). The points in the linear gradient must be transformed as described by the [current transformation matrix](#) when rendering.

If $x0 = x1$ and $y0 = y1$, then the linear gradient must paint nothing.

MDN

[CanvasRenderingContext2D.createLinearGradient](#)

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `createRadialGradient(x0, y0, r0, x1, y1, r1)` method takes six arguments, the first three representing the start circle with origin ($x0, y0$) and radius $r0$, and the last three representing the end circle with origin ($x1, y1$) and radius $r1$. The values are in coordinate space units. If either of $r0$ or $r1$ are negative, then an ["IndexSizeError" DOMException](#) must be thrown. Otherwise, the method, when invoked, must return a radial `CanvasGradient` initialized with the two specified circles.

Radial gradients must be rendered by following these steps:

1. If $x0 = x1$ and $y0 = y1$ and $r0 = r1$, then the radial gradient must paint nothing. Return.

2. Let $x(o) = (x_1 - x_0)r_0 + x_0$

- Let $y(o) = (y_1 - y_0)r_0 + y_0$

- Let $r(o) = (r_1 - r_0)r_0 + r_0$

Let the color at o be the color at that position on the gradient (with the colors coming from the [interpolation and extrapolation](#) described above).

3. For all values of θ where $r(o) > 0$, starting with the value of θ nearest to positive infinity and ending with the value of θ nearest to negative infinity, draw the circumference of the circle with radius $r(o)$ at position $(x(o), y(o))$, with the color at o , but only painting on the parts of the bitmap that have not yet been painted on by earlier circles in this step for this rendering of the gradient.

Note

This effectively creates a cone, touched by the two circles defined in the creation of the gradient, with the part of the cone before the start circle (0,0) using the color of the first offset, the part of the cone after the end circle (1,0) using the color of the last offset, and areas outside the cone untouched by the gradient ([transparent black](#)).

The resulting radial gradient must then be transformed as described by the [current transformation matrix](#) when rendering.

Gradients must be painted only where the relevant stroking or filling effects requires that they be drawn.

Patterns are represented by objects implementing the opaque `CanvasPattern` interface.

For web developers (non-normative)

`pattern = context.createPattern(image, repetition)`

Returns a `CanvasPattern` object that uses the given image and repeats in the direction(s) given by the `repetition` argument.

The allowed values for `repetition` are `repeat` (both directions), `repeat-x` (horizontal only), `repeat-y` (vertical only), and `no-repeat` (neither). If the `repetition` argument is empty, the value `repeat` is used.

If the image isn't yet fully decoded, then nothing is drawn. If the image is a canvas with no data, throws an ["InvalidStateError" DOMException](#).

`pattern.setTransform(transform)`

Sets the transformation matrix that will be used when rendering the pattern during a fill or stroke painting operation.

MDN

[CanvasRenderingContext2D.createPattern](#)

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `createPattern(image, repetition)` method, when invoked, must run these steps:

1. Let `usability` be the result of [checking the usability of image](#).

2. If `result is bad`, then return null.

3. Assert: `result is good`.

4. If `repetition` is the empty string, then set it to "`repeat`".

5. If `repetition` is not a [case-sensitive](#) match for one of "`repeat`", "`repeat-x`", "`repeat-y`", or "`no-repeat`", then throw a ["SyntaxError" DOMException](#).

6. Let `pattern` be a new `CanvasPattern` object with the image `image` and the repetition behavior given by `repetition`.

7. If `image is not origin-clean`, then mark `pattern` as `not origin-clean`.

8. Return `pattern`.

Modifying the `image` used when creating a `CanvasPattern` object after calling the `createPattern()` method must not affect the pattern(s) rendered by the `CanvasPattern` object.

Patterns have a transformation matrix, which controls how the pattern is used when it is painted. Initially, a pattern's transformation matrix must be the identity matrix.

MDN

[CanvasPattern.setTransform](#)

Support in all current engines.

Firefox 3.3+ Safari 3.1+ Chrome 6.8+

Opera 9+ Edge 79+

Edge (Legacy) No Internet Explorer No

Firefox Android 3.3+ Safari iOS 11+ Chrome Android 6.8+ WebView Android 6.8+ Samsung Internet 10.0+ Opera Android 11+

The `setTransform(transform)` method, when invoked, must run these steps:

1. Let `matrix` be the result of [creating a `DOMMatrix` from the 2D dictionary transform](#).

2. If one or more of `matrix.m11 element`, `m12 element`, `m21 element`, `m22 element`, `m41 element`, or `m42 element` are infinite or NaN, then return.

3. Reset the pattern's transformation matrix to `matrix`.

When a pattern is to be rendered within an area, the user agent must run the following steps to determine what is rendered:

1. Create an infinite [transparent black](#) bitmap.

2. Place a copy of the image on the bitmap, anchored such that its top left corner is at the origin of the coordinate space, with one coordinate space unit per [CSS pixel](#) of the image, then place repeated copies of this image horizontally to the left and right, if the repetition behavior is "`repeat-x`", or vertically up and down, if the repetition behavior is "`repeat-y`", or in all four directions all over the bitmap, if the repetition behavior is "`repeat`".

If the original image data is a bitmap image, then the value painted at a point in the area of the repetitions is computed by filtering the original image data. When scaling up, if the `imageSmoothingEnabled` attribute is set to false, then the image must be rendered using nearest-neighbor interpolation. Otherwise, the user agent may use any filtering algorithm (for example bilinear interpolation or nearest-neighbor). User agents which support multiple filtering algorithms may use the value of the `imageSmoothingQuality` attribute to guide the choice of filtering algorithm. When such a filtering algorithm requires a pixel value from outside the original image data, it must instead use the value from wrapping the pixel's coordinates to the original image's dimensions. (That is, the filter uses 'repeat' behavior, regardless of the value of the pattern's repetition behavior.)

3. Transform the resulting bitmap according to the pattern's transformation matrix.

4. Transform the resulting bitmap again, this time according to the [current transformation matrix](#).

5. Replace any part of the image outside the area in which the pattern is to be rendered with [transparent black](#).

6. The resulting bitmap is what is to be rendered, with the same origin and same scale.

If a radial gradient or repeated pattern is used when the transformation matrix is singular, then the resulting style must be [transparent black](#) (otherwise the gradient or pattern would be collapsed to a point or line, leaving the other pixels undefined). Linear gradients and solid colors always define all points even with singular transformation matrices.

4.12.5.10 Drawing rectangles to the bitmap

Objects that implement the `CanvasRect` interface provide the following methods for immediately drawing rectangles to the bitmap. The methods each take four arguments; the first two give the x and y coordinates of the top left of the rectangle, and the second two give the width `w` and height `h` of the rectangle, respectively.

The [current transformation matrix](#) must be applied to the following four coordinates, which form the path that must then be closed to get the specified rectangle: $(x, y), (x+w, y), (x+w, y+h), (x, y+h)$.

Shapes are painted without affecting the [current default path](#), and are subject to the [clipping region](#), with the exception of `clearRect()`, also [shadow effects](#), [global alpha](#), and [global composition operators](#).

For web developers (non-normative)

`context.clearRect(x, y, w, h)`

Cleans all pixels on the bitmap in the given rectangle to [transparent black](#).

`context.fillRect(x, y, w, h)`

Paints the given rectangle onto the bitmap, using the current fill style.

`context.strokeRect(x, y, w, h)`

Paints the box that outlines the given rectangle onto the bitmap, using the current stroke style.

[CanvasRenderingContext2D.clearRect](#)

Support in all current engines.

The `strokeRect(x, y, w, h)` method, when invoked, must run these steps:

- If any of the arguments are infinite or NaN, then return.
 - Take the result of [tracing the path](#) described below, using the [CanvasPathDrawingStyle](#) interface's line styles, and fill it with the [strokeStyle](#). If both `w` and `h` are zero, the path has a single subpath with just one point (x, y) , and no lines, and this method thus has no effect (the [trace a path](#) algorithm returns an empty path in that case).
- If just one of either `w` or `h` is zero, then the path has a single subpath consisting of two points, with coordinates (x, y) and $(x+w, y+h)$, in that order, connected by a single straight line.
- Otherwise, the path has a single subpath consisting of four points, with coordinates (x, y) , $(x+w, y)$, $(x+w, y+h)$, and $(x, y+h)$, connected to each other in that order by straight lines.

4.2.5.1.1 Drawing text to the bitmap

The `fillText()` and `strokeText()` methods take three or four arguments, `text`, `x`, `y`, and optionally `maxWidth`, and render the given `text` at the given (x, y) coordinates ensuring that the text isn't wider than `maxWidth` if specified, using the current `font`, `textAlign`, and `textBaseline` values. Specifically, when the methods are invoked, the user agent must run these steps:

- If any of the arguments are infinite or NaN, then return.
 - Run the [text preparation algorithm](#), passing it `text`, the object implementing the [CanvasText](#) interface, and, if the `maxWidth` argument was provided, that argument. Let `glyphs` be the result.
 - Move all the shapes in `glyphs` to the right by $x \text{ CSS pixels}$ and down by $y \text{ CSS pixels}$.
 - Paint the shapes given in `glyphs`, as transformed by the [current transformation matrix](#), with each `CSS pixel` in the coordinate space of `glyphs` mapped to one coordinate space unit.
- For `fillText()`, `fillStyle` must be applied to the shapes and `strokeStyle` must be ignored. For `strokeText()`, the reverse holds: `strokeStyle` must be applied to the result of [tracing](#) the shapes using the object implementing the [CanvasText](#) interface for the line styles, and `fillStyle` must be ignored.
- These shapes are painted without affecting the current path, and are subject to [shadow effects](#), [global alpha](#), the [clipping region](#), and [global composition operators](#).

Note

Glyphs rendered using `fillText()` and `strokeText()` can spill out of the box given by the font size (the em square size) and the width returned by `measureText()` (the text width). Authors are encouraged to use the bounding box values described above if this is an issue.

Note

A future version of the 2D context API might provide a way to render fragments of documents, rendered using CSS, straight to the canvas. This would be provided in preference to a dedicated way of doing multiline layout.

4.12.5.1.2 Drawing paths to the canvas

Objects that implement the `CanvasDrawPath` interface have a *current default path*. There is only one `current default path`, it is not part of the `drawing state`. The `current default path` is a `path`, as described above.

For web developers (non-normative)

`context.beginPath()`

Resets the `current default path`.

`context.fillStyle([fillRule])`

`context.fillStyle(path[, fillRule])`

Fills the subpaths of the `current default path` or the given path with the current fill style, obeying the given fill rule.

`context.strokeStyle()`

`context.strokeStyle(path)`

Strokes the subpaths of the `current default path` or the given path with the current stroke style.

`context.closePath()`

`context.closePath(path[, fillRule])`

Further constrains the clipping region to the `current default path` or the given path, using the given fill rule to determine what points are in the path.

`context.isPointInPath(x, y[, fillRule])`

`context.isPointInPath(path, x, y[, fillRule])`

Returns true if the given point is in the `current default path` or the given path, using the given fill rule to determine what points are in the path.

`context.isPointInStroke(x, y)`

`context.isPointInStroke(path, x, y)`

Returns true if the given point would be in the region covered by the stroke of the `current default path` or the given path, given the current stroke style.

MDN**CanvasRenderingContext2D.beginPath**

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `beginPath()` method, when invoked, must empty the list of subpaths in the context's `current default path` so that the it once again has zero subpaths.

Where the following method definitions use the term *intended path*, it means the `Path2D` argument, if one was provided, or the `current default path` otherwise.

When the intended path is a `Path2D` object, the coordinates and lines of its subpaths must be transformed according to the `current transformation matrix` on the object implementing the `CanvasTransform` interface when used by these methods (without affecting the `Path2D` object itself). When the intended path is the `current default path`, it is not affected by the transform. (This is because transformations already affect the `current default path` when it is constructed, so applying it when it is painted as well would result in a double transformation.)

MDN**CanvasRenderingContext2D.fill**

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `fill()` method, when invoked, must fill all the subpaths of the intended path, using `fillStyle`, and using the `fillRule` indicated by the `fillRule` argument. Open subpaths must be implicitly closed when being filled (without affecting the actual subpaths).

MDN**CanvasRenderingContext2D.stroke**

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `stroke()` method, when invoked, must `trace` the intended path, using this `CanvasPathDrawingStyles` object for the line styles, and then fill the resulting path using the `strokeStyle` attribute, using the `nonzero winding rule`.

Note

As a result of how the algorithm to `trace a path` is defined, overlapping parts of the paths in one stroke operation are treated as if their union was what was painted.

Note

The stroke style is affected by the transformation during painting, even if the intended path is the `current default path`.

Paths, when filled or stroked, must be painted without affecting the `current default path` or any `Path2D` objects, and must be subject to `shadow effects`, `global alpha`, the `clipping region`, and `global composition operators`. (The effect of transformations is described above and varies based on which path is being used.)

MDN**CanvasRenderingContext2D.clip**

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `clip()` method, when invoked, must create a new `clipping region` by calculating the intersection of the current clipping region and the area described by the intended path, using the `fillRule` indicated by the `fillRule` argument. Open subpaths must be implicitly closed when computing the clipping region, without affecting the actual subpaths. The new clipping region replaces the current clipping region.

When the context is initialized, the clipping region must be set to the largest infinite surface (i.e. by default, no clipping occurs).

MDN

[CanvasRenderingContext2D#isPointInPath](#)

Support in all current engines.

Firefox2+SafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)I+Internet ExplorerYes

Firefox, Android4+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

The `isPointInPath()` method, when invoked, must return true if the point given by the x and y coordinates passed to the method, when treated as coordinates in the canvas coordinate space unaffected by the current transformation, is inside the intended path as determined by the `fillRule` indicated by the `fillRule` argument; and must return false otherwise. Open subpaths must be implicitly closed when computing the area inside the path, without affecting the actual subpaths. Points on the path itself must be considered to be inside the path. If either of the arguments are infinite or NaN, then the method must return false.

MDN

[CanvasRenderingContext2D#isPointInStroke](#)

Support in all current engines.

Firefox20+SafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)NoInternet ExplorerNo

Firefox, Android20+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

The `isPointInStroke()` method, when invoked, must return true if the point given by the x and y coordinates passed to the method, when treated as coordinates in the canvas coordinate space unaffected by the current transformation, is inside the path that results from `stroke` the intended path, using the `nonzeroWindingRule`, and using the `CanvasPathDrawingStyles` interface for the fine styles; and must return false otherwise. Points on the resulting path must be considered to be inside the path. If either of the arguments are infinite or NaN, then the method must return false.

Example

This `canvas` element has a couple of checkboxes. The path-related commands are highlighted:

```
<canvas height=400 width=750>
<label><input type=checkbox id=showA> Show A</label>
<label><input type=checkbox id=showB> Show B</label>
</> ...
</>
<script>
function drawCheckBox(context, element, x, y, paint) {
  context.save();
  context.font = '10px sans-serif';
  context.textAlign = 'left';
  context.fillText('' + element.id);
  var metrics = context.measureText(element.labels[0].textContent);
  if (paint) {
    context.beginPath();
    context.strokeStyle = 'black';
    context.rect(x-5, y-5, 10, 10);
    context.fill();
    if (element.checked) {
      context.fillStyle = 'black';
      context.fillRect();
    }
    context.fillText(element.labels[0].textContent, x+5, y);
  }
  context.beginPath();
  context.rect(x-7, y-7, 12 + metrics.width*2, 14);
  context.drawFocusIfNeeded(element);
  context.restore();
}
function drawArea() { /* ... */ }
function drawRect() { /* ... */ }
function drawLine() { /* ... */ }
function redraw() {
  var canvas = document.getElementById('canvas')[0];
  var context = canvas.getContext('2d');
  context.clearRect(0, 0, canvas.width, canvas.height);
  drawCheckBox(context, document.getElementById('showA'), 20, 40, true);
  drawCheckBox(context, document.getElementById('showB'), 20, 60, true);
  if (document.getElementById('showA').checked)
    drawA();
  if (document.getElementById('showB').checked)
    drawB();
}
function processClick(event) {
  var canvas = document.getElementById('canvas')[0];
  var context = canvas.getContext('2d');
  var y = event.clientY;
  var target = event.target;
  var node = target;
  while (node) {
    --node.offsetTopLeft = node.scrollTop;
    node = node.offsetParent;
  }
  drawCheckBox(context, document.getElementById('showA'), 20, 40, false);
  if (context.isPointInPath(x, y) && document.getElementById('showA').checked)
    drawArea();
  drawRect();
  drawLine();
  if (context.isPointInPath(x, y) && document.getElementById('showB').checked)
    drawA();
  if (document.getElementById('showB').checked)
    drawB();
  redraw();
}
document.getElementById('canvas')[0].addEventListener('focus', redraw, true);
document.getElementById('canvas')[0].addEventListener('blur', redraw, true);
document.getElementById('canvas')[0].addEventListener('change', redraw, true);
document.getElementById('canvas')[0].addEventListener('click', processClick, false);
redraw();
</script>
```

4.2.5.1.1 Drawing focus rings and scrolling paths into view

For web developers (non-normative)
`context.gra�FocusIfNecessary(element)`
`context.gra�FocusIfNecessary(path, element)`

If the given element is `focused`, draws a focus ring around the `currentDefaultPath` or the given path, following the platform conventions for focus rings.

`context.scrollPathIntoView()`
`context.scrollPathIntoView(path)`

Scrolls the `currentDefaultPath` or the given path into view. This is especially useful on devices with small screens, where the whole canvas might not be visible at once.

Objects that implement the `CanvasPathInterface` interface provide the following methods to control drawing focus rings and scrolling paths into view.

MDN

[CanvasRenderingContext2D#drawFocusIfNeeded](#)

Support in all current engines.

Firefox32+SafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)I+Internet ExplorerNo

Firefox, Android32+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

The `drawFocusIfNeeded(element)` method, when invoked, must run these steps:

- If `element` is not `focused` or is not a descendant of the element with whose context the method is associated, then return.
- Draw a focus ring of the appropriate style along the intended path, following platform conventions.

Note
 Some platforms only draw focus rings around elements that have been focused from the keyboard, and not those focused from the mouse. Other platforms simply don't draw focus rings around some elements at all unless relevant accessibility features are enabled. This API is intended to follow these conventions. User agents that implement distinctions based on the manner in which the element was focused are encouraged to classify focus driven by the `focus()` method based on the kind of user interaction event from which the call was triggered (if any).

The focus ring should not be subject to the `shadowEffects`, the `globalAlpha`, the `globalCompositionOperators`, or any of the members in the `CanvasFillStrokeStyle`, `CanvasPathDrawingStyles`, `CanvasTextDrawingStyle` interfaces, but *should* be subject to the `clippingRegion`. (The effect of transformations is described above and varies based on what is being used.)

3. **Inform the user**: the focus is at the location given by the intended path. User agents may wait until the next time the `eventLoop` reaches its `updateTheRendering` step to optionally inform the user.

User agents should not implicitly close open subpaths in the intended path when drawing the focus ring.

Note

This might be a moot point, however. For example, if the focus ring is drawn as an axis-aligned bounding rectangle around the points in the intended path, then whether the subpaths are closed or not has no effect. This specification intentionally does not specify precisely how focus rings are to be drawn: user agents are expected to honor their platform's native conventions.

MDN

[CanvasRenderingContext2D#scrollPathIntoView](#)

Support in one engine only.

FirefoxNoSafariNoChromeYes

OperaYesEdgeYes

Edge (Legacy)NoInternet ExplorerNo

Firefox, AndroidNoSafari iOSNoChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidNo

The `scrollPathIntoView()` method, when invoked, must run these steps:

- Let `specifiedRectangle` be the rectangle of the bounding box of the intended path.
- Let `notionalChild` be a hypothetical element that is a rendered child of the `canvas` element whose dimensions are those of `specifiedRectangle`.
- `Scroll notionalChild into view` with behavior set to "auto", `block` set to "start", and `inline` set to "nearest".

4. Optionally, `inform the user` that the `case` or `selection` (or both) `scrolls specifiedRects` of the `canvas`. The user agent may wait until the next time the `eventLoop` reaches its `updateTheRendering` step to optionally inform the user.

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

"Inform the user", as used in this section, does not imply any persistent state change. It could mean, for instance, calling a system accessibility API to notify assistive technologies such as magnification tools so that the user's magnifier moves to the given area of the canvas. However, it does not associate the path with the element, or provide a region for tactile feedback, etc.

4.12.5.1.14 Drawing images

MDN

[CanvasRenderingContext2D.drawImage](#)

Support in all current engines.

Firefox 1.5–Safari 2–Chrome 1+

Opera 9–Edge 79+

Edge (Legacy) 12–Internet Explorer 9+

Firefox Android 4+–Safari iOS 1+–Chrome Android 18+–WebView Android 1+–Samsung Internet 1.0+–Opera Android 10.1+

Objects that implement the `CanvasRenderingContext2D` interface have the `drawImage` method to draw images.

This method can be invoked with three different sets of arguments:

- `drawImage(image, dx, dy)`
- `drawImage(image, dx, dy, dw, dh)`
- `drawImage(image, sx, sy, sw, sh, dx, dy, dw, dh)`

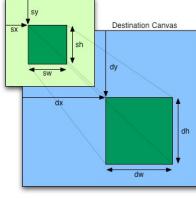

For web developers (non-normative)

`context.drawImage(image, dx, dy)`

`context.drawImage(image, dx, dy, dw, dh)`

`context.drawImage(image, sx, sy, sw, sh, dx, dy, dw, dh)`

Draws the given image onto the canvas. The arguments are interpreted as follows:

If the image isn't yet fully decoded, then nothing is drawn. If the image is a canvas with no data, throws an "[invalidStateError](#)" `DOMException`.

When the `drawImage()` method is invoked, the user agent must run these steps:

1. If any of the arguments are infinite or NaN, then return.

2. Let `usability` be the result of [checking the usability of image](#).

3. If `usability` is `bad`, then return (without drawing anything).

4. Establish the source and destination rectangles as follows:

If not specified, the `dw` and `dh` arguments must default to the values of `sw` and `sh`, interpreted such that one [CSS pixel](#) in the image is treated as one unit in the `output bitmap`'s coordinate space. If the `sx`, `sy`, `sw`, and `sh` arguments are omitted, then they must default to 0, 0, the image's [intrinsic width](#) in image pixels, and the image's [intrinsic height](#) in image pixels, respectively. If the image has no [intrinsic dimensions](#), then the `concrete object size` must be used instead, as determined using the CSS "[Concrete Object Size Resolution](#)" algorithm, with the `specified size` having neither a definite width nor height, nor any additional constraints, the object's intrinsic properties being those of the `image` argument, and the `default object size` being the size of the `output bitmap` ([CSSIMAGES](#))

The source rectangle is the rectangle whose corners are the four points $(sx, sy), (sx+sw, sy), (sx+sw, sy+sh), (sx, sy+sh)$.

The destination rectangle is the rectangle whose corners are the four points $(dx, dy), (dx+dw, dy), (dx+dw, dy+dh), (dx, dy+dh)$.

When the source rectangle is outside the source image, the source rectangle must be clipped to the source image and the destination rectangle must be clipped in the same proportion.

Note
When the destination rectangle is outside the destination image (the `output bitmap`), the pixels that land outside the `output bitmap` are discarded, as if the destination was an infinite canvas whose rendering was clipped to the dimensions of the `output bitmap`.

5. If one of the `sw` or `sh` arguments is zero, then return. Nothing is painted.

6. Paint the region of the `image` argument specified by the source rectangle on the region of the rendering context's `output bitmap` specified by the destination rectangle, after applying the `current transformation matrix` to the destination rectangle.

The image data must be processed in the original direction, even if the dimensions given are negative.

When scaling up, if the `imageSmoothingEnabled` attribute is set to true, the user agent should attempt to apply a smoothing algorithm to the image data when it is scaled. User agents which support multiple filtering algorithms may use the value of the `imageSmoothingQuality` attribute to guide the choice of filtering algorithm when the `imageSmoothingEnabled` attribute is set to true. Otherwise, the image must be rendered using nearest-neighbor interpolation.

Note
This specification does not define the precise algorithm to use when scaling an image down, or when scaling an image up when the `imageSmoothingEnabled` attribute is set to true.

Note
When a `canvas` element is drawn onto itself, the `drawing model` requires the source to be copied before the image is drawn, so it is possible to copy parts of a `canvas` element onto overlapping parts of itself.

If the original image data is a bitmap image, then the value painted at a point in the destination rectangle is computed by filtering the original image data. The user agent may use any filtering algorithm (for example bilinear interpolation or nearest-neighbor). When the filtering algorithm requires a pixel value from outside the original image data, it must instead use the value from the nearest edge pixel. (That is, the filter uses 'clamp-to-edge' behavior.) When the filtering algorithm requires a pixel value from outside the source rectangle but inside the original image data, then the value from the original image data must be used.

Note
Thus, scaling an image in parts or in whole will have the same effect. This does mean that when sprites coming from a single sprite sheet are to be scaled, adjacent images in the sprite sheet can interfere. This can be avoided by ensuring each sprite in the sheet is surrounded by a border of `transparent black`, or by copying sprites to be scaled into temporary `canvas` elements and drawing the scaled sprites from there.

Images are painted without affecting the current path, and are subject to `shadow effects`, `global alpha`, the `clipping region`, and `global composition operators`.

7. If `image` is [not origin-clean](#), then set the `CanvasRenderingContext2D`'s `origin-clean` flag to false.

4.12.5.1.15 Pixel manipulation

For web developers (non-normative)

`imagedata = new ImageData(sw, sh)`

`imagedata = context.createImageData(sw, sh)`

Returns an `ImageData` object with the given dimensions. All the pixels in the returned object are `transparent black`.

Throws an "[IndexSizeError](#)" `DOMException` if either of the width or height arguments are zero.

`imagedata = context.createImageData(imagedata)`

Returns an `ImageData` object with the same dimensions as the argument. All the pixels in the returned object are `transparent black`.

`imagedata = new ImageData(data, sw, sh)`

Returns an `ImageData` object using the data provided in the `PixelClampedArray` argument, interpreted using the given dimensions.

As each pixel in the data is represented by four numbers, the length of the data needs to be a multiple of four times the given width. If the height is provided as well, then the length needs to be exactly the width times the height times 4.

Throws an "[IndexSizeError](#)" `DOMException` if the given data and dimensions can't be interpreted consistently, or if either dimension is zero.

`imagedata = context.getImageData(x, y, sw, sh)`

Returns an `ImageData` object containing the image data for the given rectangle of the bitmap.

Throws an "[IndexSizeError](#)" `DOMException` if either of the width or height arguments are zero.

`imagedata = context.getImageData(x, y, sw, sh)`

Returns the actual dimensions of the data in the `ImageData` object, in pixels.

`imagedata.data`

Returns the one-dimensional array containing the data in RGBA order, as integers in the range 0 to 255.

`context.putImageData(imagedata, dx, dy [, dirtyX, dirtyY, dirtyWidth, dirtyHeight])`

Paints the data from the given `ImageData` object onto the bitmap. If a dirty rectangle is provided, only the pixels from that rectangle are painted.

The `globalAlpha` and `globalCompositeOperation` attributes, as well as the shadow attributes, are ignored for the purposes of this method call; pixels in the canvas are replaced wholesale, with no composition, alpha blending, no shadows, etc.

Throws an "[IndexSizeError](#)" `DOMException` if the `imagedata` object's `data` attribute value's `[ViewedArrayBuffer]` internal slot is detached.

Objects that implement the `CanvasImage` interface provide the following methods for reading and writing pixel data to the bitmap.

Firefox Android4+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

The `ImageData` constructors and the `createImageData()` methods are used to instantiate new `ImageData` objects.When the `ImageData` constructor is invoked with two numeric arguments `sw` and `sh`, it must run these steps:

1. If one or both of `sw` and `sh` are zero, then throw an `"IndexSizeError"` `DOMException`.
2. Create an `ImageData` object with parameter `pixelsPerRow` set to `sw`, and `rows` set to `sh`.
3. Initialize the image data of the newly created `ImageData` object to `transparent black`.
4. Return the newly created `ImageData` object.

When the `ImageData` constructor is invoked with its first argument being an `Uint8ClampedArray` source and its second and optional third arguments being numeric arguments `sw` and `sh`, it must run these steps:

1. Let `length` be the number of bytes in `source`.
2. If `length` is not a nonzero integral multiple of four, then throw an `"InvalidStateError"` `DOMException`.
3. Let `length` be `length` divided by four.
4. If `length` is not an integral multiple of `sw`, then throw an `"IndexSizeError"` `DOMException`.

NoteAt this step, the `length` is guaranteed to be greater than zero (otherwise the second step above would have aborted the steps), so if `sw` is zero, this step will throw the exception and return.

5. Let `height` be `length` divided by `sw`.

6. If the `sh` argument was not omitted, and its value is not equal to `height`, then throw an `"IndexSizeError"` `DOMException`.

7. Create an `ImageData` object, with parameter `pixelsPerRow` set to `sw`, `rows` set to `sh`, and using `source`. Return the newly created `ImageData` object.

NoteThe resulting object's data is not a copy of `source`, it's the actual `Uint8ClampedArray` object passed as the first argument to the constructor.When the `createImageData()` method is invoked with two numeric arguments `sw` and `sh`, it must `create an ImageData object`, with parameter `pixelsPerRow` set to the absolute magnitude of `sw`, and parameter `rows` set to the absolute magnitude of `sh`. Initialize the image data of the new `ImageData` object to `transparent black`. If both `sw` and `sh` are nonzero, then return the new `ImageData` object. If one or both of `sw` and `sh` are zero, then throw an `"IndexSizeError"` `DOMException`.When the `createImageData()` method is invoked with a single `imagedata` argument, it must `create an ImageData object`, with parameter `pixelsPerRow` set to the value of the `width` attribute of the `ImageData` object passed as the argument, and the `rows` parameter set to the value of the `height` attribute. Initialize the image data of the new `ImageData` object to `transparent black`. Return the newly created `ImageData` object.**MDN**[CanvasRenderingContext2D.getImageData](#)

1. Let `imageData` be a new uninitialized `ImageData` object.

2. If `source` is specified, then assign the `data` attribute of `imageData` to `source`.

3. If `source` is not specified, then initialize the `data` attribute of `imageData` to a new `Uint8ClampedArray` object. The `Uint8ClampedArray` object must use a new `CanvasPixelArrayBuffer` for its storage, and must have a zero start offset and a length equal to the length of its storage, in bytes. The `CanvasPixelArrayBuffer` must have the correct size to store `rows * pixelsPerRow` pixels.

If the `CanvasPixelArrayBuffer` cannot be allocated, then rethrow the `RangeError` thrown by JavaScript, and return.

4. Initialize the `width` attribute of `imageData` to `pixelsPerRow`.

5. Initialize the `height` attribute of `imageData` to `rows`.

6. Return `imageData`.

`ImageData` objects are `serializable objects`. Their `serialization steps`, given `value` and `serialized`, are:

1. Set `serialized.[[Data]]` to the `sub-serialization` of the value of `value`'s `data` attribute.

2. Set `serialized.[[Width]]` to the value of `value`'s `width` attribute.

3. Set `serialized.[[Height]]` to the value of `value`'s `height` attribute.

Their `deserialization steps`, given `serialized` and `value`, are:

1. Initialize `value`'s `data` attribute to the `sub-deserialization` of `serialized.[[Data]]`.

2. Initialize `value`'s `width` attribute to `serialized.[[Width]]`.

3. Initialize `value`'s `height` attribute to `serialized.[[Height]]`.

A `CanvasPixelArrayBuffer` in a `Bitmap` whose data is represented in left-to-right order, row by row top to bottom, starting with the top left, with each pixel's red, green, blue, and alpha components being given in that order for each pixel. Each component of each pixel represented in this array must be in the range 0..255, representing the 8 bit value for that component. The components must be assigned consecutive indices starting with 0 for the top left pixel's red component.**MDN**[CanvasRenderingContext2D.putImageData](#)

Support in all current engines.

Firefox2+SafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet ExplorerYes

Firefox Android4+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

The `putImageData()` method writes data from `ImageData` structures back to the rendering context's `output bitmap`. Its arguments are: `imagedata`, `dx`, `dy`, `dirtyX`, `dirtyY`, `dirtyWidth`, and `dirtyHeight`.When the last four arguments to this method are omitted, they must be assumed to have the values 0, 0, the `width` member of the `imagedata` structure, and the `height` member of the `imagedata` structure, respectively.

The method, when invoked, must act as follows:

1. Let `buffer` be `imagedata`'s `data` attribute value's `[ViewedArrayBuffer]` internal slot.

2. If `dirtyWidth` is true, then throw an `"InvalidStateError"` `DOMException`.

3. If `dirtyWidth` is negative, then let `dirtyX` be `dirtyX+dirtyWidth`, and let `dirtyWidth` be equal to the absolute magnitude of `dirtyWidth`.

If `dirtyHeight` is negative, then let `dirtyY` be `dirtyY+dirtyHeight`, and let `dirtyHeight` be equal to the absolute magnitude of `dirtyHeight`.

4. If `dirtyX` is negative, then let `dirtyWidth` be `dirtyWidth+dirtyX`, and let `dirtyX` be zero.

If `dirtyY` is negative, then let `dirtyHeight` be `dirtyHeight+dirtyY`, and let `dirtyY` be zero.

5. If `dirtyX+dirtyWidth` is greater than the `width` attribute of the `imagedata` argument, then let `dirtyWidth` be the value of that `width` attribute, minus the value of `dirtyX`.

6. If, after those changes, either `dirtyWidth` or `dirtyHeight` are negative or zero, then return without affecting any bitmaps.

7. For all integer values of `x` and `y` where $dirtyX \leq x < dirtyX + dirtyWidth$ and $dirtyY \leq y < dirtyY + dirtyHeight$, copy the four channels of the pixel with coordinate (x, y) in the `imagedata` data structure's `CanvasPixelArrayBuffer` to the pixel with coordinate $(dx+x, dy+y)$ in the rendering context's `output bitmap`.

Note

Due to the lossy nature of converting to and from premultiplied alpha color values, pixels that have just been set using `putImageData()` might be returned to an equivalent `getImageData()` as different values.

The current path, `transformation matrix`, `shadow attributes`, `global alpha`, the `clipping region`, and `global composition operator` must not affect the methods described in this section.

Example

In the following example, the script generates an `ImageData` object so that it can draw onto it.

```
// canvas is a reference to a <canvas> element
var context = canvas.getContext('2d');

// create a blank slate
var data = context.createImageData(canvas.width, canvas.height);

// create some plasma
FillPlasma(data, 'green'); // green plasma

// add a cloud to the plasma
AddCloud(data, data.width/2, data.height/2); // put a cloud in the middle

// paint the plasma/cloud on the canvas
context.putImageData(data, 0, 0);

// support methods
function FillPlasma(data, color) {
    ...
}
function AddCloud(data, x, y) {
    ...
}
```

Example

Here is an example of using `getImageData()` and `putImageData()` to implement an edge detection filter.

```
<!DOCTYPE HTML>
<html lang="en">
<head>
    <title>Edge detection demo</title>
    <script>
        var image = new Image();
        function init() {
            image.onload = demo;
            image.src = "image.jpeg";
        }

        function demo() {
            var canvas = document.getElementsByTagName("canvas")[0];
            var context = canvas.getContext("2d");

            // draw the image onto the canvas
            context.drawImage(image, 0, 0);

            // get the image data to manipulate
            var input = context.getImageData(0, 0, canvas.width, canvas.height);
            // get an empty slate to put the data into
            var output = context.createImageData(canvas.width, canvas.height);

            // alias some variables for convenience
            // In this case input.width and input.height
            // match canvas.width and canvas.height
            // but we'll use the former to keep the code generic.
            var w = input.width;
            var h = input.height;
            var inputData = input.data;
            var outputData = output.data;

            // edge detection
            for (var y = 0; y < h - 1; y += 1) {
                for (var x = 0; x < w - 1; x += 1) {
                    for (var c = 0; c < 3; c += 1) {
                        var i = y * w * 4 + x * 4 + c;
                        outputData[i] = 127 + -inputData[i - w * 4] - inputData[i - w * 4 + 1] +
                            -inputData[i - 4] + 8 * inputData[i] - inputData[i + 4] +
                            -inputData[i + w * 4] - inputData[i + w * 4 + 1] - inputData[i + w * 4 + 4];
                    }
                    outputData[(y * w + x) * 4 + 3] = 255; // alpha
                }
            }

            // put the image data back after manipulation
            context.putImageData(output, 0, 0);
        }
    </script>
</head>
<body><img alt="image.jpeg" onload="init()"></body>
</html>
```

A.2.5.1.8 Compositing

For web developers (non-normative)

`context.globalAlpha [= value]`

Returns the current alpha value applied to rendering operations.

Can be set, to change the alpha value. Values outside of the range 0.0..1.0 are ignored.

`context.globalCompositeOperation [= value]`

Returns the current composition operation, from the values defined in *Compositing and Blending*. [\[COMPOSITE\]](#).

Can be set, to change the composition operation. Unknown values are ignored.

All drawing operations on an object which implements the `CanvasCompositing` interface are affected by the global compositing attributes, `globalAlpha` and `globalCompositeOperation`.

MDN

CanvasRenderingContext2D.globalAlpha

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes AndroidYes Samsung InternetYes Opera AndroidYes

OperaYes EdgeYes

Edge (Legacy)12+ Internet ExplorerYes

Foxit Android4+ Safari iOSYes Chrome AndroidYes WebView Android1+ Samsung Internet1.0+ Opera Android10.1+

The `globalAlpha` attribute gives an alpha value that is applied to shapes and images before they are composited onto the `output bitmap`. The value must be in the range from 0.0 (fully transparent) to 1.0 (no additional transparency). If an attempt is made to set the attribute to a value outside this range, including Infinity and Not-a-Number (NaN) values, then the attribute must retain its previous value. When the context is created, the `globalAlpha` attribute must initially have the value 1.0.

MDN

CanvasRenderingContext2D.globalCompositeOperation

Support in all current engines.

Firefox 1.5+ Safari2+ Chrome1+

Opera9+ Edge79+

Edge (Legacy)12+ Internet Explorer9+

Foxit Android4+ Safari iOS1+ Chrome Android18+ WebView Android1+ Samsung Internet1.0+ Opera Android10.1+

The `globalCompositeOperation` attribute sets the *current composition operator*, which controls how shapes and images are drawn onto the `output bitmap`, once they have had `globalAlpha` and the current transformation matrix applied. The possible values are those defined in *Compositing and Blending*, and include the values `source-over` and `copy`. [\[COMPOSITE\]](#)

These values are all case-sensitive — they must be used exactly as defined. User agents must not recognize values that are not a *case-sensitive* match for one of the values given in *Compositing and Blending*. [\[COMPOSITE\]](#)

On setting, if the user agent does not recognize the specified value, it must be ignored, leaving the value of `globalCompositeOperation` unaffected. Otherwise, the attribute must be set to the given new value.

When the context is created, the `globalCompositeOperation` attribute must initially have the value `source-over`.

A.2.5.1.7 Image smoothing

For web developers (non-normative)

`context.imageSmoothingEnabled [= value]`

Returns whether pattern fills and the `drawImage()` method will attempt to smooth images if their pixels don't line up exactly with the display, when scaling images up.

Can be set, to change whether images are smoothed (true) or not (false).

`context.imageSmoothingQuality [= value]`

Returns the current image-smoothing-quality preference.

Can be set, to change the preferred quality of image smoothing. The possible values are `"low"`, `"medium"` and `"high"`. Unknown values are ignored.

Objects that implement the `CanvasImageSmoothing` interface have attributes that control how image smoothing is performed.

MDN

CanvasRenderingContext2D.imageSmoothingEnabled

Support in all current engines.

Firefox 5+ Safari Yes Chrome30+

OperaYes Edge79+

Edge (Legacy)15+ Internet Explorer Yes

Foxit Android4+ Safari iOSYes Chrome AndroidYes WebView Android4.4+ Samsung InternetYes Opera AndroidYes

The `imageSmoothingEnabled` attribute, on getting, must return the last value it was set to. On setting, it must be set to the new value. When the object implementing the `CanvasImageSmoothing` interface is created, the attribute must be set to true.

The `imageSmoothingQuality` attribute, on getting, must return the last value it was set to. On setting, it must be set to the new value. When the object implementing the `CanvasImageSmoothing` interface is created, the attribute must be set to `"low"`.

All drawing operations on an object which implements the `CanvasShadowTypes` interface are affected by the four global shadow attributes.

For web developers (non-normative)

```
context.shadowColor [ = value ]
  Returns the current shadow color.
  Can be set, to change the shadow color. Values that cannot be parsed as CSS colors are ignored.

context.shadowOffsetX [ = value ]
context.shadowOffsetY [ = value ]
  Returns the current shadow offset.
  Can be set, to change the shadow offset. Values that are not finite numbers are ignored.

context.shadowBlur [= value]
  Returns the current level of blur applied to shadows.
  Can be set, to change the blur level. Values that are not finite numbers greater than or equal to zero are ignored.
```

MDN

`CanvasRenderingContext2D.shadowColor`

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `shadowColor` attribute sets the color of the shadow.

When the context is created, the `shadowColor` attribute initially must be `transparent black`.

On getting, the `serialization of the color` must be returned.

On setting, the new value must be `parsed` with this `canvas` element and the color assigned. If parsing the value results in failure then it must be ignored, and the attribute must retain its previous value. [CSSCOLOR](#)

MDN

`CanvasRenderingContext2D.shadowOffsetX`

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

`CanvasRenderingContext2D.shadowOffsetY`

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `shadowOffsetX` and `shadowOffsetY` attributes specify the distance that the shadow will be offset in the positive horizontal and positive vertical distance respectively. Their values are in coordinate space units. They are not affected by the current transformation matrix.

When the context is created, the shadow offset attributes must initially have the value 0.

On getting, they must return their current value. On setting, the attribute being set must be set to the new value, except if the value is infinite or NaN, in which case the new value must be ignored.

MDN

`CanvasRenderingContext2D.shadowBlur`

Support in all current engines.

Firefox 1.5+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android 4+ Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `shadowBlur` attribute specifies the level of the blurring effect. (The units do not map to coordinate space units, and are not affected by the current transformation matrix.)

When the context is created, the `shadowBlur` attribute must initially have the value 0.

On getting, the attribute must return its current value. On setting the attribute must be set to the new value, except if the value is negative, infinite or NaN, in which case the new value must be ignored.

Shadows are only drawn if the opacity component of the alpha component of the color of `shadowColor` is nonzero and either the `shadowBlur` is nonzero, or the `shadowOffsetX` is nonzero, or the `shadowOffsetY` is nonzero.

When shadows are drawn, they must be rendered as follows:

- Let A be an infinite `transparent black` bitmap on which the source image for which a shadow is being created has been rendered.
 - Let B be an infinite `transparent black` bitmap, with a coordinate space and an origin identical to A .
 - Copy the alpha channel of A to B , offset by `shadowOffsetX` in the positive x direction, and `shadowOffsetY` in the positive y direction.
 - If `shadowBlur` is greater than 0:
 - Let σ be half the value of `shadowBlur.`
 - Perform a 2D Gaussian Blur on B , using σ as the standard deviation.
- User agents may limit values of σ to an implementation-specific maximum value to avoid exceeding hardware limitations during the Gaussian blur operation.

5. Set the red, green, and blue components of every pixel in B to the red, green, and blue components (respectively) of the color of `shadowColor`.

6. Multiply the alpha component of every pixel in B by the alpha component of the color of `shadowColor`.

7. The shadow is in the bitmap B , and is rendered as part of the `drawing model` described below.

If the current composition operation is `copy`, then shadows effectively won't render (since the shape will overwrite the shadow).

4.12.5.1.19 Filters

MDN

`CanvasRenderingContext2D.filter`

Firefox 49+ Safari No Chrome 52+

Opera No Edge 79+

Edge (Legacy) No Internet Explorer No

Firefox Android 49+ Safari iOS No Chrome Android 52+ WebView Android 52+ Samsung Internet 6.0+ Opera Android No

All drawing operations on an object which implements the `CanvasFilters` interface are affected by the global `filter` attribute.

For web developers (non-normative)

```
context.filter [ = value ]
  Returns the current filter.
  Can be set, to change the filter. Values that cannot be parsed as a <filter-function-list> value are ignored.
```

The `filter` attribute, on getting, must return the last value it was successfully set to. The value must not be re-serialized. On setting, if the new value is 'none' (not the empty string, null, or undefined), filters must be disabled for the context. Otherwise, the value must be parsed as a `<filter-function-list>` value. If the value cannot be parsed as a `<filter-function-list>` value, where property-independent style sheet syntax like 'inherit' or 'initial' is considered an invalid value, then it must be ignored, and the attribute must retain its previous value. When creating the object implementing the `CanvasFilter` interface, the attribute must be set to 'none'.

A `<filter-function-list>` value consists of a sequence of one or more filter functions or references to SVG filters. The input to the filter used as the input to the first item in the list. Subsequent items take the output of the previous item as their input. [FILTERS](#)

Coordinates used in the value of the `filter` attribute are interpreted such that one pixel is equivalent to one SVG user space unit and to one canvas coordinate space unit. Filter coordinates are not affected by the `current transformation matrix`. The current transformation matrix affects only the input to the filter. Filters are applied in the `output bitmap's` coordinate space.

When the value of the `filter` attribute defines lengths using percentages or using `em` or `ex` units, these must be interpreted relative to the `computed value` of the `font-size` property of the `font-style-source-object` at the time that the attribute is set, if it is an element. If the `computed values` are undefined for a particular case (e.g. because the `font-style-source-object` is not an element or is not `being rendered`), then the relative keywords must be interpreted relative to the default value of the `font` attribute. The `larger` and `smaller` keywords are not supported.

If the value of the `filter` attribute refers to an SVG filter in the same document, and this SVG filter changes, then the changed filter is used for the next draw operation.

If the value of the `filter` attribute refers to an SVG filter in an external resource document and that document is not loaded when a drawing operation is invoked, then the drawing operation must proceed with no filtering.

4.12.5.1.20 Working with externally-defined SVG filters

This section is non-normative.

Since drawing is performed using filter value 'none' until an externally-defined filter has finished loading, authors might wish to determine whether such a filter has finished loading before proceeding with a drawing operation. One way to accomplish this is to load the externally-defined filter elsewhere within the same page in some element that sends a `load` event (for example, an `SVGImage` element), and wait for the `load` event to be dispatched.

4.12.5.1.21 Drawing mode

When a shape or image is painted, user agents must follow these steps, in the order given (or act as if they do):

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

2. When the filter attribute is set to a value other than 'none' and all the externally-defined filters it references, if any, are in documents that are currently loaded, then use image *A* as the input to the [filter](#), creating image *B*. Otherwise, let *B* be an alias for *A*.

3. When shadows are drawn, render the shadow from image *B*, using the current shadow styles, creating image *C*.

4. When shadows are drawn, multiply the alpha component of every pixel in *C* by [globalAlpha](#).

5. When shadows are drawn, composite *C* within the [clippingRegion](#) over the current [outputBitmap](#) using the [currentCompositionOperator](#).

6. Multiply the alpha component of every pixel in *B* by [globalAlpha](#).

7. Composite *B* within the [clippingRegion](#) over the current [outputBitmap](#) using the [currentCompositionOperator](#).

When compositing onto the [outputBitmap](#), pixels that would fall outside of the [outputBitmap](#) must be discarded.

4.12.5.1.22 Best practices

When a canvas is interactive, authors should include [focusable](#) elements in the element's fallback content corresponding to each [focusable](#) part of the canvas, as in the [example above](#).

When rendering focus rings, to ensure that focus rings have the appearance of native focus rings, authors should use the [drawFocusIfNeeded\(\)](#) method, passing it the element for which a ring is being drawn. This method only draws the focus ring if the element is [focused](#), so that it can simply be called whenever drawing the element, without checking whether the element is focused or not.

In addition to drawing focus rings, authors should use the [scrollPathIntoView\(\)](#) method when an element in the canvas is focused, to make sure it is visible on the screen (if applicable).

Authors should avoid implementing text editing controls using the [canvas](#) element. Doing so has a large number of disadvantages:

- Mouse placement of the caret has to be reimplemented.
- Keyboard movement of the caret has to be reimplemented (possibly across lines, for multiline text input).
- Scrolling of the text control has to be implemented (horizontally for long lines, vertically for multiline input).
- Native text selection features have to be reimplemented.
- Native features such as spell-checking have to be reimplemented.
- Native features such as drag-and-drop have to be reimplemented.
- Native features such as page-wide text search have to be reimplemented.
- Native features specific to the user, for example custom text services, have to be reimplemented. This is close to impossible since each user might have different services installed, and there is an unbounded set of possible such services.
- Bidirectional text input has to be reimplemented.
- Multiline text editing, line wrapping has to be implemented for all relevant languages.
- Text selection has to be reimplemented.
- Drawing of bidirectional text selections has to be reimplemented.
- Platform-native keyboard shortcuts have to be reimplemented.
- Platform-native input method editors (IMEs) have to be reimplemented.
- Undo and redo functionality has to be reimplemented.
- Accessibility features such as magnification following the caret or selection have to be reimplemented.

This is a huge amount of work, and authors are most strongly encouraged to avoid doing any of it by instead using the [input](#) element, the [textarea](#) element, or the [contenteditable](#) attribute.

4.12.5.1.23 Examples

This section is non-normative.

Example

Here is an example of a script that uses canvas to draw [pretty glowing lines](#).

```
<canvas width="800" height="450"></canvas>
<script>

var context = document.getElementsByTagName('canvas')[0].getContext('2d');

var lastX = context.canvas.width * Math.random();
var lastY = context.canvas.height * Math.random();
var hue = 0;

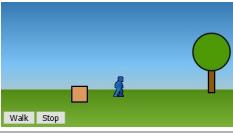

function line() {
    context.save();
    context.translate(context.canvas.width/2, context.canvas.height/2);
    context.scale(0.9, 0.9);
    context.lineWidth = 5 + Math.random() * 10;
    context.moveTo(lastX, lastY);
    lastY = context.canvas.height * Math.random();
    lastX = context.canvas.width * Math.random();
    context.bezierCurveTo(context.canvas.width * Math.random(),
        context.canvas.height * Math.random(),
        context.canvas.width * Math.random(),
        context.canvas.height * Math.random(),
        lastX, lastY);
}

hue = hue + 10 * Math.PI / 180;
context.strokeStyle = 'hsl(' + hue + ', 50%, 50%)';
context.shadowColor = 'white';
context.shadowRadius = 10;
context.stroke();
context.restore();
} setinterval(line, 50);

function blank() {
    context.fillStyle = 'rgba(0,0,0,0.1)';
    context.fillRect(0, 0, context.canvas.width, context.canvas.height);
} setinterval(blank, 40);
</script>
```

Example

The 2D rendering context for [canvas](#) is often used for sprite-based games. The following example demonstrates this:

Here is the source for this example:

```
<!DOCTYPE HTML>
<meta charset="utf-8">
<title>blue Robot Demo</title>
<style>
html { overflow: hidden; min-height: 200px; min-width: 380px; }
body { height: 200px; position: relative; margin: 0px; }
div { position: absolute; bottom: 0px; left: 0px; margin: 4px; }
</style>
<canvas width="380" height="200"></canvas>
<script>
var landscape = function (context, width, height) {
    this.offset = -width;
    this.advance = function (dx) {
        this.offset += dx;
    }
    this.horizon = height - 0.7;
    this.sky = context.createLinearGradient(0, 0, 0, this.horizon);
    this.sky.addColorStop(0.0, 'rgb(55,121,179)');
    this.sky.addColorStop(0.5, 'rgb(121,179,238)');
    this.sky.addColorStop(1.0, 'rgb(164,200,214)');
    // this created the grass gradient (from a darker green to a lighter green)
    this.warth = context.createLinearGradient(0, this.horizon, 0, height);
    this.warth.addColorStop(0.0, 'rgb(61,140,20)');
    this.warth.addColorStop(1.0, 'rgb(121,177,57)');
    this.warth.addColorStop(1.0, 'rgb(121,177,57)');
    // first, paint the sky and grass rectangles
    context.fillStyle = 'white';
    context.fillRect(0, 0, width, height);
    context.fillStyle = 'white';
    context.fillRect(0, 0, width, height - this.horizon);
    // then, draw the cloudy banner
    context.fillStyle = 'white';
    context.fillRect(0, 0, width, height - this.horizon);
    // make it cloudy by having the draw text off the top of the
    // canvas, and then just move it down to show the blurred shadow shown on the canvas
    context.save();
    context.translate(width - (this.offset + (this.width * 3.2)) % (this.width * 4.0), 0, 0);
    context.fillStyle = 'white';
    context.shadowOffsetX = 30 * this.horizon / 3; // offset down on canvas
    context.shadowBlur = 10;
    context.shadowColor = 'white';
    context.textAlign = 'left';
    context.fontFamily = '20px sans-serif';
    context.fillText('WHATNG ROCKS', 10, -30); // text up above canvas
    // then, draw the background tree
    context.save();
    context.translate(width - ((this.offset + (this.width * 0.2)) % (this.width * 1.5)) * 30, 0);
    context.beginPath();
    context.arc(5, this.horizon - 60, 30, 0, Math.PI * 2); // leaves
    context.fill();
    context.stroke();
    context.restore();
}
this.paintForeground = function (context, width, height) {
    // draw the box that goes in front
    context.beginPath();
    context.translate((width - ((this.offset + (this.width * 0.7)) % (this.width * 1.1))) * 0, 0);
    context.beginPath();
    context.arc(5, this.horizon - 5, 25, 25);
    context.fillStyle = 'rgb(220,154,94)';
    context.fill();
    context.lineWidth = 2;
    context.rect(0, this.horizon - 5, 10, -50); // trunk
    context.fill();
    context.stroke();
    context.beginPath();
    context.arc(5, this.horizon - 5, 15, 15);
    context.fillStyle = 'rgb(78,154,6)';
    context.arc(5, this.horizon - 60, 30, 0, Math.PI * 2); // leaves
    context.fill();
    context.stroke();
    context.restore();
}
var blueRoot = function () {
    </script>
</script>
```

```

this.targetMode = 'idle';
this.walk = function () {
  this.targetMode = 'walk';
};
this.stop = function () {
  this.targetMode = 'idle';
};
this.frameIndex = [
  'idle': [0], // first cell is the idle frame

4.12.5.2.2 The `ImageBitmap` rendering context

4.12.5.2.2.1 Introduction

`ImageBitmapRenderingContext` is a performance-oriented interface that provides a low overhead method for displaying the contents of `ImageBitmap` objects. It uses transfer semantics to reduce overall memory consumption. It also streamlines performance by avoiding intermediate compositing, unlike the `drawImage()` method of `CanvasRenderingContext2D`.

Using an `img` element as an intermediate for getting an image resource into a canvas, for example, would result in two copies of the decoded image existing in memory at the same time: the `img` element's copy, and the one in the canvas's backing store. This memory cost can be prohibitive when dealing with extremely large images. This can be avoided by using `ImageBitmapRenderingContext`.

Example

```

Using ImageBitmapRenderingContext, here is how to transcode an image to the JPEG format in a memory- and CPU-efficient way:

startImageBitmap((inputImageBlob), (outImage => {
  const canvas = document.createElement('canvas');
  const context = canvas.getContext('bitmaprenderer');
  const settings = {alpha: false, jpeg: true};

  const blob = toBlob(outImage, 'image/jpeg');
  // Do something with outputJPEGblob.
  // ...
});

```

4.12.5.2.2.2 The `ImageBitmapRenderingContext` interface

MDN

`ImageBitmapRenderingContext`

Firefox46+ Safari/No/Chrome66+ WebView Android66+ Samsung Internet9.0+ Opera AndroidYes

OperaYes/Fdge79+

Edge (Legacy)No Internet ExplorerNo

Firefox Android46+ Safari iOS/Chrome Android66+ WebView Android66+ Samsung Internet9.0+ Opera AndroidYes

```

IDBDatabase (Window, Worker)
interface ImageBitmapRenderingContext {
  readonly attribute (IDMCvCanvasElement or OffscreenCanvas) canvas;
  void transferFromImageBitmap (ImageBitmap bitmap);
}

dictionary ImageBitmapRenderingContextSettings {
  boolean alpha = true;
}

```

For web developers (non-normative)
context = canvas. `getContext('bitmaprenderer')` [, { [`alpha`: false] }])

Returns an `ImageBitmapRenderingContext` object that is permanently bound to a particular `canvas` element.

If the `alpha` setting is provided and set to false, then the canvas is forced to always be opaque.

`context.canvas`

Returns the `canvas` element that the context is bound to.

`context.transferFromImageBitmap`(imageBitmap)

Transfers the underlying `bitmapData` from `imageBitmap` to `context`, and the bitmap becomes the contents of the `canvas` element to which `context` is bound.

`context.transferFromImageBitmap(null)`

Replaces contents of the `canvas` element to which `context` is bound with a `transparent black` bitmap whose size corresponds to the `width` and `height` content attributes of the `canvas` element.

The `canvas` attribute must return the value it was initialized to when the object was created.

An `ImageBitmapRenderingContext` object has an `output bitmap`, which is a reference to `bitmapData`.

An `ImageBitmapRenderingContext` object has a `bitmap mode`, which can be set to `valid` or `blank`. A value of `valid` indicates that the context's `output bitmap` refers to `bitmapData` that was acquired via `transferFromImageBitmap()`. A value `blank` indicates that the context's `output bitmap` is a default transparent bitmap.

An `ImageBitmapRenderingContext` object also has an `alpha` flag, which can be set to true or false. When an `ImageBitmapRenderingContext` object has its `alpha` flag set to false, the contents of the `canvas` element to which the context is bound are obtained by compositing the context's `output bitmap` onto an `opaque black` bitmap of the same size using the source-over composite operation. If the `alpha` flag is set to true, then the `output bitmap` is used as the contents of the `canvas` element to which the context is bound. (`COMPOSITE`)

Note

The step of compositing over an `opaque black` bitmap ought to be elided whenever equivalent results can be obtained more efficiently by other means.

When a user agent is required to set an `ImageBitmapRenderingContext`'s `output bitmap`, with a `context` argument that is an `ImageBitmapRenderingContext` object and an optional argument `bitmap` that refers to `bitmapData`, it must run these steps:

1. If a `bitmap` argument was not provided, then:

1. Set `context.bitmapMode` to `blank`.

2. Let `canvas` be the `canvas` element to which `context` is bound.

3. Set `context.outputBitmap` to be `translucent black` with an `intrinsic width` equal to the `numeric value` of `canvas's width` attribute and an `intrinsic height` equal to the `numeric value` of `canvas's height` attribute, those values being interpreted in `CSS pixels`.

4. Set the `output bitmap's origin-clean` flag to true.

2. If a `bitmap` argument was provided, then:

1. Set `context.bitmapMode` to `valid`.

2. Set `context.outputBitmap` to refer to the same underlying bitmap data as `bitmap`, without making a copy.

Note

The `origin-clean` flag of `bitmap` is included in the `bitmapData` to be referenced by `context's output bitmap`.

The `ImageBitmapRenderingContext creation algorithm`, which is passed a `target` and `options`, consists of running these steps:

1. Let `settings` be the result of `converting` options to the dictionary type `ImageBitmapRenderingContextSettings`. (This can throw an exception.)

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

3. Initialize `context's` `canvas` attribute to point to `target`.
 4. Set `context's` `output bitmap` to the same bitmap as `target's` bitmap (so that they are shared).
 5. Run the steps to `set an image bitmap's backing context's output bitmap` with `context`.
 6. Initialize `context's` `alpha` flag to true.
 7. Process each of the members of `settings` as follows:
- `alpha`
If false, then set `context's` `alpha` flag to false.

8. Return `context`.

MDN

[ImageBitmapRenderingContext.transferFromImageBitmap](#)

Firefox 52+ Safari/NoChrome66+

Opera/Edge 79+

Edge (Legacy) NoInternet Explorer No

Firefox Android 52+ Safari iOS/Chrome Android 66+ WebView Android 66+ Samsung Internet 9.0+ Opera Android Yes

The `transferFromImageBitmap` method, when invoked, must run these steps:

1. Let `bitmapContext` be the `ImageBitmapRenderingContext` object on which the `transferFromImageBitmap()` method was called.
2. If `imageBitmap` is null, then run the steps to `set an image bitmap's output bitmap`, with `bitmapContext` as the `context` argument and no `bitmap` argument, then return.
3. If the value of `imageBitmap`'s `[IDetached]` internal slot is set to true, then throw an `"InvalidStateError"` `DOMException`.
4. Run the steps to `set an image bitmap's rendering context's output bitmap`, with the `context` argument equal to `bitmapContext`, and the `bitmap` argument referring to `imageBitmap`'s underlying `bitmap data`.
5. Set the value of `imageBitmap`'s `[IDetached]` internal slot to true.
6. Unset `imageBitmap`'s `bitmap data`.

4.12.5.3 The `OffscreenCanvas` interface

```
Dictionary<ImageEncodeOptions>? options;
OffscreenCanvasRenderingContextID or ImageBitmapRenderingContext or WebGLRenderingContext or WebGLRenderingContext OffscreenRenderingContext;
Dictionary<ImageEncodeOptions>? options;
    "image/png";
    unrestricted double quality;
}

new OffscreenRenderingContext( "id", "bitmaprenderer", "webgl1", "webgl2" );

[Exposed(Window, Worker), Transferable]
interface OffscreenCanvas : EventTarget {
    [BrowsingContext] OffscreenRenderingContext? getOffscreenRenderingContext();
    attribute [BrowsingRange] unsigned long long width;
    attribute [BrowsingRange] unsigned long long height;
    OffscreenRenderingContext? getContext(OffscreenRenderingContextId contextId, optional any options = null);
    ImageBitmap transferFromImageBitmap();
    Promise<OffscreenCanvas> convertToOffscreenCanvas( optional ImageEncodeOptions options = () );
}

```

`OffscreenCanvas` is an `EventTarget` so that WebGL can fire `webglcontextlost` and `webglcontextrestored` events at it. [WEBGL]

`OffscreenCanvas` objects are used to create rendering contexts, much like an `HTMLCanvasElement`, but with no connection to the DOM. This makes it possible to use canvas rendering contexts in `workers`.

MDN

[WebGLRenderingContext/commit](#)

Support in one engine only.

Firefox 44+|+Safari/NoChromeNo

Opera/No/Edge No

Edge (Legacy) No|Internet Explorer No

Firefox/Android/No/Safari/iOS/Chrome/Android/No/WebView/Android/No/Samsung/Internet/No/Opera/Android/No

An `OffscreenCanvas` object may hold a weak reference to a `placeholder canvas element`, which is typically in the DOM, whose embedded content is provided by the `OffscreenCanvas` object. The bitmap of the `OffscreenCanvas` object is pushed to the `placeholder canvas element` by calling the `commit()` method of the `OffscreenCanvas` object's rendering context. All rendering context types that can be created by an `OffscreenCanvas` object must implement a `commit()` method. The exact behavior of the commit method (e.g. whether it copies or transfers bitmaps) may vary, as defined by the rendering contexts' respective specifications. Only the `2D context for offscreen canvas` is defined in this specification.

For web developers (non-normal)

`OffscreenCanvas` = new `OffscreenCanvas`(width, height)

Returns a new `OffscreenCanvas` object that is not linked to a `placeholder canvas element`, and whose bitmap's size is determined by the `width` and `height` arguments.

`context` = `OffscreenCanvas`. `getContext(contextId, options)`

Returns an object that exposes an API for drawing on the `OffscreenCanvas` object. `contextId` specifies the desired API: `"2d"`, `"bitmaprenderer"`, `"webgl1"`, or `"webgl2"`. `options` is handled by that API.

This specification defines the `"2d"` context below, which is similar but distinct from the `"2d"` context that is created from a `canvas` element. The WebGL specifications define the `"webgl1"` and `"webgl2"` contexts. [WEBGL]

Returns null if the canvas has already been initialized with another context type (e.g., trying to get a `"2d"` context after getting a `"webgl"` context).

An `OffscreenCanvas` object has an internal `bitmap` that is initialized when the object is created. The width and height of the `bitmap` are equal to the values of the `width` and `height` attributes of the `OffscreenCanvas` object. Initially, all the bitmap's pixels are `transparent black`.

An `OffscreenCanvas` object can have a rendering context bound to it. Initially, it does not have a bound rendering context. To keep track of whether it has a rendering context or not, and what kind of rendering context it is, an `OffscreenCanvas` object also has a `context mode`, which is initially `none` but can be changed to either `2d`, `bitmaprenderer`, `webgl1`, `webgl2`, or `detached` by algorithms defined in this specification.

MDN

[OffscreenCanvas/OffscreenCanvas](#)

Support in one engine only.

Firefox 46+|+Safari/NoChrome69+

Opera 56+|+Edge 79+

Edge (Legacy) No|Internet Explorer No

Firefox/Android 46+|+Safari/iOS/Chrome/Android 66+|+WebView/Android/No/Samsung/Internet 10.0+|+Opera/Android/Yes

The constructor `OffscreenCanvas(width, height)`, when invoked, must create a new `OffscreenCanvas` object with its `bitmap` initialized to a rectangular array of `transparent black` pixels of the dimensions specified by `width` and `height`; and its `width` and `height` attributes initialized to `width` and `height` respectively.

`OffscreenCanvas` objects are `Transferable`. Their `transfer steps`, given `value` and `dataHolder`, are as follows:

1. If `value's` `context mode` is not equal to `none`, then throw an `"InvalidStateError"` `DOMException`.
2. Set `value's` `context mode` to `detached`.
3. Let `width` and `height` be the dimensions of `value's` `bitmap`.
4. Unset `value's` `bitmap`.
5. Set `dataHolder[[Width]]` to `width` and `dataHolder[[Height]]` to `height`.
6. Set `dataHolder[[PlaceholderCanvas]]` to be a weak reference to `value's` `placeholder canvas element`; if `value` has one, or null if it does not.

Their `transfer-receiving steps`, given `dataHolder` and `value`, are:

1. Initialize `value's` `bitmap` to a rectangular array of `transparent black` pixels with width given by `dataHolder[[Width]]` and height given by `dataHolder[[Height]]`.
2. If `dataHolder[[PlaceholderCanvas]]` is not null, set `value's` `placeholder canvas element` to `dataHolder[[PlaceholderCanvas]]` (while maintaining the weak reference semantics).

MDN

[OffscreenCanvas/getContext](#)

Support in one engine only.

Firefox 44+|+Safari/NoChrome69+

Opera 56+|+Edge 79+

Edge (Legacy) No|Internet Explorer No

Firefox/Android 44+|+Safari/iOS/Chrome/Android 66+|+WebView/Android/No/Samsung/Internet 10.0+|+Opera/Android/48+

1. If `options` is not an `Object`, then set `options` to null.
2. Set `options` to the result of `converting options to a JavaScript value`.
3. Run the steps in the cell of the following table whose column header matches `contextMode` and whose row header matches `contextId`:

<code>contextMode</code>	<code>contextId</code>	<code>2d</code>	<code>bitmapprenderer</code>	<code>webgl</code> or <code>webgl2</code>	<code>detached</code>
"2d"		Follow the <code>offscreen 2D context creation algorithm</code> defined in the section below, passing it this <code>OffscreenCanvas</code> object and <code>options</code> , to obtain an <code>OffscreenCanvasRenderingContext2D</code> object; if this does not throw an exception, then set this <code>OffscreenCanvas</code> object's <code>contextMode</code> to <code>2d</code> , and return the new <code>OffscreenCanvasRenderingContext2D</code> object.	Return the same object as was returned the last time the method was invoked with this same first argument.	Return null.	Throw an <code>"InvalidStateError"</code> <code>DOMException</code> .
"bitmapprenderer"		Follow the <code>ImageBitmapRenderingContext creation algorithm</code> defined in the section above, passing it this <code>OffscreenCanvas</code> object and <code>options</code> , to obtain an <code>OffscreenCanvasRenderingContext</code> object; if this does not throw an exception, then set this <code>OffscreenCanvas</code> object's <code>contextMode</code> to <code>bitmapprenderer</code> , and return the new <code>OffscreenCanvasRenderingContext</code> object.	Return null.	Return null.	Throw an <code>"InvalidStateError"</code> <code>DOMException</code> .
"webgl" or "webgl2"		Follow the instructions given in the WebGL specifications' <code>Context Creation</code> sections to obtain either a <code>WebGLRenderingContext</code> , <code>WebGL2RenderingContext</code> , or <code>null</code> ; if the returned value is null, then return null; otherwise, set this <code>OffscreenCanvas</code> object's <code>contextMode</code> to <code>webgl</code> or <code>webgl2</code> , and return the <code>WebGLRenderingContext</code> or <code>WebGL2RenderingContext</code> object. [WEBGL]	Return null.	Return null.	Return the same value as was returned the last time the method was invoked with this same first argument.

For web developers (non-normative)
<code>OffscreenCanvas</code> : <code>width</code> [= <code>value</code>] <code>OffscreenCanvas</code> : <code>height</code> [= <code>value</code>]
These attributes return the dimensions of the <code>OffscreenCanvas</code> object's <code>bitmap</code> .

They can be set, to replace the `bitmap` with a new, `transparent black` bitmap of the specified dimensions (effectively resizing it).

If either the `width` or `height` attributes of an `OffscreenCanvas` object are set (to a new value or to the same value as before) and the `OffscreenCanvas` object's `contextMode` is `2d`, then replace the `OffscreenCanvas` object's `bitmap` with a new `transparent black` bitmap and `reset the rendering context to its default state`. The new bitmap's dimensions are equal to the new values of the `width` and `height` attributes.

The resizing behavior for "`width`" and "`height`" contexts is defined in the WebGL specifications. [WEBGL]

Note
If an <code>OffscreenCanvas</code> object whose dimensions were changed has a <code>placeholderCanvas</code> element, then the <code>placeholderCanvas</code> element's <code>intrinsicSize</code> will only be updated via the <code>commit()</code> method of the <code>OffscreenCanvas</code> object's rendering context.
For web developers (non-normative)
<code>promise = offscreenCanvas . convertToBlob (options)</code>

Returns a promise that will fulfill with a new `Blob` object representing a file containing the image in the `OffscreenCanvas` object.

The argument, if provided, is a dictionary that controls the encoding options of the image file to be created. The `type` field specifies the file format and has a default value of `"image/png"`; that type is also used if the requested type isn't supported. If the image format supports variable quality (such as `"image/jpeg"`), then the `quality` field is a number in the range 0.0 to 1.0 inclusive indicating the desired quality level for the resulting image.

`canvas . transferToImageBitmap()`

Returns a newly created `ImageBitmap` object with the image in the `OffscreenCanvas` object. The image in the `OffscreenCanvas` object is replaced with a new blank image.

AMDN
<code>OffscreenCanvas</code> : convertToBlob
Support in one engine only.
Firefox 46+ Safari/NoChrome69+
Opera56+Edge79+
Edge (Legacy)NoInternet ExplorerNo
Firefox Android 46+ Safari iOSNoChrome Android69+WebView AndroidNoSamsung Internet10.0+Opera Android48+

The `convertToBlob (options)` method, when invoked, must run the following steps:

1. If the value of this `OffscreenCanvas` object's `[IDetached]` internal slot is set to true, then return a promise rejected with an `"InvalidStateError"` `DOMException`.
2. If this `OffscreenCanvas` object's `contextMode` is `2d` and the rendering context's `bitmap`'s `origin-clean` flag is set to false, then return a promise rejected with a `"SecurityError"` `DOMException`.
3. If this `OffscreenCanvas` object's `bitmap` has no pixels (i.e., either its horizontal dimension or its vertical dimension is zero) then return a promise rejected with an `"IndexSizeError"` `DOMException`.
4. Let `bitmap` be a copy of this `OffscreenCanvas` object's `bitmap`.
5. Let `result` be a new promise object.
6. Run these steps in `parallel`:
 1. Let `file` be a `serialization of bitmap as a file`, with `options`'s `type` and `quality` if present.
 2. `Queue a task` to run these steps:
 1. If `file` is null, then reject `result` with an `"EncodingError"` `DOMException`.
 2. Otherwise, resolve `result` with a new `Blob` object, created in the `relevant Realm` of this `OffscreenCanvas` object, representing `file`. [FILE API]

The `task source` for this task is the `canvas blob serialization task source`.

7. Return `result`.

AMDN
<code>OffscreenCanvas</code> : transferToImageBitmap
Support in one engine only.
Firefox 46+ Safari/NoChrome69+
Opera56+Edge79+
Edge (Legacy)NoInternet ExplorerNo
Firefox Android 46+ Safari iOSNoChrome Android69+WebView AndroidNoSamsung Internet10.0+Opera Android48+

The `transferToImageBitmap()` method, when invoked, must run the following steps:

1. If the value of this `OffscreenCanvas` object's `[IDetached]` internal slot is set to true, then throw an `"InvalidStateError"` `DOMException`.
2. If this `OffscreenCanvas` object's `contextMode` is set to `none`, then throw an `"InvalidStateError"` `DOMException`.
3. Let `image` be a newly created `ImageBitmap` object that references the same underlying bitmap data as this `OffscreenCanvas` object's `bitmap`.
4. Set this `OffscreenCanvas` object's `bitmap` to reference a newly created bitmap of the same dimensions as the previous bitmap, and with its pixels initialized to `transparent black`, or `opaque black` if the rendering context's `alpha` flag is set to false.

Note
This means that if the rendering context of this <code>OffscreenCanvas</code> is a <code>WebGLRenderingContext</code> , the value of <code>preserveDrawingBuffer</code> will have no effect. [WEBGL]

5. Return `image`.

4.12.5.3.1 The offscreen 2D rendering context

```
IDL Exports(HTMLElement, Worker)
interface OffscreenCanvasRenderingContext2D {
  void commit();
  readonly attribute OffscreenCanvas canvas;
};

OffscreenCanvasRenderingContext2D includes CanvasState;
OffscreenCanvasRenderingContext2D includes CanvasTransform;
OffscreenCanvasRenderingContext2D includes CanvasImageSmoothing;
OffscreenCanvasRenderingContext2D includes CanvasFillStrokeStyles;
OffscreenCanvasRenderingContext2D includes CanvasFilters;
OffscreenCanvasRenderingContext2D includes CanvasFontStyle;
OffscreenCanvasRenderingContext2D includes CanvasFontWeight;
OffscreenCanvasRenderingContext2D includes CanvasPath;
OffscreenCanvasRenderingContext2D includes CanvasPathDrawingStyles;
OffscreenCanvasRenderingContext2D includes CanvasPathDrawingStyles;
```

The `OffscreenCanvasRenderingContext2D` object is a rendering context for drawing to the `bitmap` of an `OffscreenCanvas` object. It is similar to the `CanvasRenderingContext2D` object, with the following differences:

- there is no support for `userInterface` features;
- its `canvas` attribute refers to an `OffscreenCanvas` object rather than a `canvas` element;
- it has a `commit()` method for pushing the rendered image to the context's `OffscreenCanvas` object's `placeholderCanvas` element.

AMDN This is a review draft of the standard and a W3C candidate recommendation.

EXPAND

The `bitmap` has an `origin-clean` flag, which can be set to true or false. Initially, when one of these bitmaps is created, its `origin-clean` flag must be set to true.

An `offscreenCanvasRenderingContext2D` object also has an `alpha` flag, which can be set to true or false. Initially, when the context is created, its alpha flag must be set to true. When an `offscreenCanvasRenderingContext2D` object has its `alpha` flag set to false, then its alpha channel must be fixed to 1.0 (fully opaque) for all pixels, and attempts to change the alpha component of any pixel must be silently ignored.

An `offscreenCanvasRenderingContext2D` object has an associated `offscreenCanvas` object, which is the `offscreenCanvas` object from which the `offscreenCanvasRenderingContext2D` object was created.

For web developers (non-normative)

`offscreenCanvasRenderingContext2D.commit()`

Copies the rendering context's `bitmap` to the bitmap of the `placeholder canvas` element of the associated `offscreenCanvas` object. The copy operation is synchronous. Calling this method is not needed for the transfer, since it happens automatically during the `event loop` execution.

`offscreenCanvas = offscreenCanvasRenderingContext2D.canvas`

Returns the associated `offscreenCanvas` object.

The `Offscreen 2D context creation algorithm`, which is passed a `target` (an `OffscreenCanvas` object) and optionally some arguments, consists of running the following steps:

- If the algorithm was passed some arguments, let `arg` be the first such argument. Otherwise, let `arg` be undefined.
- Let `settings` be the result of `converting` options to the dictionary type `CanvasRenderingContext2DSettings`. (This can throw an exception.)
- Let `context` be a new `OffscreenCanvasRenderingContext2D` object.
- Set `context`'s associated `OffscreenCanvas` object to `target`.
- Process each of the members of `settings` as follows:
 - If `alpha` is false, set `context`'s `alpha` flag to false.
- Set `context`'s `bitmap` to a newly created bitmap with the dimensions specified by the `width` and `height` attributes of `target`, and set `target`'s bitmap to the same bitmap (so that they are shared).
- If `context`'s `alpha` flag is set to true, initialize all the pixels of `context`'s `bitmap` to `transparent black`. Otherwise, initialize the pixels to `opaque black`.
- Return `context`.

The `commit()` method, when invoked, must run the following steps:

- If this `OffscreenCanvasRenderingContext2D`'s associated `OffscreenCanvas` object does not have a `placeholder canvas` element, then return.
- Let `image` be a copy of this `OffscreenCanvasRenderingContext2D`'s `bitmap`, including the value of its `origin-clean` flag.

3. Queue a task in the `placeholder canvas` element's relevant agent's `event loop` (which will be a `window event loop`) to set the `placeholder canvas` element's `output bitmap` to be a reference to `image`.

Note
If `image` has different dimensions than the bitmap previously referenced as the `placeholder canvas` element's `output bitmap`, then this task will result in a change in the `placeholder canvas` element's `intrinsic size`, which can affect document layout.

Note

Implementations are encouraged to short-circuit the graphics update steps of the `window event loop` for the purposes of updating the contents of a `placeholder canvas` element to the display. This could mean, for example, that the `commit()` method can copy the bitmap contents directly to a graphics buffer that is mapped to the physical display location of the `placeholder canvas` element. This or similar short-circuiting approaches can significantly reduce display latency, especially in cases where the `commit()` method is invoked from a `worker event loop` and the `window event loop` of the `placeholder canvas` element is busy. However, such shortcuts can not have any script-observable side-effects. This means that the committed bitmap still needs to be sent to the `placeholder canvas` element, in case the element is used as a `CanvasImageSource`, as an `ImageBitmapSource`, or in case `toDataURL()` or `toBlob()` are called on it.

The `canvas` attribute, on getting, must return this `OffscreenCanvasRenderingContext2D`'s associated `OffscreenCanvas` object.

4.12.5.4 Color spaces and color correction

The `canvas` APIs must perform color correction at only two points: when rendering images with their own gamma correction and color space information onto a bitmap, to convert the image to the color space used by the bitmaps (e.g. using the 2D Context's `drawImage()` method with an `HTMLOrSVGImageElement` object), and when rendering the actual canvas bitmap to the output device.

Note

This, in the 2D context, colors used to draw shapes onto the canvas will exactly match colors obtained through the `getImageData()` method.

The `getImageData()` method, when invoked, must not include color space information in the resources they return. Where the output format allows it, the color of pixels in resources created by `toDataURL()` must match those returned by the `getImageData()` method.

In user agents that support CSS, the color space used by a `canvas` element must match the color space used for processing any colors for that element in CSS.

The gamma correction and color space information of images must be handled in such a way that an image rendered directly using an `img` element would use the same colors as one painted on a `canvas` element that is then itself rendered. Furthermore, the rendering of images that have no color correction information (such as those returned by the `toDataURL()` method) must be rendered with no color correction.

Note

This, in the 2D context, calling the `drawImage()` method to render the output of the `toDataURL()` method to the canvas, given the appropriate dimensions, has no visible effect.

4.12.5.5 Serializing bitmaps to a file

When a user agent is to create a serialization of the bitmap as a file, given a `type` and an optional `quality`, it must create an image file in the format given by `type`. If an error occurs during the creation of the image file (e.g. an internal encoder error), then the result of the serialization is null. [PNG]

The image file's pixel data must be the bitmap's pixel data scaled to one image pixel per coordinate space unit, and if the file format used supports encoding resolution metadata, the resolution must be given as 96dpi (one image pixel per CSS pixel).

If `type` is supplied, then it must be interpreted as a `MIME type` giving the format to use. If the type has any parameters, then it must be treated as not supported.

Example
For example, the value "`image/png`" would mean to generate a PNG image, the value "`image/jpeg`" would mean to generate a JPEG image, and the value "`image/svg+xml`" would mean to generate an SVG image (which would require that the user agent track how the bitmap was generated, an unlikely, though potentially awesome, feature).

User agents must support PNG ("`image/png`"). User agents may support other types. If the user agent does not support the requested type, then it must create the file using the PNG format. [PNG]

User agents must convert the provided type to ASCII lowercase before establishing if they support that type.

For image types that do not support an alpha channel, the serialized image must be the bitmap image composited onto an `opaque black` background using the source-over operator.

If `type` is a image format that supports variable quality (such as "`image/jpeg`"), `quality` is given, and `type` is not "`image/png`", then, if `Type{quality}` is Number, and `quality` is in the range 0.0 to 1.0 inclusive, the user agent must treat `quality` as the desired quality level. Otherwise, the user agent must use its default quality value, as if the `quality` argument had not been given.

Note

The use of type-testing here, instead of simply declaring `quality` as a Web IDL `double`, is a historical artifact.

Note

Different implementations can have slightly different interpretations of "quality". When the quality is not specified, an implementation-specific default is used that represents a reasonable compromise between compression ratio, image quality, and encoding time.

4.12.5.6 Security with `canvas` elements

This section is non-normative.

Information leakage can occur if scripts from one `origin` can access information (e.g. read pixels) from images from another origin (one that isn't the `same`).

To mitigate this, bitmaps used with `canvas` elements and `ImageBitmap` objects are defined to have a flag indicating whether they are `origin-clean`. All bitmaps start with their `origin-clean` set to true. The flag is set to false when cross-origin images are used.

The `getImageData()`, `toBlob()`, and `getToDataURL()` methods check the flag and will throw a `SecurityError` if `origin-refering` rather than leak cross-origin data.

The value of the `origin-clean` flag is propagated from a source `canvas` element's bitmap to a new `ImageBitmap` object by `createImageBitmap()`. Conversely, a destination `canvas` element's bitmap will have its `origin-clean` flags set to false by `drawImage()` if the source image is an `ImageBitmap` object whose bitmap has its `origin-clean` flag set to false.

The flag can be reset in certain situations; for example, when changing the value of the `width` or the `height` content attribute of the `canvas` element to which a `CanvasRenderingContext2D` is bound, the bitmap is cleared and its `origin-clean` flag is reset.

When using an `ImageBitmapRenderingContext`, the value of the `origin-clean` flag is propagated from `ImageBitmap` objects when they are transferred to the `canvas` via `transferFromImageBitmap()`.

4.13 Custom elements

Source: caniuse.com

4.13.1 Introduction

This section is non-normative.

`Custom elements` provide a way for authors to build their own fully-featured DOM elements. Although authors could always use non-standard elements in their documents, with application-specific behavior added after the fact by scripting or similar, such elements have historically been non-conforming and not very functional. By defining a custom element, authors can inform the parser how to properly construct an element and how elements of that class should react to changes.

Custom elements are part of a larger effort to "rationalise the platform", by explaining existing platform features (like the elements of HTML) in terms of lower-level author-exposed extensibility points (like custom element definition). Although today there are many limitations on the capabilities of custom elements—both functionally and semantically—that prevent them from fully explaining the behaviors of HTML's existing elements, we hope to shrink this gap over time.

4.13.1.1 Creating an autonomous custom element

This section is non-normative.

For the purposes of illustrating how to create an `autonomous custom element`, let's define a custom element that encapsulates rendering a small icon for a country flag. Our goal is to be able to use it like so:

```
<flag-icon country="nl"></flag-icon>

To do this, we first declare a class for the custom element, extending HTMLElement:
class FlagIcon extends HTMLElement {
  constructor() {
    super();
    this._countryCode = null;
  }

  static get observedAttributes() { return ["country"]; }

  attributeChangedCallback(name, oldValue, newValue) {
    // name will always be "country" due to observeAttributes
    if (name === "country") {
      this._updateRendering();
    }
  }

  connectedCallback() {
    this._updateRendering();
  }

  get country() {
    return this._countryCode;
  }

  set country(v) {
    this.setAttribute("country", v);
  }

  _updateRendering() {
    // Left as an exercise for the reader. But, you'll probably want to
    // check this.ownerDocument.defaultView to see if we've been
    // inserted into a document with a browsing context, and avoid
    // doing any work if not.
  }
}
```

We then need to use this class to define the element:

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

At this point, our above code will work! The parser, whenever it sees the `flag-icon` tag, will construct a new instance of our `FlagIcon` class, and tell our code about its new `country` attribute, which we then use to set the element's internal state and update its rendering (when appropriate).

You can also create `flag-icon` elements using the DOM API:

```
const flagIcon = document.createElement("flag-icon")
flagIcon.country = "jp"
document.body.appendChild(flagIcon)

Finally, we can also use the custom element constructor itself. That is, the above code is equivalent to:
```

```
const flagIcon = new FlagIcon()
flagIcon.country = "jp"
document.body.appendChild(flagIcon)
```

4.13.1.2 Creating a form-associated custom element

This section is non-normative.

Adding a static `formAssociated` property, with a true value, makes an `autonomous custom element` a `form-associated custom element`. The `ElementInternals` interface helps you to implement functions and properties common to form control elements.

```
class MyCheckbox extends HTMLElement {
  static get formAssociated() { return true; }
  constructor() {
    super();
    this._internals = this.attachInternals();
    this._checked = false;
    this.addEventListener("click", this._onClick.bind(this));
  }

  get form() { return this._internals.form; }
  get name() { return this._internals.getAttribute("name"); }
  get type() { return this.localName; }

  get checked() { return this._checked; }
  set checked(flag) {
    this._checked = !!flag;
    this._internals.setAttribute(this._checked ? "on" : null);
  }

  _onClick(event) {
    this._checked = !this._checked;
  }
}
customElements.define("my-checkbox", MyCheckbox);
```

You can use the custom element `my-checkbox` like a built-in form-associated element. For example, putting it in `form` or `label` associates the `my-checkbox` element with them, and submitting the `form` will send data provided by `my-checkbox` implementation.

```
<form action="" method="post">
  <label for="agreed">I read the agreement.</label>
  <input type="checkbox" id="agreed" my-checkbox="true" name="agreed">
</form>
```

4.13.1.3 Creating a customized built-in element

This section is non-normative.

`Customized built-in elements` are a distinct kind of `custom element`, which are defined slightly differently and used very differently compared to `autonomous custom elements`. They exist to allow reuse of behaviors from the existing elements of HTML, by extending those elements with new custom functionality. This is important since many of the existing behaviors of HTML elements can unfortunately not be duplicated by using purely `autonomous custom elements`. Instead, `customized built-in elements` allow the installation of custom construction behavior, lifecycle hooks, and prototype chain onto existing elements, essentially “mixing in” these capabilities on top of the already-existing element.

`Customized built-in elements` require a distinct syntax from `autonomous custom elements` because user agents and other software key off an element's local name in order to identify the element's semantics and behavior. That is, the concept of `customized built-in elements` building on top of existing behavior depends crucially on the extended elements retaining their original local name.

In this example, we'll be creating a `customized built-in element` named `plastic-button`, which behaves like a normal button but gets fancy animation effects added whenever you click on it. We start by defining a class, just like before, although this time we extend `HTMLButtonElement` instead of `HTMLElement`:

```
class PlasticButton extends HTMLButtonElement {
  constructor() {
    super();
    this.addEventListener("click", () => {
      // Draw some fancy animation effects!
    });
  }
}
```

When defining our custom element, we have to also specify the `extends` option:

```
customElements.define("plastic-button", PlasticButton, { extends: "button" });
```

In general, the name of the element being extended cannot be determined simply by looking at what element interface it extends, as many elements share the same interface (such as `a` and `blockquote` both sharing `HTMLElement`).

To construct our `customized built-in element` from parsed HTML source text, we use the `is` attribute on a `button` element:

```
<button is="plastic-button">Click Me!</button>
```

Trying to use a `customized built-in element` as an `autonomous custom element` will not work; that is, `<plastic-button>Click me!</plastic-button>` will simply create an `HTMLElement` with no special behavior.

If you need to create a customized built-in element programmatically, you can use the following form of `createElement()`:

```
const plasticButton = document.createElement("button", { is: "plastic-button" });
plasticButton.textContent = "Click me!"
```

And as before, the constructor will also work:

```
const plasticButton2 = new PlasticButton();
const塑料按钮2 = document.createElement("button");
console.assert(plasticButton2 instanceof PlasticButton);
console.assert(plasticButton2 instanceof HTMLButtonElement);
```

Note that when creating a customized built-in element programmatically, the `is` attribute will not be present in the DOM, since it was not explicitly set. However, [it will be added to the output when serializing](#):

```
console.assert(plasticButton.hasAttribute("is"));
console.log(plasticButton.outerHTML); // will output '<button is="plastic-button"></button>'
```

Regardless of how it is created, all of the ways in which `button` is special apply to such “plastic buttons” as well: their focus behavior, ability to participate in `form submission`, the `disabled` attribute, and so on.

`Customized built-in elements` are designed to allow extension of existing HTML elements that have useful user-agent supplied behavior or APIs. As such, they can only extend existing HTML elements defined in this specification, and cannot extend legacy elements such as `beepSound`, `blink`, `isIndex`, `keygen`, `multicols`, `nextId`, or `spacer` that have been defined to use `HTMLUnknownElement` as their element interface.

One reason for this requirement is future-compatibility: if a `customized built-in element` was defined that extended a currently-unknown element, for example `combobox`, this would prevent this specification from defining a `combobox` element in the future, as consumers of the derived `customized built-in element` would have come to depend on their base element having no interesting user-agent-supplied behavior.

4.13.1.4 Drawbacks of autonomous custom elements

This section is non-normative.

As specified below, and alluded to above, simply defining and using an element called `taco-button` does not mean that such elements `represent` buttons. That is, tools such as Web browsers, search engines, or accessibility technology will not automatically treat the resulting element as a button just based on its defined name.

To convey the desired button semantics to a variety of users, while still using an `autonomous custom element`, a number of techniques would need to be employed:

- The addition of the `tabindex` attribute would make the `taco-button` `interactive content`, thus making it `focuseable`. Note that if the `taco-button` were to become logically disabled, the `tabindex` attribute would need to be removed.
- The addition of various ARIA attributes helps convey semantics to accessibility technology. For example, setting the `role` attribute to `"button"` will convey the semantics that this is a button, enabling users to successfully interact with the control using usual button-like interactions in their accessibility technology. Setting the `aria-label` attribute is necessary to give the button an `accessible name`, instead of having accessibility technology traverse its child text nodes and announce them. And setting `aria-disabled` to `"true"` when the button is logically disabled conveys to accessibility technology the button's disabled state.
- The addition of event handlers to handle commonly-expected button behaviors helps convey the semantics of the button to Web browser users. In this case, the most relevant event handler would be one that proxies appropriate `keydown` events to become `click` events, so that you can activate the button both with keyboard and by clicking.
- In addition to any default visual styling provided for `taco-button` elements, the visual styling will also need to be updated to reflect changes in logical state, such as becoming disabled; that is, whatever style sheet has rules for `taco-button` will also need to have rules for `taco-button[disabled]`.

With these points in mind, a full-featured `taco-button` that took on the responsibility of conveying button semantics (including the ability to be disabled) might look something like this:

```
class TacoButton extends HTMLElement {
  constructor(observer) { return ["disabled"]; }
  constructor() {
    super();
    this._observer = new MutationObserver(() => {
      this.setgetAttribute("aria-label", this.textContent);
    });
  }

  connectedCallback() {
    this.setgetAttribute("role", "button");
    this.setgetAttribute("tabindex", "0");
    this._observer.observe(this, {
      childList: true,
      characterData: true,
      subtree: true
    });
  }

  disconnectedCallback() {
    this._observer.disconnect();
  }

  get disabled() {
    return this.hasAttribute("disabled");
  }

  set disabled(v) {
    if (v) {
      this.setattribute("disabled", "");
      this.removeAttribute("aria-disabled");
    } else {
      this.removeAttribute("disabled");
      this.setattribute("aria-disabled", "true");
    }
  }

  attributeChangedCallback() {
    // only is called for the disabled attribute due to observedAttributes
    if (this.disabled) {
      this.setattribute("tabindex");
      this.setattribute("aria-disabled");
    } else {
      this.setattribute("tabindex", "0");
      this.setattribute("aria-disabled", "false");
    }
  }
}
```

Even with this rather-complicated element definition, the element is not a pleasure to use for consumers: it will be continually "sprouting" `tabindex` and `aria-` attributes of its own volition. This is because as of now there is no way to specify default accessibility semantics or focus behavior for custom elements, forcing the use of these attributes to do so (even though they are usually reserved for allowing the consumer to override default behavior).

In contrast, a simple `customized-built-in-element`, as shown in the previous section, would automatically inherit the semantics and behavior of the `button` element, with no need to implement these behaviors manually. In general, for any elements with nontrivial behavior and semantics that build on top of existing elements of HTML, `customized-built-in-elements` will be easier to develop, maintain, and consume.

4.12.1.5 Upgrading elements after their creation

This section is non-normative.

Because `element_definition` can occur at any time, a non-custom element could be `created`, and then later become a `custom_element` after an appropriate `definition` is registered. We call this process "upgrading" the element, from a normal element into a custom element.

`Upgrades` enable scenarios where it may be preferable for `custom_element_definitions` to be registered after relevant elements have been initially created, such as by the parser. They allow progressive enhancement of the content in the custom element. For example, in the following HTML document the element definition for `img-viewer` is loaded asynchronously:

```
<!DOCTYPE html>
<html lang="en">
<title>Image viewer example</title>

<img-viewer filter="Kelvin">
  
</img-viewer>

<script src="js/img-viewer.js" async></script>
```

The definition for the `img-viewer` element here is loaded using a `script` element marked with the `async` attribute, placed after the `<img-viewer>` tag in the markup. While the script is loading, the `img-viewer` element will be treated as an undefined element, similar to a `span`. Once the script loads, it will define the `img-viewer` element, and the existing `img-viewer` element on the page will be upgraded, applying the custom element's definition (which presumably includes applying an image filter identified by the string "Kelvin", enhancing the image's visual appearance).

Note that `upgrades` only apply to elements in the document tree. (Formally, elements that are `connected`.) An element that is not inserted into a document will stay un-upgraded. An example illustrates this point:

```
<!DOCTYPE html>
<html lang="en">
<title>Upgrade edge-cases example</title>

<example-element></example-element>

<script>
  'use strict';

  const inDocument = document.querySelector('example-element');
  const outOfDocument = document.createElement('example-element');

  // Before the element definition, both are HTMLElement:
  console.assert(inDocument instanceof HTMLElement);
  console.assert(outOfDocument instanceof HTMLElement);

  class ExampleElement extends HTMLElement {
    constructor(...args) {
      super(...args);
      customElements.define('example-element', ExampleElement);
    }
  }

  // After element definition, the in-document element was upgraded:
  console.assert(inDocument instanceof ExampleElement);
  console.assert(!outOfDocument instanceof ExampleElement);

  document.body.appendChild(outOfDocument);

  // Now that we've moved the element into the document, it too was upgraded:
  console.assert(outOfDocument instanceof ExampleElement);
</script>
```

4.13.2 Requirements for custom element constructors and reactions

When authoring `custom_element_constructors`, authors are bound by the following conformance requirements:

- A parameter-less call to `super()` must be the first statement in the constructor body, to establish the correct prototype chain and `this` value before any further code is run.
- A `return` statement must not appear anywhere inside the constructor body, unless it is a simple early-return (`return` or `return this`).
- The constructor must not use the `document.write()` or `document.open()` methods.
- The element's attributes and children must not be inspected, as in the `non-upgrade` case none will be present, and relying on upgrades makes the element less usable.
- The element must not gain any attributes or children, as this violates the expectations of consumers who use the `createElement` or `createElementNS` methods.
- In general, work should be deferred to `connectedCallback` as much as possible—especially work involving fetching resources or rendering. However, note that `connectedCallback` can be called more than once, so any initialization work that is truly one-time will need a guard to prevent it from running twice.
- In general, the constructor should be used to set up initial state and default values, and to set up event listeners and possibly a `shadow root`.

Several of these requirements are checked during `element_creation`, either directly or indirectly, and failing to follow them will result in a custom element that cannot be instantiated by the parser or DOM APIs. This is true even if the work is done inside a constructor-initiated `microtask`, as a `microtask_checkpoint` can occur immediately after construction.

When authoring `custom_element_reactions`, authors should avoid manipulating the node tree as this can lead to unexpected results.

Example

An element's `connectedCallback` can be queued before the element is disconnected, but as the callback queue is still processed, it results in a `connectedCallback` for an element that is no longer connected:

```
class CParent extends HTMLElement {
  connectedCallback() {
    this.firstChild.remove();
  }
}
customElements.define('c-parent', CParent);

class CChild extends HTMLElement {
  connectedCallback() {
    console.log("CChild connectedCallback: isConnected =", this.isConnected);
  }
}
customElements.define('c-child', CChild);

const parent = new CParent();
const child = new CChild();
parent.appendChild(child);
document.body.append(parent);
// Logs:
// CChild connectedCallback: isConnected = false
```

4.13.3 Core concepts

A `custom_element` is an element that is `custom`. Informally, this means that its constructor and prototype are defined by the author, instead of by the user agent. This author-supplied constructor function is called the `custom_element_constructor`.

Two distinct types of `custom elements` can be defined:

[MDN](#)

[Global_attributes/is](#)

Firefox63+SafariNoChrome67+

Opera55+Edge79+

Edge (Legacy)NoInternet ExplorerNo

Firfox Android63+Safari iOSNoChrome Android67+WebView Android67+Samsung Internet9.0+Opera Android48+

1. An *autonomous custom element*, which is defined with no `extends` option. These types of custom elements have a local name equal to their `defined_name`.
2. A *customized-built-in-element*, which is defined with an `extends` option. These types of custom elements have a local name equal to the value passed in their `extends` option, and their `defined_name` is used as the value of the `is` attribute, which therefore must be a `valid custom element name`.

After a `custom_element` is `created`, changing the value of the `is` attribute does not change the element's behavior, as it is saved on the element as its `is_value`.

[Autonomous custom elements](#) have the following element definition:

[Categories](#)

Flow content

Phrasing content

Block-level content

For form-associated custom elements: `listed`, `labelable`, `submitable`, and `resettable` form-associated element

[Contexts in which this element can be used:](#)

Where `phrasing_content` is expected.

[Content model:](#)

Transparent

[Content policies](#)

Global attributes, except the `is` attribute

`form`, `for`, `form-associated custom elements` — Associates the element with a `form` element

`disabled`, `for`, `form-associated custom elements` — Whether the form control is disabled

`readonly`, `for`, `form-associated custom elements` — Affects `willValidate`, plus any behavior added by the custom element author

`name`, `for`, `form-associated custom elements` — Name of the element to use for `form submission` and in the `form.elements` API

Any other attribute that has no namespace (see `proc`).

[Accessibility considerations:](#)

For `form-associated custom elements`, for authors: [for_implementers](#).

Otherwise: [for_implementers](#).

[DOM interface:](#)

Supplied by the element's author (inherits from `HTMLElement`)

An `autonomous custom_element` does not have any special meaning: it `represents` its children. A `customized-built-in_element` inherits the semantics of the element that it extends.

Any namespace-less attribute that is relevant to the element's functioning, as determined by the element's author, may be specified on an `autonomous custom_element`, so long as the attribute name is `XML-compatible` and contains no `ASCII_upper_alpha`s. The exception is the `is` attribute, which must not be specified on an `autonomous custom_element` (and which will have no effect if it is).

[Customized-built-in-elements](#) follow the normal requirements for attributes, based on the elements they extend. To add custom attribute-based behavior, use `data-*` attributes.

An `autonomous custom_element` is called a `form-associated custom_element` if the element is associated with a `custom_element_definition` whose `form-associated` field is set to true.

The `is` attribute represents the `form-associated custom_element`'s name. The `disabled` attribute is used to make the `form-associated custom_element` non-interactive and to prevent its `submission` value from being submitted. The `form` attribute is used to explicitly associate the `form-associated custom_element` with its `form_owner`.

The `readonly` attribute of `form-associated custom elements` specifies that the element is `barred from constraint validation`. User agents don't provide any other behavior for the attribute, but custom element authors should, where possible, use its presence to make their control non-editable in some appropriate fashion, similar to the behavior for the `readonly` attribute on built-in form controls.

[Constraint validation:](#) If the `readonly` attribute is specified on a `form-associated custom_element`, the element is `barred from constraint validation`.

The `reset` algorithm for `form-associated custom elements` is to `enqueue a custom_element callback reaction` with the element, callback name "`formResetCallback`", and an empty argument list.

A `valid custom_element_name` is a sequence of characters `name` that meets all of the following requirements:

- `name` must match the `PotentialCustomElementName` production:

`PotentialCustomElementName ::=`

“-” | “_” | [0-9] | “.” | [a-z] | #xB7 | [#xD0-#xD6] | [#xD8-#xF6] | [#xF8-#x37D] | [#x37F-#xFFFF] | [#x200C-#x200D] | [#x203F-#x2040] | [#x2070-#x218F] | [#x2C00-#x2FFF] | [#x3001-#xD7FF] | [#xP900-#xF0CF] | [#xFDF0-#xFFFFD] | [#x10000-#xEFFFF]

This uses the [EBNF notation](#) from the [XML specification](#) ([XML](#)).

- `name` must not be any of the following:
 - `annotation-xml`
 - `color-profile`
 - `font-face`
 - `font-face-src`
 - `font-face-uri`
 - `font-face-format`
 - `font-face-name`
 - `missing-glyph`

Note

The list of names above is the summary of all hyphen-containing element names from the [applicable specifications](#), namely [SVG 2](#) and [MathML](#). ([SVG](#)) ([MATHML](#))

Note

These requirements ensure a number of goals for [valid custom element names](#):

- They start with an [ASCII lower alpha](#), ensuring that the HTML parser will treat them as tags instead of as text.
- They do not contain any [ASCII upper alpha](#), ensuring that the user agent can always treat HTML elements ASCII-case-insensitively.
- They contain a hyphen, used for namespace and to ensure forward compatibility (since no elements will be added to HTML, SVG, or MathML with hyphen-containing local names in the future).
- They can always be created with [createElement\(\)](#) and [createElementNS\(\)](#), which have restrictions that go beyond the parser's.

Apart from these restrictions, a large variety of names is allowed, to give maximum flexibility for use cases like `<math>>` or `<caption></caption>`.

A [custom element definition](#) describes a [custom element](#) and consists of:

- `name`: A [valid custom element name](#)
- `localName`: A local name
- `constructor`: A Web IDL [Function](#) callback function type value wrapping the [custom element constructor](#)
- `list of observed attributes`: A collection of [attribute callbacks](#)
- `map`, where keys are the strings “`connectedCallback`”, “`disconnectedCallback`”, “`adoptedCallback`”, “`attributeChangedCallback`”, “`formAssociatedCallback`”, “`formDisabledCallback`”, “`formResetCallback`”, and “`formStateRestoreCallback`”. The corresponding values are either a Web IDL [Function](#) callback function type value, or null.
- `construction stack`: An array, initially empty, that is manipulated by the [upgrade an element](#) algorithm and the [HTML element constructors](#). Each entry in the list will be either an element or an *already constructed marker*.
- `form-associated boolean`: If this is true, user agent treats elements associated to this [custom element definition](#) as [form-associated custom elements](#).
- `disableInternals boolean`: Controls [attachInternals\(\)](#).
- `disableShadow boolean`: Controls [attachShadow\(\)](#).

To look up a [custom element definition](#), given a `document`, `namespace`, `localName`, and `is`, perform the following steps. They will return either a [custom element definition](#) or null:

1. If `namespace` is not the [HTML namespace](#), return null.
2. If `document`'s [browsing context](#) is null, return null.
3. Let `registry` be `document`'s [relevant global object](#)'s [CustomElementRegistry](#) object.
4. If there is [custom element definition](#) in `registry` with `name` and `localName` both equal to `localName`, return that [custom element definition](#).
5. If there is a [custom element definition](#) in `registry` with `name` equal to `is` and `localName` equal to `localName`, return that [custom element definition](#).
6. Return null.

4.13.4 The [CustomElementRegistry](#) interface

Each [Window](#) object is associated with a unique instance of a [CustomElementRegistry](#) object, allocated when the [Window](#) object is created.

Note
Custom element registries are associated with [Window](#) objects, instead of [Document](#) objects, since each [custom element constructor](#) inherits from the [HTMLElement](#) interface, and there is exactly one [HTMLElement](#) interface per [Window](#) object.

Every [CustomElementRegistry](#) has a set of [custom element definitions](#), initially empty. In general, algorithms in this specification look up elements in the registry by any of `name`, `localName`, or `constructor`.

Every [CustomElementRegistry](#) also has an `elementDefinition` flag which is used to prevent reentrant invocations of `elementDefinition`. It is initially unset.

Every [CustomElementRegistry](#) also has a `whenDefined` promise map, mapping [valid custom element names](#) to promises. It is used to implement the [whenDefined\(\)](#) method.

For web developers (non-normative)

`window.customElements.define(name, constructor)`

Defines a new [custom element](#), mapping the given name to the given constructor as an [autonomous custom element](#).

`window.customElements.define(name, constructor, { extends: baseLocalName })`

Defines a new [custom element](#), mapping the given name to the given constructor as a [customized built-in element](#) for the `element type` supplied by `baseLocalName`. A `"NotSupportedError"` [DOMException](#) will be thrown upon trying to extend a [custom element](#) or an unknown element.

`window.customElements.get(name)`

Retrieves the [custom element](#) defined for the given `name`. Returns undefined if there is no [custom element definition](#) with the given `name`.

`window.customElements.whenDefined(name)`

Returns a promise that will be fulfilled when a [custom element](#) becomes defined with the given name. (If such a [custom element](#) is already defined, the returned promise will be immediately fulfilled.) Returns a promise rejected with a `"SyntaxError"` [DOMException](#) if not given a [valid custom element name](#).

`window.customElements.getOrCreate(name, root)`

Tries to upgrade all shadow-including inclusive descendant elements of `root`, even if they are not `connected`.

[Element definition](#) is a process of adding a [custom element definition](#) to the [CustomElementRegistry](#). This is accomplished by the [define\(\)](#) method. When invoked, the `define(name, constructor, options)` method must run these steps:

1. If `constructor` is false, then throw a `TypeError`.
2. If `name` is not a [valid custom element name](#), then throw a `"SyntaxError"` [DOMException](#).
3. If this [CustomElementRegistry](#) contains an entry with `name` `name`, then throw a `"NotSupportedError"` [DOMException](#).
4. If this [CustomElementRegistry](#) contains an entry with `constructor` `constructor`, then throw a `"NotSupportedError"` [DOMException](#).

6. Let `extends` be the value of the `extends` member of `options`, or null if no such member exists.

7. If `extends` is not null, then:

1. If `extends` is a `valid custom element name`, then throw a `"NotSupportedError"` `DOMException`.
2. If the `element interface` for `extends` and the `HTML namespace` is `HTMLUnknownElement` (e.g., if `extends` does not indicate an element definition in this specification), then throw a `"NotSupportedError"` `DOMException`.
3. Set `localName` to `extends`.

8. If this `CustomElementRegistry`'s `element definition is running` flag is set, then throw a `"NotSupportedError"` `DOMException`.

9. Set this `CustomElementRegistry`'s `element definition is running` flag.

10. Let `formAssociated` be false.

11. Let `disableInternals` be false.

12. Let `disableShadow` be false.

13. Let `observedAttributes` be an empty `sequence<DOMString>`.

14. Run the following substeps while catching any exceptions:

1. Let `prototype` be `Get(prototype, "prototype")`. Rethrow any exceptions.
2. If `Type(prototype)` is not `Object`, then throw a `"TypeError"` exception.
3. Let `lifecycleCallbacks` be a map with the keys `"connectedCallback"`, `"disconnectedCallback"`, `"adoptedCallback"`, and `"attributeChangedCallback"`, each of which belongs to an entry whose value is null.
4. For each of the keys `callbackName` in `lifecycleCallbacks`, in the order listed in the previous step:
 1. Let `callbackValue` be `Get(prototype, callbackName)`. Rethrow any exceptions.
 2. If `callbackValue` is not undefined, then set the value of the entry in `lifecycleCallbacks` with key `callbackName` to the result of `converting callbackValue` to the Web IDL `function` callback type. Rethrow any exceptions from the conversion.
5. If the value of the entry in `lifecycleCallbacks` with key `"attributeChangedCallback"` is not null, then:
 1. Let `observedAttributesIterable` be `Get(prototype, "observedAttributes")`. Rethrow any exceptions.
 2. If `observedAttributesIterable` is not undefined, then set `observedAttributes` to the result of `converting observedAttributesIterable` to a `sequence<DOMString>`. Rethrow any exceptions from the conversion.
6. Let `disabledFeatures` be an empty `sequence<DOMString>`.
7. Let `disabledFeaturesIterable` be `Get(prototype, "disabledFeatures")`. Rethrow any exceptions.
8. If `disabledFeaturesIterable` is not undefined, then set `disabledFeatures` to the result of `converting disabledFeaturesIterable` to a `sequence<DOMString>`. Rethrow any exceptions from the conversion.
9. Set `disabledInternals` to true if `disabledFeatures` contains `"internals"`.
10. Set `disableShadow` to true if `disabledFeatures` contains `"shadow"`.
11. Let `formAssociated` be `Get(prototype, "formAssociated")`. Rethrow any exceptions.
12. Set `formAssociated` to the result of `converting formAssociated` to a `boolean`. Rethrow any exceptions from the conversion.
13. If `formAssociated` is true, for each of `"formAssociatedCallback"`, `"formResetCallback"`, and `"formStateRestoreCallback"` `callbackName`:
 1. Let `callbackValue` be `Get(prototype, callbackName)`. Rethrow any exceptions.
 2. If `callbackValue` is not undefined, then set the value of the entry in `lifecycleCallbacks` with key `callbackName` to the result of `converting callbackValue` to the Web IDL `function` callback type. Rethrow any exceptions from the conversion.

Then, perform the following substep, regardless of whether the above steps threw an exception or not:

1. Unset this `CustomElementRegistry`'s `element definition is running` flag.

Finally, if this first set of substeps threw an exception, then rethrow that exception (thus terminating this algorithm). Otherwise, continue onward.

15. Let `definition` be a new `custom element definition` with `name` `name`, `localName` `localName`, `constructor` `constructor`, `observed attributes` `observedAttributes`, `lifecycle callbacks` `lifecycleCallbacks`, `form-associated` `formAssociated`, `disabled internals` `disabledInternals`, and `disable shadow` `disableShadow`.

16. Add `definition` to this `CustomElementRegistry`.

17. Let `document` be this `CustomElementRegistry`'s relevant global object's `associated document`.

18. Let `upgrade candidates` be all elements that are `shadow-including descendants` of `document`, whose namespace is the `HTML namespace` and whose local name is `localName`, in `shadow-including tree order`. Additionally, if `extends` is non-null, only include elements whose `isValue` is equal to `name`.

19. For each element `element` in `upgrade candidates`, enqueue a `custom element upgrade reaction` given `element` and `definition`.

20. If this `CustomElementRegistry`'s `when-defined promise map` contains an entry with key `name`:

1. Let `promise` be the value of that entry.

2. Resolve `promise` with undefined.

3. Delete the entry with key `name` from this `CustomElementRegistry`'s `when-defined promise map`.

MDN

[CustomElementRegistry/get](#)

Support in all current engines.

Opera53+Edge79+

Edge (Legacy)NoInternet ExplorerNo

Firefox Android63+Safari iOS10.3+Chrome Android66+WebView Android66+Samsung Internet9.0+Opera Android47+

When invoked, the `get(name)` method must run these steps:

1. If this `CustomElementRegistry` contains an entry with `name` `name`, then return that entry's `constructor`.

2. Otherwise, return undefined.

MDN

[CustomElementRegistry/whenDefined](#)

Support in all current engines.

Firefox63+Safari10.1+Chrome66+

Opera53+Edge79+

Edge (Legacy)NoInternet ExplorerNo

Firefox Android63+Safari iOS10.3+Chrome Android66+WebView Android66+Samsung Internet9.0+Opera Android47+

When invoked, the `whenDefined(name)` method must run these steps:

1. If `name` is not a `valid custom element name`, then return a new promise rejected with a `"svntaxError"` `DOMException`.

2. If this `CustomElementRegistry` contains an entry with `name` `name`, then return a new promise resolved with undefined.

3. Let `map` be this `CustomElementRegistry`'s `when-defined promise map`.

4. If `map` does not contain an entry with key `name`, create an entry in `map` with key `name` and whose value is a new promise.

5. Let `promise` be the value of the entry in `map` with key `name`.

6. Return `promise`.

Example

```
The whenDefined() method can be used to avoid performing an action until all appropriate custom elements are defined. In this example, we combine it with the :defined pseudo-class to hide a dynamically-loaded article's contents until we're sure that all of the autonomous custom elements it uses are defined.

articleContainer.hidden = true;

fetch(articleURL)
  .then(response => response.text())
  .then(text => {
    articleContainer.innerHTML = text;
    return Promise.all([
      ...articleContainer.querySelectorAll(":not(:defined)"),
      ...map(e => customElements.whenDefined(e.localName))
    ]);
  })
  .then(() => {
    articleContainer.hidden = false;
  });
}
```

MDN

[CustomElementRegistry/upgrade](#)

Support in all current engines.

Firefox63+Safari/Chrome66+

Opera53+Edge79+

Edge (Legacy)NoInternet ExplorerNo

Firefox Android63+Safari iOS/Chrome Android68+WebView Android68+Samsung Internet10.0+Opera Android48+

When invoked, the `upgrade(root)` method must run these steps:

1. Let `candidates` be a `list` of all root's `shadow-including inclusive descendant` elements, in `shadow-including tree order`.

2. For each `candidate` of `candidates`, try to `upgrade candidate`.

Example

```
The upgrade() method allows upgrading of elements at will. Normally elements are automatically upgraded when they become connected, but this method can be used if you need to upgrade before you're ready to connect the element.
```

EXPAND

```
console.assert(!(el instanceof SpiderMan)); // not yet upgraded
customElements.upgrade(el);
console.assert(el instanceof SpiderMan); // upgraded!
```

4.13.5 Upgrades

To upgrade an element, given as input a [custom element definition](#) and an element `element`, run the following steps:

- If `element's custom element state` is not `"undefined"` or `"uncustomized"`, then return.

Example

One scenario where this can occur due to reentrant invocation of this algorithm, as in the following example:

```
<!DOCTYPE html>
<x>foo id="a"></x>foo
<x>foo id="b"></x>foo

<script>
// Defining enqueues upgrade reactions for both "a" and "b"
customElements.define("x-foo", class extends HTMLElement {
  constructor() {
    super();
    const b = document.querySelector("#b");
    b.remove();
    // While this constructor is running for "a", "b" is still
    // unupgraded, and so inserting it into the document will enqueue a
    // second upgrade reaction for "b" in addition to the one enqueued
    // by defining x-foo.
    document.body.appendChild(b);
  }
}</script>
```

This step will thus bail out the algorithm early when `upgrade an element` is invoked with `"b"` a second time.

- Set `element's custom element definition` to `definition`.

- Set `element's custom element state` to `"failed"`.

Note

It will be set to `"custom"` after the upgrade succeeds. For now, we set it to `"failed"` so that any reentrant invocations will hit the [above early-exit step](#).

- For each `attribute` in `element's attribute list`, in order, enqueue a `custom element callback reaction` with `element`, callback name `"attributeChangedCallback"`, and an argument list containing `attribute's local name`, `null`, `attribute's value`, and `attribute's namespace`.

- If `element` is [connected](#), then enqueue a `custom element callback reaction` with `element`, callback name `"connectedCallback"`, and an empty argument list.

- Add `element` to the end of `definition's construction stack`.

- Let `C` be `definition's constructor`.

- Run the following substeps while catching any exceptions:

- If `definition's disable shadow` is true and `element's shadow root` is non-null, then throw a `"NotSupportedError"` [DOMException](#).

Note

This is needed as `attachShadow()` does not use `look up a custom element definition` while `attachInternals()` does.

- Let `constructResult` be the result of `constructing C`, with no arguments.

Note
If `C` non-conformantly uses an API decorated with the `!CFReactions` extended attribute, then the reactions enqueued at the beginning of this algorithm will execute during this step, before `C` finishes and control returns to this algorithm. Otherwise, they will execute after `C` and the rest of the upgrade process finishes.

- If `SameValue(constructResult, element)` is false, then throw a `"TypeError"`.

Note

This can occur if `C` constructs another instance of the same custom element before calling `super()`, or if `C` uses JavaScript's `return`-override feature to return an arbitrary `HTMLElement` object from the constructor.

Then, perform the following substep, regardless of whether the above steps threw an exception or not:

- Remove the last entry from the end of `definition's construction stack`.

Note

Assuming `C` calls `super()` (as it will if it is [conformant](#)), and that the call succeeds, this will be the `already-constructed marker` that replaced the `element` we pushed at the beginning of this algorithm. (The `HTML_element_constructor` carries out this replacement.)

If `C` does not call `super()` (i.e. it is not [conformant](#)), or if any step in the `HTML_element_constructor` throws, then this entry will still be `element`.

Finally, if the above steps threw an exception, then:

- Set `element's custom element definition` to `null`.

- Empty `element's custom element reaction queue`.

- Rethrow the exception (thus terminating this algorithm).

Note

If the above steps threw an exception, then `element's custom element state` will remain `"failed"`.

- If `element` is a [form-associated custom element](#), then:

- Reset the `form owner` of `element`. If `element` is associated with a `form` element, then enqueue a `custom element callback reaction` with `element`, callback name `"formAssociatedCallback"`, and `#` as the associated `form`.

- If `element` is [disabled](#), then enqueue a `custom element callback reaction` with `element`, callback name `"formDisabledCallback"` and `✓ true`.

- Set `element's custom element state` to `"custom"`.

To try to upgrade an element, given as input an element `element`, run the following steps:

- Let `definition` be the result of `looking up a custom element definition` given `element's node document`, `element's namespace`, `element's local name`, and `element's is value`.

- If `definition` is not null, then enqueue a `custom element upgrade reaction` given `element` and `definition`.

4.13.6 Custom element reactions

A `custom element` possesses the ability to respond to certain occurrences by running author code:

- When `upgraded`, its `constructor` is run, with no arguments.
- When it `becomes connected`, its `connectedCallback` is called, with no arguments.
- When it `becomes disconnected`, its `disconnectedCallback` is called, with no arguments.
- When it is `adopted` into a new document, its `adoptedCallback` is called, given the old document and new document as arguments.
- When any of its attributes are `changed`, `appended`, `removed`, or `replaced`, its `attributeChangedCallback` is called, given the attribute's local name, old value, new value, and namespace as arguments. (An attribute's old or new value is considered to be null when the attribute is added or removed, respectively.)
- When the user agent `sets the form owner of a form-associated custom element` and doing so changes the form owner, its `formAssociatedCallback` is called, given the new form owner (or null if no owner) as an argument.
- When the form owner of a `form-associated custom element` is `reset`, its `formResetCallback` is called.
- When the `disabled` state of a `form-associated custom element` is changed, its `formDisabledCallback` is called, given the new state as an argument.
- When user agent updates a `form-associated custom element's` value on behalf of a user, its `formStateRestoreCallback` is called, given the new value and a string indicating a reason, `"restore"` or `"autocomplete"`, as arguments.

We call these reactions collectively `custom element reactions`.

The way in which `custom element reactions` are invoked is done with special care, to avoid running author code during the middle of delicate operations. Effectively, they are delayed until "just before returning to user script". This means that for most purposes they appear to execute synchronously, but in the case of complicated composite operations (like `cloning` or `range` manipulation), they will instead be delayed until after all the relevant user agent processing steps have completed, and then run together as a batch.

Additionally, the precise ordering of these reactions is managed via a somewhat-complicated stack-of-queues system, described below. The intention behind this system is to guarantee that `custom element reactions` always are invoked in the same order as their triggering actions, at least within the local context of a single `custom element`. (Because `custom element reaction` code can perform its own mutations, it is not possible to give a global ordering guarantee across multiple elements.)

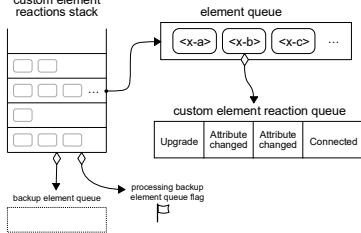

Each `similar-origin window agent`'s `custom element reactions stack`, which is initially empty. A `similar-origin window agent`'s `current element queue` is the `element queue` at the top of its `custom element reactions stack`. Each item in the stack is an `element queue`, which is initially empty as well. Each item in an `element queue` is an element. (The elements are not necessarily `custom` yet, since this queue is used for `upgrade` as well.)

Each `custom element reactions stack` has an associated `backup element queue`, which an initially-empty `element queue`. Elements are pushed onto the `backup element queue` during operations that affect the DOM without going through an API decorated with `!CFReactions`, or through the parser's `create an element for the token` algorithm. An example of this is a user-initiated editing operation which modifies the descendants or attributes of an `editable` element. To prevent reentrancy when pushing onto the `backup element queue`, each `custom element reactions stack` also has a `processing the backup element queue flag`, initially unset.

All elements have an associated `custom element reaction queue`, initially empty. Each item in the `custom element reaction queue` is of one of two types:

- An `upgrade reaction`, which will `upgrade` the custom element and contains a `custom element definition`.
- A `callback reaction`, which will call a lifecycle callback, and contains a callback function as well as a list of arguments.

This is all summarized in the following schematic diagram:

To `enqueue an element on the appropriate element queue`, given an element `element`, run the following steps:

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

2. If `reactionsStack` is empty, then:

1. Add `element` to `reactionsStack`'s `backupElementQueue`.
2. If `reactionsStack`'s `processingTheBackupElementQueue` flag is set, then return.
3. Set `reactionsStack`'s `processingTheBackupElementQueue` flag.
4. **Queue a microtask** to perform the following steps:

1. **Invoke custom element reactions** in `reactionsStack`'s `backupElementQueue`.

2. Unset `reactionsStack`'s `processingTheBackupElementQueue` flag.

3. Otherwise, add `element` to `element`'s `relevantAgent`'s `currentElementQueue`.

To enqueue a custom element callback reaction, given a `customElement` element, a callback name `callbackName`, and a list of arguments `args`, run the following steps:

1. Let `definition` be `element`'s `customElementDefinition`.
2. Let `callback` be the value of the entry in `definition`'s `lifecycleCallbacks` with key `callbackName`.
3. If `callback` is null, then return.

4. If `callbackName` is "`attributeChangedCallback`", then:

1. Let `attributeName` be the first element of `args`.

2. If `definition`'s `observedAttributes` does not contain `attributeName`, then return.

5. Add a new `callbackReaction` to `element`'s `customElementReactionQueue`, with callback function `callback` and arguments `args`.

6. Enqueue an element on the appropriate element queue given `element`.

To enqueue a custom element upgrade reaction, given an element `element` and `customElementDefinition`, run the following steps:

1. Add a new `upgradeReaction` to `element`'s `customElementReactionQueue`, with `customElementDefinition` `definition`.
2. Enqueue an element on the appropriate element queue given `element`.

To invoke custom element reactions in an `elementQueue`, run the following steps:

1. For each `customElement` element in `queue`:

1. Let `reactions` be `element`'s `customElementReactionQueue`.

2. Repeat until `reactions` is empty:

1. Remove the first element of `reactions`, and let `reaction` be that element. Switch on `reaction`'s type:

```
upgradeReaction
  Upgrade element using reaction's custom element definition.
  callbackReaction
    Invoke reaction's callback function with reaction's arguments, and with element as the callback this value.
```

If this throws an exception, catch it, and report the exception.

To ensure `customElementReactions` are triggered appropriately, we introduce the `[CEReactions]` IDL `extendedAttribute`. It indicates that the relevant algorithm is to be supplemented with additional steps in order to appropriately track and invoke `customElementReactions`.

The `[CEReactions]` extended attribute must take no arguments, and must not appear on anything other than an operation, attribute, setter, or deleter. Additionally, it must not appear on readonly attributes.

Operations, attributes, setters, or deletors annotated with the `[CEReactions]` extended attribute must run the following steps in place of the ones specified in their description:

1. Push a new `elementQueue` onto this object's `relevantAgent`'s `customElementReactionsStack`.
2. Run the originally-specified steps for this construct, catching any exceptions. If the steps return a value, let `value` be the returned value. If they throw an exception, let `exception` be the thrown exception.
3. Let `queue` be the result of `popOne` from this object's `relevantAgent`'s `customElementReactionsStack`.
4. **Invoke custom element reactions** in `queue`.
5. If an exception `exception` was thrown by the original steps, rethrow `exception`.
6. If a value `value` was returned from the original steps, return `value`.

Note

The intent behind this extended attribute is somewhat subtle. One way of accomplishing its goals would be to say that every operation, attribute, setter, and deleter on the platform must have these steps inserted, and to allow implementers to optimize away unnecessary cases (where no DOM mutation is possible that could cause `customElementReactions` to occur).

However, in practice this imprecision could lead to non-interoperable implementations of `customElementReactions`, as some implementations might forget to invoke these steps in some cases. Instead, we settled on the approach of explicitly annotating all relevant IDL constructs, as a way of ensuring interoperable behavior and helping implementations easily pinpoint all cases where these steps are necessary.

Any nonstandard APIs introduced by the user agent that could modify the DOM in such a way as to cause `enqueueing a custom element callback reaction` or `enqueueing a custom element upgrade reaction`, for example by modifying any attributes or child elements, must also be decorated with the `[CEReactions]` attribute.

Note

As of the time of this writing, the following nonstandard or not-yet-standardized APIs are known to fall into this category:

- `HTMLElement`'s `outerText` IDL attribute
- `HTMLElement`'s `webkitDirectory` and `incremental` IDL attributes
- `HTMLLinkElement`'s `disabled` and `scope` IDL attributes
- `ShadowRoot`'s `innerHTML` IDL attribute

4.13.7 The `ElementInternals` interface

For web developers (non-normative)

`element.attachInternals()`

Returns an `ElementInternals` object targeting the `customElement` element. Throws an exception if `element` is not a `customElement`, if the "internals" feature was disabled as part of the element definition, or if it is called twice on the same element.

IDL (ExposedWindow)

```
interface ElementInternals {
  // Form-associated custom elements
  void setFormValue(File or USVString or FormData? value,
    optional File or USVString or FormData? state);
  readonly attribute HTMLFormElement form;
  void setValidity(ValidityStateFlags flags,
    optional DOMString message,
    optional HTMLElement anchor);
  readonly attribute ValidityState validity;
  void setError(DOMString validationMessage);
  boolean checkValidity();
  boolean reportValidity();
  readonly attribute NodeList labels;
}

dictionary ValidityStateFlags {
  boolean valueMissing = false;
  boolean typeMismatch = false;
  boolean patternMismatch = false;
  boolean stepMismatch = false;
  boolean tooLong = false;
  boolean rangeUnderflow = false;
  boolean rangeOverflow = false;
  boolean stepMismatch = false;
  boolean badInput = false;
  boolean customError = false;
}
```

For web developers (non-normative)

`internals.setFormValue(value)`

Sets both the `state` and `submissionValue` of `internal`'s `targetElement` to `value`.

If `value` is null, the element won't participate in form submission.

`internals.setFormValue(value, state)`

Sets the `submissionValue` of `internal`'s `targetElement` to `value`, and its `state` to `state`.

If `value` is null, the element won't participate in form submission.

`internals.form`

Returns the `formOwner` of `internal`'s `targetElement`.

`internals.setValidity(flags, message [, anchor])`

Marks `internal`'s `targetElement` as suffering from the constraints indicated by the `flags` argument, and sets the element's validation message to `message`. If `anchor` is specified, the user agent might use it to indicate problems with the constraints of `internal`'s `targetElement` when the `formOwner` is validated interactively or `reportValidity()` is called.

`internals.setValidity({})`

Marks `internal`'s `targetElement` as satisfying its constraints.

`internals.willValidate`

Returns true if `internal`'s `targetElement` will be validated when the form is submitted; false otherwise.

`internals.validity`

Returns the `ValidityState` object for `internal`'s `targetElement`.

`internals.validationMessage`

Returns the error message that would be shown to the user if `internal`'s `targetElement` was to be checked for validity.

`valid = internals.checkValidity()`

`valid = internals . reportValidity()`
 Returns true if `internal's target element` has no validity problems; otherwise, returns false, fires an `invalid` event at the element, and (if the event isn't canceled) reports the problem to the user.

`internals . labels`
 Returns a `NodeList` of all the `label` elements that `internal's target element` is associated with.

Each `ElementInternal` has a `target element`, which is a `custom element`. `ElementInternal` provides various operations and attributes to allow control over internal features which the user agent provides to all elements.

Each `HTMLElement` has an `attached` `internals` boolean, initially false.

The `attachInternals()` method on an `HTMLElement` element, when invoked, must run the following steps:

1. If `element's is value` is not null, then throw a "`NotSupportedError`" `DOMException`.
2. Let `definition` be the result of `looking up a custom element definition` given `element's node document`, its namespace, its local name, and null as `is value`.
3. If `definition` is null, then throw an "`NotSupportedError`" `DOMException`.
4. If `definition's disableInternals` is true, then throw a "`NotSupportedError`" `DOMException`.
5. If `element's attached` `internals` is true, then throw an "`NotSupportedError`" `DOMException`.
6. Set `element's attached` `internals` to true.
7. Create a new `ElementInternal` instance `targeting` `element`, and return it.

Each `form-associated custom element` has `submission value`. It is used to provide one or more `entries` on form submission, and the initial value of `submission value` is null, and `submission value` can be null, a string, a `File`, or a `list` of `entries`.

Each `form-associated custom element` has `state`. It is information with which the user agent can restore a user's input for the element. The initial value of `state` is null, and `state` can be null, a string, a `File`, or a `list` of `entries`.

The `setFormValue()` method is used by the custom element author to set the element's `submission value` and `state`, thus communicating these to the user agent.

When the user agent believes it is a good idea to restore a `form-associated custom element's state`, for example after navigation or restoring the user agent, they may `enqueue a custom element callback reaction` with that element, callback name "`formStateRestoreCallback`", and an argument list containing the state to be restored, and "`restore`".

If the user agent has a form-filling assist feature, then when the feature is invoked, it may `enqueue a custom element callback reaction` with a `form-associated custom element`, callback name "`formStateRestoreCallback`", and an argument list containing the state value determined by history of state value and some heuristics, and "`autocomplete`". In general, the `state` is information specified by a user, and the `submission value` is a value after canonicalization or sanitization, suitable for submission to the server. The following examples makes this concrete:

Example
 Suppose that we have a `form-associated custom element` which asks a user to specify a date. The user specifies "`3/15/2019`", but the control wishes to submit "`2019-03-15T00:00:00Z`" to the server. "`3/15/2019`" would be a `state` of the element, and "`2019-03-15`" would be a `submission value`.
Example
 Suppose you develop a custom element emulating the behavior of the existing `checkbox` `input` type. Its `submission value` would be the value of its `value` content attribute, or the string "`on`". Its `state` would be one of "`checked`", "`unchecked`", "`checked/indeterminate`", or "`unchecked/indeterminate`".

The `setFormValue(value, state)` method of the `ElementInternal` interface must run the following steps:

1. Let `element` be this `ElementInternal's target element`.
2. If `element` is not a `form-associated custom element`, then throw a "`NotSupportedError`" `DOMException`.
3. Set `target element's submission value` to `value` if `value` is not a `FormData` object, or to a `clone` of the entry list associated with `value` otherwise.
4. If the `state` argument of the function is omitted, set `element's state` to `submission value`.
5. Otherwise, if `state` is a `FormData` object, set `element's state` to `clone` of the entry list associated with `state`.
6. Otherwise, set `element's state` to `state`.

Each `form-associated custom element` has validity flags named `valueMissing`, `typeMismatch`, `patternMismatch`, `tooLong`, `tooShort`, `rangeUnderflow`, `rangeOverflow`, `stepMismatch`, and `customError`. They are false initially.

Each `form-associated custom element` has a `validation message` string. It is the empty string initially.

Each `form-associated custom element` has a `validation anchor` element. It is null initially.

The `setValidity(flags, message, anchor)` method of the `ElementInternal` interface must run the following steps:

1. Let `element` be this `ElementInternal's target element`.
2. If `element` is not a `form-associated custom element`, then throw a "`NotSupportedError`" `DOMException`.
3. If `flags` contains one or more true values and `message` is not given or is the empty string, then throw a `TypeError`.
4. For each entry `flag` → `value` of `flags`, set `element's` validity flag with the name `flag` to `value`.
5. Set `element's validation message` to the empty string if `message` is not given or all of `element's` validity flags are false, or to `message` otherwise.
6. If `element's customError` validity flag is true, then set `element's customValidError message` to `element's validation message`. Otherwise, set `element's customValidError message` to the empty string.
7. Set `element's validation anchor` to null if `anchor` is not given. Otherwise, if `anchor` is not a `shadow-including descendant` of `element`, then throw a "`NotFoundError`" `DOMException`. Otherwise, set `element's validation anchor` to `anchor`.

The `ValidationMessage` attribute of `ElementInternal` interface, on getting, must return the `validation message` of this `ElementInternal's target element`.

When `entry construction algorithm` for a `form-associated custom element` is invoked, given an element `element` and a list `entry list`, run the following steps:

1. If `element's submission value` is a `list` of `entries`, then `append` each item of `element's submission value` to `entry list`, and return.
- Note**
 In this case, user agent does not refer to the `name` content attribute value. An implementation of `form-associated custom element` is responsible to decide names of `entries`. They can be the `name` content attribute value, they can be strings based on the `name` content attribute value, or they can be unrelated to the `name` content attribute.
2. If the element does not have a `name` attribute specified, or its `name` attribute's value is the empty string, then return.
3. If the element's `submission value` is not null, `append an entry` to `entry list` with the `name` attribute value and the `submission value`.

4.14 Common idioms without dedicated elements

4.14.1 Bread crumb navigation

This specification does not provide a machine-readable way of describing bread-crumb navigation menus. Authors are encouraged to just use a series of links in a paragraph. The `area` element can be used to mark the section containing these paragraphs as being navigation blocks.

Example

In the following example, the current page can be reached via two paths.

```
<nav>
  <a href="/">Main</a> •
  <a href="/products">Products</a> •
  <a href="/products/dishwashers">Dishwashers</a>
  <span>Second hand</span>
</p>
<p>
  <a href="#">Main</a> •
  <a href="/second-hand">Second hand</a> •
  <a href="#">Dishwashers</a>
</p>
</nav>
```

4.14.2 Tag clouds

This specification does not define any markup specifically for marking up lists of keywords that apply to a group of pages (also known as *tag clouds*). In general, authors are encouraged to either mark up such lists using `a` elements with explicit inline counts that are then hidden and turned into a presentational effect using a style sheet, or to use SVG.

Example

Here, three tags are included in a short tag cloud:

```
<style>
  .tag-cloud > li { span { display: none; }
  .tag-cloud li { display: inline; }
  .tag-cloud-1 { font-size: 0.7em; }
  .tag-cloud-2 { font-size: 0.8em; }
  .tag-cloud-3 { font-size: 1.1em; }
  .tag-cloud-4 { font-size: 1.3em; }
  .tag-cloud-5 { font-size: 1.5em; }

  @media speech {
    .tag-cloud > li > span { display:inline; }
  }
</style>
...
<ul class="tag-cloud">
  <li class="tag-cloud-4"><a title="28 instances" href="#apple">apple</a> <span>(popular)</span>
  <li class="tag-cloud-4"><a title="6 instances" href="#kiwi">kiwi</a> <span>(rare)</span>
  <li class="tag-cloud-5"><a title="41 instances" href="#pear">pear</a> <span>(very popular)</span>
</ul>
```

The actual frequency of each tag is given using the `title` attribute. A CSS style sheet is provided to convert the markup into a cloud of differently-sized words, but for user agents that do not support CSS or are not visual, the markup contains annotations like "(popular)" or "(rare)" to categorize the various tags by frequency, thus enabling all users to benefit from the information.

The `ul` element is used (rather than `ol`) because the order is not particularly important: while the list is in fact ordered alphabetically, it would convey the same information if ordered by, say, the length of the tag.

The `tag tag`-keyword is not used on these `a` elements because they do not represent tags that apply to the page itself; they are just part of an index listing the tags themselves.

4.14.3 Conversations

This specification does not define a specific element for marking up conversations, meeting minutes, chat transcripts, dialogues in screenplays, instant message logs, and other situations where different players take turns in discourse.

Instead, authors are encouraged to mark up conversations using `u` elements and punctuation. Authors who need to mark the speaker for styling purposes are encouraged to use `said` or `b`. Paragraphs with their text wrapped in the `u` element can be used for marking up stage directions.

Example

This example demonstrates this using an extract from Abbot and Costello's famous sketch, *Who's on first*:

```
<p>Costello: Look, I gotta getta first baseman?
<p>Costello: Who's on first?
<p>Costello: Who's playing first?
<p>Abbott: That's right.
<p>Costello: You're not separated.
<p>Costello: When you pay off the first baseman every month, who gets the money?
<p>Abbott: Every dollar of it.
```

Example

The following extract shows how an IM conversation log could be marked up, using the `data` element to provide Unix timestamps for each line. Note that the timestamps are provided in a format that the `time` element does not support, so the `data` element is used instead (namely, Unix `time + timestamp`). Had the author wished to mark up the data using one

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

```
<rp> <data value="1319988155">14:22</data> <rp>I'm not that nerdy, I've only seen 30% of the star trek episodes</rp>
<rp> <data value="1319988152">14:23</data> <rp>if you know what percentage of the star trek episodes you have seen, you are inarguably nerdy</rp>
<rp> <data value="1319988207">14:23</data> <rp>it's unarguably</rp>
<rp> <data value="1319988228">14:24</data> <rp>blanks</rp>
<rp> <data value="1319988200">14:24</data> <rp>you are not helping your case</rp>
```

Example

HTML does not have a good way to mark up graphs, so descriptions of interactive conversations from games are more difficult to mark up. This example shows one possible convention using [a](#) elements to list the possible responses at each point in the conversation. Another option to consider is describing the conversation in the form of a DOT file, and outputting the result as an SVG image to place in the document. [\[DRAFT\]](#)

```
<a> Next, you meet a fisher. You can say one of several greetings:
<a> "Hello there!"</a>
</dd>
<rp> She responds with "Hello, how may I help you?"; you can respond with:
<a> "I would like to buy a fish."</a>
<rp> She sells you a fish and the conversation finishes.
<a> "Can I borrow your boat?"</a>
<rp> She is surprised and asks "What are you offering in return?".</rp>
<a> "Five gold." (if you have enough)</a>
<rp> She says "Five gold. If you have enough" and ends the conversation.
<a> "Five gold." (if you don't have enough)</a>
<rp> She lends you her boat. The conversation ends.
<a> "A newspaper." (if you have one)</a>
<rp> "A pebble." (if you have one)</rp>
<rp> Your conversation options at this point are the same as they were after asking to borrow her boat, minus any options you've suggested before.
</dd>
</dd>
</dd>
<dd> "Vote for me in the next election!"</dd>
<dd> <rp> She turns away. The conversation finishes.
<a> "Madam, are you aware that your fish are running away?"</a>
<rp> She looks at you skeptically and says "Fish cannot run, miss".</rp>
<a> "You got me!"</a>
<rp> She sighs and the conversation ends.
<a> "Only kidding."</a>
<rp> "Good one!" she retorts. Your conversation options at this point are the same as those following "Hello there!" above.
<a> "Oh, then what are they doing?"</a>
<rp> She looks at her fish, giving you an opportunity to steal her boat, when you do. The conversation ends.
</dd>
</dd>
</dd>
```

Example

In some games, conversations are simpler: each character merely has a fixed set of lines that they say. In this example, a game FAQ/walkthrough lists some of the known possible responses for each character:

```
<section>
<h3>Dialogue</h3>
<p><small>Some characters repeat their lines in order each time you interact with them. You may pick from amongst their lines. Those who respond in order have numbered entries in the lists below.</small>
<h2>The Shopkeeper</h2>
<ul>
<li>How may I help you?
<li>Fresh apples!
<li>A loaf of bread for madam?
</ul>
<h2>The pilot</h2>
<ul>
<li>I'm afraid I'm late again!
</ul>
<h2>The agent</h2>
<ul>
<li>I'll be about to fly out, sorry!
<li>Sorry, I'm just waiting for flight clearance and then I'll be off!
</ul>
<h2>After the accident</h2>
<ul>
<li>I'm about to fly out, sorry!
<li>I'm not flying right now, my plane is being cleaned.
<li>Ok, it's not being cleaned, it needs a minor repair first.
<li>Ok, stop bothering me! Truth is, I had a crash.
</ul>
<h2>Cian Leader</h2>
<ul>
<li>During the first clan meeting:
<ul>
<li>Hey, have you seen my daughter? I bet she's up to something nefarious again...
<li>I was talking to her today.
<li>The name is Baileigh Daff Hooligan. How can I help you today?
<li>A glass of water? Fresh from the well!
</ul>
<li>After the earthquake:
<ul>
<li>Everyone is safe in the shelter, we just have to put out the fire!
<li>I'll go and tell the fire brigade, you keep hosing it down!
</ul>
</ul>
```

4.14.4 Footnotes

HTML does not have a dedicated mechanism for marking up footnotes. Here are the suggested alternatives.

For short inline annotations, the [title](#) attribute could be used.

Example

In this example, two parts of a dialogue are annotated with footnote-like content using the [title](#) attribute.

```
<rp> <rp><Customer><b>D:</b> Hello! I wish to register a complaint. Hello, Miss?</Customer></rp>
<rp> <rp><Shopkeeper><b>B:</b> <span title="Colloquial pronunciation of 'What do you'">What's up?</span></Shopkeeper></rp>
<rp> <rp><Customer><b>D:</b> Uh, I'm sorry, I have a cold. I wish to make a complaint.</Customer></rp>
<rp> <rp><Shopkeeper><b>B:</b> Sorry, <span title="This is, of course, a lie.">we're closing for lunch</span>.
```

Note

Unfortunately, relying on the [title](#) attribute is currently discouraged as many user agents do not expose the attribute in an accessible manner as required by this specification (e.g. requiring a pointing device such as a mouse to cause a tooltip to appear, which excludes keyboard-only users and touch-only users, such as anyone with a modern phone or tablet).

Note

If the [title](#) attribute is used, CSS can be used to draw the reader's attention to the elements with the attribute.

Example

For example, the following CSS places a dashed line below elements that have a [title](#) attribute.

```
CSS:<title> { border-bottom: thin dashed; }
```

For longer annotations, the [a](#) element should be used, pointing to an element later in the document. The convention is that the contents of the link be a number in square brackets.

Example

In this example, a footnote in the dialogue links to a paragraph below the dialogue. The paragraph then reciprocally links back to the dialogue, allowing the user to return to the location of the footnote.

```
<rp> Announcer: Number 16: The <rp>hand</rp>.
<rp> Interviewer: Good evening. I have with me in the studio tonight Mr Polevaluter, who for the past few years has been contradicting people. Mr Polevaluter, why <rp>and</rp> you contradict people?
<rp> <rp><Customer><b>D:</b> <sup><a href="#fn1" id="r1">1</a></sup></Customer></rp>
<rp> Interviewer: You told me you did!
<rp> <rp><Customer><b>D:</b> No, I didn't!
<rp> <rp><Shopkeeper><b>B:</b> This is, naturally, a lie, but paradoxically if it were true he could not say so without contradicting the interviewer and thus making it false.</Shopkeeper></rp>
</rp>
```

For side notes, longer annotations that apply to entire sections of the text rather than just specific words or sentences, the [aside](#) element should be used.

Example

In this example, a sidebar is given after a dialogue, giving it some context.

```
<rp> <rp><span class="speaker">Customer</span>: I will not buy this record, it is scratched.
<rp> <rp><span class="speaker">Shopkeeper</span>: I will not buy this record, it is scratched.
<rp> <rp><span class="speaker">Customer</span>: No no no, this is a tobacconist.
<rp> <rp><span class="speaker">Shopkeeper</span>: No no no, this is a tobacconist.
<rp> <rp><span class="speaker">Customer</span>: Well, the British Empire lay in ruins, and foreign nationalists frequented the streets - many of them Hungarians (including the author of the book). The author of the book, 'Vajt has been publishing incompetently-written phrase books.
</aside>
```

For figures or tables, footnotes can be included in the relevant [Caption](#) or [Caption](#) element, or in surrounding prose.

Example

In this example, a table has cells with footnotes that are given in prose. A [Figure](#) element is used to give a single legend to the combination of the table and its footnotes.

```
<table>
<caption>Table 1. Alternative activities for Knights.</caption>
<thead>
<tr>
<th>Activity</th>
<th>Location</th>
<th>Cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dance</td>
<td>Anywhere possible</td>
<td>10</td>
</tr>
<tr>
<td>Routines, chorus scenes</td>
<td>hundreds</td>
<td>2</td>
</tr>
<tr>
<td>Undisclosed</td>
<td>Undisclosed</td>
<td><sup>3</sup></td>
</tr>
<tr>
<td>Dining</td>
<td>a href="#fn3">3</td>
<td><sup>4</sup></td>
</tr>
<tr>
<td>Cost of ham, jam, and spam</td>
<td>a href="#fn4">4</td>
<td><sup>5</sup></td>
</tr>
</tbody>
</table>
<sup>1</sup> Assumed.</p>
```

```
<p id="fn4">A lot.</p>
</figure>
```

4.15 Disabled elements

An element is said to be *actually disabled* if it is one of the following:

- a `button` element that is `disabled`
- an `input` element that is `disabled`
- a `select` element that is `disabled`
- a `textarea` element that is `disabled`
- an `optgroup` element that has a `disabled` attribute
- an `option` element that is `disabled`
- a `fieldset` element that is a `disabled` `fieldset`
- a `form-associated` custom element that is `disabled`

Note

This definition is used to determine what elements are `focusable` and which elements match the `:enabled` and `:disabled` pseudo classes.

4.16 Matching HTML elements using selectors and CSS

4.16.1 Case-sensitivity of the CSS '`attr()`' function

CSS *Values and Units* leaves the case-sensitivity of attribute names for the purpose of the `attr()` function to be defined by the host language. [CSSVALUES]

When comparing the attribute name part of a CSS `attr()` function to the names of namespace-less attributes on `HTML elements` in `HTML documents`, the name part of the CSS `attr()` function must first be converted to ASCII lowercase. The same function when compared to other attributes must be compared according to its original case. In both cases, the comparison is `case-sensitive`.

Note

This is the same as comparing the name part of a CSS `attribute selector`, specified in the next section.

4.16.2 Case-sensitivity of selectors

Selectors leaves the case-sensitivity of element names, attribute names, and attribute values to be defined by the host language. [SELECTORS]

When comparing a CSS element `type selector` to the names of `HTML elements` in `HTML documents`, the CSS element `type selector` must first be converted to ASCII lowercase. The same selector when compared to other elements must be compared according to its original case. In both cases, the comparison is `case-sensitive`.

When comparing the name part of a CSS `attribute selector` to the names of attributes on `HTML elements` in `HTML documents`, the name part of the CSS `attribute selector` must first be converted to ASCII lowercase. The same selector when compared to other attributes must be compared according to its original case. In both cases, the comparison is `case-sensitive`.

Attribute `selectors` on an `HTML element` in an `HTML document` must treat the values of attributes with the following names as `ASCII case-insensitive`:

- accept
- accept-charset
- align
- alink
- axis
- bgcolor
- charset
- checked
- clear
- codetype
- dir
- compact
- declare
- defer
- dir
- direction
- disabled
- enctype
- face
- frame
- hreflang
- hreflang-equiv
- lang
- language
- link
- media
- method
- multiple
- nohref
- nosize
- nospace
- nowrap
- readonly
- rev
- rules
- scope
- scrolling
- selected
- shape
- target
- text
- type
- valign
- wraptype
- vlink

Example

For example, the selector `[bgcolor="#ffff00"]` will match any HTML element with a `bgcolor` attribute with values including `#ffff00`, `#FFFF00` and `#fff000`. This happens even if `bgcolor` has no effect for a given element (e.g., `div`).

The selector `[type=a a]` will match any HTML element with a `type` attribute whose value is `a`, but not whose value is `A`, due to the `a` flag.

All other attribute values and everything else must be treated as entirely `case-sensitive` for the purposes of selector matching. This includes:

- `IDs` and `classes` in `quirks mode` and `limited-quirks mode`
- the names of elements not in the `HTML` namespace
- the names of `HTML elements` in `XML documents`
- the names of attributes of elements not in the `HTML` namespace
- the names of attributes of `HTML elements` in `XML documents`
- the names of attributes that themselves have namespaces

Note

Selectors defines that ID and class selectors (such as `#foo` and `.bar`), when matched against elements in documents that are in `quirks mode`, will be matched in an `ASCII case-insensitive` manner. However, this does not apply for attribute selectors with `"id"` or `"class"` as the name part. The selector `[class="foobar"]` will treat its value as `case-sensitive` even in `quirks mode`.

4.16.3 Pseudo-classes

`MDN`

`Pseudo-classes`

There are a number of dynamic selectors that can be used with HTML. This section defines when these selectors match HTML elements. [SELECTORS] [CSSUI]

`:defined`

`MDN`

`:defined`

Support in all current engines.

Firefox 63+ | Safari 10+ | Chrome 54+ | WebView Android 54+ | Samsung Internet 6.0+ | Opera Android 41+

The `:defined` pseudo-class must match any element that is `defined`.

`:link`

`MDN`

`:link`

Support in all current engines.

Firefox 1+ | Safari 1+ | Chrome 1+

Opera 3.5+ | Edge 79+

Edge (Legacy) 12+ | Internet Explorer 3+

Firefox 4+ | Safari iOS 3.2+ | Chrome Android 18+ | WebView Android 1.5+ | Samsung Internet 1.0+ | Opera Android 14+

`:visited`

`MDN`

`:visited`

Support in all current engines.

Firefox 1+ | Safari 1+ | Chrome 1+

Opera 3.5+ | Edge 79+

Edge (Legacy) 12+ | Internet Explorer 4+

Firefox Android 4+ | Safari iOS 18+ | Chrome Android 18+ | WebView Android 4.4+ | Samsung Internet 1.0+ | Opera Android 10.1+

All `a` elements that have an `href` attribute, all `area` elements that have an `href` attribute, and all `link` elements that have an `href` attribute, must match one of `:link` and `:visited`.

Other specifications might apply more specific rules regarding how these elements are to match these `pseudo-classes`, to mitigate some privacy concerns that apply with straightforward implementations of this requirement.

:active

Support in all current engines.

Firefox 1+Safari 1+Chrome 1+

Opera 5+Edge 79+

Edge (Legacy) 12+Internet Explorer 4+

Firefox Android 4+Safari iOS 1+Chrome Android 18+WebView Android 1+Samsung Internet 1.0+Opera Android 10.1+

The `:active` pseudo-class is defined to match an element “while an element is *being activated* by the user”.

To determine whether a particular element is *being activated* for the purposes of defining the `:active` pseudo-class only, an HTML user agent must use the first relevant entry in the following list.

If the element has a descendant that is currently matching the `:active` pseudo-class

The element is *being activated*.

If the element is the `labeled control` of a `label` element that is currently matching `:active`

The element is *being activated*.

If the element is a `button` element

If the element is an `input` element whose `type` attribute is in the `Submit Button`, `Image Button`, `Reset Button`, or `Button` state

The element is *being activated* if it is *in a formal activation state* and it is not `disabled`.

Example

For example, if the user is using a keyboard to push a `button` element by pressing the space bar, the element would match this `:pseudo-class` in between the time that the element received the `keydown` event and the time the element received the `keyup` event.

If the element is an `a` element that has an `href` attribute

If the element is an `area` element that has an `href` attribute

If the element is a `link` element that has an `href` attribute

If the element is `focuseable`

The element is *being activated* if it is *in a formal activation state*.

If the element is *being actively pointed at*

The element is *being activated*.

An element is said to be *in a formal activation state* between the time the user begins to indicate an intent to trigger the element’s `activation behavior` and either the time the user stops indicating an intent to trigger the element’s `activation behavior`, or the time the element’s `activation behavior` has finished running, which ever comes first.

An element is said to be *being actively pointed at* while the user indicates the element using a pointing device while that pointing device is in the “down” state (e.g. for a mouse, between the time the mouse button is pressed and the time it is depressed; for a finger in a multitouch environment, while the finger is touching the display surface).

:hover**MDN****:hover**

Support in all current engines.

Firefox 1+Safari 2+Chrome 1+

Opera 4+Edge 79+

Edge (Legacy) 12+Internet Explorer 4+

Firefox Android 4+Safari iOS 1+Chrome Android 18+WebView Android 37+Samsung Internet 1.0+Opera Android 10.1+

The `:hover` pseudo-class is defined to match an element “while the user designates an element with a pointing device”. For the purposes of defining the `:hover` pseudo-class only, an HTML user agent must consider an element as being one that the user designates if it is:

- An element that the user indicates using a pointing device.
- An element that has a descendant that the user indicates using a pointing device.
- An element that is the `labeled control` of a `label` element that is currently matching `:hover`.

Example

Consider in particular a fragment such as:

```
<p><label for=a><input id=a></label><span id=b><input id=c></span></p>
```

If the user designates the element with ID “a” with their pointing device, then the `label` element (and all its ancestors not shown in the snippet above), the `label` element, the element with ID “a”, and the element with ID “c” will match the `:hover` pseudo-class. The element with ID “a” matches it from condition 1, the `label` and `span` elements match it because of condition 2 (one of their descendants is designated), and the element with ID “c” matches it through condition 3 (its `label` element matches `:hover`). However, the element with ID “b” does not match `:hover`; its descendant is not designated, even though it matches `:hover`.

:focus**MDN****:focus**

Support in all current engines.

Firefox 1+Safari 1+Chrome 1+

Opera 7+Edge 79+

Edge (Legacy) 12+Internet Explorer 8+

Firefox Android 4+Safari iOS 1+Chrome Android 18+WebView Android 1+Samsung Internet 1.0+Opera Android 10.1+

For the purposes of the CSS `:focus` pseudo-class, an element has the focus when:

- its `top-level browsing context` has the system focus;
- it is not itself a `browsing context container`; and
- at least one of the following is true:
 - it is one of the elements listed in the `focus chain` of the `currently focused area of the top-level browsing context`, or
 - its `shadow root shadowRoot` is not null and `shadowRoot` is the `root` of at least one element that `has the focus`.

:focus**MDN****:focus**

Support in all current engines.

Firefox 1+Safari 1.3+Chrome 1+

Opera 9.5+Edge 79+

Edge (Legacy) 12+Internet Explorer 9+

Firefox Android 4+Safari iOS 2+Chrome Android 18+WebView Android 2+Samsung Internet 1.0+Opera Android 10.1+

For the purposes of the CSS `:target` pseudo-class, the `:page`’s target elements are a list containing the `:page`’s `target element`, if it is not null, or containing no elements, if it is. [SELECTIONS]

:enabled**MDN****:enabled**

Support in all current engines.

Firefox 1+Safari 3.1+Chrome 1+

Opera 9+Edge 79+

Edge (Legacy) 12+Internet Explorer 9+

Firefox Android 4+Safari iOS 3.1+Chrome Android 18+WebView Android 2+Samsung Internet 1.0+Opera Android 10.1+

The `:enabled` pseudo-class must match any element that is `actually disabled`.

:disabled**MDN****:disabled**

Support in all current engines.

Firefox 1+Safari 3.1+Chrome 1+

Opera 9+Edge 79+

Edge (Legacy) 12+Internet Explorer 9+

Firefox Android 4+Safari iOS 3.1+Chrome Android 18+WebView Android 2+Samsung Internet 1.0+Opera Android 10.1+

The `:disabled` pseudo-class must match any element that is `actually disabled`.

:checked**MDN****:checked**

Support in all current engines.

Firefox 1+Safari 3.1+Chrome 1+

Opera 9+Edge 79+

Edge (Legacy) 12+Internet Explorer 9+

Firefox Android 4+Safari iOS 3.1+Chrome Android 18+WebView Android 2+Samsung Internet 1.0+Opera Android 10.1+

The `:checked` pseudo-class must match any element falling into one of the following categories:

- `input` elements whose `type` attribute is in the `Radio Button` state and whose `checkedness` state is true
- `option` elements whose `selectedness` is true

:
: **MDN**

indeterminate

Support in all current engines.

Firefox2+Safari3+Chrome1+

Opera9+Edge79+

Edge (Legacy)12+Internet Explorer10+

Firefox Android4+Safari iOS1+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android10.1+

The `:indeterminate` pseudo-class must match any element falling into one of the following categories:

- `input` elements whose `type` attribute is in the `Checkbox` state and whose `:indeterminate` IDL attribute is set to true
- `input` elements whose `type` attribute is in the `Radio Button` state and whose `radio button value` contains no `input` elements whose `checkedness` state is true.
- `progress` elements with no `value` content attribute

:
: **MDN**

default

Support in all current engines.

Firefox4+Safari5+Chrome10+

Opera10+Edge79+

Edge (Legacy)NoInternet ExplorerNo

Firefox Android4+Safari iOS5+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android10.1+

The `:default` pseudo-class must match any element falling into one of the following categories:

- `button` elements that are their form's `default button`
- `input` elements whose `type` attribute is in the `Submit Button` or `Image Button` state, and that are their form's `default button`
- `input` elements to which the `checkbox` attribute applies and that have a `checked` attribute
- `option` elements that have a `selected` attribute

:
: **placeholder-show**

The `:placeholder-show` pseudo-class must match any element falling into one of the following categories:

- `input` elements that have a `placeholder` attribute whose value is currently being presented to the user.
- `textarea` elements that have a `placeholder` attribute whose value is currently being presented to the user.

:
: **valid**

valid

Support in all current engines.

Firefox4+Safari5+Chrome10+

Opera10+Edge79+

Edge (Legacy)12+Internet Explorer10+

Firefox Android4+Safari iOS5+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android10.1+

The `:valid` pseudo-class must match any element falling into one of the following categories:

- elements that are `candidates for constraint validation` and that `satisfy their constraints`
- `form` elements that are not the `form owner` of any elements that themselves are `candidates for constraint validation` but do not `satisfy their constraints`
- `fieldset` elements that have no descendant elements that themselves are `candidates for constraint validation` but do not `satisfy their constraints`

:
: **invalid**

invalid

Support in all current engines.

Firefox4+Safari5+Chrome10+

Opera10+Edge79+

Edge (Legacy)12+Internet Explorer10+

Firefox Android4+Safari iOS5+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android10.1+

The `:invalid` pseudo-class must match any element falling into one of the following categories:

- elements that are `candidates for constraint validation` but that do not `satisfy their constraints`
- `form` elements that are the `form owner` of one or more elements that themselves are `candidates for constraint validation` but do not `satisfy their constraints`
- `fieldset` elements that have one or more descendant elements that themselves are `candidates for constraint validation` but do not `satisfy their constraints`

:
: **in-range**

in-range

Support in all current engines.

Firefox29+Safari5.1+Chrome10+

Opera11+Edge79+

Edge (Legacy)13+Internet ExplorerNo

Firefox Android6+Safari iOS5+Chrome Android18+WebView Android2.3+Samsung Internet1.0+Opera Android1.1+

The `:in-range` pseudo-class must match all elements that are `candidates for constraint validation`, `have range limitations`, and that are neither `suffering from an underflow` nor `suffering from an overflow`.

:
: **out-of-range**

out-of-range

Support in all current engines.

Firefox29+Safari5.1+Chrome10+

Opera11+Edge79+

Edge (Legacy)13+Internet ExplorerNo

Firefox Android16+Safari iOS5+Chrome Android18+WebView Android2.3+Samsung Internet1.0+Opera Android1.1+

The `:out-of-range` pseudo-class must match all elements that are `candidates for constraint validation`, `have range limitations`, and that are either `suffering from an underflow` or `suffering from an overflow`.

:
: **required**

required

Support in all current engines.

Firefox4+Safari5+Chrome10+

Opera10+Edge79+

Edge (Legacy)12+Internet Explorer10+

Firefox Android4+Safari iOS5+Chrome Android18+WebView Android4.4.3+Samsung Internet1.0+Opera Android10.1+

The `:required` pseudo-class must match any element falling into one of the following categories:

- `input` elements that are `required`
- `select` elements that have a `required` attribute
- `textarea` elements that have a `required` attribute

:
: **optional**

optional

Support in all current engines.

Firefox4+Safari5+Chrome10+

Opera10+Edge79+

Edge (Legacy)12+Internet Explorer10+

Firefox Android4+Safari iOS5+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android10.1+

The `:optional` pseudo-class must match any element falling into one of the following categories:

- `input` elements to which the `required` attribute applies that are not `required`
- `select` elements that do not have a `required` attribute
- `textarea` elements that do not have a `required` attribute

:
: **read-only**

read-only

Firefox1.5+Safari4+Chrome1+

Opera20+Edge79+

Edge (Legacy) No Internet Explorer No

Firefox, Android 49+ Safari iOS No Chrome Android No WebView Android No Samsung Internet No Opera Android No

The `:dir(rtl) pseudo-class` must match all elements whose `directionality` is "rtl".

:dir(rtl)

The `:dir(rtl) pseudo-class` must match all elements whose `directionality` is "rtl".

:dir(rtl)

Support: css-read-only-write Chrome for Android 81+ Chrome 36+ iOS Safari 9.0+ Safari 9+ Firefox 78+ Samsung Internet 4+ Edge 13+ UC Browser for Android 12.12+ IE None Opera 23+ Opera Mini None Firefox for Android NoneSource: [caniuse.com](#)

Note

This specification does not define when an element matches the `:lang()` dynamic `pseudo-class`, as it is defined in sufficient detail in a language-agnostic fashion in *Selectors*: [SELECTORS]

5 Microdata

5.1 Introduction

5.1.1 Overview

This section is non-normative.

Sometimes, it is desirable to annotate content with specific machine-readable labels, e.g. to allow generic scripts to provide services that are customized to the page, or to enable content from a variety of cooperating authors to be processed by a single script in a consistent manner.

For this purpose, authors can use the microdata features described in this section. Microdata allows nested groups of name-value pairs to be added to documents, in parallel with the existing content.

5.1.2 The basic syntax

*This section is non-normative.*At a high level, microdata consists of a group of name-value pairs. The groups are called `items`, and each name-value pair is a property. Items and properties are represented by regular elements.To create an item, the `itemscope` attribute is used.To add a property to an item, the `itemprop` attribute is used on one of the `item`'s descendants.

Example

Here there are two items, each of which has the property "name":

```
<div itemscope>
  <div> name is <span itemprop="name">Elizabeth</span>.</div>
<div itemscope>
  <div> name is <span itemprop="name">Daniel</span>.</div>
```

Markup without the microdata-related attributes does not have any effect on the microdata model.

Example

These two examples are exactly equivalent, at a microdata level, as the previous two examples respectively:

```
<div itemscope>
  <div> <em> name </em> is <span itemprop="name">&lt;strong>liz</strong>abeth</span>.</p>
</div>

<section>
  <div itemscope>
    <div> <p>My name is <span itemprop="name"><a href="/?user=daniel1">Daniel</a></span>.</p>
    </div>
  </div>
</section>
```

Properties generally have values that are strings.

Example

Here the item has three properties:

```
<div itemscope>
  <div> name is <span itemprop="name">David</span>.</p>
  <div> called <span itemprop="familyName">Four Parts Mater</span>.</p>
  <div> an <span itemprop="nationality">British</span>.</p>
</div>
```

When a string value is a [URL](#), it is expressed using the `a` element and its `href` attribute, the `img` element and its `src` attribute, or other elements that link to or embed external resources.

Example

In this example, the item has one property, "image", whose value is a URL:

```
<div itemscope>
  
</div>
```

When a string value is in some machine-readable format unsuitable for human consumption, it is expressed using the `value` attribute of the `data` element, with the human-readable version given in the element's contents.

Example

Here, there is an item with a property whose value is a product ID. The ID is not human-friendly, so the product's name is used the human-visible text instead of the ID.

```
<div itemscope>
  <data itemprop="product-id" value="967BA0U873">The Instigator 2000</data>
</div>
```

For numeric data, the `number` element and its `value` attribute can be used instead.

Example

Here a rating is given using a `meter` element.

```
<div itemscope="http://schema.org/Product">
  <span>Panasonic Fridge-601-white.jpg</span>
  
  <div>aggregateRating<span>http://schema.org/AggregateRating</span>
    <meter>3.5</meter>
    <span>Rated 3.5/5</span>
    <small>(Based on <span>reviewCount</span> reviews)</small>
  </div>
</div>
```

Similarly, for date- and time-related data, the `time` element and its `datetime` attribute can be used instead.

Example

In this example, the item has one property, "birthday", whose value is a date:

```
<div itemscope>
  <div> I was born on <time itemprop="birthday" datetime="2009-05-10">May 10th 2009</time>.
</div>
```

Properties can also themselves be groups of name-value pairs, by putting the `itemscope` attribute on the element that declares the property.Items that are not part of others are called [top-level microdata items](#).

Example

In this example, the outer item represents a person, and the inner one represents a band:

```
<div itemscope>
  <div> <span itemprop="name">Amanda</span>.
</div>
```

The outer item here has two properties, "name" and "band". The "name" is "Amanda", and the "band" is an item in its own right, with two properties, "name" and "size". The "name" of the band is "Jazz Band", and the "size" is "12".
The outer item in this example is a top-level microdata item.

Properties that are not descendants of the element with the `itemscope` attribute can be associated with the `item` using the `itemref` attribute. This attribute takes a list of IDs of elements to crawl in addition to crawling the children of the element with the `itemscope` attribute.

Example

This example is the same as the previous one, but all the properties are separated from their `items`:

```
<div itemscope id="amanda" itemref="a b c">
  <p><a href="#" itemprop="url" itemscope itemref="a"></p>
  <div id="b" itemprop="band" itemscope itemref="c"></div>
  <div id="c">
    <p><span itemprop="name">Jazz Band</span></p>
    <p><span itemprop="size">12</span> players</p>
  </div>
```

This gives the same result as the previous example. The first item has two properties, "name", set to "Amanda", and "band", set to another item. That second item has two further properties, "name", set to "Jazz Band", and "size", set to "12".

An `item` can have multiple properties with the same name and different values.

Example

This example describes an ice cream, with two flavors:

```
<div itemscope>
  <p>flavors in my favorite ice cream:</p>
  <ul>
    <li itemprop="flavor">Lemon sorbet</li>
    <li itemprop="flavor">Apricot sorbet</li>
  </ul>
</div>
```

This thus results in an item with two properties, both "flavor", having the values "Lemon sorbet" and "Apricot sorbet".

An element introducing a property can also introduce multiple properties at once, to avoid duplication when some of the properties have the same value.

Example

Here we see an item with two properties, "favorite-color" and "favorite-fruit", both set to the value "orange":

```
<div itemscope>
  <span itemprop="favorite-color favorite-fruit">orange</span>
</div>
```

It's important to note that there is no relationship between the microdata and the content of the document where the microdata is marked up.

Example

There is no semantic difference, for instance, between the following two examples:

```
<figure>
  <img alt="castle.jpg" itemscope itemtype="https://example.org/castle">
  <caption><span itemprop="name">The Castle</span> (1986)</caption>
</figure>

<span itemscope><meta itemprop="name" content="The Castle"></span>
<img alt="castle.jpg" itemscope itemtype="https://example.org/castle">
<caption>The Castle (1986)</caption>
</figure>
```

Both have a figure with a caption, and both, completely unrelated to the figure, have an item with a name-value pair with the name "name" and the value "The Castle". The only difference is that if the user drags the caption out of the document, in the former case, the item will be included in the drag-and-drop data. In neither case is the image in any way associated with the item.

5.1.3 Typed items

This section is non-normative.

The examples in the previous section show how information could be marked up on a page that doesn't expect its microdata to be re-used. Microdata is most useful, though, when it is used in contexts where other authors and readers are able to cooperate to make new uses of the markup.

For this purpose, it is necessary to give each `item` a type, such as "<https://example.com/person>", or "<https://example.org/cat>", or "<https://band.example.net>". Types are identified as URLs.

The type for a `item` is given as the value of an `itemtype` attribute on the same element as the `itemscope` attribute.

Example

Here, the item's type is "<https://example.org/animals#cat>":

```
<section itemscope itemtype="https://example.org/animals#cat">
  <ol itemprop="name"><li>Hedral</li>
    <li>A male american domestic shorthair, with a fluffy black fur with white paws and belly.</li>
  </ol>
  
</section>
```

In this example the "<https://example.org/animals#cat>" item has three properties, a "name" ("Hederal"), a "desc" ("Hederal is..."), and an "img" ("hederal.jpeg").

The type gives the context for the properties, thus selecting a vocabulary: a property named "class" given for an item with the type "<https://census.example/person>" might refer to the economic class of an individual, while a property named "class" given for an item with the type "<https://example.com/school/teacher>" might refer to the classroom a teacher has been assigned. Several types can share a vocabulary. For example, the types "<https://example.org/people/teacher>" and "<https://example.org/people/engineer>" could be defined to use the same vocabulary (though maybe some properties would not be especially useful in both cases, e.g. maybe the "<https://example.org/people/engineer>" type might not typically be used with the "classroom" property). Multiple types defined to use the same vocabulary can be given for a single item by listing the URLs as a space-separated list in the attribute's value. An item cannot be given two types if they do not use the same vocabulary, however.

5.1.4 Global identifiers for items

This section is non-normative.

Sometimes, an `item` gives information about a topic that has a global identifier. For example, books can be identified by their ISBN number.

Vocabularies (as identified by the `itemtype` attribute) can be designed such that `item`s get associated with their global identifier in an unambiguous way by expressing the global identifiers as URLs given in an `itemid` attribute.

The exact meaning of the URLs given in `itemid` attributes depends on the vocabulary used.

Example

Here, an item is talking about a particular book:

```
<ol itemscope itemtype="https://vocab.example.net/book">
  <li itemid="urn:isbn:0-333-34032-8">
    <dt>Title</dt>
    <dd itemprop="title">The Reality Dysfunction</dd>
    <dt>Author</dt>
    <dd itemprop="author">Peter F. Hamilton</dd>
    <dt>Publication date</dt>
    <dd itemprop="pubdate" datetimex="1996-01-26">26 January 1996</dd>
  </li>
</ol>
```

The "<https://vocab.example.net/book>" vocabulary in this example would define that the `itemid` attribute takes a [URI](#), pointing to the ISBN of the book.

5.1.5 Selecting names when defining vocabularies

This section is non-normative.

Using microdata means using a vocabulary. For some purposes, an ad-hoc vocabulary is adequate. For others, a vocabulary will need to be designed. Where possible, authors are encouraged to re-use existing vocabularies, as this makes content re-use easier.

When designing new vocabularies, identifiers can be created either using URLs, or, for properties, as plain words (with no dots or colons). For URLs, conflicts with other vocabularies can be avoided by only using identifiers that correspond to pages that the author has control over.

Example

For instance, if Jon and Adam both write content at <https://example.com/>, at <https://example.com/~jon/>... and <https://example.com/~adam/>..., respectively, then they could select identifiers of the form "<https://example.com/~jon/name>" and "<https://example.com/~adam/name>" respectively.

Properties whose names are just plain words can only be used within the context of the types for which they are intended; properties named using URLs can be reused in items of any type. If an item has no type, and is not part of another item, then if its properties have names that are just plain words, they are not intended to be globally unique, and are instead only intended for limited use. Generally speaking, authors are encouraged to use either properties with globally unique names (URLs) or ensure that their items are typed.

Example

Here, an item is an "<https://example.org/animals#cat>", and most of the properties have names that are words defined in the context of that type. There are also a few additional properties whose names come from other vocabularies.

```
<section itemscope itemtype="https://example.org/animals#cat">
  <ol itemprop="name"><li>Hederal</li>
    <li>A male american domestic shorthair, with a fluffy black fur with white paws and belly.</li>
  </ol>
  
  <span itemprop="color">black</span>
  <span itemprop="color">white</span>
  <span itemprop="desc">Hederal is a male american domestic shorthair, with a fluffy black fur with white paws and belly.</span>
</section>
```

This example has one item with the type "<https://example.org/animals#cat>" and the following properties:

Property	Value
name	Hederal
https://example.com/fn	Hederal
desc	Hederal is a male american domestic shorthair, with a fluffy black fur with white paws and belly.
https://example.com/color/black	
https://example.com/color/white	
img	https://example.com/color/black/hederal.jpeg

5.2 Encoding microdata

5.2.1 The microdata model

The microdata model consists of groups of name-value pairs known as `item`s.

Each group is known as an `item`. Each `item` can have `itemtypes`, a `global identifier` (if the vocabulary specified by the `item type` supports `global identifiers for items`), and a list of name-value pairs. Each name in the name-value pair is known as a `property`, and each `property` has one or more `values`. Each `value` is either a string or itself a group of name-value pairs (an `item`). The names are unordered relative to each other, but if a particular name has multiple values, they do have a relative order.

5.2.2 Items

MDN

Global identifiers for items

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

Every [HTML element](#) may have an `itemscope` attribute specified. The `itemscope` attribute is a [boolean attribute](#).

An element with the `itemscope` attribute specified creates a new [item](#), a group of name-value pairs.

[MDN](#)

[Global_attributes/itemtype](#)

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

Elements with an `itemscope` attribute may have an `itemtype` attribute specified, to give the [item type](#) of the [item](#).

The `itemtype` attribute, if specified, must have a value that is an [unordered set of unique space-separated tokens](#) that are [case-sensitive](#), each of which is a [valid URL string](#) that is an [absolute URL](#), and all of which are defined to use the same vocabulary. The attribute's value must have at least one token.

The [item types](#) of an [item](#) are the tokens obtained by [splitting the element's itemtype attribute's value on ASCII whitespace](#). If the `itemtype` attribute is missing or parsing it in this way finds no tokens, the [item](#) is said to have no [item types](#).

The [item types](#) must all be types defined in [applicable specifications](#) and must all be defined to use the same vocabulary.

Except if otherwise specified by that specification, the [URL](#) given as the `itemtype` should not be automatically dereferenced.

[Note](#)

A specification could define that its `itemtype` can be dereferenced to provide the user with help information, for example. In fact, vocabulary authors are encouraged to provide useful information at the given [URL](#).

[Item types](#) are opaque identifiers, and user agents must not dereference unknown `itemtypes`, or otherwise deconstruct them, in order to determine how to process [items](#) that use them.

The `itemtype` attribute must not be specified on elements that do not have an `itemscope` attribute specified.

An [item](#) is said to be a [typed item](#) when either it has an `itemtype`, or it is the [value](#) of a [property](#) of a [typed item](#). The [relevant types](#) for a [typed item](#) is the [item's item types](#), if it has any, or else is the [relevant types](#) of the [item](#) for which it is a [property's value](#).

[MDN](#)

[Global_attributes/itemid](#)

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

Elements with an `itemscope` attribute and an `itemid` attribute that references a vocabulary that is defined to support [global identifiers](#) for [items](#) may also have an `itemref` attribute specified, to give a global identifier for the [item](#), so that it can be related to other [items](#) on pages elsewhere on the Web.

The `itemid` attribute, if specified, must have a value that is a [valid URL potentially surrounded by spaces](#).

The [global identifier](#) of an [item](#) is the value of its element's `itemid` attribute, if it has one, [parsed](#) relative to the [node document](#) of the element on which the attribute is specified. If the `itemid` attribute is missing or if resolving it fails, it is said to have no [global identifier](#).

The `itemid` attribute must not be specified on elements that do not have both an `itemscope` attribute and an `itemtype` attribute specified, and must not be specified on elements with an `itemscope` attribute whose `itemtype` attribute specifies a vocabulary that does not [support global identifiers for items](#), as defined by that vocabulary's specification.

The exact meaning of a [global identifier](#) is determined by the vocabulary's specification. It is up to such specifications to define whether multiple items with the same global identifier (whether on the same page or on different pages) are allowed to exist, and what the processing rules for that vocabulary are with respect to handling the case of multiple items with the same ID.

[MDN](#)

[Global_attributes/itemref](#)

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

Elements with an `itemscope` attribute may have an `itemref` attribute specified, to give a list of additional elements to crawl to find the name-value pairs of the [item](#).

The `itemref` attribute, if specified, must have a value that is an [unordered set of unique space-separated tokens](#) that are [case-sensitive](#), consisting of [IDs](#) of elements in the same [page](#).

The `itemref` attribute must not be specified on elements that do not have an `itemscope` attribute specified.

[Note](#)

The `itemref` attribute is not part of the microdata data model. It is merely a syntactic construct to aid authors in adding annotations to pages where the data to be annotated does not follow a convenient tree structure. For example, it allows authors to mark up data in a table so that each column defines a separate [item](#), while keeping the properties in the cells.

[Example](#)

This example shows a simple vocabulary used to describe the products of a model railway manufacturer. The vocabulary has just five property names:

```
product-code
name
description
scale
digital
```

If present, one of "Digital", "Delta", or "Systems" (potentially with leading or trailing whitespace) indicating that the product has a digital decoder of the given type.

track-type

For track-specific products, one of "K", "M", "C" (potentially with leading or trailing whitespace) indicating the type of track for which the product is intended.

This vocabulary has four defined [item types](#):

```
https://md.example.com/loco
Locomotive stock with an engine
https://md.example.com/locomotives
Locomotive stock
https://md.example.com/track
Track pieces
https://md.example.com/lighting
Equipment with lighting
```

Each [item](#) that uses this vocabulary can be given one or more of these types, depending on what the product is.

Thus, a locomotive might be marked up as:

```
<dd itemscope itemtype="https://md.example.com/loco"
     https://md.example.com/lighting">
<dt>Name:
<dd itemscope="name">Tank Locomotive (DB 80)
<dt>Product code:
<dd itemscope="product-code">33041
<dt>Scale:
<dd itemscope="scale">HO
<dt>Digital:
<dd itemscope="digital">Delta
</dd>
```

A turnout lantern retrofit kit might be marked up as:

```
<dd itemscope itemtype="https://md.example.com/track
     https://md.example.com/lighting">
<dt>Name:
<dd itemscope="name">Turnout Lantern Kit
<dt>Product code:
<dd itemscope="product-code">74470
<dt>Purpose:
<dd>For retrofitting 2 <span itemscope="track-type">C</span> Track
turnouts. <meta itemscope="scale" content="HO">
</dd>
```

A passenger car with no lighting might be marked up as:

```
<dd itemscope itemtype="https://md.example.com/passengers"
     https://md.example.com/lighting">
<dt>Name:
<dd itemscope="name">Express Train Passenger Car (DB Am 203)
<dt>Product code:
<dd itemscope="product-code">9710
<dt>Scale:
<dd itemscope="scale">HO
</dd>
```

Great care is necessary when creating new vocabularies. Often, a hierarchical approach to types can be taken that results in a vocabulary where each item only ever has a single type, which is generally much simpler to manage.

5.2.3 Names: the `itemprop` attribute

[MDN](#)

[Global_attributes/itemprop](#)

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Firefox AndroidYes Safari iOSYes Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidYes

Every [HTML_element](#) may have an [itemprop](#) attribute specified, if doing so [adds one or more properties](#) to one or more [items](#) (as defined below).

The [itemprop](#) attribute, if specified, must have a value that is an [unordered set of unique space-separated tokens](#) that are [case-sensitive](#), representing the names of the name-value pairs that it adds. The attribute's value must have at least one token.

Each token must be either:

- If the item is a [typed item](#): a [defined property name](#) allowed in this situation according to the specification that defines the [relevant types](#) for the item, or
- A [valid URL string](#) that is an [absolute URL](#), defined as an item property name allowed in this situation by a vocabulary specification, or
- A [valid URL string](#) that is an [absolute URL](#), used as a proprietary item property name (i.e. one used by the author for private purposes, not defined in a public specification), or
- If the item is not a [typed item](#): a string that contains no U+002E FULL STOP characters (.) and no U+003A COLON characters (:), used as a proprietary item property name (i.e. one used by the author for private purposes, not defined in a public specification).

Specifications that introduce [defined property names](#) must ensure all such property names contain no U+002E FULL STOP characters (.), no U+003A COLON characters (:), and no [ASCII whitespace](#).

Note
The rules above disallow U+003A COLON characters (:) in non-URL values because otherwise they could not be distinguished from URLs. Values with U+002E FULL STOP characters (.) are reserved for future extensions. [ASCII whitespace](#) are disallowed because otherwise the values would be parsed as multiple tokens.

When an element with an [itemprop](#) attribute [adds a property](#) to multiple [items](#), the requirement above regarding the tokens applies for each [item](#) individually.

The [property names](#) of an element are the tokens that the element's [itemprop](#) attribute is found to contain when its value is [split on ASCII whitespace](#), with the order preserved but with duplicates removed (leaving only the first occurrence of each name).

Within an [item](#), the properties are unordered with respect to each other, except for properties with the same name, which are ordered in the order they are given by the algorithm that defines [the properties of an item](#).

Example

In the following example, the "a" property has the values "1" and "2", *in that order*, but whether the "a" property comes before the "b" property or not is not important:

```
<div itemscope>
  <p itemprop="a">1</p>
  <p itemprop="a">2</p>
  <p itemprop="a">text</p>
</div>
```

Thus, the following is equivalent:

```
<div itemscope>
  <p itemprop="a">text</p>
  <p itemprop="a">1</p>
  <p itemprop="a">2</p>
</div>
```

And the following:

```
<div id="x">
  <p itemprop="a">1</p>
</div>

<div itemscope itemref="x">
  <p itemprop="a">text</p>
  <p itemprop="a">1</p>
  <p itemprop="a">2</p>
</div>
```

5.2.4 Values

The [property value](#) of a name-value pair added by an element with an [itemprop](#) attribute is as given for the first matching case in the following list:

If the element also has an [itemscope](#) attribute

The value is the [item](#) created by the element.

If the element is a [meta](#) element

The value is the value of the element's [content](#) attribute, if any, or the empty string if there is no such attribute.

If the element is an [audio](#), [embed](#), [iframe](#), [img](#), [source](#), [track](#), or [video](#) element

The value is the [resulting URL string](#) that results from [parsing](#) the value of the element's [src](#) attribute relative to the [node document](#) of the element at the time the attribute is set, or the empty string if there is no such attribute or if [parsing](#) it results in an error.

If the element is an [a](#), [area](#), or [img](#) element

The value is the [resulting URL string](#) that results from [parsing](#) the value of the element's [href](#) attribute relative to the [node document](#) of the element at the time the attribute is set, or the empty string if there is no such attribute or if [parsing](#) it results in an error.

If the element is a [p](#), [text](#), or [img](#) element

The value is the [resulting URL string](#) that results from [parsing](#) the value of the element's [data](#) attribute relative to the [node document](#) of the element at the time the attribute is set, or the empty string if there is no such attribute or if [parsing](#) it results in an error.

If the element is a [area](#) element

The value is the value of the element's [value](#) attribute, if it has one, or the empty string otherwise.

If the element is a [meta](#) element

The value is the value of the element's [value](#) attribute, if it has one, or the empty string otherwise.

If the element is a [time](#) element

The value is the element's [datetime value](#).

Otherwise

The value is the element's [descendant text content](#).

The [URL property elements](#) are the [a](#), [area](#), [audio](#), [embed](#), [iframe](#), [img](#), [link](#), [object](#), [source](#), [track](#), and [video](#) elements.

If a property's [value](#), as defined by the property's definition, is an [absolute URL](#), the property must be specified using a [URL property element](#).

Note

These requirements do not apply just because a property value happens to match the syntax for a URL. They only apply if the property is explicitly defined as taking such a value.

Example

For example, a book about the first moon landing could be called "mission:moon". A "title" property from a vocabulary that defines a title as being a string would not expect the title to be given in an [a](#) element, even though it looks like a [URL](#). On the other hand, if there was a (rather narrowly scoped!) vocabulary for "books whose titles look like URLs" which had a "title" property defined to take a URL, then the property would expect the title to be given in an [a](#) element (or one of the other [URL property elements](#)), because of the requirement above.

5.2.5 Associating names with items

To find the [properties of an item](#) defined by the element [root](#), the user agent must run the following steps. These steps are also used to flag [microdata errors](#).

1. Let [results](#), [memory](#), and [pending](#) be empty lists of elements.
2. Add the element [root](#) to [memory](#).
3. Add the child elements of [root](#), if any, to [pending](#).
4. If [root](#) has an [itemref](#) attribute, [split the value of that itemref attribute on ASCII whitespace](#). For each resulting token [ID](#), if there is an element in the [tree](#) of [root](#) with the [ID](#) [ID](#), then add the first such element to [pending](#).
5. While [pending](#) is not empty:
 1. Remove an element from [pending](#) and let [current](#) be that element.
 2. If [current](#) is already in [memory](#), there is a [microdata error](#); continue.
 3. Add [current](#) to [memory](#).
 4. If [current](#) does not have an [itemscope](#) attribute, then: add all the child elements of [current](#) to [pending](#).
 5. If [current](#) has an [itemprop](#) attribute specified and has one or more [property names](#), then add [current](#) to [results](#).
6. Sort [results](#) in [tree order](#).
7. Return [results](#).

A document must not contain any [items](#) for which the algorithm to find the [properties of an item](#) finds any [microdata errors](#).

An [item](#) is a [top-level microdata item](#) if its element does not have an [itemprop](#) attribute.

All [itemref](#) attributes in a [document](#) must be such that there are no cycles in the graph formed from representing each [item](#) in the [document](#) as a node in the graph and each [property](#) of an item whose [value](#) is another item as an edge in the graph connecting those two items.

A document must not contain any elements that have an [itemprop](#) attribute that would not be found to be a property of any of the [items](#) in that document were their [properties](#) all to be determined.

Example

In this example, a single license statement is applied to two works, using [itemref](#) from the items representing the works:

```
<!DOCTYPE HTML>
<html lang="en">
  <head>
    <title>Photo gallery</title>
  </head>
  <body>
    <h1>My photos</h1>
    <img itemref="work" itemprop="http://n.whatwg.org/work" itemtype="licensee">
    <img itemref="work" alt="A white house, boarded up, sits in a forest.">
    <img itemprop="work" alt="A white house, boarded up, sits in a forest.">
    <img itemref="work" alt="The house I found.">
    <img itemref="work" alt="Outside the house is a mailbox. It has a leaflet inside.">
    <img itemprop="work" alt="The mailbox.">
  </body>
</html>
```

The above results in two items with the type "http://n.whatwg.org/work", one with:

```
work  images/house.jpeg
title  The house I found.
```

...and one with:
work
 images/mailbox.jpeg
title
 The mailbox.
license
 <http://www.opensource.org/licenses/mit-license.php>

5.2.6 Microdata and other namespaces

Currently, the `itemscope`, `itemprop`, and other microdata attributes are only defined for `HTML elements`. This means that attributes with the literal names "`itemscope`", "`itemprop`", etc, do not cause microdata processing to occur on elements in other namespaces, such as SVG.

Example

Thus, in the following example there is only one item, not two.

```
<p itemscope>/p <!-- this is an item (with no properties and no type) -->
<svg itemscope></svg> <!-- this is not, it's just an SVG element with an invalid unknown attribute -->
```

5.3 Sample microdata vocabularies

The vocabularies in this section are primarily intended to demonstrate how a vocabulary is specified, though they are also usable in their own right.

5.3.1 vCard

An item with the `item-type` <http://microformats.org/profile/hcard> represents a person's or organization's contact information.

This vocabulary does not support global identifiers for items.

The following are the type's [defined property names](#). They are based on the vocabulary defined in *vCard Format Specification (vCard)* and its extensions, where more information on how to interpret the values can be found. [RFC6350]

kind

Describes what kind of contact the item represents.

The `value` must be text that, when compared in a [case-sensitive](#) manner, is equal to one of the [kind strings](#).

A single property with the name `kind` may be present within each `item` with the type <http://microformats.org/profile/hcard>.

fn

Gives the formatted text corresponding to the name of the person or organization.

The `value` must be text.

Exactly one property with the name `fn` must be present within each `item` with the type <http://microformats.org/profile/hcard>.

n

Gives the structured name of the person or organization.

The `value` must be an `item` with zero or more of each of the `family-name`, `given-name`, `additional-name`, `honorific-prefix`, and `honorific-suffix` properties.

Exactly one property with the name `n` must be present within each `item` with the type <http://microformats.org/profile/hcard>.

family-name (inside `n`)

Gives the family name of the person, or the full name of the organization.

The `value` must be text.

Any number of properties with the name `family-name` may be present within the `item` that forms the `value` of the `n` property of an `item` with the type <http://microformats.org/profile/hcard>.

given-name (inside `n`)

Gives the given-name of the person.

The `value` must be text.

Any number of properties with the name `given-name` may be present within the `item` that forms the `value` of the `n` property of an `item` with the type <http://microformats.org/profile/hcard>.

additional-name (inside `n`)

Gives the any additional names of the person.

The `value` must be text.

Any number of properties with the name `additional-name` may be present within the `item` that forms the `value` of the `n` property of an `item` with the type <http://microformats.org/profile/hcard>.

honorific-prefix (inside `n`)

Gives the honorific prefix of the person.

The `value` must be text.

Any number of properties with the name `honorific-prefix` may be present within the `item` that forms the `value` of the `n` property of an `item` with the type <http://microformats.org/profile/hcard>.

honorific-suffix (inside `n`)

Gives the honorific suffix of the person.

The `value` must be text.

Any number of properties with the name `honorific-suffix` may be present within the `item` that forms the `value` of the `n` property of an `item` with the type <http://microformats.org/profile/hcard>.

nickname

Gives the nickname of the person or organization.

Note
The nickname is the descriptive name given instead of or in addition to the one belonging to a person, place, or thing. It can also be used to specify a familiar form of a proper name specified by the `ra` or `ra` properties.

The `value` must be text.

Any number of properties with the name `nickname` may be present within each `item` with the type <http://microformats.org/profile/hcard>.

photo

Gives a photograph of the person or organization.

The `value` must be an [absolute URL](#).

Any number of properties with the name `photo` may be present within each `item` with the type <http://microformats.org/profile/hcard>.

bday

Gives the birth date of the person or organization.

The `value` must be a [valid date string](#).

A single property with the name `bday` may be present within each `item` with the type <http://microformats.org/profile/hcard>.

anniversary

Gives the birth date of the person or organization.

The `value` must be a [valid date string](#).

A single property with the name `anniversary` may be present within each `item` with the type <http://microformats.org/profile/hcard>.

ssex

Gives the biological sex of the person.

The `value` must be one of `f`, meaning "female", `m`, meaning "male", `n`, meaning "none or not applicable", `o`, meaning "other", or `u`, meaning "unknown".

A single property with the name `ssex` may be present within each `item` with the type <http://microformats.org/profile/hcard>.

gender-identity

Gives the gender identity of the person.

The `value` must be text.

A single property with the name `gender-identity` may be present within each `item` with the type <http://microformats.org/profile/hcard>.

addr

Gives the delivery address of the person or organization.

The `value` must be an `item` with zero or more `type-post-office-box`, `extended-address`, and `street-address` properties, and optionally a `locality` property, optionally a `region` property, optionally a `postal-code` property, and optionally a `country-name` property.

If no `type` properties are present within an `item` that forms the `value` of an `addr` property of an `item` with the type <http://microformats.org/profile/hcard>, then the `address-type string work` is implied.

Any number of properties with the name `addr` may be present within each `item` with the type <http://microformats.org/profile/hcard>.

type (inside `addr`)

Gives the type of delivery address.

The `value` must be text that, when compared in a [case-sensitive](#) manner, is equal to one of the [address-type strings](#).

Any number of properties with the name `type` may be present within the `item` that forms the `value` of an `addr` property of an `item` with the type <http://microformats.org/profile/hcard>, but within each such `addr` property `item` there must only be one `type` property per distinct value.

post-office-box (inside `addr`)

Gives the post office box component of the delivery address of the person or organization.

The `value` must be text.

Any number of properties with the name `post-office-box` may be present within the `item` that forms the `value` of an `addr` property of an `item` with the type <http://microformats.org/profile/hcard>.

note

Gives a note about the item.

extended-address (inside adr)

Gives an additional component of the delivery address of the person or organization.

The value must be text.

Any number of properties with the name extended-address may be present within the item that forms the value of an adr property of an item with the type <http://microformats.org/profile/hcard>.

Note
[Card] urges authors not to use this field.

street-address (inside adr)

Gives the street address component of the delivery address of the person or organization.

The value must be text.

Any number of properties with the name street-address may be present within the item that forms the value of an adr property of an item with the type <http://microformats.org/profile/hcard>.

locality (inside adr)

Gives the locality component (e.g. city) of the delivery address of the person or organization.

The value must be text.

A single property with the name locality may be present within the item that forms the value of an adr property of an item with the type <http://microformats.org/profile/hcard>.

region (inside adr)

Gives the region component (e.g. state or province) of the delivery address of the person or organization.

The value must be text.

A single property with the name region may be present within the item that forms the value of an adr property of an item with the type <http://microformats.org/profile/hcard>.

postal-code (inside adr)

Gives the postal code component of the delivery address of the person or organization.

The value must be text.

A single property with the name postal-code may be present within the item that forms the value of an adr property of an item with the type <http://microformats.org/profile/hcard>.

country-name (inside adr)

Gives the country name component of the delivery address of the person or organization.

The value must be text.

A single property with the name country-name may be present within the item that forms the value of an adr property of an item with the type <http://microformats.org/profile/hcard>.

tel

Gives the telephone number of the person or organization.

The value must be either text that can be interpreted as a telephone number as defined in the CCITT specifications E.163 and X.121, or an item with zero or more type properties and exactly one value property. [E163] [X121]

If no type properties are present within an item that forms the value of a tel property of an item with the type <http://microformats.org/profile/hcard>, or if the value of such a tel property is text, then the telephone type string voice is implied.

Any number of properties with the name tel may be present within each item with the type <http://microformats.org/profile/hcard>.

type (inside tel)

Gives the type of telephone number.

The value must be text, when compared in a case-sensitive manner, is equal to one of the telephone type strings.

Any number of properties with the name type may be present within the item that forms the value of a tel property of an item with the type <http://microformats.org/profile/hcard>, but within each such tel property item there must only be one type property per distinct value.

value (inside tel)

Gives the actual telephone number of the person or organization.

The value must be text that can be interpreted as a telephone number as defined in the CCITT specifications E.163 and X.121. [E163] [X121]

Exactly one property with the name value must be present within the item that forms the value of a tel property of an item with the type <http://microformats.org/profile/hcard>.

email

Gives the e-mail address of the person or organization.

The value must be text.

Any number of properties with the name email may be present within each item with the type <http://microformats.org/profile/hcard>.

link

Gives a URI for instant messaging and presence protocol communications with the person or organization.

The value must be an absolute URL.

Any number of properties with the name link may be present within each item with the type <http://microformats.org/profile/hcard>.

lang

Gives a language understood by the person or organization.

The value must be a valid BCP 47 language tag. [BCP47].

Any number of properties with the name lang may be present within each item with the type <http://microformats.org/profile/hcard>.

tz

Gives the time zone of the person or organization.

The value must be text and must match the following syntax:

1. Either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. One or more ASCII digits.
3. Optionally*, a U+002E FULL STOP character (.) followed by one or more ASCII digits.
4. A U+003A COLON character (:).
5. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
6. One or more ASCII digits.
7. Optionally*, a U+002E FULL STOP character (.) followed by one or more ASCII digits.

The optional components marked with an asterisk (*) should be included, and should have six digits each.

Note
The value specifies latitude and longitude, in that order (i.e., "LAT LON" ordering), in decimal degrees. The longitude represents the location east and west of the prime meridian as a positive or negative real number, respectively. The latitude represents the location north and south of the equator as a positive or negative real number, respectively.

Any number of properties with the name tz may be present within each item with the type <http://microformats.org/profile/hcard>.

geo

Gives the geographical position of the person or organization.

The value must be text and must match the following syntax:

1. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. One or more ASCII digits.
3. Optionally*, a U+002E FULL STOP character (.) followed by one or more ASCII digits.
4. A U+003A COLON character (:).
5. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
6. One or more ASCII digits.
7. Optionally*, a U+002E FULL STOP character (.) followed by one or more ASCII digits.

The optional components marked with an asterisk (*) should be included, and should have six digits each.

Note
The value specifies latitude and longitude, in that order (i.e., "LAT LON" ordering), in decimal degrees. The longitude represents the location east and west of the prime meridian as a positive or negative real number, respectively. The latitude represents the location north and south of the equator as a positive or negative real number, respectively.

Any number of properties with the name geo may be present within each item with the type <http://microformats.org/profile/hcard>.

title

Gives the job title, functional position or function of the person or organization.

The value must be text.

Any number of properties with the name title may be present within each item with the type <http://microformats.org/profile/hcard>.

role

Gives the role, occupation, or business category of the person or organization.

The value must be text.

Any number of properties with the name role may be present within each item with the type <http://microformats.org/profile/hcard>.

logo

Gives the logo of the person or organization.

The value must be an absolute URL.

Any number of properties with the name logo may be present within each item with the type <http://microformats.org/profile/hcard>.

agent

Gives the contact information of another person who will act on behalf of the person or organization.

The value must be either an item with the type <http://microformats.org/profile/hcard> or an absolute URL, or text.

Any number of properties with the name agent may be present within each item with the type <http://microformats.org/profile/hcard>.

org

Gives the name and units of the organization.

The value must be either text or an item with one organization-name property and zero or more organization-unit properties.

Any number of properties with the name org may be present within each item with the type <http://microformats.org/profile/hcard>.

organization-name (inside org)

The [value](#) must be text.

Exactly one property with the name [organization-name](#) must be present within the [item](#) that forms the [value](#) of an [org](#) property of an [item](#) with the type <http://microformats.org/profile/hcard>.

[organization-unit](#) (inside [org](#))

Gives the name of the organization unit.

The [value](#) must be text.

Any number of properties with the name [organization-unit](#) may be present within the [item](#) that forms the [value](#) of the [org](#) property of an [item](#) with the type <http://microformats.org/profile/hcard>.

[member](#)

Gives a [URL](#), that represents a member of the group.

The [value](#) must be an [absolute URL](#).

Any number of properties with the name [member](#) may be present within each [item](#) with the type <http://microformats.org/profile/hcard> if the [item](#) also has a property with the name [kind](#) whose value is "[group](#)".

[related](#)

Gives a relationship to another entity.

The [value](#) must be an [item](#) with one [rel](#) property and one [rel](#) properties.

Any number of properties with the name [related](#) may be present within each [item](#) with the type <http://microformats.org/profile/hcard>.

[uri](#) (inside [related](#))

Gives the [URI](#), for the related entity.

The [value](#) must be an [absolute URL](#).

Exactly one property with the name [uri](#) must be present within the [item](#) that forms the [value](#) of a [related](#) property of an [item](#) with the type <http://microformats.org/profile/hcard>.

[rel](#) (inside [related](#))

Gives the relationship between the entity and the related entity.

The [value](#) must be text, when compared in a [case-sensitive](#) manner, is equal to one of the [relationship strings](#).

Exactly one property with the name [rel](#) must be present within the [item](#) that forms the [value](#) of a [related](#) property of an [item](#) with the type <http://microformats.org/profile/hcard>.

[categories](#)

Gives the name of a category or tag that the person or organization could be classified as.

The [value](#) must be text.

Any number of properties with the name [categories](#) may be present within each [item](#) with the type <http://microformats.org/profile/hcard>.

[note](#)

Gives supplemental information or a comment about the person or organization.

The [value](#) must be text.

Any number of properties with the name [note](#) may be present within each [item](#) with the type <http://microformats.org/profile/hcard>.

[rev](#)

Gives the revision date and time of the contact information.

The [value](#) must be text that is a [valid global date and time string](#).

Note

The value distinguishes the current revision of the information for other renditions of the information.

Any number of properties with the name [rev](#) may be present within each [item](#) with the type <http://microformats.org/profile/hcard>.

[sound](#)

Gives a sound file relating to the person or organization.

The [value](#) must be an [absolute URL](#).

Any number of properties with the name [sound](#) may be present within each [item](#) with the type <http://microformats.org/profile/hcard>.

[uid](#)

Gives a globally unique identifier corresponding to the person or organization.

The [value](#) must be text.

A single property with the name [uid](#) may be present within each [item](#) with the type <http://microformats.org/profile/hcard>.

[url](#)

Gives a [URL](#), relating to the person or organization.

The [value](#) must be an [absolute URL](#).

Any number of properties with the name [url](#) may be present within each [item](#) with the type <http://microformats.org/profile/hcard>.

The [kind](#) strings are:

[individual](#)

Indicates a single entity (e.g. a person).

[group](#)

Indicates multiple entities (e.g. a mailing list).

[org](#)

Indicates a single entity that is not a person (e.g. a company).

[location](#)

Indicates a geographical place (e.g. an office building).

The [address type](#) strings are:

[home](#)

Indicates a delivery address for a residence.

[work](#)

Indicates a delivery address for a place of work.

The [telephone type](#) strings are:

[home](#)

Indicates a residential number.

[work](#)

Indicates a telephone number for a place of work.

[text](#)

Indicates that the telephone number supports text messages (SMS).

[vcard](#)

Indicates a voice telephone number.

[fax](#)

Indicates a facsimile telephone number.

[cell](#)

Indicates a cellular telephone number.

[video](#)

Indicates a video conferencing telephone number.

[pager](#)

Indicates a paging device telephone number.

[telephone](#)

Indicates a telecommunication device for people with hearing or speech difficulties.

The [relationship](#) strings are:

[emergency](#)

An emergency contact.

[agent](#)

Another entity that acts on behalf of this entity.

[contact](#)

[acquaintance](#)

[friend](#)

[met](#)

[worker](#)

[colleague](#)

```

neighbor
child
parent
 sibling
spouse
kin
munge
crush
date
sweetheart
me

```

Has the meaning defined in XFN: [\[XFN\]](#)

5.3.1.1 Conversion to Card

Given a list of nodes *nodes* in a *Document*, a user agent must run the following algorithm to extract any vCard data represented by those nodes (only the first vCard is returned):

1. If none of the nodes in *nodes* are *items* with the *item type* <http://microformats.org/profile/hcard>, then there is no vCard. Abort the algorithm, returning nothing.
2. Let *node* be the first node in *nodes* that is an *item* with the *item type* <http://microformats.org/profile/hcard>.
3. Let *output* be an empty string.
4. **Add a vCard line** with the type "BEGIN" and the value "VCARD" to *output*.
5. **Add a vCard line** with the type "PROFILE" and the value "VCARD" to *output*.
6. **Add a vCard line** with the type "VERSION" and the value "4.0" to *output*.
7. **Add a vCard line** with the type "SOURCE" and the result of *escaping the vCard text string* that is the document's *URL* as the value to *output*.
8. If the *title* element is not null, **Add a vCard line** with the type "NAME" and with the result of *escaping the vCard text string* obtained from the *the title element's descendant text content* as the value to *output*.
9. Let *sex* be the empty string.
10. Let *gender-identity* be the empty string.

11. For each element *element* that is *a property of the item node*: for each name *name* in *element's property names*, run the following substeps:

1. Let *parameters* be an empty set of name-value pairs.

2. Run the appropriate set of substeps from the following list. The steps will set a variable *value*, which is used in the next step.

If the property's *value* is an *item subitem* and *name* is *name*:

1. Let *value* be the empty string.
2. Append to *value* the result of *collecting the first vCard subproperty* named *family-name* in *subitem*.
3. Append a U+003B SEMICOLON character (;) to *value*.
4. Append to *value* the result of *collecting the first vCard subproperty* named *given-name* in *subitem*.
5. Append a U+003B SEMICOLON character (;) to *value*.
6. Append to *value* the result of *collecting the first vCard subproperty* named *additional-name* in *subitem*.
7. Append a U+003B SEMICOLON character (;) to *value*.
8. Append to *value* the result of *collecting the first vCard subproperty* named *honorable-prefix* in *subitem*.
9. Append a U+003B SEMICOLON character (;) to *value*.
10. Append to *value* the result of *collecting the first vCard subproperty* named *honorable-suffix* in *subitem*.

If the property's *value* is an *item subitem* and *name* is *adr*:

1. Let *value* be the empty string.
2. Append to *value* the result of *collecting vCard subproperties* named *post-office-box* in *subitem*.
3. Append a U+003B SEMICOLON character (;) to *value*.
4. Append to *value* the result of *collecting vCard subproperties* named *extended-address* in *subitem*.
5. Append a U+003B SEMICOLON character (;) to *value*.
6. Append to *value* the result of *collecting vCard subproperties* named *street-address* in *subitem*.
7. Append a U+003B SEMICOLON character (;) to *value*.
8. Append to *value* the result of *collecting the first vCard subproperty* named *locality* in *subitem*.
9. Append a U+003B SEMICOLON character (;) to *value*.
10. Append to *value* the result of *collecting the first vCard subproperty* named *region* in *subitem*.
11. Append a U+003B SEMICOLON character (;) to *value*.
12. Append to *value* the result of *collecting the first vCard subproperty* named *postal-code* in *subitem*.
13. Append a U+003B SEMICOLON character (;) to *value*.
14. Append to *value* the result of *collecting the first vCard subproperty* named *country-name* in *subitem*.
15. If there is a property named *type* in *subitem*, and the first such property has a *value* that is not an *item* and whose value consists only of ASCII alphanumeric, then add a parameter named "TYPE" whose value is the *value* of that property to *parameters*.

If the property's *value* is an *item subitem* and *name* is *org*:

1. Let *value* be the empty string.
2. Append to *value* the result of *collecting the first vCard subproperty* named *organization-name* in *subitem*.
3. For each property named *organization-unit* in *subitem*, run the following steps:
 1. If the *value* of the property is an *item*, then skip this property.
 2. Append a U+003B SEMICOLON character (;) to *value*.
3. Append the result of *escaping the vCard text string* given by the *value* of the property to *value*.

If the property's *value* is an *item subitem* with the *item type* <http://microformats.org/profile/hcard> and *name* is *related*:

1. Let *value* be the empty string.
2. If there is a property named *url* in *subitem*, and its element is a *URL property element*, then append the result of *escaping the vCard text string* given by the *value* of the first such property to *value*, and add a parameter with the name "VALUE" and the value "URI" to *parameters*.
3. If there is a property named *rel* in *subitem*, and the first such property has a *value* that is not an *item* and whose value consists only of ASCII alphanumeric, then add a parameter named "RELATION" whose value is the *value* of that property to *parameters*.

If the property's *value* is an *item* and *name* is none of the above:

1. Let *value* be the result of *collecting the first vCard subproperty* named *value* in *subitem*.
2. If there is a property named *type* in *subitem*, and the first such property has a *value* that is not an *item* and whose value consists only of ASCII alphanumeric, then add a parameter named "TYPE" whose value is the *value* of that property to *parameters*.

If the property's *value* is not an *item* and its *name* is *url*:

If this is the first such property to be found, set the property's *value*.

If the property's *value* is not an *item* and its *name* is *gender-identity*:

If this is the first such property to be found, set *gender-identity* to the property's *value*.

Otherwise (the property's *value* is not an *item*)

1. Let *value* be the property's *value*.
2. If *element* is one of the *URL property elements*, add a parameter with the name "VALUE" and the value "URI" to *parameters*.
3. Otherwise, if *name* is *bday* or *anniversary* and the *value* is a *valid date string*, add a parameter with the name "VALUE" and the value "DATE" to *parameters*.
4. Otherwise, if *name* is *url* and the *value* is a *valid global date and time string*, add a parameter with the name "VALUE" and the value "DATE-TIME" to *parameters*.
5. Prefix every U+005C REVERSE SOLIDUS character (\\) in *value* with another U+005C REVERSE SOLIDUS character (\\).
6. Prefix every U+002C COMMA character (,) in *value* with a U+005C REVERSE SOLIDUS character (\\).
7. Unless *name* is *geo*, prefix every U+003B SEMICOLON character (;) in *value* with a U+005C REVERSE SOLIDUS character (\\).
8. Replace every U+000D CARRIAGE RETURN (0x0A) LINE FEED character pair (CRLF) in *value* with a U+005C REVERSE SOLIDUS character (\\) followed by a U+006E LATIN SMALL LETTER N character (n).
9. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in *value* with a U+005C REVERSE SOLIDUS character (\\) followed by a U+006E LATIN SMALL LETTER N character (n).

3. **Add a vCard line** with the type *type*, the parameters *parameters*, and the value *value* to *output*.

12. If either *sex* or *gender-identity* has a value that is not the empty string, **Add a vCard line** with the type "GENDER" and the value consisting of the concatenation of *sex*, a U+003B SEMICOLON character (,), and *gender-identity* to *output*.

13. **Add a vCard line** with the type "END" and the value "VCARD" to *output*.

When the above algorithm says that the user agent is to *add a vCard line* consisting of a type *type*, optionally some parameters, and a value *value* to a string *output*, it must run the following steps:

1. Let *line* be an empty string.
2. Append *type*, *converted to ASCII uppercase*, to *line*.
3. If there are any parameters, then for each parameter, in the order that they were added, run these substeps:
 1. Append a U+003B SEMICOLON character (;) to *line*.
 2. Append the parameter's name to *line*.
 3. Append a U+003D EQUALS SIGN character (=) to *line*.
 4. Append the parameter's value to *line*.

5. Append *value* to *line*.
6. Let *maximum length* be 75.
7. While *line*'s *length* is greater than *maximum length*:
 1. Append the first *maximum length* code points of *line* to *output*.
 2. Remove the first *maximum length* code points from *line*.
 3. Append a U+000D CARRIAGE RETURN character (CR) to *output*.
 4. Append a U+000A LINE FEED character (LF) to *output*.
 5. Append a U+0020 SPACE character to *output*.
 6. Let *maximum length* be 74.
 8. Append (what remains of) *line* to *output*.
 9. Append a U+000D CARRIAGE RETURN character (CR) to *output*.
 10. Append a U+000A LINE FEED character (LF) to *output*.

When the steps above require the user agent to obtain the result of collecting *vCard subproperties* named *subname* in *subitem*, the user agent must run the following steps:

1. Let *value* be the empty string.
2. For each property named *subname* in the item *subitem*, run the following substeps:
 1. If the *value* of the property is itself an *item*, then skip this property.
 2. If this is not the first property named *subname* in *subitem* (ignoring any that were skipped by the previous step), then append a U+002C COMMA character (,) to *value*.
 3. Append the result of escaping the vCard text string given by the *value* of the property to *value*.
3. Return *value*.

When the steps above require the user agent to obtain the result of collecting the first vCard subproperty named *subname* in *subitem*, the user agent must run the following steps:

1. If there are no properties named *subname* in *subitem*, then return the empty string.
 2. If the *value* of the first property named *subname* in *subitem* is an *item*, then return the empty string.
 3. Return the result of escaping the vCard text string given by the *value* of the first property named *subname* in *subitem*.
- When the above algorithms say the user agent is to escape the vCard text string value, the user agent must use the following steps:
1. Prefix every U+005C REVERSE SOLIDUS character () in *value* with another U+005C REVERSE SOLIDUS character ()�.
 2. Prefix every U+002C COMMA character (,) in *value* with a U+005C REVERSE SOLIDUS character ()�.
 3. Prefix every U+003B SEMICOLON character (;) in *value* with a U+005C REVERSE SOLIDUS character ()�.
 4. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in *value* with a U+005C REVERSE SOLIDUS character () followed by a U+006E LATIN SMALL LETTER N character (n).
 5. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in *value* with a U+005C REVERSE SOLIDUS character () followed by a U+006E LATIN SMALL LETTER N character (n).
 6. Return the mutated *value*.

Note

This algorithm can generate invalid vCard output, if the input does not conform to the rules described for the http://microformats.org/profile/hcard#item_type and [defined property names](#).

5.3.1.2 Examples

This section is non-normative.

Example

Here is a long example vCard for a fictional character called "Jack Bauer":

```
<section id="jack" itemscope itemtype="http://microformats.org/profile/hcard">
<ol itemprop="fn">
<li><span itemscope="" itemtype="vcard">
<span itemscope="given-name">Jack</span>
<span itemscope="family-name">Bauer</span>
</li>
</ol>

<ol itemscope="org" itemscope="" itemtype="vcard">
<li><span itemscope="organization-name">Counter-Terrorist Unit</span>
<span itemscope="organization-unit">Los Angeles Division</span>
</li>
</ol>
<ol itemscope="adr" itemscope="" itemtype="vcard">
<li><span itemscope="street-address">10201 W. Pico Blvd.</span><br>
<span itemscope="locality">Los Angeles</span>
<span itemscope="postal-code">90064</span><br>
<span itemscope="country-name">United States</span><br>
</li>
<li><span itemscope="geo" value="34.052339,-118.410623"></span>
</li>
</ol>
<ol itemscope="tel" itemscope="" itemtype="vcard">
<li><span itemscope="value" value="1 (310) 597 3781"></span> <span itemscope="type">work</span>
<meta itemscope="type" content="voice">
<meta itemscope="type" content="text">
<li><a href="https://en.wikipedia.org/wiki/Jack_Bauer">I'm on Wikipedia</a>
<li><span itemscope="type" value="mailto:j.bauer@la.ctu.gov.invalid">j.bauer@la.ctu.gov.invalid</span>
<li><a href="tel:(310) 555 3781" itemscope="type" value="tel">(310) 555 3781</a> <span itemscope="type" content="cell">mobile phone</span>
</li>
</ol>
<ins datetime="2010-01-20T21:00:00+01:00">
<span itemscope="type" value="2009-01-20T21:00:00+01:00">
<span itemscope="tel" itemscope="" itemtype="vcard"><strong>Date:</strong></span>
<span itemscope="type" value="tel:(310) 555 3781" itemscope="type" content="tel">(310) 555 3781</span>
<span itemscope="type" value="tel:(310) 555 3781" itemscope="type" content="text">(310) 555 3781</span>
</span>
</ins>
</section>
```

The odd line wrapping is needed because newlines are meaningful in microdata: newlines would be preserved in a conversion to, for example, the vCard format.

Example

This example shows a site's contact details (using the `address` element) containing an address with two street components:

```
<address itemscope="" itemtype="http://microformats.org/profile/hcard">
<strong itemscope="fn" itemtype="vcard"><span itemscope="given-name">Alfred</span>
<span itemscope="family-name">Fischer</span></strong> <br>
<span itemscope="adr" itemscope="" itemtype="vcard">
<span itemscope="street-address">1600 Amphitheatre Parkway</span> <br>
<span itemscope="street-address">Building 43, Second Floor</span> <br>
<span itemscope="locality">Mountain View</span>
<span itemscope="region">>CA</span> <span itemscope="postal-code">94043</span>
</span>
</address>
```

Example

The vCard vocabulary can be used to just mark up people's names:

```
<span itemscope itemtype="http://microformats.org/profile/hcard">
<strong itemscope="fn" itemtype="vcard"><span itemscope="given-name">George Washington</span>
<span itemscope="family-name">Washington</span></strong>
<span itemscope="type" value="George Washington" itemscope="vcard"></span>
</span>
```

This creates a single item with a two name-value pairs, one with the name "fn" and the value "George Washington", and the other with the name "n" and a second item as its value, the second item having the two name-value pairs "given-name" and "family-name" with the values "George" and "Washington" respectively. This is defined to map to the following vCard:

```
BEGIN:VCARD
PROFILE:VCARD
VERSION:4.0
SOUND:User's address
FN:George Washington
N:Washington;George;;
END:VCARD
```

5.3.2 vEvent

An item with the `item_type` <http://microformats.org/profile/hecalendar#event> represents an event.

This vocabulary does not support global identifiers for items.

The following are the type's [defined property names](#). They are based on the vocabulary defined in *Internet Calendaring and Scheduling Core Object Specification (iCalendar)*, where more information on how to interpret the values can be found. [RFC5545]

Note

Only the parts of the iCalendar vocabulary relating to events are used here; this vocabulary cannot express a complete iCalendar instance.

attach

Gives the address of an associated document for the event.

The `value` must be an absolute URL.

Any number of properties with the name `attach` may be present within each `item` with the type <http://microformats.org/profile/hecalendar#event>.

categories

Gives the name of a category or tag that the event could be classified as.

The `value` must be text.

Any number of properties with the name `categories` may be present within each `item` with the type <http://microformats.org/profile/hecalendar#event>.

class

Gives the access classification of the information regarding the event.

The `value` must be text with one of the following values:

- [private](#)
- [confidential](#)

⚠Warning!
This is merely advisory and cannot be considered a confidentiality measure.

A single property with the name `class` may be present within each `item` with the type <http://microformats.org/profile/hcalendar#event>.

comment

Gives a comment regarding the event.

The `value` must be text.

Any number of properties with the name `comment` may be present within each `item` with the type <http://microformats.org/profile/hcalendar#event>.

description

Gives a detailed description of the event.

The `value` must be text.

A single property with the name `description` may be present within each `item` with the type <http://microformats.org/profile/hcalendar#event>.

geo

Gives the geographical position of the event.

The `value` must be text and must match the following syntax:

1. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. One or more [ASCII digits](#).
3. Optionally*, a U+002E FULL STOP character (.) followed by one or more [ASCII digits](#).
4. A U+003B SEMICOLON character (;).
5. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
6. One or more [ASCII digits](#).
7. Optionally*, a U+002E FULL STOP character (.) followed by one or more [ASCII digits](#).

The optional components marked with an asterisk (*) should be included, and should have six digits each.

Note
The value specifies latitude and longitude, in that order (i.e., "LAT LON" ordering), in decimal degrees. The longitude represents the location east and west of the prime meridian as a positive or negative real number, respectively. The latitude represents the location north and south of the equator as a positive or negative real number, respectively.

A single property with the name `geo` may be present within each `item` with the type <http://microformats.org/profile/hcalendar#event>.

location

Gives the location of the event.

The `value` must be text.

A single property with the name `location` may be present within each `item` with the type <http://microformats.org/profile/hcalendar#event>.

resources

Gives a resource that will be needed for the event.

The `value` must be text.

Any number of properties with the name `resources` may be present within each `item` with the type <http://microformats.org/profile/hcalendar#event>.

status

Gives the confirmation status of the event.

The `value` must be text with one of the following values:

- [tentative](#)
- [confirmed](#)
- [cancelled](#)

A single property with the name `status` may be present within each `item` with the type <http://microformats.org/profile/hcalendar#event>.

summary

Gives a short summary of the event.

The `value` must be text.

User agents should replace U+000A LINE FEED (LF) characters in the `value` by U+0020 SPACE characters when using the value.

A single property with the name `summary` may be present within each `item` with the type <http://microformats.org/profile/hcalendar#event>.

dtend

Gives the date and time by which the event ends.

If the property with the name `dtend` is present within an `item` with the type <http://microformats.org/profile/hcalendar#event> that has a property with the name `dtstart` whose value is a [valid date string](#), then the `value` of the property with the name `dtend` must be text that is a [valid date string](#) also. Otherwise, the `value` of the property must be text that is a [valid global date and time string](#).

In either case, the `value` be later in time than the value of the `dtstart` property of the same `item`.

Note

The time given by the `dtend` property is not inclusive. For day-long events, therefore, the `dtend` property's `value` will be the day *after* the end of the event.

A single property with the name `dtend` may be present within each `item` with the type <http://microformats.org/profile/hcalendar#event>, so long as that <http://microformats.org/profile/hcalendar#event> does not have a property with the name `duration`.

dtstart

Gives the date and time at which the event starts.

The `value` must be text that is either a [valid date string](#) or a [valid global date and time string](#).

Exactly one property with the name `dtstart` must be present within each `item` with the type <http://microformats.org/profile/hcalendar#event>.

duration

Gives the duration of the event.

The `value` must be text that is a [valid event duration string](#).

The duration represented is the sum of all the durations represented by integers in the value.

A single property with the name `duration` may be present within each `item` with the type <http://microformats.org/profile/hcalendar#event>, so long as that <http://microformats.org/profile/hcalendar#event> does not have a property with the name `dtend`.

transp

Gives whether the event is to be considered as consuming time on a calendar, for the purpose of free-busy time searches.

The `value` must be text with one of the following values:

- [opaque](#)
- [transparent](#)

A single property with the name `transp` may be present within each `item` with the type <http://microformats.org/profile/hcalendar#event>.

contact

Gives the contact information for the event.

The `value` must be text.

Any number of properties with the name `contact` may be present within each `item` with the type <http://microformats.org/profile/hcalendar#event>.

url

Gives a [URL](#) for the event.

The `value` must be an [absolute URL](#).

A single property with the name `url` may be present within each `item` with the type <http://microformats.org/profile/hcalendar#event>.

uid

Gives a globally unique identifier corresponding to the event.

The `value` must be text.

A single property with the name `uid` may be present within each `item` with the type <http://microformats.org/profile/hcalendar#event>.

exdate

Gives a date and time at which the event does not occur despite the recurrence rules.

The `value` must be text that is either a [valid date string](#) or a [valid global date and time string](#).

Any number of properties with the name `exdate` may be present within each `item` with the type <http://microformats.org/profile/hcalendar#event>.

rdate

Gives a date and time at which the event recurs.

The `value` must be text that is one of the following:

- [a valid date string](#)
- [a valid global date and time string](#)
- [a valid global date and time string](#) followed by a U+002F SOLIDUS character (/) followed by a second [valid global date and time string](#) representing a later time.
- [a valid global date and time string](#) followed by a U+002F SOLIDUS character (/) followed by a [valid event duration string](#).

Any number of properties with the name `rdate` may be present within each `item` with the type <http://microformats.org/profile/hcalendar#event>.

rrule

Gives a rule for finding dates and times at which the event occurs.

A single property with the name `vrule` may be present within each `item` with the type <http://microformats.org/profile/calendar#vevent>.

`created`
Gives the date and time at which the event information was first created in a calendaring system.
The `value` must be text that is a [valid global date and time string](#).

A single property with the name `created` may be present within each `item` with the type <http://microformats.org/profile/calendar#vevent>.

`last-modified`
Gives the date and time at which the event information was last modified in a calendaring system.
The `value` must be text that is a [valid global date and time string](#).

A single property with the name `last-modified` may be present within each `item` with the type <http://microformats.org/profile/calendar#vevent>.

`sequence`
Gives a revision number for the event information.
The `value` must be text that is a [valid non-negative integer](#).

A single property with the name `sequence` may be present within each `item` with the type <http://microformats.org/profile/calendar#vevent>.

A string is a *valid vevent duration string* if it matches the following pattern:

1. A U+0050 LATIN CAPITAL LETTER P character (P).
2. One of the following:
 - A valid `non-negative integer` followed by a U+0057 LATIN CAPITAL LETTER W character (W). The integer represents a duration of that number of weeks.
 - At least one, and possibly both in this order, of the following:
 1. A valid `non-negative integer` followed by a U+0044 LATIN CAPITAL LETTER D character (D). The integer represents a duration of that number of days.
 2. A U+0054 LATIN CAPITAL LETTER T character (T) followed by any one of the following, or the first and second or the third of the following in that order, or all three of the following in this order:
 1. A valid `non-negative integer` followed by a U+0048 LATIN CAPITAL LETTER H character (H). The integer represents a duration of that number of hours.
 2. A valid `non-negative integer` followed by a U+004D LATIN CAPITAL LETTER M character (M). The integer represents a duration of that number of minutes.
 3. A valid `non-negative integer` followed by a U+0033 LATIN CAPITAL LETTER S character (S). The integer represents a duration of that number of seconds.

5.3.2.1 Conversion to iCalendar

Given a list of nodes `nodes` in a `Document`, a user agent must run the following algorithm to extract any `vEvent` data represented by those nodes:

1. If none of the nodes in `nodes` are `items` with the type <http://microformats.org/profile/calendar#vevent>, then there is no `vEvent` data. Abort the algorithm, returning nothing.
2. Let `output` be an empty string.
3. Add an `iCalendar line` with the type `"BEGIN"` and the value `"VCALENDAR"` to `output`.
4. Add an `iCalendar line` with the type `"PROPID"` and the value equal to a user-agent-specific string representing the user agent to `output`.
5. Add an `iCalendar line` with the type `"VERSION"` and the value `"2.0"` to `output`.
6. For each node `node` in `nodes` that is an `item` with the type <http://microformats.org/profile/calendar#vevent>, run the following steps:

1. Add an `iCalendar line` with the type `"BEGIN"` and the value `"VEVENT"` to `output`.
2. Add an `iCalendar line` with the type `"DTSTAMP"` and a value consisting of an iCalendar DATE-TIME string representing the current date and time, with the annotation `"VALUE=DATE-TIME"`, to `output`. [RFC5545]

3. For each element `element` that is a `property-of-the-item node`: for each name `name` in `element's property names`, run the appropriate set of substeps from the following list:

If the property's `value` is an `item`:

Skip the property.

If the property is `attendee`:

If the property is `dtstart`:

If the property is `duration`:

If the property is `dtend`:

If the property is `last-modified`:

Let `value` be the result of stripping all U+002D HYPHEN-MINUS (-) and U+003A COLON (:) characters from the property's `value`.

If the property's `value` is a `valid date string` then add an `iCalendar line` with the type `name` and the value `value` to `output`, with the annotation `"VALUE=DATE"`.

Otherwise, if the property's `value` is a `valid global date and time string` then add an `iCalendar line` with the type `name` and the value `value` to `output`, with the annotation `"VALUE=DATE-TIME"`.

Otherwise skip the property.

Otherwise:

Add an `iCalendar line` with the type `name` and the property's `value` to `output`.

4. Add an `iCalendar line` with the type `"END"` and the value `"VEVENT"` to `output`.

7. Add an `iCalendar line` with the type `"END"` and the value `"VCALENDAR"` to `output`.

When the above algorithm says that the user agent is to add an `iCalendar line` consisting of a type `type`, a value `value`, and optionally an annotation, to a string `output`, it must run the following steps:

1. Let `line` be an empty string.
2. Append type, `converted to ASCII uppercase`, to `line`.
3. If there is an annotation:
 1. Append a U+003B SEMICOLON character (;) to `line`.
 2. Append the annotation to `line`.
4. Append a U+003A COLON character (:) to `line`.
5. Prefix every U+005C REVERSE SOLIDUS character () in `value` with another U+005C REVERSE SOLIDUS character ()�.
6. Prefix every U+002C COMMA character (,) in `value` with a U+005C REVERSE SOLIDUS character ()�.
7. Prefix every U+003B SEMICOLON character (;) in `value` with a U+005C REVERSE SOLIDUS character ()�.
8. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in `value` with a U+005C REVERSE SOLIDUS character () followed by a U+006E LATIN SMALL LETTER N character (n).
9. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in `value` with a U+005C REVERSE SOLIDUS character () followed by a U+006E LATIN SMALL LETTER N character (n).
10. Append `value` to `line`.
11. Let `maximum length` be 75.
12. While `line's length` is greater than `maximum length`:
 1. Append the first `maximum length` code points of `line` to `output`.
 2. Remove the first `maximum length` code points from `line`.
 3. Append a U+000D CARRIAGE RETURN character (CR) to `output`.
 4. Append a U+000A LINE FEED character (LF) to `output`.
 5. Append a U+0020 SPACE character to `output`.
 6. Let `maximum length` be 74.
13. Append (what remains of) `line` to `output`.
14. Append a U+000D CARRIAGE RETURN character (CR) to `output`.
15. Append a U+000A LINE FEED character (LF) to `output`.

Note
This algorithm can generate invalid iCalendar output if the input does not conform to the rules described for the http://microformats.org/profile/calendar#item_type_and_defined_property_names.

5.3.2.2 Examples

This section is non-normative.

Example

Here is an example of a page that uses the vEvent vocabulary to mark up an event:

```
<body itemscope itemtype="http://microformats.org/profile/calendar#vevent">
...
<div itemscope="summary">Bluesday Tuesday: Money Road</div>
<time itemscope="dtstart" datetime="2009-05-05T18:00:00Z">May 5th @ 7pm</time>
<time itemscope="dtend" datetime="2009-05-05T21:00:00Z">9pm</time>
at <span itemscope="location">The Roadhouse</span></p>
<p><a href="http://livewrum.co.uk/2009/05/bluesday-tuesday-money-road" rel="bookmark" itemscope="url">Link to this page!</a>
...
<meta itemscope="description" content="via livewrum.co.uk">
</body>
```

The `getCalendar()` function is left as an exercise for the reader.

The same page could offer some markup, such as the following, for copy-and-pasting into blogs:

```
<div itemscope itemtype="http://microformats.org/profile/calendar#vevent">
...
<div itemscope="summary">Bluesday Tuesday: Money Road</div>
<time itemscope="dtstart" datetime="2009-05-05T18:00:00Z">May 5th @ 7pm</time>
<time itemscope="dtend" datetime="2009-05-05T21:00:00Z">9pm</time>
at <span itemscope="location">The Roadhouse</span></p>
<p><a href="http://livewrum.co.uk/2009/05/bluesday-tuesday-money-road" rel="bookmark" itemscope="url">Read this event on livewrum.co.uk!</a>
...
<meta itemscope="description" content="via livewrum.co.uk">
</div>
```

See also [Example](#).

An item with the [item type](#) <http://o.whatwg.org/work> represents a work (e.g. an article, an image, a video, a song, etc). This type is primarily intended to allow authors to include licensing information for works.

The following are the type's [defined property names](#):

`work`

Identifies the work being described.

The [value](#) must be an [absolute URL](#).

Exactly one property with the name `work` must be present within each `item` with the type <http://o.whatwg.org/work>.

`title`

Gives the name of the work.

A single property with the name `title` may be present within each `item` with the type <http://o.whatwg.org/work>.

`author`

Gives the name or contact information of one of the authors or creators of the work.

The [value](#) must be either an `item` with the type <http://o.whatwg.org/profile/hcard> or text.

Any number of properties with the name `author` may be present within each `item` with the type <http://o.whatwg.org/work>.

`license`

Identifies one of the licenses under which the work is available.

The [value](#) must be an [absolute URL](#).

Any number of properties with the name `license` may be present within each `item` with the type <http://o.whatwg.org/work>.

5.3.3.1 Examples

This section is non-normative.

Example

This example shows an embedded image entitled *My Pond*, licensed under the Creative Commons Attribution-Share Alike 4.0 International License and the MIT license simultaneously.

```
<figure itemscope itemtype="http://o.whatwg.org/work">

<caption>
  <p><code>itemprop="title">My Pond</code></p>
  <p><code>itemprop="license">
    <a href="https://creativecommons.org/licenses/by-sa/4.0/">Creative
    Commons Attribution-Share Alike 4.0 International License</a>
  </code></p>
  <p><code>itemprop="license">
    <a href="http://www.opensource.org/licenses/mit-license.php">MIT
    license</a></code></p>
  </caption>
</figure>
```

5.4 Converting HTML to other formats

5.4.1 JSON

Given a list of nodes `nodes` in a `Document`, a user agent must run the following algorithm to extract the microdata from those nodes into a JSON form:

1. Let `result` be an empty object.
2. Let `items` be an empty array.
3. For each `node` in `nodes`, check if the element is a [top-level microdata item](#), and if it is then [get the object](#) for that element and add it to `items`.
4. Add an entry to `result` called "`items`" whose value is the array `items`.
5. Return the result of serializing `result` to JSON in the shortest possible way (meaning no whitespace between tokens, no unnecessary zero digits in numbers, and only using Unicode escapes in strings for characters that do not have a dedicated escape sequence), and with a lowercase "`u`" used, when appropriate, in the representation of any numbers.

[JSON]

Note

This algorithm returns an object with a single property that is an array, instead of just returning an array, so that it is possible to extend the algorithm in the future if necessary.

When the user agent is to [get the object](#) for an item `item`, optionally with a list of elements `memory`, it must run the following substeps:

1. Let `result` be an empty object.
2. If no `memory` was passed to the algorithm, let `memory` be an empty list.
3. Add `item` to `memory`.
4. If the `item` has any `itemTypes`, add an entry to `result` called "`type`" whose value is an array listing the `itemTypes` of `item`, in the order they were specified on the `itemType` attribute.
5. If the `item` has a `globalIdentifier`, add an entry to `result` called "`id`" whose value is the `globalIdentifier` of `item`.
6. Let `properties` be an empty object.
7. For each element `element` that has one or more `propertyNames` and is one of the `properties` of `item`, in the order those elements are given by the algorithm that returns [the properties of an item](#), run the following substeps:
 1. Let `value` be the `propertyName` of `element`.
 2. If `value` is an `item`, then let `value` be the string "ERROR". Otherwise, [get the object](#) for `value`, passing a copy of `memory`, and then replace `value` with the object returned from those steps.
 3. For each name `name` in `element's` `propertyNames`, run the following substeps:
 1. If there is no entry named `name` in `properties`, then add an entry named `name` to `properties` whose value is an empty array.
 2. Append `value` to the entry named `name` in `properties`.
 8. Add an entry to `result` called "`properties`" whose value is the object `properties`.
 9. Return `result`.

Example

For example, take this markup:

```
<!DOCTYPE HTML>
<html>
<head>
<title>My Blog</title>
<article itemscope itemtype="http://schema.org/BlogPosting">
<h1 itemprop="headline">Progress report</h1>
<p><code>itemprop="datePublished">2013-08-29</code></p>
<a href="#" itemprop="url" href="#c1">Comments</a>
</head>
<p>All in all, he's doing well with his swim lessons. The biggest thing was he had trouble
swimming head in, but we got it down.</p>
<section>
<h3>Comments</h3>
<ol>
<li itemscope itemtype="comment" itemprop="UserComments" id="c1">
<link itemprop="url" href="#c1">
<div>
<p>Posted by: <span itemprop="creator" itemprop="Person">Dreg</span>
<span itemprop="name">Dreg</span>
<><time itemprop="commentTime" datetime="2013-08-29T15:15:00Z">15 minutes ago</time></p>
</div>
</li>
</ol>
</section>
</article>
<article itemscope="comment" itemtype="http://schema.org/UserComments" id="c2">
<footnote>
<p>What you say "we got it down..."</p>
</footnote>
</article>
</article>
```

It would be turned into the following JSON by the algorithm above (supposing that the page's URL was <https://blog.example.com/progress-report>):

```
{
  "items": [
    {
      "type": [ "http://schema.org/BlogPosting" ],
      "properties": [
        {
          "name": "headline",
          "value": "Progress report"
        },
        {
          "name": "datePublished",
          "value": "2013-08-29"
        },
        {
          "name": "url",
          "value": "https://blog.example.com/progress-report?comments=0"
        }
      ],
      "comment": [
        {
          "type": [ "http://schema.org/UserComments" ],
          "properties": [
            {
              "name": "url",
              "value": "https://blog.example.com/progress-report#c1"
            },
            {
              "name": "creator",
              "value": [
                {
                  "type": [ "http://schema.org/Person" ],
                  "properties": [
                    {
                      "name": "name",
                      "value": "Dreg"
                    }
                  ]
                }
              ],
              "commentTime": [ "2013-08-29" ]
            }
          ]
        },
        {
          "type": [ "http://schema.org/UserComments" ],
          "properties": [
            {
              "name": "url",
              "value": "https://blog.example.com/progress-report#c2"
            },
            {
              "name": "creator",
              "value": [
                {
                  "type": [ "http://schema.org/Person" ],
                  "properties": [
                    {
                      "name": "name",
                      "value": "Charlotte"
                    }
                  ]
                }
              ],
              "commentTime": [ "2013-08-29" ]
            }
          ]
        }
      ]
    }
  ]
}
```

6 User interaction

6.1 The `hidden` attribute

Support: hiddenChrome for Android 8+; Chrome 6+; iOS Safari 5.0+; Safari 5.1+; Firefox 4+; Samsung Internet 4+; Edge 12+; UC Browser for Android 12.12+; IE 11+; Opera Mini all+; Firefox for Android 68+

Source: [caniuse.com](#)

MDN

Global attributes/hidden

Support in all current engines.

Firefox Yes; Safari Yes; Chrome Yes

Opera Yes; Edge Yes

Edge (Legacy) 12+; Internet Explorer 11

Firefox Android Yes; Safari iOS Yes; Chrome Android Yes; WebView Android+; Samsung Internet Yes; Opera Android Yes

All `HTML_element` may have the `hidden` content attribute set. The `hidden` attribute is a `boolean_attribute`. When specified on an element, it indicates that the element is not yet, or is no longer, directly relevant to the page's current state, or that it is being used to declare content to be reused by other parts of the page as opposed to being directly accessed by the user. Agent users should not render elements that have the `hidden` attribute specified. This requirement may be implemented indirectly through the style layer. For example, an HTML+CSS user agent could implement these requirements using the rules specified in the [Rendering section](#).

Note
because this attribute is typically implemented using CSS, it's also possible to override it using CSS. For instance, a rule that applies `display: block` to all elements will cancel the effects of the `hidden` attribute. Authors therefore have to take care when writing their style sheets to make sure that the attribute is still styled as expected.

Example

In the following skeletal example, the attribute is used to hide the Web game's main screen until the user logs in:

```
<h1>The Example Game</h1>
<section id="login">
  <form>
    <input type="text" name="username"/>
    <input type="password" name="password"/>
    <input type="button" value="Log In" />
    <!-- calls login() once the user's credentials have been checked -->
  </form>
</script>
<script>
  function login() {
    // switch screens
    document.getElementById('login').hidden = true;
    document.getElementById('game').hidden = false;
  }
</script>
</section>
<section id="game" hidden>
  ...
</section>
```

The `hidden` attribute must not be used to hide content that could legitimately be shown in another presentation. For example, it is incorrect to use `hidden` to hide panels in a tabbed dialog, because the tabbed interface is merely a kind of overflow presentation — one could equally well just show all the form controls in one big page with a scrollbar. It is similarly incorrect to use this attribute to hide content just from one presentation — if something is marked `hidden`, it is hidden from all presentations, including, for instance, screen readers.

Elements that are not themselves `hidden` must not [hyperlink](#) to elements that are `hidden`. The `for` attributes of `label` and `output` elements that are not themselves `hidden` must similarly not refer to elements that are `hidden`. In both cases, such references would cause user confusion.

Elements and scripts may, however, refer to elements that are `hidden` in other contexts.

Example

For example, it would be incorrect to use the `href` attribute to link to a section marked with the `hidden` attribute. If the content is not applicable or relevant, then there is no reason to link to it.

It would be fine, however, to use the ARIA `aria-describedby` attribute to refer to descriptions that are themselves `hidden`. While hiding the descriptions implies that they are not useful alone, they could be written in such a way that they are useful in the specific context of being referenced from the images that they describe.

Similarly, a `canvas` element with the `hidden` attribute could be used by a scripted graphics engine as an off-screen buffer, and a form control could refer to a hidden `form` element using its `form` attribute.

Elements in a section hidden by the `hidden` attribute are still active, e.g. scripts and form controls in such sections still execute and submit respectively. Only their presentation to the user changes.

The `hidden` IDL attribute must [reflect](#) the content attribute of the same name.

6.2 Inert subtrees

Note

This section does **not** define or create any content attribute named "inert". This section merely defines an abstract concept of inertness.

A node (in particular elements and text nodes) can be marked as `inert`. When a node is `inert`, then the user agent must act as if the node was absent for the purposes of targeting user interaction events, may ignore the node for the purposes of text search user interfaces (commonly known as "find in page"), and may prevent the user from selecting text in that node. User agents should allow the user to override the restrictions on search and text selection, however.

Example

For example, consider a page that consists of just a single `inert` paragraph positioned in the middle of a `body`. If a user moves their pointing device from the `body` over to the `inert` paragraph and clicks on the paragraph, no `mouseover` event would be fired, and the `mousemove` and `click` events would be fired on the `body` element rather than the paragraph.

Note

When a node is `inert`, it generally cannot be focused. Inert nodes that are [commands](#) will also get disabled.

While a `browsing_context_container` is marked as `inert`, its `nesting_browsing_context`'s `active_document`, and all nodes in that `document`, must be marked as `inert`.

An element is *expressly inert* if it is `inert` and its `node_document` is not `inert`.
A `document` is *blocked* by a modal dialog subject if `subject` is the topmost `dialog` element in `document`'s `top_layer`. While `document` is so blocked, every node that is `connected` to `document`, with the exception of the `subject` element and its `shadow-including descendants`, must be marked `inert`. (The elements excepted by this paragraph can additionally be marked `inert` through other means; being part of a modal dialog does not "protect" a node from being marked `inert`.)

Note

The `dialog` element's `showModal()` method causes this mechanism to trigger, by adding the `dialog` element to its `node_document`'s `top_layer`.

6.3 Tracking user activation

To prevent abuse of certain APIs that could be annoying to users (e.g., opening popups or vibrating phones), user agents allow these APIs only when the user is actively interacting with the web page or has interacted with the page at least once. This "active interaction" state is maintained through the mechanisms defined in this section.

6.3.1 Data model

For the purpose of tracking user activation, each `window` *W* has a *last activation timestamp*. This is a number indicating the last time *W* got an [activation notification](#). It corresponds to a `DOMHighResTimeStamp` value except for two cases: positive infinity indicates that *W* has never been activated, while negative infinity indicates that a [user activation-gated API](#) has [consumed](#) the last user activation of *W*. The initial value is positive infinity.

A user agent also defines a *transient activation duration*, which is a constant number indicating how long a user activation is available for certain [user activation-gated APIs](#) (e.g., for opening popups).

Note

The `transient_activation_duration` is expected to be at most a few seconds, so that the user can possibly perceive the link between an interaction with the page and the page calling the activation-gated API.

These two values imply two boolean user activation states for *W*:

Sticky activation

When the `current_high_resolution_time` is greater than or equal to the `last_activation_timestamp` in *W*, *W* is said to have *sticky activation*.

This is *W*'s historical activation state, indicating whether the user has ever interacted in *W*. It starts false, then changes to true (and never changes back to false) when *W* gets the very first [activation notification](#).

Transient activation

When the `current_high_resolution_time` is greater than or equal to the `last_activation_timestamp` in *W*, and less than the `last_activation_timestamp` in *W* plus the `transient_activation_duration`, then *W* is said to have *transient activation*.

This is *W*'s current activation state, indicating whether the user has interacted in *W* recently. This starts with a false value, and remains true for a limited time after every [activation notification](#) *W* gets.

The `transient_activation` state is considered *expired* if it becomes false because the `transient_activation` duration time has elapsed since the last user activation. Note that it can become false even before the expiry time through an [activation consumption](#).

6.3.2 Processing model

When a user interaction in a `browsing_context` *B* causes firing of an [activation_triggering_input_event](#) in *B*'s `active_document` *D*, the user agent must perform the following *activation_notification* steps before [dispatching](#) the event:

1. Let `browsingContexts` be a list consisting of:

- *B*,
- all `ancestor_browsing_contexts` of *B*, and
- all the `descendant_browsing_contexts` of *D* that have `active_documents` from the `same_origin` as that of *D*.

2. Let `windows` be the list of `window` objects constructed by taking the `[Window]` internal slot value of `browsingContext`'s `windowProxy` object for each `browsingContext` in `browsingContexts`.

3. For each `window` in `windows`, set `window`'s `last_activation_timestamp` to the `current_high_resolution_time`.

An `activation_triggering_input_event` is any event whose `isTrusted` attribute is true and whose `type` is one of:

- `change`
- `click`
- `contextmenu`
- `dblclick`
- `mousedown`
- `pointerdown`
- `pointermove`
- `pointerup`
- `touchstart`
- `touchend`
- `touchcancel`

The event set is inconsistent across major browsers. See [issue #3849](#).

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

1. If W 's `browsingContext` is null, then return.
2. Let top be W 's `browsingContext's top-level browsing context`.
3. Let `browsingContexts` be the `list of the descendant browsing contexts of top's active document`.
4. [Append top to browsingContexts](#).
5. Let `windows` be the list of `window` objects constructed by taking the `[Window]` internal slot value of `browsingContext's windowProxy` object for each `browsingContext` of `browsingContexts`.
6. [For each](#) `window` in `windows`, if `window's last activation timestamp` is not positive infinity, then set `window's last activation timestamp` to negative infinity.

The spec is not clear about how to traverse a tree of documents. See [issue #5020](#).

Note

Note the asymmetry in the sets of `browsing contexts` in the page that are affected by an `activation notification` vs an `activation consumption`: an activation consumption changes (to false) the `transient activation` states for all browsing contexts in the page, but an activation notification changes (to true) the states for a subset of those browsing contexts. The exhaustive nature of consumption here is deliberate: it prevents malicious sites from making multiple calls to an `activation consuming API` from a single user activation (possibly by exploring a deep hierarchy of `frames`).

6.3 APIs gated by user activation

APIs that are dependent on user activation are classified into three different levels. The levels are as follows, sorted by their "strength of dependence" on user activation (from weakest to strongest):

Sticky activation-gated APIs

These APIs require the `sticky activation` state to be true, so they are blocked until the very first user activation.

Transient activation-gated APIs

These APIs require the `transient activation` state to be true, but they don't `consume` it, so multiple calls are allowed per user activation until the transient state `expires`.

Transient activation-consuming APIs

These APIs require the `transient activation` state to be true, and they `consume user activation` in each call to prevent multiple calls per user activation.

6.4 Activation behavior of elements

Certain elements in HTML have an `activation behavior`, which means that the user can activate them. This is always caused by a `click` event.

The user agent should allow the user to manually trigger elements that have an `activation behavior`, for instance using keyboard or voice input, or through mouse clicks. When the user triggers an element with a defined `activation behavior` in a manner other than clicking it, the default action of the interaction event must be to [fire a click event](#) at the element.

For web developers (non-normative)

`element.click()`

Acts as if the element was clicked.

Each element has an associated `click in progress flag`, which is initially unset.

The `click()` method must run the following steps:

1. If this element is a form control that is `disabled`, then return.
2. If this element's `click in progress flag` is set, then return.
3. Set this element's `click in progress flag`.
4. [Fire a synthetic mouse event](#) named `click` at this element, with the `not trusted` flag set.
5. Unset this element's `click in progress flag`.

6.5 Focus

6.5.1 Introduction

This section is non-normative.

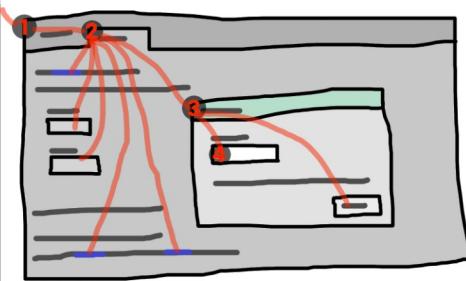

An HTML user interface typically consists of multiple interactive widgets, such as form controls, scrollable regions, links, dialog boxes, browser tabs, and so forth. These widgets form a hierarchy, with some (e.g. browser tabs, dialog boxes) containing others (e.g. links, form controls).

When interacting with an interface using a keyboard, key input is channeled from the system, through the hierarchy of interactive widgets, to an active widget, which is said to be `focused`.

Example

Consider an HTML application running in a browser tab running in a graphical environment. Suppose this application had a page with some text controls and links, and was currently showing a modal dialog, which itself had a text control and a button.

The hierarchy of focusable widgets, in this scenario, would include the browser window, which would have, amongst its children, the browser tab containing the HTML application. The tab itself would have as its children the various links and text controls, as well as the dialog. The dialog itself would have as its children the text control and the button.

If the widget with `focus` in this example was the text control in the dialog box, then key input would be channeled from the graphical system to the Web browser, then to the tab, then to the dialog, and finally to the text control.

Keyboard events are always targeted at this `focused` element.

6.5.2 Data model

The term `focuseable area` is used to refer to regions of the interface that can become the target of keyboard input. Focuseable areas can be elements, parts of elements, or other regions managed by the user agent.

Each `focuseable area` has a `DOM anchor`, which is a `Node` object that represents the position of the `focuseable area` in the DOM. (When the `focuseable area` is itself a `Node`, it is its own `DOM anchor`) The `DOM anchor` is used in some APIs as a substitute for the `focuseable area` when there is no other DOM object to represent the `focuseable area`.

The following table describes what objects can be `focuseable areas`. The cells in the left column describe objects that can be `focuseable areas`; the cells in the right column describe the `DOM anchors` for those elements. (The cells that span both columns are non-normative examples.)

<code>Focuseable area</code>	<code>Examples</code>	<code>DOM anchor</code>
------------------------------	-----------------------	-------------------------

Elements that meet all the following criteria:

- the element's `tabindex` value is a non-negative integer, or the element is determined by the user agent to be focuseable;
- the element is either not a `shadow host`, or has a `shadow root` whose `delegates focus` is false;
- the element is not `actually disabled`;
- the element is not `expressly inert`;
- the element is either `being rendered` or `being used as relevant canvas fallback content`.

The element itself.

`Example`
`<iframe><input type="text">`, sometimes `` (depending on platform conventions).

The shapes of `area` elements in an `image map` associated with an `img` element that is `being rendered` and is not `expressly inert`.

The `img` element.

`Example`

In the following example, the `area` element creates two shapes, one on each image. The `DOM anchor` of the first shape is the first `area` element, and the `DOM anchor` of the second shape is the second `area` element.

```
<map id="wallmap"><area alt="Enter Door" coords="10,10,100,200" href="door.html"></map>

```

The element for which the `focuseable area` is a subwidget.

The user-agent provided subwidgets of elements that are `being rendered` and are not `actually disabled` or `expressly inert`.

The element for which the `focuseable area` was created.

`Example`

The `controls` in the user interface that is exposed to the user for a `video` element, the up and down buttons in a spin-control version of `<input type="range multiple">`, the two range control widgets in a `<input type="range multiple">`, the part of a `details` element's rendering that enabled the element to be opened or closed using keyboard input

The scrollable regions of elements that are `being rendered` and are not `expressly inert`.

The element for which the box that the scrollable region scrolls was created.

`Example`

The `viewport` of a `document` that has a non-null `browsing context` and is not `inert`.

The `document` for which the `viewport` was created.

`Example`

The contents of an `iframe`.

The element.

Any other element or part of an element determined by the user agent to be a `focuseable area`, especially to aid with accessibility or to better match platform conventions.

The element.

`Example`

A user agent could make all list item bullets `sequentially focuseable`, so that a user can more easily navigate lists.

`Example`

Similarly, a user agent could make all elements with `title` attributes `sequentially focuseable`, so that their advisory information can be accessed.

`Note`
A `browsing context container` (e.g. an `iframe`) is a `focuseable area`, but key events rooted to a `browsing context container` get immediately routed to its `nested browsing context's active document`. Similarly, in sequential focus navigation a `browsing context container` essentially acts merely as a placeholder for its `nested browsing context's active document`.

One `focuseable area` in each `document` is designated the `focuseable area of the document`. Which control is so designated changes over time, based on algorithms in this specification.

EXPAND

1. Let *candidate* be *topLevelBC's active document*.
2. If the designated *focused area* of the *document* is a *browsing context container* with a non-null *nested browsing context*, then let *candidate* be the *active document* of that *browsing context container's nested browsing context*, and redo this step.
3. If *candidate* has a *focused area*, set *candidate* to *candidate's focused area*.
4. Return *candidate*.

An element that is the *DOM anchor* of a *focusable area* is said to *gain focus* when that *focusable area* becomes the *currently focused area of a top-level browsing context*. When an element is the *DOM anchor* of a *focusable area* of the *currently focused area of a top-level browsing context*, it is *focused*.

The *focus chain* of a *focusable area* *subject* is the ordered list constructed as follows:

1. Let *current object* be *subject*.
2. Let *output* be an empty list.
3. *Loop*: Append *current object* to *output*.
4. If *current object* is an *area* element's shape, append that *area* element to *output*.
- Otherwise, if *current object* is a *focusable area* whose *DOM anchor* is an element that is not *current object* itself, append that *DOM anchor* element to *output*.
- If *current object* is a *form* whose *browsing context* is a *child browsing context*, then set *current object* to *current object's browsing context's containing* and return to the step labeled *loop*.
6. Return *output*.

Note

The chain starts with *subject* and (if *subject* is or can be the *currently focused area of a top-level browsing context*) continues up the focus hierarchy up to the *document* of the *top-level browsing context*.

All elements that are *focusable areas* are said to be *focusable*.

There are two special types of focusability for *focusable areas*:

- A *focusable area* is said to be *sequentially focusable* if it is included in its *document's sequential focus navigation order* and the user agent determines that it is sequentially focusable.
- A *focusable area* is said to be *click focusable* if the user agent determines that it is click focusable. User agents should consider focusable areas with non-null *tabindex values* to be click focusable.

Note

Elements which are not *focusable* are not *focusable areas*, and thus not *sequentially focusable* and not *click focusable*.

Note

Being *focusable* is a statement about whether an element can be focused programmatically, e.g. via the *focus()* method or *autofocus* attribute. In contrast, *sequentially focusable* and *click focusable* govern how the user agent responds to user interaction: respectively, to *sequential focus navigation* and as *activation behavior*.

The user agent might determine that an element is not *sequentially focusable* even if it is *focusable* and is included in its *document's sequential focus navigation order*, according to user preferences. For example, macOS users can set the user agent to skip non-form control elements, or can skip links when doing *sequential focus navigation* with just the *Tab* key (as opposed to using both the *option* and *Tab* keys).

Similarly, the user agent might determine that an element is not *click focusable* even if it is *focusable*. For example, in some user agents, clicking on a non-editable form control does not focus it, i.e. the user agent has determined that such controls are not click focusable.

Thus, an element can be *focusable*, but neither *sequentially focusable* nor *click focusable*. For example, in some user agents, a non-editable form-control with a negative-integer *tabindex value* would not be focusable via user interaction, only via programmatic APIs.

When a user activates a *click focusable focusable area*, the user agent must run the *focus steps* on the *focusable area* with *focus trigger* set to "click".

Note

Note that focusing is not an *activation behavior*, i.e. calling the *click()* method on an element or dispatching a synthetic *click* event on it won't cause the element to get focused.

A node is a *focus navigation scope owner* if it is a *document*, a *shadow host* or a *slot*.

Each *focus navigation scope owner* has a *focus navigation scope*, which is a list of elements. Its contents are determined as follows:

Every element *element* has an *associated focus navigation owner*, which is either null or a *focus navigation scope owner*. It is determined by the following algorithm:

1. If *element's* parent is null, then return null.
2. If *element's* parent is a *shadow host*, then return *element's assigned slot*.
3. If *element's* parent is a *shadow root*, then return the parent's *host*.
4. If *element's* parent is the *document element*, then return the parent's *node document*.
5. Return *element's* parent's *associated focus navigation owner*.

Then, the contents of a given *focus navigation scope owner's focus navigation scope* are all elements whose *associated focus navigation owner* is *owner*.

Note
The order of elements within a *focus navigation scope* does not impact any of the algorithms in this specification. Ordering only becomes important for the *tabindex-ordered focus navigation scope* and *flattened tabindex-ordered focus navigation scope* concepts defined below.

A *tabindex-ordered focus navigation scope* is a list of *focusable areas* and *focus navigation scope owners*. Every *focus navigation scope owner* has a *tabindex-ordered focus navigation scope*, whose contents are determined as follows:

- It contains all elements in *owner's focus navigation scope* that are themselves *focus navigation scope owners*, except the elements whose *tabindex value* is a negative integer.
- It contains all of the *focusable areas* whose *DOM anchor* is an element in *owner's focus navigation scope*, except the *focusable areas* whose *tabindex value* is a negative integer.

The order within a *tabindex-ordered focus navigation scope* is determined by each element's *tabindex value*, as described in the section below.

Note

The rules there do not give a precise ordering, as they are composed mostly of "should" statements and relative orderings.

A flattened *tabindex-ordered focus navigation scope* is a list of *focusable areas*. Every *focus navigation scope owner* owns a distinct *flattened tabindex-ordered focus navigation scope*, whose contents are determined by the following algorithm:

1. Let *result* be a *clone* of *owner's tabindex-ordered focus navigation scope*.
2. For each item of *result*:
 1. If *item* is not a *focus navigation scope owner*, then *continue*.
 2. If *item* is not a *focusable area*, then replace *item* with all of the items in *item's flattened tabindex-ordered focus navigation scope*.
 3. Otherwise, insert the contents of *item's flattened tabindex-ordered focus navigation scope* after *item*.

6.5.3 The *tabindex* attribute

[MDN](#)

[Global_attributes/tabindex](#)

Support in all current engines.

FirefoxYes SafariYes ChromeYes

OperaYes EdgeYes

Edge (Legacy)12+ Internet ExplorerYes

Firefox AndroidYes Safari iOSYes Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidYes

The *tabindex* content attribute allows authors to make an element and regions that have the element as its *DOM anchor* be *focusable areas*, allow or prevent them from being *sequentially focusable*, and determine their relative ordering for *sequential focus navigation*.

Support: *tabindex-attr* Chrome for Android 81+ Chrome 15+ iOS Safari 3.2+ Safari 5.1+ Firefox 4+ Edge 12+ IE 7+ Opera 9.5+ Firefox for Android 68+

Source: [caniuse.com](#)

The name "tab index" comes from the common use of the *Tab* key to navigate through the focusable elements. The term "tabbing" refers to moving forward through *sequentially focusable focusable areas*.

The *tabindex* attribute, if specified, must have a value that is a *valid integer*. Positive numbers specify the relative position of the element's *focusable areas* in the *sequential focus navigation order*, and negative numbers indicate that the control is not *sequentially focusable*.

Developers should use caution when using values other than 0 or -1 for their *tabindex* attributes as this is complicated to do correctly.

Note

The following provides a non-normative summary of the behaviors of the possible *tabindex* attribute values. The below processing model gives the more precise rules.

omitted (or non-negative integer values)

The user agent will decide whether the element is *focusable*, and if it is, whether it is *sequentially focusable* or *click focusable* (or both).

-1 (or other negative integer values)

Causes the element to be *focusable*, and indicates that the author would prefer the element to be *click focusable* but not *sequentially focusable*. The user agent might ignore this preference for click and sequential focusability, e.g., for specific element types according to platform conventions, or for keyboard-only users.

0

Causes the element to be *focusable*, and indicates that the author would prefer the element to be both *click focusable* and *sequentially focusable*. The user agent might ignore this preference for click and sequential focusability.

positive integer values

Behaves the same as 0, but in addition creates a relative ordering within a *tabindex-ordered focus navigation scope*, so that elements with higher *tabindex* attribute value come later.

Note that the *tabindex* attribute cannot be used to make an element non-focusable. The only way a page author can do that is by *disabling* the element, or making it *inert*.

An element with the *tabindex* attribute specified is *interactive content*.

The *tabindex* value of an element is the value of its *tabindex* attribute, parsed using the *rules for parsing integers*. If parsing fails or the attribute is not specified, then the *tabindex value* is null.

The *tabindex value* of a *focusable area* is the *tabindex value* of its *DOM anchor*.

The *tabindex value* of an element must be interpreted as follows:

If the value is null

The user agent should follow platform conventions to determine if the element should be considered as a *focusable area* and if so, whether the element and any *focusable areas* that have the element as their *DOM anchor* are *sequentially focusable*, and if so, what their relative position in their *tabindex-ordered focus navigation scope* is to be. If the element is a *focus navigation scope owner*, it must be included in its *tabindex-ordered focus navigation scope*, even if it is not a *focusable area*.

The relative ordering within a *tabindex-ordered focus navigation scope* for elements and *focusable areas* that belong to the same *focus navigation scope* and whose *tabindex value* is null should be in *shadow-including tree order*.

Modulo platform conventions, it is suggested that the following elements should be considered as *focusable areas*:

- *input* elements that have an *href* attribute
- *link* elements that have an *href* attribute
- *button* elements
- *input* elements whose *type* attribute are not in the *Hidden* state
- *select* elements
- *textarea* elements
- *summary* elements that are the first *summary* element child of a *details* element
- Elements with a *draggable* attribute set, if that would enable the user agent to allow the user to begin a drag operation for those elements without the use of a pointing device.

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

- Browsing context containers

If the value is a negative integer

The user agent must consider the element as a [focusable area](#), but should omit the element from any [tabindex-ordered focus navigation scope](#).

Note
One valid reason to ignore the requirement that sequential focus navigation not allow the author to lead to the element would be if the user's only mechanism for moving the focus is sequential focus navigation. For instance, a keyboard-only user would be unable to click on a text control with a negative [tabindex](#), so that user's user agent would be well justified in allowing the user to tab to the control regardless.

If the value is zero

The user agent must allow the element to be considered as a [focusable area](#) and should allow the element and any [focusable areas](#) that have the element as their [DOM anchor](#) to be [sequentially focusable](#).

The relative ordering within a [tabindex-ordered focus navigation scope](#) for elements and [focusable areas](#) that belong to the same [focus navigation scope](#) and whose [tabindex](#) value is zero should be in [shadow-including tree order](#).

If the value is greater than zero

The user agent must allow the element to be considered as a [focusable area](#) and should allow the element and any [focusable areas](#) that have the element as their [DOM anchor](#) to be [sequentially focusable](#), and should place the element — referenced as [candidate](#) below — and the aforementioned [focusable areas](#) in the [tabindex-ordered focus navigation scope](#) where the element is a part of so that, relative to other elements and [focusable areas](#) that belong to the same [focus navigation scope](#), they:

- before any [focusable area](#) whose [DOM anchor](#) is an element whose [tabindex](#) attribute has been omitted or whose value, when parsed, returns an error,
- before any [focusable area](#) whose [DOM anchor](#) is an element whose [tabindex](#) attribute has a value equal to or less than zero,
- after any [focusable area](#) whose [DOM anchor](#) is an element whose [tabindex](#) attribute has a value greater than zero but less than the value of the [tabindex](#) attribute on [candidate](#),
- after any [focusable area](#) whose [DOM anchor](#) is an element whose [tabindex](#) attribute has a value equal to the value of the [tabindex](#) attribute on [candidate](#) but that is located earlier than [candidate](#) in [shadow-including tree order](#),
- before any [focusable area](#) whose [DOM anchor](#) is an element whose [tabindex](#) attribute has a value equal to the value of the [tabindex](#) attribute on [candidate](#) but that is located later than [candidate](#) in [shadow-including tree order](#), and
- before any [focusable area](#) whose [DOM anchor](#) is an element whose [tabindex](#) attribute has a value greater than the value of the [tabindex](#) attribute on [candidate](#).

MDN

Support in all current engines

Firefox1+Safari6+Chrome1+

OperaYesEdge79+

Edge (Legacy)18Internet Explorer8+

Firefox Android4+Safari iOSYesChrome Android18+WebView Android4.4+Samsung Internet1.0+Opera AndroidYes

The [tabIndex](#) IDL attribute must reflect the value of the [tabindex](#) content attribute. The default value is 0 if the element is an [area](#), [button](#), [frame](#), [iframe](#), [input](#), [object](#), [select](#), [textarea](#), or [SVG](#) element, or is a [summary](#) element that is a [summary for its parent details](#). The default value is -1 otherwise.

Note

The varying default value based on element type is a historical artifact.

6.5.4 Processing model

To get the [focusable area](#) for a [focus target](#) that is either an element that is not a [focusable area](#), or is a [browsing context](#), given an optional string [focus trigger](#), run the first matching set of steps from the following list:

If [focus target](#) is an [area](#) element with one or more shapes that are [focusable areas](#)

Return the shape corresponding to the first [img](#) element in [tree order](#) that uses the image map to which the [area](#) element belongs.

If [focus target](#) is an element with one or more scrollable regions that are [focusable areas](#)

Return the elements' first scrollable region, according to a pre-order, depth-first traversal of the [flat tree](#) ([CSSSCOPING](#))

If [focus target](#) is the [document element](#) of its [Document](#)

Return the [Document's viewport](#)

If [focus target](#) is a [browsing context](#)

Return the [browsing context's active document](#).

If [focus target](#) is a [browsing context container](#) with a non-null [nested browsing context](#)

Return the [browsing context container's nested browsing context's active document](#).

If [focus target](#) is a [shadow host](#) whose [shadow root's delegates focus](#) is true

- If [focus target](#) is a [shadow-including inclusive ancestor](#) of the [currently focused area of a top-level browsing context's DOM anchor](#), then return null.

2. Otherwise:

- If [focus trigger](#) is "click", then let [possible focus delegates](#) be the list of all [click focusable focusable areas](#) whose [DOM anchor](#) is a descendant of [focus target](#) in the [flat tree](#).
- Otherwise, let [possible focus delegates](#) be the list of all [focusable areas](#) whose [DOM anchor](#) is a descendant of [focus target](#) in the [flat tree](#).
- Return the first [focusable area](#) in [tree order](#) in [possible focus delegates](#), or null if [possible focus delegates](#) is empty.

Note

For [sequential focusability](#), the handling of [shadow hosts](#) and [delegates focus](#) is done when constructing the [sequential focus navigation order](#). That is, the [focusing steps](#) will never be called on such [shadow hosts](#) as part of sequential focus navigation.

Otherwise

Return null.

The [focusing steps](#) for an object [new focus target](#) that is either a [focusable area](#), or an element that is not a [focusable area](#), or a [browsing context](#), are as follows. They can optionally be run with a [fallback target](#) and a string [focus trigger](#).

1. If [new focus target](#) is not a [focusable area](#), then set [new focus target](#) to the result of [getting the focusable area](#) for [new focus target](#), given [focus trigger](#) if it was passed.

2. If [new focus target](#) is null, then:

- If no [fallback target](#) was specified, then return.

2. Otherwise, set [new focus target](#) to the [fallback target](#).

3. If [new focus target](#) is a [browsing context container](#) with non-null [nested browsing context](#), then set [new focus target](#) to the [nested browsing context's active document](#), and redo this step.

4. If [new focus target](#) is a [focusable area](#) and its [DOM anchor](#) is [inert](#), then return.

5. If [new focus target](#) is the [currently focused area of a top-level browsing context](#), then return.

6. Let [old chain](#) be the [focus chain](#) of the [currently focused area of a top-level browsing context](#) in which [new focus target](#) finds itself.

7. Let [new chain](#) be the [focus chain](#) of [new focus target](#).

8. Run the [focus update steps](#) with [old chain](#), [new chain](#), and [new focus target](#) respectively.

User agents must [immediately](#) run the [focusing steps](#) for a [focusable area](#) or [browsing context](#) [candidate](#) whenever the user attempts to move the focus to [candidate](#).

The [unfocusing steps](#) for an object [old focus target](#) that is either a [focusable area](#) or an element that is not a [focusable area](#) are as follows:

1. If [old focus target](#) is [inert](#), then return.

2. If [old focus target](#) is an [area](#) element and one of its shapes is the [currently focused area of a top-level browsing context](#), or if [old focus target](#) is an element with one or more scrollable regions, and one of them is the [currently focused area of a top-level browsing context](#), then let [old focus target](#) be the [currently focused area of a top-level browsing context](#).

3. Let [old chain](#) be the [focus chain](#) of the [currently focused area of a top-level browsing context](#).

4. If [old focus target](#) is not one of the entries in [old chain](#), then return.

5. If [old focus target](#) is a [focusable area](#), then let [new focus target](#) be its [Document's viewport](#).

Otherwise, let [new focus target](#) be null.

6. If [new focus target](#) is not null, then run the [focusing steps](#) for [new focus target](#).

When the [currently focused area of a top-level browsing context](#) is somehow unfocused without another element being explicitly focused in its stead, the user agent must [immediately](#) run the [unfocusing steps](#) for that object.

Note

The [unfocusing steps](#) do not always result in the focus changing, even when applied to the [currently focused area of a top-level browsing context](#). For example, if the [currently focused area of a top-level browsing context](#) is a [viewport](#), then it will usually keep its focus regardless until another [focusable area](#) is explicitly focused with the [focusing steps](#).

Focus fixup rule: When the designated [focused area of the document](#) is removed from that [document](#) in some way (e.g. it stops being a [focusable area](#), it is removed from the DOM, it becomes [expressly inert](#), etc.), designate the [Document's viewport](#) to be the new [focused area of the document](#).

Example

For example, this might happen because an element is removed from its [document](#), or has a [hidden](#) attribute added. It might also happen to an [input](#) element when the element gets [disabled](#).

Example
In a [document](#) whose [focused area](#) is a [button](#) element, removing, disabling, or hiding that button would cause the page's new [focused area](#) to be the [viewport](#) of the [document](#). This would, in turn, be reflected through the [activation API](#) as the [body element](#).

The [focus update steps](#), given an [old chain](#), a [new chain](#), and a [new focus target](#) respectively, are as follows:

1. If the last entry in [old chain](#) and the last entry in [new chain](#) are the same, pop the last entry from [old chain](#) and redo this step.

2. For each entry [entry](#) in [old chain](#), in order, run these substeps:

- If [entry](#) is an [input](#) element, and the [change event applies](#) to the element, and the element does not have a defined [activation behavior](#), and the user has changed the element's [value](#) or its list of [selected files](#) while the control was focused without committing that change (such that it is different to what it was when the control was first focused), then fire an [event](#) named [change](#) at the element, with the [bubbles](#) attribute initialized to true.

- If [entry](#) is an [input](#), let [blur event target](#) be [entry](#).

If [entry](#) is a [Document](#) object, let [blur event target](#) be the [document](#) object's [relevant global object](#).

Otherwise, let [blur event target](#) be null.

3. If [entry](#) is the last entry in [old chain](#), and [entry](#) is an [element](#), and the last entry in [new chain](#) is also an [element](#), then let [related blur target](#) be the last entry in [new chain](#). Otherwise, let [related blur target](#) be null.

4. If [blur event target](#) is not null, fire a [focus event](#) named [blur](#) at [blur event target](#), with [related blur target](#) as the related target.

Note

In some cases, e.g. if [entry](#) is an [area](#) element's shape, a scrollable region, or a [viewport](#), no event is fired.

3. Apply any relevant platform-specific conventions for focusing [new focus target](#). (For example, some platforms select the contents of a text control when that control is focused.)

4. For each entry [entry](#) in [new chain](#), in reverse order, run these substeps:

- If [entry](#) is a [focusable area](#), designate [entry](#) as the [focused area of the document](#).

- If [entry](#) is an [element](#), let [focus event target](#) be [entry](#).

If [entry](#) is a [Document](#) object, let [focus event target](#) be that [Document](#) object's [relevant global object](#).

3. If *entry* is the last entry in *new chain*, and *entry* is an [Element](#), and the last entry in *old chain* is also an [Element](#), then let *related focus target* be the last entry in *old chain*. Otherwise, let *related focus target* be null.

4. If *focus event target* is not null, fire a [focus event](#) named [focus](#) at *focus event target*, with *related focus target* as the related target.

Note
In some cases, e.g. if *entry* is an [area](#) element's shape, a scrollable region, or a [viewport](#), no event is fired.

To fire a [focus event](#) named *e* at an element *t* with a given related target *r*, fire an [event](#) named *e* at *t*, using [FocusEvent](#), with the *relatedTarget* attribute initialized to *r*, the *view* attribute initialized to *t*'s [node document's relevant global object](#), and the *composed* flag set.

When a key event is to be routed in a [top-level browsing context](#), the user agent must run the following steps:

1. Let *target area* be the [currently focused area](#) of the [top-level browsing context](#).
2. If *target area* is a [focusable area](#), let *target node* be *target area*'s [DOM anchor](#). Otherwise, *target area* is a [shape](#); let *target node* be *target area*.
3. If *target node* is a [Document](#) that has a [body element](#), then let *target node* be the [body element](#) of that [document](#).
- Otherwise, if *target node* is a [Document](#) object that has a non-null [document element](#), then let *target node* be that [document element](#).
- If *target node* is not [inert](#), then:

Note
It is possible for the [currently focused area](#) of a [top-level browsing context](#) to be [inert](#), for example if a [modal dialog](#) is shown, and then that [shape](#) element is made [inert](#). It is likely to be the result of a logic error in the application, though.

1. Let *canHandle* be the result of [disabling](#) the key event at *target node*.

2. If *canHandle* is true, then let *target area* handle the key event. This might include [firing a click event](#) at *target node*.

The *has focus* steps, given a [Document](#) object *target*, are as follows:

1. Let *candidate* be *target*'s [top-level browsing context's active document](#).

2. While true:

1. If *candidate* is *target*, then return true.
2. If the [focused area](#) of *candidate* is a [browsing context container](#) with a non-null [nested browsing context](#), then set *candidate* to the [active document](#) of that [browsing context container's nested browsing context](#).
3. Otherwise, return false.

6.5.5 Sequential focus navigation

Each [Document](#) has a [sequential focus navigation order](#), which orders some or all of the [focusable areas](#) in the [Document](#) relative to each other. Its contents and ordering are given by the [flattened tabindex-ordered focus navigation scope](#) of the [Document](#).

Note

Per the rules defining the [flattened tabindex-ordered focus navigation scope](#), the ordering is not necessarily related to the [tree order](#) of the [Document](#).

If a [focusable area](#) is omitted from the [sequential focus navigation order](#) of its [Document](#), then it is unreachable via [sequential focus navigation](#).

There can also be a [sequential focus navigation starting point](#). It is initially unset. The user agent may set it when the user indicates that it should be moved.

Example

For example, the user agent could set it to the position of the user's click if the user clicks on the document contents.

When the user requests that focus move from the [currently focused area](#) of a [top-level browsing context](#) to the next or previous [focusable area](#) (e.g. as the default action of pressing the [tab](#) key), or when the user requests that focus sequentially move to a [top-level browsing context](#) in the first place (e.g. from the browser's location bar), the user agent must use the following algorithm:

1. Let *starting point* be the [currently focused area](#) of a [top-level browsing context](#); if the user requested to move focus sequentially from there, or else the [top-level browsing context](#) itself, if the user instead requested to move focus from outside the [top-level browsing context](#).

2. If there is a [sequential focus navigation starting point](#) defined and it is inside *starting point*, then let *starting point* be the [sequential focus navigation starting point](#) instead.

3. Let *direction* be [forward](#) if the user requested the [next control](#), and [backward](#) if the user requested the [previous control](#).

Note
Typically, pressing [tab](#) requests the [next control](#), and pressing [shift+tab](#) requests the [previous control](#).

4. *Loop*: Let *selection mechanism* be [sequential](#) if the *starting point* is a [browsing context](#) or if *starting point* is in its [Document's sequential focus navigation order](#).

Otherwise, *starting point* is not in its [Document's sequential focus navigation order](#); let *selection mechanism* be [DOM](#).

5. Let *candidate* be the result of running the [sequential navigation search algorithm](#) with *starting point*, *direction*, and *selection mechanism* as the arguments.

6. If *candidate* is not null, then run the [focusing steps](#) for *candidate* and return.

7. Otherwise, unset the [sequential focus navigation starting point](#).

8. If *starting point* is the [top-level browsing context](#) or a [focusable area](#) in the [top-level browsing context](#), the user agent should transfer focus to its own controls appropriately (if any), honouring *direction*, and then return.

Example

For example, if *direction* is [backward](#), then the last [sequentially focusable](#) control before the browser's rendering area would be the control to focus.

If the user agent has [no sequentially focusable](#) controls — a kiosk-mode browser, for instance — then the user agent may instead restart these steps with the *starting point* being the [top-level browsing context](#) itself.

9. Otherwise, *starting point* is a [focusable area](#) in a [child browsing context](#). Set *starting point* to that [child browsing context's container](#) and return to the step labeled *loop*.

The [sequential navigation search algorithm](#) consists of the following steps. This algorithm takes three arguments: *starting point*, *direction*, and *selection mechanism*.

1. Pick the appropriate cell from the following table, and follow the instructions in that cell.

The appropriate cell is the one that is from the column whose header describes *direction* and from the first row whose header describes *starting point* and *selection mechanism*.

direction is forward

starting point is a browsing context Let *candidate* be the first [puttable sequentially focusable area](#) in *starting point's active document*, if any; or else null
selection mechanism is DOM Let *candidate* be the first [puttable sequentially focusable area](#) in the [home document](#) following *starting point*, if any; or else null
selection mechanism is sequential Let *candidate* be the first [puttable sequentially focusable area](#) in the [home sequential focus navigation order](#) following *starting point*, if any; or else null Let *candidate* be the last [puttable sequentially focusable area](#) in the [home sequential focus navigation order](#) preceding *starting point*, if any; or else null

direction is backward

Let *candidate* be the last [puttable sequentially focusable area](#) in *starting point's active document*, if any; or else null
Let *candidate* be the last [puttable sequentially focusable area](#) in the [home document](#) preceding *starting point*, if any; or else null
Let *candidate* be the last [puttable sequentially focusable area](#) in the [home sequential focus navigation order](#) preceding *starting point*, if any; or else null

A suitable [sequentially focusable area](#) is a [focusable area](#) whose [DOM anchor](#) is not [inert](#) and is [sequentially focusable](#).

The [home document](#) is the [document](#) to which *starting point* belongs.

The [home sequential focus navigation order](#) is the [home document's sequential focus navigation order](#), but is only used when the *starting point* is in [sequential focus navigation order](#) (when it's not, *selection mechanism* will be [DOM](#)).

2. If *candidate* is a [browsing context container](#) with a non-null [nested browsing context](#), then let *new candidate* be the result of running the [sequential navigation search algorithm](#) with *candidate's nested browsing context* as the first argument, *direction* as the second, and *sequential* as the third.

If *new candidate* is null, then let *starting point* be *candidate*, and return to the top of this algorithm. Otherwise, let *candidate* be *new candidate*.

3. Return *candidate*.

6.5.6 Focus management APIs

```
IDictionary<FocusOptions> {
  boolean preventScroll = false;
}
```

For web developers (non-normative)

[documentOrShadowRoot.activeElement](#)

Returns the deepest element in the document through which or to which key events are being routed. This is, roughly speaking, the focused element in the document.

For the purposes of this API, when a [child browsing context](#) is focused, its [container is focused](#) in the [parent browsing context](#). For example, if the user moves the focus to a text control in an [iframe](#), the [iframe](#) is the element returned by the [getBoundingClientRect](#) API in the [iframe's node document](#).

Similarly, when the focused element is in a different [node tree](#) than [documentOrShadowRoot](#), the element returned will be the [host](#) that's located in the same [node tree](#) as [documentOrShadowRoot](#) if [documentOrShadowRoot](#) is a [shadow-including inclusive ancestor](#) of the focused element, and null if not.

[document.hasFocus\(\)](#)

Returns true if key events are being routed through or to the document; otherwise, returns false. Roughly speaking, this corresponds to the document, or a document nested inside this one, being focused.

[window.focus\(\)](#)

Moves the focus to the window's [browsing context](#), if any.

[element.focus\({ preventScroll: true }\)](#)

Moves the focus to the element.

If the element is a [browsing context container](#), moves the focus to its [nested browsing context](#) instead.

By default, this method also scrolls the element into view. Providing the [preventScroll](#) option and setting it to true prevents this behavior.

[element.blur\(\)](#)

Moves the focus to the [viewport](#). Use of this method is discouraged; if you want to focus the [viewport](#), call the [focus\(\)](#) method on the [document's document element](#).

Do not use this method to hide the focus ring if you find the focus ring unsightly. Instead, use a CSS rule to override the [outline](#) property, and provide a different way to show what element is focused. Be aware that if an alternative focusing style isn't made available, the page will be significantly less usable for people who primarily navigate pages using a keyboard, or those with reduced vision who use focus outlines to help them navigate the page.

Example

For example, to hide the outline from links and instead use a yellow background to indicate focus, you could use:

```
css:link:focus, visited:focus { outline: none; background: yellow; color: black; }
```

Edge (Legacy)12+Internet Explorer9+

Firefox Android5+Safari iOS1+Chrome Android18+WebView Android4.4+Samsung Internet1.0+Opera Android10.1+

The [blur\(\)](#) method, when invoked, should run the [unfocusing steps](#) for the element on which the method was called. User agents may selectively or uniformly ignore calls to this method for usability reasons.**Example**For example, if the [blur\(\)](#) method is unwise being used to remove the focus ring for aesthetics reasons, the page would become unusable by keyboard users. Ignoring calls to this method would thus allow keyboard users to interact with the page.**6.5.7 The [autofocus](#) attribute****Support:** autofocusChrome for Android 8.1+Chrome 5+iOS Safari NoneSafari 5+Firefox 4+Samsung Internet 4+Edge 12+UC Browser for Android NoneIE 10+Opera 9.5+Opera Mini NoneFirefox for Android 68+Source: caniuse.comThe [autofocus](#) content attribute allows the author to indicate that an element is to be focused as soon as the page is loaded or as soon as the [dialog](#) within which it finds itself is shown, allowing the user to just start typing without having to manually focus the main element.The [autofocus](#) attribute is a [boolean attribute](#).An element's [nearest ancestor autofocus scoping root element](#) is the element itself if the element is a [dialog](#) element, or else is the element's nearest ancestor [dialog](#) element, if any, or else is the element's last [inclusive ancestor](#) element.There must not be two elements with the same [nearest ancestor autofocus scoping root element](#) that both have the [autofocus](#) attribute specified.Each [document](#) has an [autofocus candidates](#) [list](#), initially empty.Each [document](#) has an [autofocus processed flag](#) boolean, initially false.When an element with the [autofocus](#) attribute specified is [inserted into a document](#), run the following steps:

1. If the user has indicated (for example, by starting to type in a form control) that they do not wish focus to be changed, then optionally return.
2. Let *target* be the element's [node document](#).
3. If *target*'s [browsing context](#) is null, then return.
4. If *target*'s [active sandboxing flag set](#) has the [sandbox automatic features browsing context flag](#), then return.
5. Let *topDocument* be the [active document](#) of *target*'s [browsing context](#)'s [top-level browsing context](#).
6. If *target*'s [origin](#) is not the [same](#) as the [origin](#) of *topDocument*, then return.
7. If *topDocument*'s [autofocus processed flag](#) is false, then [remove](#) the element from *topDocument*'s [autofocus candidates](#), and [append](#) the element to *topDocument*'s [autofocus candidates](#).

NoteWe do not check if an element is a [focussable area](#) before storing it in the [autofocus candidates](#) list, because even if it is not a focussable area when it is inserted, it could become one by the time [flush autofocus candidates](#) sees it.To [flush autofocus candidates](#) for a document *topDocument*, run these steps:

1. If *topDocument*'s [autofocus processed flag](#) is true, then return.
2. Let *candidates* be *topDocument*'s [autofocus candidates](#).
3. If *candidates* is [empty](#), then return.
4. If *topDocument*'s [focused area](#) is not *topDocument* itself, or *topDocument*'s [URL](#)'s [fragment](#) is not empty, then:
 1. [Empty](#) *candidates*.
 2. Set *topDocument*'s [autofocus processed flag](#) to true.
 3. Return.
5. While *candidates* is not [empty](#):

1. Let `element` be `candidates[0]`.
2. Let `doc` be `element's node document`.
3. If `doc` is not `fully active`, then `remove element` from `candidates`, and `continue`.
4. If `doc's browsing context's top-level browsing context` is not same as `topDocument's browsing context`, then `remove element` from `candidates`, and `continue`.
5. If `doc's script-blocking style sheet counter` is greater than 0, then return.

Note
In this case, `element` is the currently-best candidate, but `doc` is not ready for autofocusing. We'll try again next time `flush autofocus candidates` is called.

6. `Remove element` from `candidates`.

7. Let `inclusiveAncestorDocuments` be a `list` consisting of `doc`, plus the `active documents` of each of `doc's browsing context's ancestor browsing contexts`.

8. If `URL's fragment` of any `document` in `inclusiveAncestorDocuments` is not empty, then `continue`.

9. Let `target` be `element`.

10. If `target` is not a `focuseable area`, then set `target` to the result of `getting the focuseable area` for `target`.

Note
`Autofocus candidates` can contain elements which are not `focuseable areas`. In addition to the special cases handled in the `get the focuseable area` algorithm, this can happen because a non-`focuseable area` element with an `autofocus` attribute was `inserted into a document` and it never became focuseable, or because the element was focuseable but its status changed while it was stored in `autofocus candidates`.

11. If `target` is not null, then:

1. `Empty` `candidates`.

2. Set `topDocument's autofocus processed flag` to true.

3. Run the `focusing steps` for `target`.

Note

This handles the automatic focusing during document load. The `show()` and `showModal()` methods of `dialog` elements also processes the `autofocus` attribute.

Note

Focusing the element does not imply that the user agent has to focus the browser window if it has lost focus.

OMON

HTML SelectElement/autofocus

Support in all current engines.

FirefoxYes SafariYes ChromeYes

OperaYes EdgeYes

Edge (Legacy)12+ Internet Explorer10+

Firefox Android4.4+ Safari iOS8+ Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidNo

The `autofocus` IDL attribute must `reflect` the `content` attribute of the same name.

Example

In the following snippet, the text control would be focused when the document was loaded.

```
<input maxlength="256" name="q" value="" autofocus>
<input type="submit" value="Search">
```

Example

The `autofocus` attribute applies to all elements, not just to form controls. This allows examples such as the following:

```
<div contenteditable autofocus>Edit <strong>me!</strong></div>
```

6.6 Assigning keyboard shortcuts

6.6.1 Introduction

This section is non-normative.

Each element that can be activated or focused can be assigned a single key combination to activate it, using the `accesskey` attribute.

The exact shortcut is determined by the user agent, based on information about the user's keyboard, what keyboard shortcuts already exist on the platform, and what other shortcuts have been specified on the page, using the information provided in the `accesskey` attribute as a guide.

In order to ensure that a relevant keyboard shortcut is available on a wide variety of input devices, the author can provide a number of alternatives in the `accesskey` attribute.

Each alternative consists of a single character, such as a letter or digit.

User agents can provide users with a list of the keyboard shortcuts, but authors are encouraged to do so also. The `accessKeyLabel` IDL attribute returns a string representing the actual key combination assigned by the user agent.

Example

In this example, an author has provided a button that can be invoked using a shortcut key. To support full keyboards, the author has provided "C" as a possible key. To support devices equipped only with numeric keypads, the author has provided "1" as another possibly key.

```
<input type="button" value="Collect" onclick="collect()">
  <span>accesskey="C 1"></span>
```

Example

To tell the user what the shortcut key is, the author has this script here opted to explicitly add the key combination to the button's label:

```
function addShortcutKeyLabel(button) {
  if (button.accessKeyLabel != '') {
    button.value += ' (' + button.accessKeyLabel + ')';
  }
  addShortcutKeyLabel(document.getElementById(''+button.id+''));
```

Browsers on different platforms will show different labels, even for the same key combination, based on the convention prevalent on that platform. For example, if the key combination is the Control key, the Shift key, and the letter C, a Windows browser might display "ctrl+shift+c", whereas a Mac browser might display "⌘+c", while an Emacs browser might just display "c-c". Similarly, if the key combination is the Alt key and the Escape key, Windows might use "Alt+Esc", Mac might use "c-esc", and an Emacs browser might use "M-esc" or "Esc Esc".

In general, therefore, it is unwise to attempt to parse the value returned from the `accessKeyLabel` IDL attribute.

6.6.2 The `accesskey` attribute

OMON

Global_attributes/accesskey

Support in all current engines.

FirefoxYes SafariYes ChromeYes

OperaYes EdgeYes

Edge (Legacy)12+ Internet ExplorerYes

Firefox AndroidYes Safari iOS8+ Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidYes

All `HTML elements` may have the `accesskey` content attribute set. The `accesskey` attribute's value is used by the user agent as a guide for creating a keyboard shortcut that activates or focuses the element.

If specified, the value must be an `ordered set of unique space-separated tokens` that are `case-sensitive`, each of which must be exactly one code point in length.

Example

In the following example, a variety of links are given with access keys so that keyboard users familiar with the site can more quickly navigate to the relevant pages:

```
<a title="Consortium Activities" accesskey="A" href="#Consortium/activities#Activities">Activities</a>
<a title="Technical Reports" accesskey="T" href="#TR/#Technical Reports">Technical Reports</a>
<a title="Alphabetical Site Index" accesskey="S" href="#Index/#sites">Site Index</a>
<a title="About This Site" accesskey="B" href="#Consortium/#About Consortium">About Consortium</a>
<a title="Contact Consortium" accesskey="C" href="#Consortium/contact#Contact">Contact</a>
</p>
</div>
```

Example

In the following example, the search field is given two possible access keys, "s" and "0" (in that order). A user agent on a device with a full keyboard might pick `Ctrl+Alt+S` as the shortcut key, while a user agent on a small device with just a numeric keypad might pick just the plain unadorned key `s`:

```
<form action="#" method="get">
  <label>Search <input type="search" name="q" accesskey="s 0"/></label>
  <input type="submit">
</form>
```

Example

In the following example, a button has possible access keys described. A script then tries to update the button's label to advertise the key combination the user agent selected.

```
<input type="submit" accesskey="N @ 1" value="Compose">
<script>
function labelButton(button) {
  if (button.accessKeyLabel != '') {
    button.value += ' (' + button.accessKeyLabel + ')';
  }
  var inputs = document.getElementsByTagName('input');
  for (var i = 0; i < inputs.length; i++) {
    if (inputs[i].type == "submit") {
      labelButton(inputs[i]);
    }
  }
}</script>
```

On one user agent, the button's label might become "`Compose (⌘S)`". On another, it might become "`Compose (Alt+↑+1)`". If the user agent doesn't assign a key, it will be just "`compose`". The exact string depends on what the `assigned access key` is, and on how the user agent represents that key combination.

6.6.3 Processing model

An element's `assigned access key` is a key combination derived from the element's `accesskey` content attribute. Initially, an element must not have an `assigned access key`.

Whenever an element's `accesskey` attribute is set, changed, or removed, the user agent must update the element's `assigned access key` by running the following steps:

Firefox1+Safari1.2+Chrome1+

Opera9+Edge79+

Edge (Legacy)12+Internet Explorer4+

Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android10.1+

Documents have a `designMode`, which can be either enabled or disabled.**For web developers (non-normative)**`document.designMode [= value]`

Returns "on" if the document is editable, and "off" if it isn't.

Can be set, to change the document's current state. This focuses the document and resets the selection in that document.

The `designMode` IDL attribute on the `Document` object takes two values, "on" and "off". On setting, the new value must be compared in an [ASCII case-insensitive](#) manner to these two values; if it matches the "on" value, then `designMode` must be enabled, and if it matches the "off" value, then `designMode` must be disabled. Other values must be ignored.On getting, if `designMode` is enabled, the IDL attribute must return the value "on"; otherwise it is disabled, and the attribute must return the value "off".The last state set must persist until the document is destroyed or the state is changed. Initially, documents must have their `designMode` disabled.When the `designMode` changes from being disabled to being enabled, the user agent must [immediately](#) reset the document's `activeRange`'s start and end boundary points to be at the start of the `Document`, and then run the [focusing steps](#) for the `document` element of the `Document`, if non-null.**6.7.3 Best practices for in-page editors**Authors are encouraged to set the `white-space` property on `editingHost` and on markup that was originally created through these editing mechanisms to the value 'pre-wrap'. Default HTML whitespace handling is not well suited to WYSIWYG editing, and line wrapping will not work correctly in some corner cases if `white-space` is left at its default value.**Example**As an example of problems that occur if the default 'normal' value is used instead, consider the case of the user typing "yellow_ball", with two spaces (here represented by "_") between the words. With the editing rules in place for the default value of `white-space` ('normal'), the resulting markup will either consist of "yellow ball" or "yellow nbsp;ball"; i.e., there will be a non-breaking space between the two words in addition to the regular space. This is necessary because the 'normal' value for `white-space` requires adjacent regular spaces to be collapsed together.

In the former case, "yellow" might wrap to the next line ("u" being used here to represent a non-breaking space) even though "yellow" alone might fit at the end of the line; in the latter case, "ball", if wrapped to the start of the line, would have visible indentation from the non-breaking space.

When `white-space` is set to 'pre-wrap', however, the editing rules will instead simply put two regular spaces between the words, and should the two words be split at the end of a line, the spaces would be neatly removed from the rendering.**6.7.4 Editing APIs**The definition of the terms `activeRange`, `editingHost`, `editingHost`, and `editable`, the user interface requirements of elements that are `editingHost` or `editable`, the `execCommand()`, `queryCommandEnabled()`, `queryCommandIndeterminate()`, `queryCommandState()`, `queryCommandSupported()`, and `queryCommandValue()` methods, text selections, and the `deleteTheSelection()` algorithm are defined in `execCommand()` [EXECCOMMAND]**6.7.5 Spelling and grammar checking****Support:** spellcheck-attribute Chrome for Android (limited) 81+Chrome 9+iOS Safari (limited) 3.2+Safari 5.1+Firefox 2+Samsung Internet (limited) 4+Edge 12+UC Browser for Android (limited) 12.12+IE 10+Opera 10.5+Opera Mini (limited) all+Firefox for Android (limited) 68+Source: [caniuse.com](https://caniuse.com/#search=spellcheck)**AMDN****Global_attributes/spellcheck**

Support in all current engines.

FirefoxYesSafariYesChrome9+

OperaYesEdge79+

Edge (Legacy)12+Internet Explorer11

Firefox Android57+Safari iOS9.3+Chrome Android47+WebView Android47+Samsung Internet5.0+Opera Android37+

User agents can support the checking of spelling and grammar of editable text, either in form controls (such as the value of `textArea` elements), or in elements in an `editingHost` (e.g. using `contentEditable`).For each element, user agents must establish a `default behavior`, either through defaults or through preferences expressed by the user. There are three possible default behaviors for each element:**true-by-default**The element will be checked for spelling and grammar if its contents are editable and spellchecking is not explicitly disabled through the `spellcheck` attribute.**false-by-default**The element will never be checked for spelling and grammar unless spellchecking is explicitly enabled through the `spellcheck` attribute.**inherit-by-default**

The element's default behavior is the same as its parent element's. Elements that have no parent element cannot have this as their default behavior.

The `spellcheck` attribute is an [enumerated attribute](#) whose keywords are the empty string, `true` and `false`. The empty string and the `true` keyword map to the `true` state. The `false` keyword maps to the `false` state. In addition, there is a third state, the `default` state, which is the [missing_value_default](#) and the [invalid_value_default](#).**Note**
The `true` state indicates that the element is to have its spelling and grammar checked. The `default` state indicates that the element is to act according to a default behavior, possibly based on the parent element's own `spellcheck` state, as defined below. The `false` state indicates that the element is not to be checked.**For web developers (non-normative)**`element.spellcheck [= value]`

Returns true if the element is to have its spelling and grammar checked; otherwise, returns false.

Can be set, to override the default and set the `spellcheck` content attribute.The `spellcheck` IDL attribute, on getting, must return true if the element's `spellcheck` content attribute is in the `true` state, or if the element's `spellcheck` content attribute is in the `default` state and the element's `default behavior` is `true-by-default`, or if the element's `spellcheck` content attribute is in the `default` state and the element's `default behavior` is `inherit-by-default` and the element's parent element's `spellcheck` IDL attribute would return true; otherwise, if none of those conditions applies, then the attribute must instead return false.**Note**The `spellcheck` IDL attribute is not affected by user preferences that override the `spellcheck` content attribute, and therefore might not reflect the actual spellchecking state.On setting, if the new value is true, then the element's `spellcheck` content attribute must be set to the literal string "`true`", otherwise it must be set to the literal string "`false`".

User agents must only consider the following pieces of text as checkable for the purposes of this feature:

- The value of `input` elements whose `type` attributes are in the `Text`, `Search`, `URL`, or `E-mail` states and that are `mutable` (i.e. that do not have the `readonly` attribute specified and that are not `disabled`).
- The value of `textArea` elements that do not have a `readonly` attribute and that are not `disabled`.
- Text in `textArea` nodes that are children of `editingHost` or `editable` elements.
- Text in attributes of `editingHost` elements.

For text that is part of a `text` node, the element with which the text is associated is the element that is the immediate parent of the first character of the word, sentence, or other piece of text. For text in attributes, it is the attribute's element. For the values of `input` and `textArea` elements, it is the element itself.

To determine if a word, sentence, or other piece of text in an applicable element (as defined above) is to have spelling- and grammar-checking enabled, the UA must use the following algorithm:

- If the user has disabled the checking for this text, then the checking is disabled.
- Otherwise, if the user has enabled the checking for this text to always be enabled, then the checking is enabled.
- Otherwise, if the element with which the text is associated has a `spellcheck` content attribute, then, if that attribute is in the `true` state, then checking is enabled; otherwise, if that attribute is in the `false` state, then checking is disabled.
- Otherwise, if there is an ancestor element with a `spellcheck` content attribute that is not in the `default` state, then, if the nearest such ancestor's `spellcheck` content attribute is in the `true` state, then checking is enabled; otherwise, checking is disabled.
- Otherwise, if the element's `default behavior` is `true-by-default`, then checking is enabled.
- Otherwise, if the element's `default behavior` is `false-by-default`, then checking is disabled.
- Otherwise, if the element's parent element has its checking enabled, then checking is enabled.
- Otherwise, checking is disabled.

If the checking is enabled for a word/sentence/text, the user agent should indicate spelling and grammar errors in that text. User agents should take into account the other semantics given in the document when suggesting spelling and grammar corrections. User agents may use the language of the element to determine what spelling and grammar rules to use, or may use the user's preferred language settings. UAs should use `input` element attributes such as `pattern` to ensure that the resulting value is valid, where possible.

If checking is disabled, the user agent should not indicate spelling or grammar errors for that text.

Example

The element with ID "a" in the following example would be the one used to determine if the word "Hello" is checked for spelling errors. In this example, it would not be.

<div contentEditable="true">Hello
</div>

The element with ID "b" in the following example would have checking enabled (the leading space character in the attribute's value on the `input` element causes the attribute to be ignored, so the ancestor's value is used instead, regardless of the default).

<p spellcheck="true"><label htmlFor="b"><input spellcheck=" false" id="b"></label></p>

Note

This specification does not define the user interface for spelling and grammar checkers. A user agent could offer on-demand checking, could perform continuous checking while the checking is enabled, or could use other interfaces.

6.7.6 Autocapitalization**AMDN****Global_attributes/autocapitalize**

Support in one engine only.

FirefoxNoSafari?Chrome No

Opera?Edge No

Edge (Legacy)?Internet Explorer?

Firefox AndroidNoSafari?iOS?Chrome Android66+WebView Android66+Samsung Internet?Opera Android?

Some methods of entering text, for example virtual keyboards on mobile devices, also assist users by automatically capitalizing the first letter of sentences (when composing text in a language with this convention). A virtual keyboard that implements autocapitalization might automatically switch to showing uppercase letters (but allow the user to toggle it back to lowercase) when a letter that should be autocapitalized is about to be typed. Other types of input, for example voice input, may perform autocapitalization in a way that does not give users an option to intervene first. The `autocapitalize` attribute allows authors to control such behavior.The `autocapitalize` attribute, as typically implemented, does not affect behavior when typing on a physical keyboard. (For this reason, as well as the ability for users to override the autocapitalization behavior in some cases or edit the text after initial input, the attribute must not be relied on for any sort of input validation.)The `autocapitalize` attribute can be used on an `editingHost` to control autocapitalization behavior for the hosted editable region, on an `input` or `textArea` element to control the behavior for inputting text into that element, or on a `form` element to control the default behavior for all `autocapitalize-inheriting` elements associated with the `form` element.The `autocapitalize` attribute never causes autocapitalization to be enabled for `input` elements whose `type` attribute is in one of the `URL`, `E-mail`, or `Password` states. (This behavior is included in the `usedAutocapitalizationHint` algorithm below.)The autocapitalization processing model is based on selecting among five `autocapitalization hints`, defined as follows:

The user agent and input method should use make their own determination of whether or not to enable autocapitalization.

none

No autocapitalization should be applied (all letters should default to lowercase).

sentences

The first letter of each sentence should default to a capital letter; all other letters should default to lowercase.

words

The first letter of each word should default to a capital letter; all other letters should default to lowercase.

characters

All letters should default to uppercase.

The `autocapitalize` attribute is an [enumerated attribute](#) whose states are the possible [autocapitalization hints](#). The [autocapitalization hint](#) specified by the attribute's state combines with other considerations to form the [used autocapitalization hint](#), which informs the behavior of the user agent. The keywords for this attribute and their state mappings are as follows:

Keyword State

`off` `none`

`on` `sentences`

`words` `words`

`characters` `characters`

The [invalid value default](#) is the `sentences` state. The [missing value default](#) is the `default` state.

For web developers (non-normative)

`element.autocapitalize = value`

Return the current autocapitalization state for the element, or an empty string if it hasn't been set. Note that for `input` and `textarea` elements that inherit their state from a `form` element, this will return the autocapitalization state of the `form` element, but for an element in an editable region, this will not return the autocapitalization state of the editing host (unless this element is, in fact, the [editing host](#)).

Can be set, to set the `autocapitalize` content attribute (and thereby change the autocapitalization behavior for the element).

To compute the [own autocapitalization hint](#) of an element `element`, run the following steps:

- If the `autocapitalize` content attribute is present on `element`, and its value is not the empty string, return the state of the attribute.
- If `element` is an [autocapitalize-inheriting element](#) and has a non-null `form owner`, return the [own autocapitalization hint](#) of `element's form owner`.
- Return `default`.

The `autocapitalize` IDL attribute, on getting, must return the string value corresponding to [own autocapitalization hint](#) of the element, with the exception that the `default` state maps to the empty string. On setting, it must set the `autocapitalize` content attribute to the given new value.

User agents that support customizable autocapitalization behavior for a text input method and wish to allow web developers to control this functionality should, during text input into an element, compute the [used autocapitalization hint](#) for the element. This will be an [autocapitalization hint](#) that describes the recommended autocapitalization behavior for text input into the element.

User agents or input methods may choose to ignore or override the [used autocapitalization hint](#) in certain circumstances.

The [used autocapitalization hint](#) for an element `element` is computed using the following algorithm:

- If `element` is an `input` element whose `type` attribute is in one of the [URL](#), [E-mail](#), or [Password](#) states, then return `default`.
- If `element` is an `input` element or a `textarea` element, then return `element's own autocapitalization hint`.
- If `element` is an [editing host](#) or an [editable element](#), then return the [own autocapitalization hint](#) of the [editing host](#) of `element`.
- Assert: this step is never reached, since text input only occurs in elements that meet one of the above criteria.

6.7.7 Input modalities: the `inputmode` attribute

Support: input-inputmode Chrome for Android 81+Chrome 66+iOS Safari 12.2+Safari NoneFirefox NoneSamsung Internet 9.2+Edge 79+UC Browser for Android NoneIE NoneOpera 53+Opera Mini NoneFirefox for Android None

Source: [caniuse.com](https://caniuse.com/#search=inputmode)

MDN

[Global attributes/inputmode](#)

FirefoxNoSafariNoChrome6+

Opera53+Edge79+

Edge (Legacy)NoInternet ExplorerNo

Firefox AndroidNoSafari iOS12.2+Chrome Android66+WebView Android66+Samsung Internet9.0+Opera Android47+

User agents can support the `inputmode` attribute on form controls (such as the value of `textarea` elements), or in elements in an [editing host](#) (e.g., using `contenteditable`).

The `inputmode` content attribute is an [enumerated attribute](#) that specifies what kind of input mechanism would be most helpful for users entering content.

Keyword

Description

<code>none</code>	The user agent should not display a virtual keyboard. This keyword is useful for content that renders its own keyboard control.
<code>text</code>	The user agent should display a virtual keyboard capable of text input in the user's locale.
<code>tel</code>	The user agent should display a virtual keyboard capable of telephone number input. This should include digits for the digits 0 to 9, the "+" character, and the "*" character. In some locales, this can also include alphabetic mnemonic labels (e.g., in the US, the key labeled "2" is historically also labeled with the letters A, B, and C).
<code>uri</code>	The user agent should display a virtual keyboard capable of text input in the user's locale, with keys for aiding in the input of URLs , such as that for the "/" and ":" characters and for quick input of strings commonly found in domain names such as "www." or ".com".
<code>email</code>	The user agent should display a virtual keyboard capable of text input in the user's locale, with keys for aiding in the input of e-mail addresses, such as that for the "@" character and the "." character.
<code>numeric</code>	The user agent should display a virtual keyboard capable of numeric input. Numeric keys and the format separator for the locale should be shown.
<code>decimal</code>	The user agent should display a virtual keyboard capable of fractional numeric input. Numeric keys and the format separator for the locale should be shown.
<code>search</code>	The user agent should display a virtual keyboard optimized for search.

The `inputMode` IDL attribute must reflect the `inputmode` content attribute, [limited to only known values](#).

When `inputmode` is unspecified (or is in a state not supported by the user agent), the user agent should determine the default virtual keyboard to be shown. Contextual information such as the `input type` or `pattern` attributes should be used to determine which type of virtual keyboard should be presented to the user.

6.7.8 Input modalities: the `enterkeyhint` attribute

User agents can support the `enterkeyhint` attribute on form controls (such as the value of `textarea` elements), or in elements in an [editing host](#) (e.g., using `contenteditable`).

The `enterkeyhint` content attribute is an [enumerated attribute](#) that specifies what action label (or icon) to present for the enter key on virtual keyboards. This allows authors to customize the presentation of the enter key in order to make it more helpful for users.

Keyword

Description

<code>enter</code>	The user agent should present a cue for the operation 'enter', typically inserting a new line.
<code>done</code>	The user agent should present a cue for the operation 'done', typically meaning there is nothing more to input and the IME will be closed.
<code>go</code>	The user agent should present a cue for the operation 'go', typically meaning to take the user to the target of the text they typed.
<code>next</code>	The user agent should present a cue for the operation 'next', typically taking the user to the next field that will accept text.
<code>previous</code>	The user agent should present a cue for the operation 'previous', typically taking the user to the previous field that will accept text.
<code>search</code>	The user agent should present a cue for the operation 'search', typically taking the user to the results of searching for the text they typed.
<code>send</code>	The user agent should present a cue for the operation 'send', typically delivering the text to its target.

The `enterKeyHint` IDL attribute must reflect the `enterkeyhint` content attribute, [limited to only known values](#).

When `enterkeyhint` is unspecified (or is in a state not supported by the user agent), the user agent should determine the default action label (or icon) to present. Contextual information such as the `input mode`, `type`, or `pattern` attributes should be used to determine which action label (or icon) to present on the virtual keyboard.

6.8 Drag and drop

Support: dragdropChrome for Android 81+Chrome 4+iOS Safari NoneSafari 3.1+Firefox 3.5+Samsung Internet NoneEdge 18+UC Browser for Android NoneIE (limited) 5.5+Opera 12+Opera Mini NoneFirefox for Android None

Source: [caniuse.com](https://caniuse.com/#search=dragdrop)

MDN

[HTML_Drag_and_Drop_API](#)

This section defines an event-based drag-and-drop mechanism.

This specification does not define exactly what a *drag-and-drop operation* actually is.

On a visual medium with a pointing device, a drag operation could be the default action of a `mousedown` event that is followed by a series of `mousemove` events, and the drop could be triggered by the mouse being released.

When using an input modality other than a pointing device, users would probably have to explicitly indicate their intention to perform a drag-and-drop operation, stating what they wish to drag and where they wish to drop it, respectively.

However it is implemented, drag-and-drop operations must have a starting point (e.g. where the mouse was clicked, or the start of the selection or element that was selected for the drag), may have any number of intermediate steps (elements that the mouse moves over during a drag, or elements that the user picks as possible drop points as they cycle through possibilities), and must either have an end point (the element above which the mouse button was released, or the element that was finally selected), or be canceled. The end point must be the last element selected as a possible drop point before the drop occurs (so if the operation is not canceled, there must be at least one element in the middle step).

6.8.1 Introduction

This section is non-normative.

To make an element draggable, give the element a `draggable` attribute, and set an event listener for `dragstart` that stores the data being dragged.

The event handler typically needs to check that it's not a text selection that is being dragged, and then needs to store data into the `dataTransfer` object and set the allowed effects (copy, move, link, or some combination).

For example:

```
<p>What fruits do you like?</p>
<ol ondragstart="dragStartHandler(event)">
  <li draggable="true" data-value="fruit-apple">Apples</li>
  <li draggable="true" data-value="fruit-orange">Oranges</li>
  <li draggable="true" data-value="fruit-peach">Peaches</li>
</ol>

var internalIDNType = 'text/x-example'; // set this to something specific to your site
function dragStartHandler(event) {
  if (event.dataTransfer) {
    // use the element's data-value** attribute as the value to be moving;
    event.dataTransfer.setData(internalIDNType, event.target.dataset.value);
  }
}
```

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

```
        event.preventDefault(); // don't allow selection to be dragged
    }
</script>
```

To accept a drop, the drop target has to listen to the following events:

1. The `dragstart` event handler reports whether or not the drop target is potentially willing to accept the drop, by canceling the event.
2. The `dragover` event handler specifies what feedback will be shown to the user, by setting the `dropEffect` attribute of the `DataTransfer` associated with the event. This event also needs to be canceled.
3. The `drop` event handler has a final chance to accept or reject the drop. If the drop is accepted, the event handler must perform the drop operation on the target. This event needs to be canceled, so that the `dropEffect` attribute's value can be used by the source. Otherwise, the drop operation is rejected.

For example:

```
<p>Drop your favorite fruits below!</p>
<code><dragstart="dragStartHandler(event)" ondragover="dragOverHandler(event)" ondrop="dropHandler(event)"></code>
<script>
var internalDNDType = 'text/*example'; // set this to something specific to your site
// Set up dragginHandler
var items = event.dataTransfer.items;
for (var i = 0; i < items.length; ++i) {
    if (item.kind == 'string' && item.type == internalDNDType) {
        event.preventDefault();
        return;
    }
}
// Set up dropHandler
function dropHandler(event) {
    var li = document.createElement('li');
    var data = event.dataTransfer.getData(internalDNDType);
    if (data == 'apple') {
        li.textContent = 'Apples';
    } else if (data == 'fruit-orange') {
        li.textContent = 'Orange';
    } else if (data == 'fruit-peach') {
        li.textContent = 'Peach';
    } else {
        li.textContent = 'Unknown Fruit';
    }
    event.target.appendChild(li);
}</script>
```

To remove the original element (the one that was dragged) from the display, the `dragging` event can be used.

For our example here, that means updating the original markup to handle that event:

```
<p>What fruits do you like?</p>
<code><dragstart="dragStartHandler(event)" ondragend="dragEndHandler(event)"></code>
<script>
function dragStartHandler(event) {
    // ...
}
function dragEndHandler(event) {
    if (event.dataTransfer.dropEffect == 'move') {
        // remove the dragged element
        event.target.parentNode.removeChild(event.target);
    }
}</script>
```

6.8.2 The drag data store

The data that underlies a drag-and-drop operation, known as the `drag data store`, consists of the following information:

- A `drag data store item list`, which is a list of items representing the dragged data, each consisting of the following information:

The drag data item kind

The kind of data:

`Text`

Text.

`File`

Binary data with a file name.

The drag data item type string

A Unicode string giving the type or format of the data, generally given by a [MIME-type](#). Some values that are not [MIME-types](#) are special-cased for legacy reasons. The API does not enforce the use of [MIME-types](#); other values can be used as well. In all cases, however, the values are all [converted to ASCII lowercase](#) by the API.

There is a limit of one `text item` per [item type string](#).

The actual data:

A Unicode or binary string, in some cases with a file name (itself a Unicode string), as per [the drag data item kind](#).

The `drag data store item list` is ordered in the order that the items were added to the list; most recently added last.

- The following information, used to generate the UI feedback during the drag:

◦ User-agent-defined default feedback information, known as the `drag data store default feedback`.

◦ Optionally, a bitmap image and the coordinate of a point within that image, known as the `drag data store bitmap` and `drag data store hot spot coordinate`.

- A `drag data store mode`, which is one of the following:

Read/write mode

For the `dragstart` event. New data can be added to the `drag data store`.

Read-only mode

For the `drop` event. The list of items representing dragged data can be read, including the data. No new data can be added.

Protected mode

For all other events. The formats and kinds in the `drag data store` list of items representing dragged data can be enumerated, but the data itself is unavailable and no new data can be added.

- A `drag data store allowed effects state`, which is a string.

When a `drag data store` is created, it must be initialized such that its `drag data store item list` is empty, it has no `drag data store default feedback`, it has no `drag data store bitmap` and `drag data store hot spot coordinate`, its `drag data store mode` is `protected mode`, and its `drag data store allowed effects state` is the string "`uninitialized`".

6.8.3 The DataTransfer interface

`DataTransfer` objects are used to expose the `drag data store` that underlies a drag-and-drop operation.

DOM

`DataTransfer`

Support in all current engines.

Firefox 3+>Safari 3.1+Chrome 3+

Opera 12+Edge 79+

Edge (Legacy)12+Internet Explorer 10+

Firefox Android 4+>Safari iOS2+>Chrome Android 18+>WebView Android 37+>Samsung Internet 1.0+>Opera Android 12+

```
IDL [Exposed=Window,
      Scriptable]
interface DataTransfer {
    attribute DOMString dropEffect;
    attribute DOMString effectAllowed;
    [SameObject] readonly attribute DataTransferItemList items;
    void setDragImage(Element image, long x, long y);
    /* old interface */
    readonly attribute FrozenArray<DOMString> types;
    DOMString getBlob(DOMString format);
    void setBlob(DOMString format, Blob data);
    void clearBlob(optional DOMString format);
    [SameObject] readonly attribute FileList files;
}
```

For web developers (non-normative)

```
dataTransfer = new DataTransfer()
```

Creates a new `DataTransfer` object with an empty `drag data store`.

```
dataTransfer.dropEffect [= value]
```

Returns the kind of operation that is currently selected. If the kind of operation isn't one of those that is allowed by the `effectAllowed` attribute, then the operation will fail.

Can be set, to change the selected operation.

The possible values are `"none"`, `"copy"`, `"link"`, and `"move"`.

```
dataTransfer.effectAllowed [= value]
```

Returns the kinds of operations that are to be allowed.

Can be set (during the `dragstart` event), to change the allowed operations.

The possible values are `"none"`, `"copy"`, `"copyLink"`, `"copyMove"`, `"link"`, `"linkMove"`, `"move"`, `"all"`, and `"uninitialized"`.

```
dataTransfer.items
```

Returns a `DataTransferItemList` object, with the drag data.

```
dataTransfer.setDragImage(element,x,y)
```

dataTransfer · types
 Returns a [frozen array](#) listing the formats that were set in the [dragstart](#) event. In addition, if any files are being dragged, then one of the types will be the string "file".
dataTransfer · getBtaData(format)
 Returns the specified data. If there is no such data, returns the empty string.
dataTransfer · setBtaData(format, data)
 Adds the specified data.
dataTransfer · clearBtaData([format])
 Removes the data of the specified formats. Removes all data if the argument is omitted.
dataTransfer · file
 Returns a [FileList](#) of the files being dragged, if any.

[dataTransfer](#) objects that are created as part of [drag-and-drop events](#) are only valid while those events are being fired.

A [dataTransfer](#) object is associated with a [drag data store](#) while it is valid.

A [dataTransfer](#) object has an associated [types array](#), which is a [frozenArray<DOMString>](#), initially empty. When the contents of the [dataTransfer](#) object's [drag data store item list](#) change, or when the [dataTransfer](#) object becomes no longer associated with a [drag data store](#), run the following steps:

1. Let L be an empty sequence.
2. If the [dataTransfer](#) object is still associated with a [drag data store](#), then:
 1. For each item in the [dataTransfer](#) object's [drag data store item list](#) whose [kind](#) is [text](#), add an entry to L consisting of the item's [type string](#).
 2. If there are any items in the [dataTransfer](#) object's [drag data store item list](#) whose [kind](#) is [File](#), then add an entry to L consisting of the string "files". (This value can be distinguished from the other values because it is not lowercase.)
3. Set the [dataTransfer](#) object's [types array](#) to the result of [creating a frozen array](#) from L .

Firefox, Android50+ Safari iOS6+ Chrome Android18+ WebView Android4.4+ Samsung Internet1.0+ Opera AndroidNo

The `clear()` method, if the `DataTransferItemList` object is in the *read/write mode*, must remove all the items from the `drag data store`. Otherwise, it must do nothing.

6.8.3.2 The `DataTransferItem` interface

Each `DataTransferItem` object is associated with a `DataTransfer` object.

MDN

[DataTransferItem](#)

Support in all current engines

Firefox50+ Safari5.1+ Chrome11+

Opera12+ Edge79+

Edge (Legacy) 12+ Internet ExplorerNo

Firefox, Android50+ Safari iOS5+ Chrome Android18+ WebView Android4+ Samsung Internet1.0+ Opera AndroidNo

```
IDL [Exposed=Window]
interface DataTransferItem {
  readonly attribute DOMString kind;
  readonly attribute DOMString type;
  void getAsString([Function(optionalStringCallback)]);
  File getAsFile();
};

callback FunctionStringCallback = void (DOMString data);
```

For web developers (non-normative)

`item` [list](#)

Returns the `drag data item kind`, one of: "string", "file".

`item` [type](#)

Returns the `drag data item type string`.

`item` [getAsString\(callback\)](#)

Invokes the callback with the string data as the argument, if the `drag data item kind` is `text`.

`file = item` [getAsFile\(\)](#)

Returns a `File` object, if the `drag data item kind` is `File`.

While the `DataTransferItem` object's `DataTransfer` object is associated with a `drag data store` and that `drag data store`'s `drag data store item list` still contains the item that the `DataTransferItem` object represents, the `DataTransferItem` object's `mode` is the same as the `drag data store mode`. When the `DataTransferItem` object's `DataTransfer` object is *not* associated with a `drag data store`, or if the item that the `DataTransferItem` object represents has been removed from the relevant `drag data store item list`, the `DataTransferItem` object's `mode` is the *disabled mode*. The `drag data store` referenced in this section (which is used only when the `DataTransferItem` object is *not* in the *disabled mode*) is the `drag data store` with which the `DataTransferItem` object's `DataTransfer` object is associated.

MDN

Firefox, Android50+ Safari iOS5+ Chrome Android18+ WebView Android4+ Samsung Internet1.0+ Opera AndroidNo

The `getAsString(callback)` method must run the following steps:

- If the `callback` is null, return.
- If the `DataTransferItem` object is not in the `read/write mode` or the `read-only mode`, return. The callback is never invoked.
- If the `drag data item kind` is not `File`, then return. The callback is never invoked.
- Otherwise, `queue a task` to invoke `callback`, passing the actual data of the item represented by the `DataTransferItem` object as the argument.

MDN

`DataTransferItem.getAsString()`

Support in all current engines.

Firefox50+ Safari5.1+ Chrome11+

Opera12+ Edge79+

Edge (Legacy)12+ Internet ExplorerNo

Firefox Android50+ Safari iOS5+ Chrome Android8+ WebView Android4+ Samsung Internet1.0+ Opera AndroidNo

The `getAsFile()` method must run the following steps:

- If the `DataTransferItem` object is not in the `read/write mode` or the `read-only mode`, then return null.
- If the `drag data item kind` is not `File`, then return null.
- Return a new `File` object representing the actual data of the item represented by the `DataTransferItem` object.

6.8.4 The `dragevent` interface

MDN

`DragEvent/DragEvent`

Support in all current engines.

Firefox3.5+Safari3.1+Chrome46+

Opera12+ Edge79+

Edge (Legacy)12+ Internet Explorer10+

Firefox Android4.4+ Safari iOS8+ Chrome Android No WebView Android No Samsung Internet No Opera Android No

The drag-and-drop processing model involves several events. They all use the `dragevent` interface.

MDN

`DragEvent`

Support in all current engines.

Firefox3.5+Safari3.1+Chrome3+

Opera12+ Edge79+

Edge (Legacy)12+ Internet Explorer10+

Firefox Android4.4+ Safari iOS8+ Chrome Android No WebView Android No Samsung Internet No Opera Android No

IDL(`!ReplacesWindow`, `Constructor(DOMString type, optional DragEventInit eventInitDict = {})`)

```
interface DragEvent : MouseEvent {
  readonly attribute DataTransfer? dataTransfer;
};

dictionary DragEventInit : MouseEventInit {
  DataTransfer? dataTransfer = null;
};
```

For web developers (non-normative)

`event.dataTransfer`

Returns the `DataTransfer` object for the event.

Note

Although, for consistency with other event interfaces, the `dragevent` interface has a constructor, it is not particularly useful. In particular, there's no way to create a useful `DataTransfer` object from script, as `DataTransfer` objects have a processing and security model that is coordinated by the browser during drag-and-drops.

MDN

`DragEvent/dataTransfer`

Support in all current engines.

Firefox3.5+Safari3.1+Chrome46+

OperaYesEdge79+

Edge (Legacy)12+ Internet Explorer10+

Firefox AndroidYes Safari iOSNo Chrome Android No WebView Android No Samsung Internet No Opera Android No

The `dataTransfer` attribute of the `dragevent` interface must return the value it was initialized to. It represents the context information for the event.

When a user agent is required to fire a DND event named `e` at an element, using a particular `drag data store`, and optionally with a specific `related target`, the user agent must run the following steps:

- Let `dataDragStoreWasChanged` be false.
- If no specific `related target` was provided, set `related target` to null.
- Let `window` be the `relevant global object` of the `Document` object of the specified target element.
- If `e` is `dragstart`, then set the `drag data store mode` to the `read/write mode` and set `dataDragStoreWasChanged` to true.
- If `e` is `drop`, set the `drag data store mode` to the `read-only mode`.
- Let `dataTransfer` be a newly created `DataTransfer` object associated with the given `drag data store`.
- Set the `effectAllowed` attribute to the `drag data store`'s `drag data store allowed effects` attribute.
- Set the `dragEffect` attribute to "`none`" if `e` is `dragstart`, `drag`, `dragexit`, or `dragleave`; to the value corresponding to the `current drag operation` if `e` is `drop` or `dragend`; and to a value based on the `effectAllowed` attribute's value and the drag-and-drop source, as given by the following table, otherwise (i.e. if `e` is `dragenter` or `dragover`):

<code>effectAllowed</code>	<code>dragEffect</code>
" <code>copy</code> "	" <code>copy</code> "
" <code>copyLink</code> "	" <code>copy</code> ", or, if appropriate, " <code>link</code> "
" <code>copyMove</code> "	" <code>copy</code> ", or, if appropriate, " <code>move</code> "
" <code>link</code> "	" <code>link</code> ", or, if appropriate, either " <code>link</code> " or " <code>move</code> "
" <code>linkMove</code> "	" <code>link</code> ", or, if appropriate, " <code>move</code> "
" <code>move</code> "	" <code>move</code> "
" <code>uninitialized</code> " when what is being dragged is a selection from a text control	" <code>copy</code> ", or, if appropriate, either " <code>link</code> " or " <code>move</code> "
" <code>uninitialized</code> " when what is being dragged is a selection	" <code>copy</code> ", or, if appropriate, either " <code>link</code> " or " <code>move</code> "
" <code>uninitialized</code> " when what is being dragged is an <code>a</code> element with an <code>href</code> attribute	" <code>link</code> ", or, if appropriate, either " <code>copy</code> " or " <code>move</code> "
Any other case	" <code>link</code> ", or, if appropriate, either " <code>link</code> " or " <code>move</code> "

Where the table above provides *possibly appropriate alternatives*, user agents may instead use the listed alternative values if platform conventions dictate that the user has requested those alternate effects.

Example

For example, Windows platform conventions are such that dragging while holding the "alt" key indicates a preference for linking the data, rather than moving or copying it. Therefore, on a Windows system, if "`link`" is an option according to the table above while the "alt" key is depressed, the user agent could select that instead of "`copy`" or "`move`".

- Let `e` be the result of `creating an event` using `dragevent`.
- Initialize `e`'s `type` attribute to `e`, its `pinned` attribute to true, its `view` attribute to `window`, its `relatedTarget` attribute to `related target`, and its `dataTransfer` attribute to `dataTransfer`.
- If `e` is not `dragstart`, `dragleave`, or `dragend`, then initialize `e`'s `cancelable` attribute to true.
- Initialize `e`'s mouse and key attributes initialized according to the state of the input devices as they would be for user interaction events.
- If there is no relevant pointing device, then initialize `e`'s `screenX`, `screenY`, `clientX`, `clientY`, and `button` attributes to 0.
- Dispatch** `e` at the specified target element.
- Set the `drag data store allowed effects` to the current value of `dataTransfer`'s `effectAllowed` attribute. (It can only have changed value if `e` is `dragstart`.)
- If `dataDragStoreWasChanged` is true, then set the `drag data store mode` back to the `protected mode`.
- Break the association between `dataTransfer` and the `drag data store`.

6.8.5 Processing model

When the user attempts to begin a drag operation, the user agent must run the following steps. User agents must act as if these steps were run even if the drag actually started in another document or application and the user agent was not aware that the drag was occurring until it intersected with a document under the user agent's purview.

- Determine what is being dragged, as follows:

If the drag operation was invoked on a selection, then it is the selection that is being dragged.

Otherwise, if the drag operation was invoked on a `Document`, it is the first element, going up the ancestor chain, starting at the node that the user tried to drag, that has the IDL attribute `draggable` set to true. If there is no such element, then nothing is being dragged; return, the drag-and-drop operation is never started.

Otherwise, the drag operation was invoked outside the user agent's purview. What is being dragged is defined by the document or application where the drag was started.

Note
`link` elements and `a` elements with an `href` attribute have their `draggable` attribute set to true by default.

- Create a `drag data store`. All the DND events fired subsequently by the steps in this section must use this `drag data store`.

If it is a selection that is being dragged, then the `source node` is the `Text` node that the user started the drag on (typically the `Text` node that the user originally clicked). If the user did not specify a particular node, for example if the user just told the user agent to begin a drag of "the selection", then the `source node` is the first `Text` node containing a part of the selection.

Otherwise, if it is an element that is being dragged, then the `source node` is the element that is being dragged.

Otherwise, the `source node` is part of another document or application. When this specification requires that an event be dispatched at the `source node` in this case, the user agent must instead follow the platform-specific conventions relevant to that situation.

Note

Multiple events are fired on the `source node` during the course of the drag-and-drop operation.

4. Determine the `list of dragged nodes`, as follows:

If it is a selection that is being dragged, then the `list of dragged nodes` contains, in `tree order`, every node that is partially or completely included in the selection (including all their ancestors).

Otherwise, the `list of dragged nodes` contains only the `source node`, if any.

5. If it is a selection that is being dragged, then add an item to the `drag data store item list`, with its properties set as follows:

`The drag data item type string`

`"text/plain"`

`The drag data item kind`

`Text`

The actual data

The text of the selection

Otherwise, if any files are being dragged, then add one item per file to the `drag data store item list`, with their properties set as follows:

`The drag data item type string`

The MIME type of the file, if known, or `"application/octet-stream"` otherwise.

`The drag data item kind`

`File`

The actual data

The file's contents and name.

Note

Dragging files can currently only happen from outside a [browsing context](#), for example from a file system manager application.

If the drag initiated outside of the application, the user agent must add items to the `drag data store item list` as appropriate for the data being dragged, honoring platform conventions where appropriate; however, if the platform conventions do not use [MIME types](#) to label dragged data, the user agent must make a best-effort attempt to map the types to MIME types, and, in any case, all the `drag data item type strings` must be converted to ASCII lowercase.

User agents may also add one or more items representing the selection or dragged element(s) in other forms, e.g. as HTML.

6. If the `list of dragged nodes` is not empty, then [extract the microdata from those nodes into a JSON form](#), and add one item to the `drag data store item list`, with its properties set as follows:

`The drag data item type string`

`application/microdata+json`

`The drag data item kind`

`Text`

The actual data

The resulting JSON string.

7. Run the following substeps:

1. Let `urls` be an empty list of [absolute URLs](#).

2. For each `node` in the `list of dragged nodes`:

If the node is an `a` element with an `href` attribute

Add to `urls` the result of [parsing](#) the element's `href` content attribute relative to the element's `node document`.

If the node is an `img` element with a `src` attribute

Add to `urls` the result of [parsing](#) the element's `src` content attribute relative to the element's `node document`.

3. If `urls` is still empty, then return.

4. Let `url string` be the result of concatenating the strings in `urls`, in the order they were added, separated by a U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF).

5. Add one item to the `drag data store item list`, with its properties set as follows:

`The drag data item type string`

`"text/uri-list"`

`The drag data item kind`

`Text`

The actual data

`url string`

8. Update the `drag data store default feedback` as appropriate for the user agent (if the user is dragging the selection, then the selection would likely be the basis for this feedback; if the user is dragging an element, then that element's rendering would be used; if the drag began outside the user agent, then the platform conventions for determining the drag feedback should be used).

9. [Fire a DND event named `dragstart` at the `source node`](#).

If the event is canceled, then the drag-and-drop operation should not occur; return.

Note

Since events with no event listeners registered are, almost by definition, never canceled, drag-and-drop is always available to the user if the author does not specifically prevent it.

10. [Initiate the drag-and-drop operation](#) in a manner consistent with platform conventions, and as described below.

The drag-and-drop feedback must be generated from the first of the following sources that is available:

1. The `drag data store bitmap`, if any. In this case, the `drag data store hot spot coordinate` should be used as hints for where to put the cursor relative to the resulting image. The values are expressed as distances in [CSS pixels](#) from the left side and from the top side of the image respectively. [\[CSS\]](#)

2. The `drag data store default feedback`.

From the moment that the user agent is *initiate the drag-and-drop operation*, until the end of the drag-and-drop operation, device input events (e.g. mouse and keyboard events) must be suppressed.

During the drag operation, the element directly indicated by the user as the drop target is called the *immediate user selection*. (Only elements can be selected by the user; other nodes must not be made available as drop targets.) However, the *immediate user selection* is not necessarily the *current target element*, which is the element currently selected for the drop part of the drag-and-drop operation.

The *immediate user selection* changes as the user selects different elements (either by pointing at them with a pointing device, or by selecting them in some other way). The *current target element* changes when the *immediate user selection* changes, based on the results of event listeners in the document, as described below.

Both the *current target element* and the *immediate user selection* can be null, which means no target element is selected. They can also both be elements in other (DOM-based) documents, or other (non-Web) programs altogether. (For example, a user could drag text to a word-processor.) The *current target element* is initially null.

In addition, there is also a *current drag operation*, which can take on the values `"none"`, `"copy"`, `"link"`, and `"move"`. Initially, it has the value `"none"`. It is updated by the user agent as described in the steps below.

User agents must, as soon as the drag operation is *initiated* and every 350ms (+200ms) thereafter for as long as the drag operation is ongoing, [queue a task](#) to perform the following steps in sequence:

1. If the user agent is still performing the previous iteration of the sequence (if any) when the next iteration becomes due, return for this iteration (effectively "skipping missed frames" of the drag-and-drop operation).

2. [Fire a DND event named `drag` at the `source node`](#). If this event is canceled, the user agent must set the `current drag operation` to `"none"` (no drag operation).

3. If the `drag` event was not canceled and the user has not ended the drag-and-drop operation, check the state of the drag-and-drop operation, as follows:

1. If the user is indicating a different *immediate user selection* than during the last iteration (or if this is the first iteration), and if this *immediate user selection* is not the same as the *current target element*, then [fire a DND event named `dragexit`](#) at the *current target element*, and then update the *current target element* as follows:

If the new *immediate user selection* is null

 Set the *current target element* to null also.

If the new *immediate user selection* is in a non-DOM document or application

 Set the *current target element* to the *immediate user selection*.

Otherwise

[Fire a DND event named `dragenter`](#) at the *immediate user selection*.

 If the event is canceled, then set the *current target element* to the *immediate user selection*.

 Otherwise, run the appropriate step from the following list:

 If the *immediate user selection* is a text control (e.g., `textarea`, or an `input` element whose `type` attribute is in the `Text` state) or an `editing host` or `editable` element, and the `drag data store item list` has an item with the `drag data item type string` `"text/plain"` and the `drag data item kind` `Text`

 Set the *current target element* to the *immediate user selection* anyway.

 If the *immediate user selection* is the `body element`

 Leave the *current target element* unchanged.

 Otherwise

[Fire a DND event named `dragover`](#) at the `body element`, if there is one, or at the `document object`, if not. Then, set the *current target element* to the `body element`, regardless of whether that event was canceled or not.

2. If the previous step caused the *current target element* to change, and if the previous target element was not null or a part of a non-DOM document, then [fire a DND event named `dragleave`](#) at the previous target element, with the new *current target element* as the specific *related target*.

3. If the *current target element* is a DOM element, then [fire a DND event named `dragover`](#) at this *current target element*.

If the `dragover` event is not canceled, then run the appropriate step from the following list:

If the *current target element* is a text control (e.g., `textarea`, or an `input` element whose `type` attribute is in the `Text` state) or an `editing host` or `editable` element, and the `drag data store item list` has an item with the `drag data item type string` `"text/plain"` and the `drag data item kind` `Text`

 Set the `current drag operation` to either `"copy"` or `"move"`, as appropriate given the platform conventions.

Otherwise

 Reset the `current drag operation` to `"none"`.

Otherwise (if the `dragover` event is canceled), set the `current drag operation` based on the values of the `effectAllowed` and `dropEffect` attributes of the `dragEvent` object's `dataTransfer` object as they stood after the event `dispatched` finished, as per the following table:

<code>effectAllowed</code>	<code>dropEffect</code>	Drag operation Feedback
<code>"uninitialized"</code>	<code>"copy"</code>	Data will be copied if dropped here.
<code>"uninitialized"</code>	<code>"link"</code>	Data will be linked if dropped here.
<code>"uninitialized"</code>	<code>"move"</code>	Data will be moved if dropped here.
<code>"copy"</code>	<code>"copy"</code>	N/A
<code>"link"</code>	<code>"link"</code>	N/A
<code>"move"</code>	<code>"move"</code>	N/A
<code>"copy"</code>	<code>"link"</code>	N/A
<code>"link"</code>	<code>"copy"</code>	N/A
<code>"move"</code>	<code>"link"</code>	N/A
<code>"link"</code>	<code>"move"</code>	N/A
<code>"move"</code>	<code>"move"</code>	N/A

Any other case

N/A

4. Otherwise, if the *current target element* is not a DOM element, use platform-specific mechanisms to determine what drag operation is being performed (none, copy, link, or move), and set the `current drag operation` accordingly.

5. Update the drag feedback (e.g. the mouse cursor) to match the `current drag operation`, as follows:

Drag operation Feedback

<code>"copy"</code>	Data will be copied if dropped here.
---------------------	--------------------------------------

<code>"link"</code>	Data will be linked if dropped here.
---------------------	--------------------------------------

<code>"move"</code>	Data will be moved if dropped here.
---------------------	-------------------------------------

<code>"none"</code>	N/A
---------------------	-----

4. Otherwise, if the user ended the drag-and-drop operation (e.g. by releasing the mouse button in a mouse-driven drag-and-drop interface), or if the `drag` event was canceled, then this will be the last iteration. Run the following steps, then stop the drag-and-drop operation:

1. If the `current_drag_operation` is `"none"` (no drag operation), or, if the user ended the drag-and-drop operation by canceling it (e.g. by hitting the `Escape` key), or if the `current_target_element` is null, then the drag operation failed. Run these substeps:

1. Let `dropped` be false.
2. If the `current_target_element` is a DOM element, fire a DND event named `dragleave` at it; otherwise, if it is not null, use platform-specific conventions for drag cancellation.
3. Set the `current_drag_operation` to `"none"`.

Otherwise, the drag operation might be a success; run these substeps:

1. Let `dropped` be true.
2. If the `current_target_element` is a DOM element, fire a DND event named `drag` at it; otherwise, use platform-specific conventions for indicating a drop.
3. If the event is canceled, set the `current_drag_operation` to the value of the `dragEffect` attribute of the `dragevent` object's `dataTransfer` object as it stood after the event `dispatch` finished.

Otherwise, the event is not canceled; perform the event's default action, which depends on the exact target as follows:

If the `current_target_element` is a text control (e.g., `textarea`, or an `input` element whose `type` attribute is in the `Text` state) or an `editing host` or `editable` element, and the `drag_data_store_item_list` has an item with the `drag_data_item_type` string `"text/plain"` and the `drag_data_item_kind` `text`

Insert the actual data of the first item in the `drag_data_store_item_list` to have a `drag_data_item_type` string of `"text/plain"` and a `drag_data_item_kind` that is `text` into the text control or `editing host` or `editable` element in a manner consistent with platform-specific conventions (e.g. inserting it at the current mouse cursor position, or inserting it at the end of the field).

Otherwise:

Reset the `current_drag_operation` to `"none"`.

2. Fire a DND event named `dragend` at the `source node`.

3. Run the appropriate steps from the following list as the default action of the `dragend` event:

If `dropped` is true, the `current_target_element` is a `text control` (see below), the `current_drag_operation` is `"move"`, and the source of the drag-and-drop operation is a selection in the DOM that is entirely contained within an `editing host`

`Delete the selection.`

If `dropped` is true, the `current_target_element` is a `text control` (see below), the `current_drag_operation` is `"move"`, and the source of the drag-and-drop operation is a selection in a text control

The user agent should delete the dragged selection from the relevant text control.

If `dropped` is false or if the `current_drag_operation` is `"none"`

The drag was canceled. If the platform conventions dictate that this be represented to the user (e.g. by animating the dragged selection going back to the source of the drag-and-drop operation), then do so.

Otherwise:

The event has no default action.

For the purposes of this step, a `text control` is a `textarea` element or an `input` element whose `type` attribute is in one of the `Text`, `Search`, `Td`, `URL`, `E-mail`, `Password`, or `Number` states.

Note

User agents are encouraged to consider how to react to drags near the edge of scrollable regions. For example, if a user drags a link to the bottom of the `viewport` on a long page, it might make sense to scroll the page so that the user can drop the link lower on the page.

Note

This model is independent of which `Document` object the nodes involved are from; the events are fired as described above and the rest of the processing model runs as described above, irrespective of how many documents are involved in the operation.

[This section is non-normative.](#)

The following events are involved in the drag-and-drop model.

Event name	Target	Cancelable?	Drag data store mode	dragEffect	Default Action
------------	--------	-------------	----------------------	------------	----------------

<code>dragstart</code>	<code>Source node</code>	✓ Cancelable	Read/write mode	<code>"none"</code>	Initiate the drag-and-drop operation
	<code>Source node</code>	✓ Cancelable	Protected mode	<code>"none"</code>	Continue the drag-and-drop operation
<code>dragstart</code>	Immediate user selection or the body element	✓ Cancelable	Protected mode	Based on <code>effectAllowed</code> value	Reject immediate user selection as potential target element
<code>dragstart</code>	Previous target element	—	Protected mode	<code>"none"</code>	None
<code>dragstart</code>	Previous target element	—	Protected mode	<code>"none"</code>	None
<code>dragstart</code>	Current target element	✓ Cancelable	Protected mode	Based on <code>effectAllowed</code> value	Reset the <code>current_drag_operation</code> to <code>"none"</code>
<code>drop</code>	Current target element	✓ Cancelable	Read-only mode	Current drag operation	Varies
<code>dragend</code>	Source node	—	Protected mode	Current drag operation	Varies

Not shown in the above table: all these events bubble, are composed, and the `effectAllowed` attribute always has the value it had after the `dragstart` event, defaulting to `"uninitialized"` in the `dragstart` event.

6.8.7 The `draggable` attribute

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

MDN[Global_attributes/draggable](#)

Support in all current engines.

Firefox2+SafariYesChromeYes

Opera12+EdgeYes

Edge (Legacy)12+Internet ExplorerYes

Firefox, Android4+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpen AndroidYes

All [HTML elements](#) may have the `draggable` content attribute set. The `draggable` attribute is an [enumerated attribute](#). It has three states. The first state is `true` and it has the keyword `true`. The second state is `false` and it has the keyword `false`. The third state is `auto`; it has no keywords but it is the [missing value default](#) and the [invalid value default](#).

The `true` state means the element is draggable; the `false` state means that it is not. The `auto` state uses the default behavior of the user agent.

An element with a `draggable` attribute should also have a [title](#) attribute that names the element for the purpose of non-visual interactions.

For web developers (non-normative)`element.draggable = value`

Returns true if the element is draggable; otherwise, returns false.

Can be set, to override the default and set the `draggable` content attribute.

The `draggable` IDL attribute, whose value depends on the content attribute's in the way described below, controls whether or not the element is draggable. Generally, only text selections are draggable, but elements whose `draggable` IDL attribute is true become draggable as well.

If an element's `draggable` content attribute has the state `true`, the `draggable` IDL attribute must return true.

Otherwise, if the element's `draggable` content attribute has the state `false`, the `draggable` IDL attribute must return false.

Otherwise, the element's `draggable` content attribute has the state `auto`. If the element is an `img` element, an `object` element that `represents` an image, or an `a` element with an `href` content attribute, the `draggable` IDL attribute must return true; otherwise, the `draggable` IDL attribute must return false.

If the `draggable` IDL attribute is set to the value `false`, the `draggable` content attribute must be set to the literal value "`false`". If the `draggable` IDL attribute is set to the value `true`, the `draggable` content attribute must be set to the literal value "`true`".

6.8.8 Security risks in the drag-and-drop model

User agents must not make the data added to the `DataTransfer` object during the `dragstart` event available to scripts until the `drop` event, because otherwise, if a user were to drag sensitive information from one document to a second document, crossing a hostile third document in the process, the hostile document could intercept the data.

For the same reason, user agents must consider a drop to be successful only if the user specifically ended the drag operation — if any scripts end the drag operation, it must be considered unsuccessful (canceled) and the `drop` event must not be fired.

User agents should take care to not start drag-and-drop operations in response to script actions. For example, in a mouse-and-window environment, if a script moves a window while the user has their mouse button depressed, the UA would not consider that to start a drag. This is important because otherwise UAs could cause data to be dragged from sensitive sources and dropped into hostile documents without the user's consent.

User agents should filter potentially active (scripted) content (e.g. HTML) when it is dragged and when it is dropped, using a safest of known-safe features. Similarly, [relative URLs](#) should be turned into absolute URLs to avoid references changing in unexpected ways. This specification does not specify how this is performed.

Example

Consider a hostile page providing some content and getting the user to select and drag and drop (or indeed, copy and paste) that content to a victim page's [contenteditable](#) region. If the browser does not ensure that only safe content is dragged, potentially unsafe content such as scripts and event handlers in the selection, once dropped (or pasted) into the victim site, get the privileges of the victim site. This would enable a cross-site scripting attack.

7 Loading Web pages

This section describes features that apply most directly to Web browsers. Having said that, except where specified otherwise, the requirements defined in this section do apply to all user agents, whether they are Web browsers or not.

7.1 Browsing contexts

A [browsing context](#) is an environment in which [Document](#) objects are presented to the user.

Note

A tab or window in a Web browser typically contains a [browsing context](#), as does an [iframe](#) or [frame](#) in a [frameset](#).

A [browsing context](#) has a corresponding [WindowProxy](#) object.

A [browsing context](#) has an [opener](#) [browsing context](#), which is null or a [browsing context](#). It is initially null.

A [browsing context](#) has a [disowned](#) boolean. It is initially false.

A [browsing context](#) has an [is_closing](#) boolean. It is initially false.

A [browsing context](#) has a [session history](#), which lists the [Document](#) objects that the [browsing context](#) has presented, is presenting, or will present. A [browsing context](#)'s [active document](#) is its [WindowProxy](#) object's [\[Window\]](#) internal slot value's [associated document](#). A [Document](#)'s [browsing context](#) is the [browsing context](#) whose [session history](#) contains the [Document](#), if any such browsing context exists and has not been [disowned](#), and null otherwise.

Note

In general, there is a 1-to-1 mapping from the [Window](#) object to the [Document](#) object, as long as the [Document](#) object has a non-null [browsing context](#). There is one exception. A [Window](#) can be reused for the presentation of a second [Document](#) in the same [browsing context](#), such that the mapping is then 1-to-2. This occurs when a [browsing context](#) is [navigated](#) from the initial [about:blank](#) [Document](#) to another, with [replacement](#) enabled.

Note

A [Document](#) object necessarily has a non-null [browsing context](#). In particular, data mining tools are likely to never instantiate browsing contexts. A [Document](#) created using an API such as [createDocument\(\)](#) never has a non-null [browsing context](#). And the [Document](#) originally created for an [iframe](#) element, which has since been [removed](#) from the [Document](#), has no associated [browsing context](#), since that browsing context was [disowned](#).

7.1.1 Creating browsing contexts

To set the active document of a [browsing context](#) `browsingContext` to a [Document](#) object `document`, run these steps:

1. Let `window` be `document`'s [relevant global object](#).

Per this standard `window` can be created before `window`, which does not make much sense. See [issue #2688](#).

2. Set `browsingContext`'s [WindowProxy](#) object's [\[Window\]](#) internal slot value to `window`.

3. Set `window`'s [associated document](#) to `document`.

4. Set `window`'s [relevant settings object](#)'s [execution ready flag](#).

A [browsing context](#) has an associated [creator origin](#) (null or returns an [origin](#)), [creator URL](#) (null or returns a [URL](#)), and [creator base URL](#) (null or returns a [URL](#)). These are all initially null.

To determine the [origin](#), given [browsing context](#) [browsingContext](#), [URL url](#), [sandboxing flag set](#) `sandboxFlags`, and two [origin](#) [invocationOrigin](#) and [activeDocumentNavigationOrigin](#):

1. If `sandboxFlags` has its [sandboxed origin](#) [browsing context flag set](#), then return a new [opaque origin](#).

2. If `url` is null, then return a new [opaque origin](#).

3. If `activeDocumentOrigin` is not null, and `url`'s [scheme](#) is "`javascript`", then return `activeDocumentNavigationOrigin`.

4. If `invocationOrigin` is non-null and `url` is [about:blank](#), then return `invocationOrigin`.

Note

The result here is that two documents end up with the same underlying [origin](#), meaning that `document.domain` affects both.

5. If `url` is [about:srcdoc](#), then return the [origin](#) of `browsingContext`'s [container document](#).

6. Return `url`'s [origin](#).

To create a new [browsing context](#), given null or a [Document](#) object `creator` and [browsing context group](#):

1. Let `browsingContext` be a new [browsing context](#).

2. If `creator` is non-null, then set `browsingContext`'s [creator origin](#) to return `creator`'s [origin](#), `browsingContext`'s [creator URL](#) to return `creator`'s [URL](#), and `browsingContext`'s [creator base URL](#) to return `creator`'s [base URL](#).

3. Let `sandboxFlags` be the result of [determining the origin](#) given `browsingContext`, [about:blank](#), `sandboxFlags`, `browsingContext`'s [creator origin](#), and null.

4. Let `featurePolicy` be the result of [creating a feature policy](#) given `browsingContext` and `origin`. [FEATUREPOLICY](#)

5. Let `agent` be the result of [obtaining a similar-origin window agent](#) given `origin` and `group`.

7. Let `realm execution context` be the result of [creating a new JavaScript realm](#) with the following customizations:

- o For the agent, use `agent`. This pointer is not yet defined in the JavaScript specification; see [b39ecma262#1357](#).

- o For the global object, create a new [Window](#) object.

- o For the global `this` binding, use `browsingContext`'s [WindowProxy](#) object.

8. Set up a [window environment settings object](#) with `realm execution context`, and let `settingsObject` be the result.

9. Let `document` be a new [Document](#), marked as an [HTML document](#) in [quirks mode](#), whose [content type](#) is "`text/html`", `origin`, [active sandboxing flag set](#) is `sandboxFlags`, `feature policy` is `feature policy`, and which is both [ready for post-load tasks](#) and [completely loaded](#) immediately.

10. Ensure that `document` has a single child [html](#) node, which itself has two empty child nodes: a [head](#) element, and a [body](#) element.

11. Set the [active document](#) of `browsingContext` to `document`.

12. If `browsingContext`'s [creator URL](#) is non-null, then set `document`'s [referrer](#) to the [serialization](#) of it.

13. If `creator` is non-null, then set `document`'s [referrer policy](#) to `creator`'s [referrer policy](#).

14. Add `document` to `browsingContext`'s [session history](#).

15. Return `browsingContext`.

To create a new top-level [browsing context](#):

1. Let `group` be the result of [creating a new browsing context group](#).

2. Return group's [browsing context set](#)[0].

Note

This creates a [top-level browsing context](#).

To create a new auxiliary [browsing context](#), given a [browsing context](#) `opener`:

1. Let `group` be `opener`'s [top-level browsing context's group](#).

2. Assert: `group` is non-null, as [navigating](#) invokes this directly.

3. Let `browsingContext` be the result of [creating a new browsing context](#) with `opener`'s [active document](#) and `group`.

4. Append `browsingContext` to `group`.
5. Set `browsingContext's` `opener` `browsing context` to `opener`.
6. Assert: `browsingContext's` `creator origin` is non-null.
7. If `browsingContext's` `creator origin` is `same origin` with `browsingContext's active document's` `origin`, then copy the `sessionStorage` storage area of `opener` into `browsingContext's` set of session storage areas. These areas must be considered separate, not affecting each other in any way.
8. Return `browsingContext`.

Note

This creates a **top-level browsing context** that is also an **auxiliary browsing context**.

To create a new nested **browsing context**, given an element `element`:

1. Let `browsingContext` be the result of `creating a new browsing context` with `element's` `node document` and `element's` `node document's` `browsing context's` **top-level browsing context's** `group`.
2. Set `element's` `nesting browsing context` to `browsingContext`.
3. If `element` has a `name` attribute, then set `browsingContext's` `name` to the value of this attribute.

7.1.2 Related browsing contexts

Certain elements (for example, `iframe` elements) can instantiate further **browsing contexts**. These elements are called **browsing context containers**.

Each **browsing context container** has a **nested browsing context**, which is either a **browsing context** or null. It is initially null.

The **container** of a **browsing context** `bc` is the **browsing context container** whose **nested browsing context** is `bc`, or null if there is no such element.

Each **browsing context** `bc` has a **container document**, which is the result of running these steps:

1. If `bc's` `container` is null, then return null.
2. Return `bc's` `container's` `node document`.

Note

This is equal to `bc's` `container's` **shadow-including root** as `bc's` `container` has to be connected.

A **browsing context** `child` is said to be a **child browsing context** of another **browsing context** `parent`, if `child's` `container document` is non-null and `child's` `container document's` `browsing context` is `parent`.

A **browsing context** `child` is a **document-tree child** **browsing context** of `parent` if `child` is a **child browsing context** and `child's` `container` is **in a document tree**.

A **browsing context** `child` may have a **parent browsing context**. This is the unique **browsing context** that has `child` as a **child browsing context**, if any such browsing context exists. Otherwise, the **browsing context** has no **parent browsing context**.

A **browsing context** `A` is said to be an **ancestor** of a **browsing context** `B` if there exists a **browsing context** `A'` that is a **child browsing context** of `A` and that is itself an **ancestor** of `B`, or if the **browsing context** `A` is the **parent browsing context** of `B`.

A **browsing context** that has no **parent browsing context** is the **top-level browsing context** for itself and all of the **browsing contexts** for which it is an **ancestor browsing context**.

A **top-level browsing context** has an associated group (null or a **browsing context group**). It is initially null.

It is possible to create new **browsing contexts** that are related to a **top-level browsing context** while their `container` is null. Such **browsing contexts** are called **auxiliary browsing contexts**. Auxiliary **browsing contexts** are always **top-level browsing contexts**.

The transitive closure of **parent browsing contexts** for a **browsing context** that is a **child browsing context** gives the list of **ancestor browsing contexts**.

The list of the **descendant browsing contexts** of a `Document` `d` is the (ordered) list returned by the following algorithm:

1. Let `list` be an empty `List`.
2. For each **browsing context** `nestedContainer`, whose `nested browsing context` is non-null and whose `shadow-including root` is `d`, in `shadow-including tree order`:
 1. Let `nestedBC` be `nestedContainer's` `nesting browsing context`.
 2. Append `nestedBC` to `list`.
 3. Extend `list` with the list of the **descendant browsing contexts** of `nestedBC's` `active document`.
3. Return `list`.

A `Document` `d` is said to be **fully active** when `d's` `browsing context` is non-null, `d's` `browsing context's` `active document` is `d`, and either `d's` `browsing context` is a **top-level browsing context**, or `d's` `container document` is **fully active**.

Because they are associated with an element, **child browsing contexts** are always tied to a specific `Document` in their **parent browsing context**. User agents must not allow the user to interact with **child browsing contexts** of elements that are in `Documents` that are not themselves **fully active**.

Example

The following example illustrates the differences between **active** and **fully active** `Document` objects. Here `a.html` is loaded into a browser window, `b-1.html` starts out loaded into an `iframe` as shown, and `b-2.html` and `c.html` are omitted (they can simply be an empty document).

```
<!-- a.html -->
<!DOCTYPE html>
<html><head>
<title>Browsing context A</title>
<iframe src="b-1.html"></iframe>
<button onclick="frames[0].location.href = 'b-2.html'>Click me</button>
<!-- b-1.html -->
<!DOCTYPE html>
<html><head>
<title>Browsing context B</title>
<iframe src="c.html"></iframe>
```

At this point, the documents given by `a.html`, `b-1.html`, and `c.html` are all the **active documents** of their respective **browsing contexts**. They are also all **fully active**.

After clicking on the `button`, and thus loading a new `Document` from `b-2.html` into **browsing context B**, we have the following results:

- The `a.html` `Document` remains both the **active document** of **browsing context A**, and **fully active**.
- The `b-1.html` `Document` is now not the **active document** of **browsing context B**. As such it is also not **fully active**.
- The new `b-2.html` `Document` is now the **active document** of **browsing context B**, and is also **fully active**.
- The `c.html` `Document` is still the **active document** of **browsing context C**. However, since `C`'s `container document` is the `b-1.html` `Document`, which is itself not **fully active**, this means the `c.html` `Document` is now not **fully active** (even though it is **active**).

For more explorations of the complexities involved here, especially as it impacts **the session history**, see *A Model of Navigation History*: [\[NAVMODEL\]](#)

A **child browsing context** can be put into a **delaying load events mode**. This is used when it is `navigated`, to `delay the load event` of its `container` before the new `Document` is created.

The **document family** of a **browsing context** consists of the union of all the `Document` objects in that **browsing context's** `session history` and the **document families** of all those `Document` objects. The **document family** of a `Document` object consists of the union of all the **document families** of the **browsing contexts** in the **list of the descendant browsing contexts** of the `Document` object.

The content `Document` of a **browsing context container** is the result of the following algorithm:

1. If `container's` `nesting browsing context` is null, then return null.
2. Let `context` be `container's` `nesting browsing context`.
3. Let `document` be `context's` `active document`.
4. If `document's` `origin` and `container's` `node document's` `origin` are not `same origin-domain`, then return null.
5. Return `document`.

7.1.2.1 Navigating related browsing contexts in the DOM**For web developers (non-normative)**

`window.top`
Returns the `WindowProxy` for the **top-level browsing context**.

`window.opener` [= `value`]
Returns the `WindowProxy` for the **opener browsing context**.

Returns null if there isn't one or if it has been set to null.
Can be set to null.

`window.parent`
Returns the `WindowProxy` for the **parent browsing context**.

`window.frameElement`
Returns the `Element` for the **browsing context container**.

Returns null if there isn't one, and in cross-origin situations.

MDN**Window.top**

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `top` attribute's getter must run these steps:

1. If this `Window` object's `browsing context` is null, then return null.
2. Return this `Window` object's `browsing context's` `top-level browsing context's` `WindowProxy` object.

The `open` attribute's getter must run these steps:

1. Let `current` be this `Window` object's `browsing context`.
2. If `current` is null, then return null.
3. If `current's` `disown` is true, then return null.

5. Return *current's* `opener` *browsing context's* `WindowProxy` object.

The `opener` attribute's setter must run these steps:

1. If the given value is null and this `Window` object's `browsing context` is non-null, then set this `Window` object's `browsing context`'s `disowned` to true.

2. If the given value is non-null, then return `OrdinaryDefineOwnProperty`(this `Window` object, "opener", { [[Value]]: the given value, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true }).

Note

If a `browsing context`'s `disowned` is true, its `window.opener` attribute is null. That prevents scripts in the `browsing context` from changing any properties of its `opener` *browsing context's* `Window` object (i.e., the `Window` object from which the `browsing context` was created).

Otherwise, if a `browsing context`'s `disowned` is false, then scripts in the `browsing context` can use `window.opener` to change properties of its `opener` *browsing context's* `Window` object. For example, a script running in the `browsing context` can change the value of `window.opener.location`, causing the `opener` *browsing context* to navigate to a completely different document.

OMDN

`Window.parent`

Support in all current engines.

Firefox1+Safari1.3+Chrome1+

Open3+Edge79+

Edge (Legacy)12+Internet Explorer9+

Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android10.1+

The `parent` attribute's getter must run these steps:

1. Let *current* be this `Window` object's `browsing context`.

2. If *current* is null, then return null.

3. If *current* is a `child` *browsing context* of another *browsing context* `parent`, then return *parent's* `WindowProxy` object.

4. Assert: *current* is a `top-level` *browsing context.*

5. Return *current's* `WindowProxy` object.

OMDN

`Window.frameElement`

Support in all current engines.

Firefox1+SafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet ExplorerYes

Firefox AndroidYes Safari iOSYes Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidYes

The `frameElement` attribute's getter must run these steps:

1. Let *current* be this `Window` object's `browsing context`.

2. If *current* is null, then return null.

3. Let *container* be *current's* `containing`.

4. If *container* is null, then return null.

5. If *container's* `node document's` `origin` is not `same origin as` the `current settings object's` `origin`, then return null.

6. Return *container*.

Example

An example of when these IDL attributes can return null is as follows:

```
<!DOCTYPE html>
<html></html>

<script>
  <!-- Select -->
  const element = document.querySelector("iframe");
  const iframeWindow = element.contentWindow;
  window.assert(iframeWindow === null);
  console.assert(iframeWindow.top === null);
  console.assert(iframeWindow.parent === null);
  console.assert(iframeWindow.frameElement === null);
</script>
```

Here the `browsing context` corresponding to `iframeWindow` was `discarded` when `element` was removed from the document.

7.1.3 Security

A `browsing context` *A* is familiar with a second `browsing context` *B* if one of the following conditions is true:

- Either the `origin` of the `active document` of *A* is the `same` as the `origin` of the `active document` of *B*, or
- The `browsing context` *A* is a `child` *browsing context* and its `top-level` *browsing context* is *B*, or
- The `browsing context` *A* is an `auxiliary` *browsing context* and it is `linked with` *B*'s `top-level` *browsing context*, or
- The `browsing context` *B* is not a `top-level` *browsing context*, but there exists an `ancestor` *browsing context* of *B* whose `active document` has the `same origin` as the `active document` of *A* (possibly in fact being *A* itself).

A `browsing context` *A* is allowed to navigate a second `browsing context` *B* if the following algorithm returns true:

1. If *A* is not the same `browsing context` as *B*, and *A* is not one of the `ancestor` *browsing contexts* of *B*, and *B* is not a `top-level` *browsing context*, and *A*'s `active document's` `active sandboxing flag` set has its `sandboxed navigation browsing context flag` set, then return false.

2. Otherwise, if *B* is a `top-level` *browsing context*, and is one of the `ancestor` *browsing contexts* of *A*, then:

1. If *A*'s `WindowProxy`'s `[Window]` value has `transient activation` and *A*'s `active document's` `active sandboxing flag` set has its `sandboxed top-level navigation with user activation browsing context flag` set, then return false.

2. Otherwise, if *A*'s `WindowProxy`'s `[Window]` value does not have `transient activation` and *A*'s `active document's` `active sandboxing flag` set has its `sandboxed top-level navigation without user activation browsing context flag` set, then return false.

3. Otherwise, if *B* is a `top-level` *browsing context*, and is neither *A* nor one of the `ancestor` *browsing contexts* of *A*, and *A*'s `document's` `active sandboxing flag` set has its `sandboxed navigation browsing context flag` set, and *A* is not the `one permitted sandboxed navigator` of *B*, then return false.

4. Return true.

An element has a `browsing context scope origin` if its `Document's` `browsing context` is a `top-level` *browsing context* or if all of its `Document's` `ancestor` *browsing contexts* all have `active documents` whose `origin` are the `same origin` as the element's `node document's` `origin`. If an element has a `browsing context scope origin`, then its value is the `origin` of the element's `node document`.

7.1.4 Groupings of browsing contexts

A user agent holds a `browsing context group` (a `set` of `browsing context` *groups*).

A `browsing context` group holds a `browsing context` set (a `set` of `top-level` *browsing contexts*).

A `browsing context` group has an associated `cluster map` (a weak `map` of `agent cluster keys` to `agent clusters`). User agents are responsible for collecting agent clusters when it is deemed that nothing can access them anymore.

To create a new `browsing context` group, run these steps:

1. Let `group` be a new `browsing context` group.

2. `Append` `group` to the user agent's `browsing context group set`.

3. Let `browsingContext` be the result of `creating a new browsing context` with `null` and `group`.

4. `Append` `browsingContext` to `group`.

5. Return `group`.

To append a `top-level` *browsing context* `browsingContext` to a `browsing context group` `group`, run these steps:

1. `Append` `browsingContext` to `group's` `browsing context set`.

2. Set `browsingContext's` `group` to `group`.

To remove a `top-level` *browsing context* `browsingContext`, run these steps:

1. Assert: `browsingContext's` `group` is non-null, because a `browsing context` only gets `discarded` once.

2. Let `group` be `browsingContext's` `group`.

3. Set `browsingContext's` `group` to `null`.

4. `Remove` `browsingContext` from `group's` `browsing context set`.

5. If `group's` `browsing context set` is `empty`, then `remove` `group` from the user agent's `browsing context group set`.

Note

`Append` and `remove` are primitive operations that help define the lifetime of a `browsing context group`. They are called from `creating a new browsing context group`, `creating a new auxiliary browsing context`, and `discarding a browsing context`.

Note

The HTML Standard used to define "unit of related browsing contexts" and "unit of related similar-origin browsing contexts". These have been removed as they were not adequate.

7.1.5 Browsing context names

Browsing contexts can have a `browsing context name`. Unless stated otherwise, it is the empty string.

A `valid browsing context name` is any string with at least one character that does not start with a U+005F LOW LINE character. (Names starting with an underscore are reserved for special keywords.)

A `valid browsing context name` or `keyword` is any string that is either a `valid browsing context name` or that is an `ASCII case-insensitive` match for one of: `_blank`, `_self`, `_parent`, or `_top`.

These values have different meanings based on whether the page is sandboxed or not, as summarized in the following (non-normative) table. In this table, "current" means the `browsing context` that the link or script is in, "parent" means the `parent` *browsing context* of the one the link or script is in, "top" means the `top-level` *browsing context* of the one the link or script is in, "new" means a new `top-level` *browsing context* or `auxiliary` *browsing context* is to be created, subject to various user preferences and user agent policies, "none" means that nothing will happen, and "maybe new" means the same as "new" if the `"allow-new-page"` keyword is also specified on the `sandbox` attribute (or if the user overrode the sandboxing), and the same as "none" otherwise.

	<code>_blank</code>	<code>_self</code>	<code>_parent</code>	<code>_top</code>	<code>new</code>	<code>none</code>	<code>maybe new</code>
<code>browsing context name</code>	Same as the <code>browsing context name</code> of the <code>browsing context</code> that the link or script is in.	Same as the <code>browsing context name</code> of the <code>browsing context</code> that the link or script is in.	Same as the <code>browsing context name</code> of the <code>browsing context</code> that the link or script is in.	Same as the <code>browsing context name</code> of the <code>browsing context</code> that the link or script is in.	New <code>top-level</code> <i>browsing context</i> with the <code>browsing context name</code> of the <code>browsing context</code> that the link or script is in.	The same as the <code>browsing context name</code> of the <code>browsing context</code> that the link or script is in.	New <code>top-level</code> <i>browsing context</i> with the <code>browsing context name</code> of the <code>browsing context</code> that the link or script is in.

Keyword	Ordinary effect	Effect in an <code>iFrame</code> with... <code>sandbox="allow-top-navigation"</code>
none specified, for links and form submissions	current	current
<code>empty</code> string	current	current
<code>_blank</code>	new	maybe new
<code>_self</code>	current	current
<code>_parent</code> if there isn't a parent	current	current
<code>_parent</code> if parent is also top	parent/top	parent/top
<code>_parent</code> if there is one and it's not top	parent	none
<code>_top</code> if <code>top</code> is current	top	none
<code>_top</code> if <code>top</code> is not current	new	maybe new
name that doesn't exist	specified descendant	specified descendant
name that exists and is a descendant	current	current
name that exists and is current	specified ancestor	specified ancestor
name that exists and is an ancestor that is top	specified ancestor	none
name that exists and is an ancestor that is not top	specified ancestor	none
other name that exists with common top	specified	specified
name that exists with different top, if <code>familiar</code> and <code>one permitted sandboxed navigator</code>	specified	specified
name that exists with different top, if <code>familiar</code> but not <code>one permitted sandboxed navigator</code>	specified	none
name that exists with different top, not <code>familiar</code>	new	maybe new

Most of the restrictions on sandboxed browsing contexts are applied by other algorithms, e.g. the `navigating` algorithm, not the rules for choosing a browsing context given below.

The rules for choosing a browsing context, given a `browsing context name`, a `browsing context current`, and a boolean `noopen` are as follows:

1. Let `chosen` be null.
2. Let `new` be false.
3. Let `sandboxingFlagSet` be `current`'s `active document's active sandboxing flag set`.
4. If `name` is the empty string or an ASCII case-insensitive match for "`_self`", then set `chosen` to `current`.
5. Otherwise, if `name` is an ASCII case-insensitive match for "`_parent`", set `chosen` to `current`'s `parent browsing context`, if any, and `current` otherwise.
6. Otherwise, if `name` is an ASCII case-insensitive match for "`_top`", set `chosen` to `current`'s `top-level browsing context`, if any, and `current` otherwise.
7. Otherwise, if `name` is an ASCII case-insensitive match for "`_blank`", there exists a browsing context whose `name` is the same as `name`, `current` is `familiar with` that browsing context, and the user agent determines that the two browsing contexts are related enough that it is ok if they reach each other, set `chosen` to that browsing context. If there are multiple matching browsing contexts, the user agent should set `chosen` to one in some arbitrary consistent manner, such as the most recently opened, most recently focused, or more closely related.

This will be made more precise in [issue #113](#).

8. Otherwise, a new browsing context is being requested, and what happens depends on the user agent's configuration and abilities — it is determined by the rules given for the first applicable option from the following list:

If `current's WindowProxy's [[Window]]` value does not have `transient activation` and the user agent has been configured to not show popups (i.e. the user agent has a "popup blocker" enabled)

The user agent may inform the user that a popup has been blocked.

If `sandboxingFlagSet` has the `sandboxed auxiliary navigation browsing context flag set`

The user agent may offer the user one of:

1. Set `chosen` to the result of `creating a new top-level browsing context` and set `new` to true.
2. Set `chosen` to an existing `top-level browsing context`.

⚠️ Warning!

If this case occurs, it means that an author has explicitly sandboxed the document that is trying to open a link.

>Note

If the user declines or the user agent doesn't offer the above, the variables remain unchanged.

If the user agent has been configured such that in this instance it will create a new browsing context

1. Set `new` to true.
2. If `noopen` is true, then set `chosen` to the result of `creating a new top-level browsing context`.
3. Otherwise:
 1. Set `chosen` to the result of `creating a new auxiliary browsing context` with `current`.
 2. If `sandboxingFlagSet's sandboxed navigation browsing context flag` is set, then `current` must be set as `chosen's one permitted sandboxed navigator`.
 4. If `sandboxingFlagSet's sandbox propagates to auxiliary browsing contexts flag` is set, then all the flags that are set in `sandboxingFlagSet` must be set in `chosen's popup sandboxing flag set`.
 5. If `name` is not an ASCII case-insensitive match for "`_blank`", then set `chosen's name` to `name`.

Note

If the newly created `browsing context` is immediately `navigated`, then the navigation will be done with `replacement` enabled.

If the user agent has been configured such that in this instance it will reuse `current`

Set `chosen` to `current`.

If the user agent has been configured such that in this instance it will not find a browsing context

Do nothing.

Note

User agents are encouraged to provide a way for users to configure the user agent to always reuse `current`.

9. Return `chosen` and `new`.

7.2 Security infrastructure for `Window`, `WindowProxy`, and `Location` objects

Although typically objects cannot be accessed across `origins`, the web platform would not be true to itself if it did not have some legacy exceptions to that rule that the web depends upon.

7.2.1 Integration with IDL

When `perform a security check` is invoked, with a `platformObject`, `identifier`, and `type`, run these steps:

1. If `platformObject` is not a `Window` or `Location` object, then return.
2. Repeat for each `e` that is an element of `!CrossOriginProperties!(platformObject)`:
 1. If `SameValue(e[[Property]], identifier)` is true, then:
 1. If `type` is "`method`" and `e` has neither `[[NeedsGet]]` nor `[[NeedsSet]]`, then return.
 2. Otherwise, if `type` is "`getter`" and `e.[[NeedsGet]]` is true, then return.
 3. Otherwise, if `type` is "`setter`" and `e.[[NeedsSet]]` is true, then return.
 3. If `! IsPlatformObjectSameOrigin(platformObject)` is false, then throw a `"SecurityError" DOMException`.

7.2.2 Shared internal slot: `!CrossOriginPropertyDescriptorMap`

`Window` and `Location` objects both have a `!CrossOriginPropertyDescriptorMap` internal slot, whose value is initially an empty map.

Note
The `!CrossOriginPropertyDescriptorMap` internal slot contains a map with entries whose keys are `(currentGlobal, objectGlobal, propertyKey)`-tuples and values are property descriptors, as a memoization of what is visible to scripts when `currentGlobal` inspects a `Window` or `Location` object from `objectGlobal`. It is filled lazily by `CrossOriginGetPropertyHelper`, which consults its future lookups.

User agents should allow a value held in the map to be garbage collected along with its corresponding key when nothing holds a reference to any part of the value. That is, as long as garbage collection is not observable.

Example
For example, with `const href = Object.getOwnPropertyDescriptor(crossOriginLocation, "href")`, set the value and its corresponding key in the map cannot be garbage collected as that would be observable.

User agents may have an optimization whereby they remove key-value pairs from the map when `document.domain` is set. This is not observable as `document.domain` cannot revisit an earlier value.

Example
For example, setting `document.domain` to "example.com" on `www.example.com` means user agents can remove all key-value pairs from the map where part of the key is `www.example.com`, as that can never be part of the `origin` again and therefore the corresponding value could never be retrieved from the map.

7.2.3 Shared abstract operations

7.2.3.1 `CrossOriginProperties (O)`

1. Assert: `O` is a `Location` or `Window` object.
2. If `O` is a `Location` object, then return `{ [[Property]]: "href", [[NeedsGet]]: false, [[NeedsSet]]: true, { [[Property]]: "replace" } }`.
3. Let `crossOriginWindowProperties` be `{ [[Property]]: "window", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "self", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "location", [[NeedsGet]]: true, [[NeedsSet]]: true, { [[Property]]: "close" } }, { [[Property]]: "closed", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "parent", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "frames", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "length", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "top", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "postMessage" } }`.
4. Repeat for each `e` that is an element of `O's document.child browsing context name property set`.
 1. Add `{ [[Property]]: e, [[HideFromKeys]]: true }` as the last element of `crossOriginWindowProperties`.
5. Return `crossOriginWindowProperties`.

Note

Indexed properties do not need to be safelisted as they are handled directly by the `WindowProxy` object.

7.2.3.2 `CrossOriginPropertyFallback (P)`

1. If `P` is "`chan`", `@toStringTag`, `@hasInstance`, or `@isConcatSpreadable`, then return `PropertyDescriptor{ [[Value]]: undefined, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }`.
2. Throw a `"SecurityError" DOMException`.

7.2.3.3 `IsPlatformObjectSameOrigin (O)`

1. Return true if the `current settings object's origin` is `same origin domain` with `O's relevant settings object's origin`, and false otherwise.

[View the latest version of this page \(v0.1\)](#)

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Note
If this abstract operation returns undefined and there is no custom behavior, the caller needs to throw a `"SecurityError"` `DOMException`. In practice this is handled by the caller calling `CrossOriginPropertyFallback`.

- Let `crossOriginKey` be a tuple consisting of the `current settings object`, `O's relevant settings object`, and `P`.
- Repeat for each `e` that is an element of `! CrossOriginProperties(O)`:
 - If `SameValue(e.[[Property]], P)` is true, then:
 - If the value of the `[[CrossOriginPropertyDescriptorMap]]` internal slot of `O` contains an entry whose key is `crossOriginKey`, then return that entry's value.
 - Let `originalDesc` be `OrdinaryGetOwnProperty(O, P)`.
 - Let `crossOriginDesc` be undefined.
 - If `e.[[NeedsGet]]` and `e.[[NeedsSet]]` are absent, then:
 - Let `value` be `originalDesc.[[Value]]`.
 - If `! IsCallable(value)` is true, then set `value` to an anonymous built-in function, created in the `current Realm Record`, that performs the same steps as the IDL operation `P` on object `O`.
 - Set `crossOriginDesc` to `PropertyDescriptor{ [[Value]]: value, [[Enumerable]]: false, [[Writable]]: false, [[Configurable]]: true }`.
 - Otherwise:
 - Let `crossOriginGet` be undefined.
 - If `e.[[NeedsGet]]` is true, then set `crossOriginGet` to an anonymous built-in function, created in the `current Realm Record`, that performs the same steps as the getter of the IDL attribute `P` on object `O`.
 - Let `crossOriginSet` be undefined.
 - If `e.[[NeedsSet]]` is true, then set `crossOriginSet` to an anonymous built-in function, created in the `current Realm Record`, that performs the same steps as the setter of the IDL attribute `P` on object `O`.
 - Set `crossOriginDesc` to `PropertyDescriptor{ [[Get]]: crossOriginGet, [[Set]]: crossOriginSet, [[Enumerable]]: false, [[Configurable]]: true }`.
 - Create an entry in the value of the `[[CrossOriginPropertyDescriptorMap]]` internal slot of `O` with key `crossOriginKey` and value `crossOriginDesc`.
 - Return `crossOriginDesc`.
- Return undefined.

Note
The reason that the property descriptors produced here are configurable is to preserve the [invariants of the essential internal methods](#) required by the JavaScript specification. In particular, since the value of the property can change as a consequence of navigation, it is required that the property be configurable. (However, see [tc39/ecma262 issue #672](#) and references to it elsewhere in this specification for cases where we are not able to preserve these invariants, for compatibility with existing Web content.) [JAVASCRIPT1](#)

Note
The reason the property descriptors are non-enumerable, despite this mismatching the same-origin behavior, is for compatibility with existing Web content. See [issue #3183](#) for details.

7.2.3.5 CrossOriginGet (O, P, Receiver)

- Let `desc` be `O.[[GetOwnProperty]](P)`.
- Assert: `desc` is not undefined.
- If `! IsDataDescriptor(desc)` is true, then return `desc.[[Value]]`.
- Assert: `IsAccessorDescriptor(desc)` is true.
- Let `getter` be `desc.[[Get]]`.
- If `getter` is undefined, then throw a `"SecurityError"` `DOMException`.
- Return `? Call(getter, Receiver)`.

7.2.3.6 CrossOriginSet (O, P, V, Receiver)

- Let `desc` be `O.[[GetOwnProperty]](P)`.
- Assert: `desc` is not undefined.
- If `desc.[[Set]]` is present and its value is not undefined, then:
 - Perform `? Call(setter, Receiver, !V)`.
 - Return true.
- Throw a `"SecurityError"` `DOMException`.

7.2.3.7 CrossOriginOwnPropertyKeys (O)

- Let `keys` be a new empty `List`.
- Repeat for each `e` that is an element of `! CrossOriginProperties(O)`:
 - If `e.[[HideFromKeys]]` is not true, `append e.[[Property]]` to `keys`.
 - If `keys` does not contain `"then"`, then `append "then"` to `keys`.
- Return the concatenation of `keys` and `w.[@toStringTag], w.[@hasInstance], w.[@isConcatSpreadable]`.

7.3 The Window object

```
IDL([GlobalWindow,
Exposed<Window>,
LegacyNameableObjectProperties]
interface Window {
  // the current browsing context
  [Unforgeable] readonly attribute WindowProxy window;
  [Unforgeable] readonly attribute Document document;
  attribute DOMString name;
  [Replaceable] readonly attribute Location location;
  readonly attribute History history;
  [Replaceable] readonly attribute BarProp notifications;
  [Replaceable] readonly attribute BarProp mailbar;
  [Replaceable] readonly attribute BarProp scrollbars;
  [Replaceable] readonly attribute BarProp statusbar;
  attribute DOMString status;
  void close();
  void [Settable] attribute Boolean closed;
  void stop();
  void [Settable] attribute String title;
  // other browsing contexts
  [Replaceable] readonly attribute WindowProxy frames;
  [Replaceable] readonly attribute UnsignedLong length;
  [Replaceable] readonly attribute WindowProxy top;
  attribute any opener;
  [Replaceable] readonly attribute WindowProxy parent;
  [Replaceable] optional DOMString url = "", optional DOMString target = "_blank", optional [TreatNullAs=EmptyString] DOMString features = "";
  getter Object(DOMString name);
  WindowProxy open(optional DOMString url = "", optional DOMString target = "_blank", optional [TreatNullAs=EmptyString] DOMString features = "");
  // object on the prototype chain. Indeed, this does not make the global object an exotic object.
  // Indexed access is taken care of by the WindowProxy exotic object.
  // the user agent
  [Replaceable] readonly attribute ApplicationCache applicationCache;
  // user prompts
  void alert();
  void [Settable] (DOMString message);
  void [Settable] (optional DOMString message = "");
  DOMString prompt(optional DOMString message = "", optional DOMString default = "");
  void print();
  void postMessage(any message, USVString targetOrigin, optional Sequence<Object> transfer = []);
  void [Settable] (any message, optional WindowPostMessageOptions options = {});
  // Window includes GlobalEventHandlers;
  // Window includes GlobalEventHandlers;
  dictionary WindowPostMessageOptions : PostMessageOptions {
    USVString targetOrigin = "*";
  };
}
```

For web developers (non-normative)

```
window, window
window.window
window.frames
window.self
```

These attributes all return `window`.

`window.document`
Returns the `Document` associated with `window`.

`window.defaultView`
Returns the `Window` object of the `active document`.

The `window` object has an *associated document*, which is a `Document` object. It is set when the `window` object is created, and only ever changed during `navigation` from the initial `about:blank` `Document`.

The `window` object's *browsing context* is the `window` object's *associated document's browsing context*.

Note
It is either null or a `browsing context`.

The `document` IDL attribute, on getting, must return this `Window` object's `associated Document`.[Note](#)

The `Document` object associated with a `Window` object can change in exactly one case: when the `navigate` algorithm creates a new `Document` object for the first page loaded in a `browsing context`. In that specific case, the `Window` object of the original `about:blank` page is reused and gets a new `Document` object.

For historical reasons, `Window` objects must also have a writable, configurable, non-enumerable property named `HTMLDocument` whose value is the `Document` interface object.

7.3.1 APIs for creating and navigating browsing contexts by name

For web developers (non-normative)`window = window.open(url[, target[, features]])`Opens a window to show `url` (defaults to `about:blank`), and returns it. The `target` argument gives the name of the new window. If a window exists with that name already, it is reused. The `features` argument can be used to influence the rendering of the new window.`window.name [= value]`

Returns the name of the window.

Can be set, to change the name.

`window.closed()`

Closes the window.

`window.closed`

Returns true if the window has been closed, false otherwise.

`window.stop()`

Cancels the document load.

The `window.open` steps, given a string `url`, a string `target`, and a string `features`, are as follows:

1. If the `event loop's termination nesting level` is nonzero, return null.
2. Let `entry settings` be the `entry settings` object.
3. Let `source browsing context` be the `responsible browsing context` specified by `entry settings`.
4. If `target` is the empty string, then set `target` to "`_blank`".
5. Let `tokenizedFeatures` be the result of `tokenizing features`.
6. Let `noopener` and `norreferrer` be false.
7. If `tokenizedFeatures["no opener"]` exists, then:
 1. Set `no opener` to the result of `parsing tokenizedFeature("no opener") as a boolean feature`.
 2. Remove `tokenizedFeatures["no opener"]`.
8. If `tokenizedFeatures["no referrer"]` exists, then:
 1. Set `no referrer` to the result of `parsing tokenizedFeature("no referrer") as a boolean feature`.
 2. Remove `tokenizedFeatures["no referrer"]`.
9. If `no referrer` is true, then set `no opener` to true.

10. Let `target browsing context` and `new` be the result of applying the rules for choosing a browsing context given `target`, `source browsing context`, and `no opener`.**Example**

If there is a user agent that supports control-clicking a link to open it in a new tab, and the user control-clicks on an element whose `onclick` handler uses the `window.open()` API to open a page in an `a frame` element, the user agent could override the selection of the target browsing context to instead target a new tab.

11. If `target browsing context` is null, then return null.12. If `new` is true, then `set up browsing context features` for `target browsing context` given `tokenizedFeatures`. ([CSSOMVIEW](#))13. Let `uriRecord` be the `URL` "`about:blank`".14. If `url` is not the empty string or `new` is true, then:

1. If `url` is not the empty string, then `parse url` relative to `entry settings`, and set `uriRecord` to the `resulting URL record`, if any. If the `parse a URL` algorithm failed, then throw a `"syntaxError"` `PDMException`.
2. Let `request` be a new `Request` whose `URL` is `uriRecord`.
3. If `no referrer` is true, then set `request.referrer` to "`no referrer`".
4. If `uriRecord` is "`about:blank`" and `new` is true, then `queue a task to fire an event` named `load` at `target browsing context's Window object`, with the legacy `target override flag` set.
5. Otherwise, `navigate target browsing context to request`, with the `exceptions enabled flag` set. If `new` is true, then `replacement must be enabled`. The `source browsing context` is `source browsing context`. Rethrow any exceptions.

15. If `no opener` is true, then return null.16. Otherwise, if `new` is false, set `target browsing context's opener browsing context` to `source browsing context`.**Note**

If `new` is true this is done as part of `creating a new auxiliary browsing context`.

MDN[Window/open](#)

Support in all current engines.

Firefox1+Safari1+Chrome1+

Opera3+Edge79+

Edge (Legacy)12+Internet Explorer4+

Firefox, Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android10.1+

The `open(url, target, features)` method on `Window` objects provides a mechanism for [navigating](#) an existing [browsing context](#) or opening and navigating an [auxiliary browsing context](#).

When the method is invoked, the user agent must run the `window.open steps` with `url`, `target`, and `features`.

To [tokenize the features argument](#):

1. Let `tokenizedFeatures` be a new [ordered map](#).

2. Let `position` point at the first code point of `features`.

3. [While position](#) is not past the end of `features`:

1. Let `name` be the empty string.

2. Let `value` be the empty string.

3. [Collect a sequence of code points](#) that are [feature separators](#) from `features` given `position`. This skips past leading separators before the name.

4. [Collect a sequence of code points](#) that are not [feature separators](#) from `features` given `position`. Set `name` to the collected characters, [converted to ASCII lowercase](#).

5. Set `name` to the result of [normalizing the feature name](#).

6. [While position](#) is not past the end of `features` and the code point at `position in features` is not U+003D (=):

1. If the code point at `position in features` is U+002C (,), or if it is not a [feature separator](#), then `break`.

2. Advance `position` by 1.

7. If the code point at `position in features` is a [feature separator](#):

1. While `position` is not past the end of `features` and the code point at `position in features` is a [feature separator](#):

1. If the code point at `position in features` is U+002C (,), then `break`.

2. Advance `position` by 1.

Note
This skips to the first U+003D (=) but does not skip past a U+002C (,) or a non-separator.

2. [Collect a sequence of code points](#) that are not [feature separators](#) code points from `features` given `position`. Set `value` to the collected code points, [converted to ASCII lowercase](#).

8. If `name` is not the empty string, then set `tokenizedFeatures[name]` to `value`.

4. Return `tokenizedFeatures`.

A code point is a [feature separator](#) if it is [ASCII whitespace](#), U+003D (=), or U+002C (,).

For legacy reasons, there are some aliases of some feature names. To [normalize a feature name](#), switch on `name`:

```
"screen"
  Return "left".
"screen"
  Return "top".
"innerWidth"
  Return "width".
"innerHeight"
  Return "height".
Anything else
  Return name.
```

To [parse a boolean feature](#) given a string `value`:

1. If `value` is the empty string, then return true.

2. If `value` is a case-sensitive match for `yes`, then return true.

3. Let `parsed` be the result of [parsing value as an integer](#).

4. If `parsed` is an error, then set it to 0.

5. Return false if `parsed` is 0, and true otherwise.

MDN[Window/name](#)

Support in all current engines.

FirefoxYesSafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet Explorer?

Firefox, AndroidYesSafari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

The `name` attribute's getter must run these steps:

1. If this `Window` object's [browsing context](#) is null, then return the empty string.

2. Return this `Window` object's [browsing context's name](#).

The `name` attribute's setter must run these steps:

1. If this `Window` object's [browsing context](#) is null, then return.

2. Set this `Window` object's [browsing context's name](#) to the given value.

Note
The name gets reset when the browsing context is [navigated](#) to another [origin](#).

MDN[Window/close](#)

Support in all current engines.

Firefox1+Safari1+Chrome1+

Opera3+Edge79+

Edge (Legacy)12+Internet Explorer4+

Firefox, Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android10.1+

The `close()` method must run these steps:

1. Let `current` be this `Window` object's [browsing context](#).

2. If `current` is null or its [is_closing](#) is true, then return.

3. If all the following are true

- `current` is [script-closable](#)
- the [document settings object's responsible browsing context](#) is familiar with `current`
- the [document settings object's responsible browsing context](#) is allowed to [navigate](#) `current`

then:

1. Set `current's is_closing` to true.

2. [Queue a task](#) on the DOM manipulation task source to [close current](#).

A [browsing context](#) is [script-closable](#) if it is an [auxiliary browsing context](#) that was created by a script (as opposed to by an action of the user), or if it is a [top-level browsing context](#) whose [session history](#) contains only one [document](#).

The `closed` attribute's getter must return true if this `Window` object's [browsing context](#) is null or its [is_closing](#) is true, and false otherwise.

MDN[Window/stop](#)

Support in all current engines.

FirefoxYesSafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet ExplorerNo

Firefox, AndroidYesSafari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

The `stop()` method must [stop document loading](#) given this `Window` object's [associated document](#).

7.3.2 Accessing other browsing contexts

This section is under review and subject to change.

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

`window.length`
Returns the number of [document-tree child browsing contexts](#).
`window[index]`
Returns the indicated [document-tree child browsing context](#).

The number of [document-tree child browsing contexts](#) of a `window` object W is the result of running these steps:

1. If W 's [browsing context](#) is null, then return 0.
2. Return the number of [document-tree child browsing contexts](#) of W 's [browsing context](#).

MDN

[Window.length](#)

Support in all current engines.

FirefoxYes SafariYes ChromeYes

OperaYes FidgE Yes

Edge (Legacy)12+ Internet Explorer?

Firefox AndroidYes Safari iOSYes Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidYes

The `length` IDL attribute's getter must return the [number of document-tree child browsing contexts](#) of this `window` object.

Note

Indexed access to [document-tree child browsing contexts](#) is defined through the `[!GetOwnProperty]` internal method of the `WindowProxy` object.

7.3.3 Named access on the `window` object

For web developers (non-normative)

`window[name]`

Returns the indicated element or collection of elements.

As a general rule, relying on this will lead to brittle code. Which IDs end up mapping to this API can vary over time, as new features are added to the Web platform, for example. Instead of this, use `document.getElementById()` or `document.querySelector()`.

The [document-tree child browsing context name](#) property set of a `window` object w is the return value of running these steps:

1. If w 's [browsing context](#) is null, then return the empty list.
2. Let `childBrowsingContexts` be all [document-tree child browsing contexts](#) of w 's [browsing context](#) whose [browsing context name](#) is not the empty string, in order, and including only the first [document-tree child browsing context](#) with a given [name](#) if multiple [document-tree child browsing contexts](#) have the same one.
3. Remove each [browsing context](#) from `childBrowsingContexts` whose [active document](#)'s [origin](#) is not same [origin](#) with w 's [relevant settings object](#)'s [origin](#) and whose [browsing context name](#) does not match the name of its [container](#)'s [name](#) content attribute value.
4. Return the [browsing context names](#) of `childBrowsingContexts`, in same order.

Example

This means that in the following example, hosted on <https://example.org/>, assuming <https://elsewhere.example.com/> sets `window.name` to "spices", evaluating `window.spices` after everything has loaded will yield undefined:

```
<iframe src="https://elsewhere.example.com/"></iframe>
<iframe name="spices"></iframe>
```

The `window` object [supports named properties](#). The [supported property names](#) of a `window` object w at any moment consist of the following, in [tree order](#) according to the element that contributed them, ignoring later duplicates:

- w 's [document-tree child browsing context name property set](#):
- the value of the [name](#) content attribute for all `object`, `form`, `img`, and `object` elements that have a non-empty [name](#) content attribute and are [in a document tree](#) with w 's [associated document](#) as their [root](#); and
- the value of the [id](#) content attribute for all `HTML element`s that have a non-empty [id](#) content attribute and are [in a document tree](#) with w 's [associated document](#) as their [root](#).

To determine the value of a named property `name` in a `window` object w , the user agent must return the value obtained using the following steps:

1. Let `objects` be the list of [named objects](#) of w with the name `name`.

Note

There will be at least one such object, by definition.

2. If `objects` contains a [browsing context](#), then return the `WindowProxy` object of the nested [browsing context](#) of the first [browsing context container](#) in [tree order](#) whose [nested browsing context](#) is in `objects`.
3. Otherwise, if `objects` has only one element, return that element.
4. Otherwise return a `NodeCollection` rooted at w 's [associated document](#), whose filter matches only [named objects](#) of w with the name `name`. (By definition, these will all be elements.)

Named objects of a `window` object w with the name `name`, for the purposes of the above algorithm, consist of the following:

- w 's [document-tree child browsing contexts](#) of w 's [associated document](#), whose `name` is `name`;
- `object`, `form`, `img`, or `object` elements that have a [name](#) content attribute whose value is `name` and are [in a document tree](#) with w 's [associated document](#) as their [root](#); and
- `HTML element`s that have an `id` content attribute whose value is `name` and are [in a document tree](#) with w 's [associated document](#) as their [root](#).

7.3.4 Discarding browsing contexts

To discard a `Document` `document`:

1. Set `document's` [safelyreadable](#) state to false.
2. Run any [unloading document cleanup steps](#) for `document` that are defined by this specification and [other applicable specifications](#).
3. [Abort](#) `document`.
4. Remove any [tasks](#) associated with `document` in any [task source](#), without running those tasks.
5. [Discard](#) all the [child browsing contexts](#) of `document`.
6. For each [SessionHistoryEntry](#) entry with a `Document` object equal to `document`, remove entry's `document` object.
7. Set `document's` [browsing context](#) to null.

8. [Remove](#) `document` from the [owner](#) set of each `WorkerGlobalScope` object whose set [contains](#) `document`.

To discard a [browsing context](#) `browsingContext`, run these steps:

1. [Discard](#) all `Document` objects for all the entries in `browsingContext's` [session history](#).
2. If `browsingContext` is a [top-level browsing context](#), then [remove](#) `browsingContext`.

User agents may [discard top-level browsing contexts](#) at any time (typically, in response to user requests, e.g., when a user force-closes a window containing one or more [top-level browsing contexts](#)). Other [browsing contexts](#) must be discarded once their `WindowProxy` object is eligible for garbage collection, in addition to the other places where this specification requires them to be discarded.

7.3.5 Closing browsing contexts

To close a [browsing context](#) `browsingContext`, run these steps:

1. [Prompt to unload](#) `browsingContext's` [active document](#). If the user [refused to allow the document to be unloaded](#), then return.
2. [Unload](#) `browsingContext's` [active document](#).
3. Remove `browsingContext` from the user interface (e.g., close or hide its tab in a tabbed browser).
4. [Discard](#) `browsingContext`.

User agents should offer users the ability to arbitrarily [close](#) any [top-level browsing context](#).

7.3.6 Browser interface elements

To allow Web pages to integrate with Web browsers, certain Web browser interface elements are exposed in a limited way to scripts in Web pages.

Each interface element is represented by a `BarProp` object:

```
IDL:[Exposed=Window]
interface BarProp {
  readonly attribute boolean visible;
};
```

For web developers (non-normative)

`window.location.visible`

Returns true if the location bar is visible; otherwise, returns false.

`window.menuBar.visible`

Returns true if the menu bar is visible; otherwise, returns false.

`window.personalBar.visible`

Returns true if the personal bar is visible; otherwise, returns false.

`window.scrollbars.visible`

Returns true if the scrollbars are visible; otherwise, returns false.

`window.statusBar.visible`

Returns true if the status bar is visible; otherwise, returns false.

`window.toolbar.visible`

Returns true if the toolbar is visible; otherwise, returns false.

The `visible` attribute's getter must run these steps:

1. If this `barprop` object's [relevant global object](#)'s [browsing context](#) is null, then return false.

3. Return true or a value determined by the user agent to most accurately represent the visibility state of the user interface element that the object represents, as described below.

The following `barProp` objects must exist for each `window` object:

`location bar barProp object`

Represents the user interface element that contains a control that displays the `URL` of the `active document`, or some similar interface concept.

`menu bar barProp object`

Represents the user interface element that contains a list of commands in menu form, or some similar interface concept.

`personal bar barProp object`

Represents the user interface element that contains links to the user's favorite pages, or some similar interface concept.

`scrollbar barProp object`

Represents the user interface element that contains a scrolling mechanism, or some similar interface concept.

`status bar barProp object`

Represents a user interface element found immediately below or after the document, as appropriate for the user's media, which typically provides information about ongoing network activity or information about elements that the user's pointing device is current indicating. If the user agent has no such user interface element, then the object may act as if the corresponding user interface element was absent (i.e. its `visible` attribute may return false).

`toolbar barProp object`

Represents the user interface element found immediately above or before the document, as appropriate for the user's media, which typically provides `session history` traversal controls (back and forward buttons, reload buttons, etc). If the user agent has no such user interface element, then the object may act as if the corresponding user interface element was absent (i.e. its `visible` attribute may return false).

For historical reasons, the `status` attribute on the `window` object must, on getting, return the last string it was set to, and on setting, must set itself to the new value. When the `window` object is created, the attribute must be set to the empty string. It does not do anything else.

7.3.7 Script settings for `window` objects

When the user agent is set up to set up a `window` environment settings object, given a JavaScript execution context, execution context and an optional `environment` reserved environment, it must run the following steps:

1. Let `realm` be the value of `execution context`'s Realm component.

2. Let `window` be `realm`'s `global object`.

3. Let `url` be a copy of the `URL` of `window`'s `associated document`.

4. Let `settings object` be a new `environment settings object` whose algorithms are defined as follows:

The `realm execution context`

Return `execution context`.

The `module map`

Return the `module map` of `window`'s `associated document`.

The `responsible browsing context`

Return `window`'s `browsing context`.

The `responsible event loop`

Return the `event loop` associated with `window`'s `relevant agent`.

The `responsible document`

Return `window`'s `associated document`.

The `API URL character encoding`

Return the current `character encoding` of `window`'s `associated document`.

The `API base URL`

Return the current `base URL` of `window`'s `associated document`.

The `origin`

The `HTTPS state`Return the `HTTPS state` of `window's associated Document`.The `referrer policy`

1. Let `document` be `window's associated Document`.
2. While `document` is an `iframe` `embed` `document` and `document's referrer policy` is the empty string, set `document` to `document's browsing context's container document`.
3. Return `document's referrer policy`.

5. If reserved environment is given, then:

1. Set `settings object's id` to reserved environment's `creation URL`, `settings object's creation URL` to reserved environment's `creation URL`, `settings object's target browsing context` to reserved environment's `target browsing context`, and `settings object's active service worker` to reserved environment's `active service worker`.
2. Set reserved environment's `id` to the empty string.

NoteThe identity of the reserved environment is considered to be fully transferred to the created environment settings object. The reserved environment is not searchable by the environment's `id` from this point on.6. Otherwise, set `settings object's id` to a new unique opaque string, `settings object's creation URL` to `url`, `settings object's target browsing context` to null, and `settings object's active service worker` to null.7. Set `realm's [[HostDefined]]` field to `settings object`.8. Return `settings object`.**7.4 The `WindowProxy` exotic object**`WindowProxy` is an exotic object that wraps a `Window` ordinary object, redirecting most operations through to the wrapped object. Each `browsing context` has an associated `WindowProxy` object. When the `browsing context` is navigated, the `Window` object wrapped by the `browsing context`'s associated `WindowProxy` object is changed.The `WindowProxy` exotic object must use the ordinary internal methods except where it is explicitly specified otherwise below.There is no `WindowProxy interface object`.Every `WindowProxy` object has a `[[Window]]` internal slot representing the wrapped `Window` object.**Note**Although `WindowProxy` is named as a "proxy", it does not do polymorphic dispatch on its target's internal methods as a real proxy would, due to a desire to reuse machinery between `WindowProxy` and `Location` objects. As long as the `Window` object remains an ordinary object this is unobservable and can be implemented either way.**7.4.1 [[GetPrototypeOf]] ()**

1. Let `W` be the value of the `[[Window]]` internal slot of `this`.
2. If ! `IsPlatformObjectSameOrigin(W)` is true, then return ? `OrdinaryGetPrototypeOf(W)`.
3. Return null.

7.4.2 [[SetPrototypeOf]] (`V`)

1. Return ? `OrdinarySetPrototypeOf(this, V)`.

7.4.3 [[IsExtensible]] ()

1. Return true.

7.4.4 [[PreventExtensions]] ()

1. Return false.

7.4.5 [[GetOwnProperty]] (`P`)

1. Let `W` be the value of the `[[Window]]` internal slot of `this`.
2. If `P` is an `array index property name`, then:
 1. Let `index` be ! `ToInteger(P)`.
 2. Let `maxProperties` be the `number of document-tree child browsing contexts` of `W`.
 3. Let `value` be undefined.
3. If `maxProperties` is greater than 0 and `index` is less than `maxProperties`, then set `value` to the `WindowProxy` object of the `index`th `document-tree child browsing context` of `W`'s `browsing context`, sorted in the order that their `browsing context contained` elements were most recently inserted into `W`'s `associated document`, the `WindowProxy` object of the most recently inserted `browsing context contained`'s `nesting` `browsing context` being last.
4. If `value` is undefined, then:
 1. If ! `IsPlatformObjectSameOrigin(W)` is true, then return undefined.
 2. Throw a "`SecurityError`" `DOMException`.

6. If `P` is not an `array index property name`, then return ? `OrdinaryGetOwnProperty(W, P)`.**Note**
This is a willful violation of the JavaScript specification's invariants of the essential internal methods to maintain compatibility with existing Web content. See [tc39/ecma262 issue #672](#) for more information. [\[JAVASCRIPT\]](#)7. If `property` is ! `CrossOriginGetOwnPropertyHelper(W, P)`.8. If `property` is not undefined, then return `property`.9. If `property` is undefined and `P` is `W`'s `document-tree child browsing context name property set`, then:

1. Let `value` be the `WindowProxy` object of the `named object` of `W` with the name `P`.
2. Return `PropertyDescriptor` { `[[Value]]`: `value`, `[[Enumerable]]`: false, `[[Writable]]`: false, `[[Configurable]]`: true }.

Note
The reason the property descriptors are non-enumerable, despite this mismatching the same-origin behavior, is for compatibility with existing Web content. See [issue #3183](#) for details.10. Return ? `CrossOriginGetPropertyFallback(P)`.**7.4.6 [[DefineOwnProperty]] (`P, Desc`)**

1. Let `W` be the value of the `[[Window]]` internal slot of `this`.
2. If ! `IsPlatformObjectSameOrigin(W)` is true, then:
 1. If `P` is an `array index property name`, return false.
 2. Return ? `OrdinaryDefineOwnProperty(W, P, Desc)`.

Note
This is a willful violation of the JavaScript specification's invariants of the essential internal methods to maintain compatibility with existing Web content. See [tc39/ecma262 issue #672](#) for more information. [\[JAVASCRIPT\]](#)3. Throw a "`SecurityError`" `DOMException`.**7.4.7 [[Get]] (`P, Receiver`)**

1. Let `W` be the value of the `[[Window]]` internal slot of `this`.
2. If ! `IsPlatformObjectSameOrigin(W)` is true, then return ? `OrdinaryGet(this, P, Receiver)`.
3. Return ? `CrossOriginGet(this, P, Receiver)`.

Note`this` is passed rather than `W` as `OrdinaryGet` and `CrossOriginGet` will invoke the `[[GetOwnProperty]]` internal method.**7.4.8 [[Set]] (`P, V, Receiver`)**

1. Let `W` be the value of the `[[Window]]` internal slot of `this`.
2. If ! `IsPlatformObjectSameOrigin(W)` is true, then return ? `OrdinarySet(this, P, V, Receiver)`.
3. Return ? `CrossOriginSet(this, P, V, Receiver)`.

Note`this` is passed rather than `W` as `OrdinarySet` and `CrossOriginSet` will invoke the `[[GetOwnProperty]]` internal method. `OrdinarySet` will also invoke the `[[DefineOwnProperty]]` internal method.**7.4.9 [[Delete]] (`P`)**

1. Let `W` be the value of the `[[Window]]` internal slot of `this`.
2. If ! `IsPlatformObjectSameOrigin(W)` is true, then:
 1. If `P` is an `array index property name`, then:
 1. Let `desc` be ! `OrdinaryGetOwnProperty(P)`.
 2. If `desc` is undefined, then return true.
 3. Return false.
 2. Return ? `OrdinaryDelete(W, P)`.

Note
This is a willful violation of the JavaScript specification's invariants of the essential internal methods to maintain compatibility with existing Web content. See [tc39/ecma262 issue #672](#) for more information. [\[JAVASCRIPT\]](#)**7.4.10 [[OwnPropertyKeys]] ()**

1. Let `W` be the value of the `[[Window]]` internal slot of `this`.
2. Let `keys` be a new empty `List`.
3. Let `maxProperties` be the `number of document-tree child browsing contexts` of `W`.
4. Let `index` be 0.
5. Repeat while `index < maxProperties`,

2. Increment *index* by 1.

6. If ! *IsPlatformObjectSameOrigin*(*W*) is true, then return the concatenation of *keys* and ! *OrdinaryOwnPropertyKeys*(*W*).

7. Return the concatenation of *keys* and ! *CrossOriginOwnPropertyKeys*(*W*).

7.5 Origin

Origins are the fundamental currency of the Web's security model. Two actors in the Web platform that share an origin are assumed to trust each other and to have the same authority. Actors with differing origins are considered potentially hostile versus each other, and are isolated from each other to varying degrees.

Example

If Example Bank's Web site, hosted at `bank.example.com`, tries to examine the DOM of Example Charity's Web site, hosted at `charity.example.org`, a `"SecurityError"` `DOMException` will be raised.

An *origin* is one of the following:

An *opaque origin*

An internal value, with no serialization it can be recreated from (it is serialized as "`null`" per [serialization of an origin](#)), for which the only meaningful operation is testing for equality.

A *tuple origin*

A tuple consists of:

- A *scheme* ([scheme](#)).
- A *host* ([host](#)).
- A *port* ([port](#)).
- A *domain* (null or a [domain](#)). Null unless stated otherwise.

Note

Origins can be shared, e.g., among multiple [document](#) objects. Furthermore, *origins* are generally immutable. Only the *domain* of a *tuple origin* can be changed, and only through the [document.domain](#) API.

The effective domain of an *origin* is computed as follows:

1. If *origin* is an [opaque origin](#), then return null.

2. If *origin*'s *domain* is non-null, then return *origin*'s *domain*.

3. Return *origin*'s [host](#).

Various specification objects are defined to have an *origin*. These *origins* are determined as follows:

For [document](#) objects

The [create a new browsing context](#) and [navigation](#) algorithms assign the *origin* at construction time. Otherwise, the default default behavior as defined in [DOM](#) applies. [\[DOM\]](#)

For images of [img](#) elements

If the *image data* is [CORS-cross-origin](#)

A unique [opaque origin](#) assigned when the image is created.

If the *image data* is [CORS-same-origin](#)

The [img](#) element's node document's *origin*.

For [audio](#) and [video](#) elements

If the *media data* is [CORS-cross-origin](#)

A unique [opaque origin](#) assigned when the *media data* is fetched.

If the *media data* is [CORS-same-origin](#)

The [media](#) element's node document's *origin*.

Other specifications can override the above definitions by themselves specifying the origin of a particular [document](#) object, image, or [media element](#).

The [serialization of an origin](#) is the string obtained by applying the following algorithm to the given *origin* *origin*:

1. If *origin* is an [opaque origin](#), then return "`null`".

2. Otherwise, let *result* be *origin*'s [scheme](#).

3. Append ":" /" to *result*.

4. Append *origin*'s [host](#) [serialized](#) to *result*.

5. If *origin*'s [port](#) is non-null, append a U+003A COLON character (:), and *origin*'s [port serialized](#), to *result*.

6. Return *result*.

Example

The [serialization](#) of ("`https://xn--maraa-rrta.example`", `null`, `null`) is "`https://xn--maraa-rrta.example`".

Note

There used to also be a [Unicode serialization of an origin](#). However, it was never widely adopted.

Two *origins*, *A* and *B*, are said to be *same origin* if the following algorithm returns true:

1. If *A* and *B* are the same [opaque origin](#), then return true.

2. If *A* and *B* are both [tuple origins](#) and their [schemes](#), [hosts](#), and [port](#) are identical, then return true.

3. Return false.

Two *origins*, *A* and *B*, are said to be *same origin-domain* if the following algorithm returns true:

1. If *A* and *B* are the same [opaque origin](#), then return true.

2. If *A* and *B* are both [tuple origins](#), run these substeps:

1. If *A* and *B*'s [schemes](#) are identical, and their [domains](#) are identical and non-null, then return true.

2. Otherwise, if *A* and *B* are [same origin](#) and their [domains](#) are identical and null, then return true.

3. Return false.

Two *origins*, *A* and *B*, are said to be *schemefully same site* if the following algorithm returns true:

1. If *A* and *B* are the same [opaque origin](#), then return true.

2. If *A* and *B* are both [tuple origins](#), then:

1. Let *hostA* be *A*'s [host](#), and let *hostB* be *B*'s [host](#).

2. If *hostA* equal *hostB*, and *hostA*'s [registrable domain](#) is non-null, then return true.

3. If *hostA*'s [registrable domain](#) equals *hostB*'s [registrable domain](#) and is non-null, then return true.

3. Return false.

Two *origins*, *A* and *B*, are said to be *same site* if both of the following statements are true:

• *A* and *B* are [schemefully same site](#)

• *A* and *B* are either both [opaque origins](#), or both [tuple origins](#) with the same [scheme](#)

Note

Unlike the [same origin](#) and [same origin-domain](#) concepts, for [schemefully same site](#) and [same site](#), the [port](#) and [domain](#) components are ignored.

⚠ Warning!

For the reasons explained in [URL](#), the [same site](#) and [schemefully same site](#) concepts should be avoided when possible, in favor of [same origin](#) checks.

Example

Assuming that `suffix.example` is a [public suffix](#) and that `example.com` is not:

<i>A</i>	<i>B</i>	schemefully same site	same site
(" <code>https://example.com</code> ")	(" <code>https://sub.example.com</code> ")	✓	✓
(" <code>https://example.com</code> ")	(" <code>https://sub-other.example.com</code> ")	✓	✗
(" <code>https://example.com</code> ")	(" <code>https://non-secure.example.com</code> ")	✓	✗
(" <code>https://x.suffix.example</code> ")	(" <code>https://sub.r.suffix.example</code> ")	✓	✓
(" <code>https://x.suffix.example</code> ")	(" <code>https://sub-other.r.suffix.example</code> ")	✓	✓
(" <code>https://x.suffix.example</code> ")	(" <code>https://other.suffix.example</code> ")	✗	✗
(" <code>https://x.suffix.example</code> ")	(" <code>https://suffix.example</code> ")	✗	✗
(" <code>https://suffix.example</code> ")	(" <code>https://suffix.example</code> ")	✗	✗

(Here we have omitted the [port](#) and [domain](#) components since they are not considered.)

7.5.1 Relaxing the same-origin restriction

MDN

Document/domain

Support in all current engines.

OperaYesEdge79+

Edge (Legacy)12+Internet Explorers?

Firefox AndroidYes Safari iOSYes Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidYes

For web developers (non-normative)`document.domain [= domain]`

Returns the current domain used for security checks.

Can be set to a value that removes subdomains, to change the `origin's domain` to allow pages on other subdomains of the same domain (if they do the same thing) to access each other. (Can't be set in sandboxed `iframes`.)To determine if a string `hostSuffixString` is a registrable domain suffix of or is equal to a `host originalHost`, run these steps:

1. If `hostSuffixString` is the empty string, then return false.
2. Let `host` be the result of `parsing hostSuffixString`.
3. If `host` is failure, then return false.
4. If `host` does not `equal originalHost`, then:
 1. If `host` or `originalHost` is not a `domain`, then return false.

NoteThis excludes `hosts` that are an IPv4 address or an IPv6 address.2. If `host`, prefixed by a U+002E FULL STOP (.), does not exactly match the end of `originalHost`, then return false.3. If `host equals host's public suffix`, then return false. [\[URL\]](#)

5. Return true.

The `domain` attribute's getter must run these steps:

1. Let `effectiveDomain` be this `Document` object's `origin's effective domain`.
2. If `effectiveDomain` is null, then return the empty string.
3. Return `effectiveDomain serialized`.

The `domain` attribute's setter must run these steps:

1. If this `Document` object's `browsing context` is null, then throw a `"SecurityError" DOMException`.
2. If this `Document` object's active sandboxing flag set has its `sandboxed document.domain browsing context flag` set, then throw a `"SecurityError" DOMException`.
3. If this `Document` object is not allowed to use the `"document.domain"` feature, then throw a `"SecurityError" DOMException`.
4. Let `effectiveDomain` be this `Document` object's `origin's effective domain`.
5. If `effectiveDomain` is null, then throw a `"SecurityError" DOMException`.
6. If the given value is not a registrable domain suffix of and is not equal to `effectiveDomain`, then throw a `"SecurityError" DOMException`.
7. Set this `Document` object's `origin's domain` to the result of `parsing` the given value.

NoteThe `document.domain` attribute is used to enable pages on different hosts of a domain to access each other's DOMs.**⚠️ Warning!**Do not use the `document.domain` attribute when using shared hosting. If an untrusted third party is able to host an HTTP server at the same IP address but on a different port, then the same-origin protection that normally protects two different sites on the same host will fail, as the ports are ignored when comparing origins after the `document.domain` attribute has been used.**7.6 Sandboxing**A `sandboxing flag set` is a set of zero or more of the following flags, which are used to restrict the abilities that potentially untrusted resources have:**The sandboxed navigation browsing context flag**This flag prevents content from navigating browsing contexts other than the sandboxed browsing context itself (or browsing contexts further nested inside it), `auxiliary browsing contexts` (which are protected by the `sandboxed auxiliary navigation browsing context flag` defined next), and the `top-level browsing context` (which is protected by the `sandboxed top-level navigation without user activation browsing context flag` and `sandboxed top-level navigation with user activation browsing context flag` defined below).If the `sandboxed auxiliary navigation browsing context flag` is not set, then in certain cases the restrictions nonetheless allow popups (new `top-level browsing contexts`) to be opened. These `browsing contexts` always have one permitted sandboxed navigator, set when the browsing context is created, which allows the `browsing context` that created them to actually navigate them. (Otherwise, the `sandboxed navigation browsing context flag` would prevent them from being navigated even if they were opened.)**The sandboxed auxiliary navigation browsing context flag**This flag prevents content from creating new auxiliary browsing contexts, e.g. using the `target` attribute or the `window.open()` method.**The sandboxed top-level navigation without user activation browsing context flag**This flag prevents content from navigating their top-level browsing context and prevents content from closing their top-level browsing context. It is consulted only when the sandboxed browsing context's `WindowProxy`'s `[Window]` value does not have `transient activation`.When the `sandboxed top-level navigation without user activation browsing context flag` is not set, content can navigate its `top-level browsing context`, but other `browsing contexts` are still protected by the `sandboxed navigation browsing context flag` and possibly the `sandboxed auxiliary navigation browsing context flag`.**The sandboxed top-level navigation with user activation browsing context flag**This flag prevents content from navigating their top-level browsing context and prevents content from closing their top-level browsing context. It is consulted only when the sandboxed browsing context's `WindowProxy`'s `[Window]` value has `transient activation`.As with the `sandboxed top-level navigation without user activation browsing context flag`, this flag only affects the `top-level browsing context`; if it is not set, other `browsing contexts` might still be protected by other flags.**The sandboxed plugins browsing context flag**This flag prevents content from instantiating `plugins`, whether using the `embed` element, the `object` element, or through `navigation` of their nested browsing context, unless those `plugins` can be `secured`.**The sandboxed origin browsing context flag**This flag forces content into a unique `origin`, thus preventing it from accessing other content from the same `origin`.This flag also prevents script from reading or writing to the `document.cookie` IDL attribute, and blocks access to `localStorage`.**The sandboxed forms browsing context flag**

This flag blocks form submission.

The sandboxed pointer lock browsing context flagThis flag disables the Pointer Lock API (`[POINTERLOCK]`).**The sandboxed scripts browsing context flag**

This flag blocks script execution.

The sandboxed automatic features browsing context flagThis flag blocks features that trigger automatically, such as `automatically-playing-a-video` or `automatically-focusing-a-form-control`.**The sandboxed document.domain browsing context flag**This flag prevents content from using the `document.domain` setter.**The sandbox propagates to auxiliary browsing contexts flag**This flag prevents content from escaping the sandbox by ensuring that any `auxiliary browsing context` it creates inherits the content's active sandboxing flag set.**The sandboxed modals flag**

This flag prevents content from using any of the following features to produce modal dialogs:

- `window.alert()`
- `window.confirm()`
- `window.print()`
- `window.prompt()`
- `beforeunload` event

The sandboxed orientation lock browsing context flagThis flag disables the ability to lock the screen orientation. [\[SCREENORIENTATION\]](#)**The sandboxed presentation browsing context flag**This flag disables the Presentation API. [\[PRESENTATION\]](#)When the user agent is to parse a `sandboxing directive`, given a string `input`, a `sandboxing flag set` output, it must run the following steps:

1. Split `input` on ASCII whitespace, to obtain `tokens`.
2. Let `output` be empty.
3. Add the following flags to `output`:
 - The `sandboxed navigation browsing context flag`.
 - The `sandboxed auxiliary navigation browsing context flag`, unless `tokens` contains the `allow-popups` keyword.
 - The `sandboxed top-level navigation without user activation browsing context flag`, unless `tokens` contains the `allow-top-navigation` keyword.
 - The `sandboxed top-level navigation with user activation browsing context flag`, unless `tokens` contains either the `allow-top-navigation-by-user-activation` keyword or the `allow-top-navigation` keyword.

NoteThis means that if the `allow-top-navigation` is present, the `allow-top-navigation-by-user-activation` keyword will have no effect. For this reason, specifying both is a document conformance error.• The `sandboxed plugins browsing context flag`.• The `sandboxed origin browsing context flag`, unless `tokens` contains the `allow-same-origin` keyword.**Note**The `allow-same-origin` keyword is intended for two cases.

First, it can be used to allow content from the same site to be sandboxed to disable scripting, while still allowing access to the DOM of the sandboxed content.

Second, it can be used to embed content from a third-party site, sandboxed to prevent that site from opening pop-up windows, etc., without preventing the embedded page from communicating back to its originating site, using the database APIs to store data, etc.

- The `sandboxed forms` `browsing context flag`, unless `tokens` contains the `allow-forms` keyword.
- The `sandboxed pointer lock` `browsing context flag`, unless `tokens` contains the `allow-pointer-lock` keyword.
- The `sandboxed scripts` `browsing context flag`, unless `tokens` contains the `allow-scripts` keyword.
- The `sandboxed automatic features` `browsing context flag`, unless `tokens` contains the `allow-features` keyword (defined above).

Note
 This flag is relaxed by the same keyword as scripts, because when scripts are enabled these features are trivially possible anyway, and it would be unfortunate to force authors to use script to do them when sandboxed rather than allowing them to use the declarative features.

- The `sandboxed document domains` `browsing context flag`.
- The `sandbox` propagates to auxiliary `browsing contexts` flag, unless `tokens` contains the `allow-popups-to-escape-sandbox` keyword.
- The `sandboxed modal` flag, unless `tokens` contains the `allow-modals` keyword.
- The `sandboxed orientation lock` `browsing context flag`, unless `tokens` contains the `allow-orientation-lock` keyword.
- The `sandboxed presentation` `browsing context flag`, unless `tokens` contains the `allow-presentation` keyword.

Every `top-level browsing context` has a `popup sandboxing flag set`, which is a `sandboxing flag set`. When a `browsing context` is created, its `popup sandboxing flag set` must be empty. It is populated by the rules for choosing a `browsing context`.

Every `browsing context` that is an `iframe` element's `nested browsing context` has an `iframe` `sandboxing flag set`, which is a `sandboxing flag set`. Which flags in an `iframe` `sandboxing flag set` are set at any particular time is determined by the `iframe` element's `sandbox` attribute.

Every `Document` has an `active` `sandboxing flag set`, which is a `sandboxing flag set`. When the `Document` is created, its `active` `sandboxing flag set` must be empty. It is populated by the navigation algorithm.

Every resource that is obtained by the navigation algorithm has a forced `sandboxing flag set`, which is a `sandboxing flag set`. A resource by default has no flags set in its `forced` `sandboxing flag set`, but other specifications can define that certain flags are set.

Note
 In particular, the `forced` `sandboxing flag set` is used by Content Security Policy (CSP).

To determine sandboxing flags for a `browsing context` `browsing context`, return the union of the flags that are present in the following `sandboxing flag sets`:

- If `browsing context` is a `top-level browsing context`, then: the flags set on the `popup` `sandboxing flag set`.
- If `browsing context` is an `iframe` element's `nested browsing context`, then: the flags set on the `iframe` `sandboxing flag set`.
- If `browsing context` is a `child browsing context`, then: the flags set on `browsing context`'s `container document`'s `active` `sandboxing flag set`.

7.7 Session history and navigation

7.7.1 The session history of browsing contexts

The sequence of `Document`s in a `browsing context` is its `session history`. Each `browsing context`, including `child browsing contexts`, has a distinct session history. A `browsing context`'s session history consists of a flat list of `session history entries`. Each `session history entry` consists, at a minimum, of a `URL`, and each entry may in addition have `serialized state`, a `Document` object, form data, a scroll restoration mode, a scroll position, a `browsing context name`, and other information associated with it.

Note
 Each entry, when first created, has a `Document`. However, when a `Document` is not `active`, it's possible for it to be `discarded` to free resources. The `URL` and other data in a `session history entry` is then used to bring a new `Document` into being to take the place of the original, in case the user agent finds itself having to reactivate that `Document`.

Note
 Titles associated with `session history entries` need not have any relation with the current `title` of the `Document`. The title of a `session history entry` is intended to explain the state of the document at that point, so that the user can navigate the document's history.

URLs without associated `serialized state` are added to the session history as the user (or script) navigates from page to page.

Each `Document` object in a `browsing context`'s session history is associated with a unique `#history` object which must all model the same underlying `session history`.

The `history` attribute of the `Window` interface must return the object implementing the `History` interface for this `Window` object's `associated Document`.

`Serialized state` is a serialization (via `StructuredSerializeForStorage`) of an object representing a user interface state. We sometimes informally refer to "state objects", which are the objects representing user interface state supplied by the author, or alternately the objects created by deserializing (via `StructuredDeserialize`) serialized state.

Pages can `add serialized state` to the session history. These are then `deserialized` and `returned to the script` when the user (or script) goes back in the history, thus enabling authors to use the "navigation" metaphor even in one-page applications.

Note

`Serialized state` is intended to be used for two main purposes: first, storing a parsed description of the state in the `URL`, so that in the simple case an author doesn't have to do the parsing (though one would still need the parsing for handling `URLs` passed around by users, so it's only a minor optimization). Second, so that the author can store state that one wouldn't store in the URL because it only applies to the current `Document` instance and it would have to be reconstructed if a new `Document` were opened.

An example of the latter would be something like keeping track of the precise coordinate from which a pop-up `div` was made to animate, so that if the user goes back, it can be made to animate to the same location. Or alternatively, it could be used to keep a pointer into a cache of data that would be fetched from the server based on the information in the `URL`, so that when going back and forward, the information doesn't have to be fetched again.

At any point, one of the entries in the session history is the `current entry`. This is the entry representing the `active document` of the `browsing context`. Which entry is the `current entry` is changed by the algorithms defined in this specification, e.g. during `session history traversal`.

Note

The `current entry` is usually an entry for the `URL` of the `Document`. However, it can also be one of the entries for `serialized state` added to the history by that document.

An entry with `persisted user state` is one that also has user-agent defined state. This specification does not specify what kind of state can be stored.

Example

For example, some user agents might want to persist the scroll position, or the values of form controls.

Note

User agents that persist the value of form controls are encouraged to also persist their directionality (the value of the element's `dir` attribute). This prevents values from being displayed incorrectly after a history traversal when the user had originally entered the values with an explicit, non-default directionality.

MDN

[History/scrollRestoration](#)

Support in all current engines.

Firefox46+SafariYesChrome46+

Opera33+Edge79+

Edge (Legacy)NoInternet ExplorerNo

Firefox AndroidYes Safari iOSYes Chrome Android46+WebView AndroidNoSamsung Internet5.0+Opera AndroidYes

An entry's `scroll restoration mode` indicates whether the user agent should restore the persisted scroll position (if any) when traversing to it. The scroll restoration mode may be one of the following:

"auto"

The user agent is responsible for restoring the scroll position upon navigation.

"manual"
 The page is responsible for restoring the scroll position and the user agent does not attempt to do so automatically

If unspecified, the `scroll restoration mode` of a new entry must be set to "auto".

Entries that contain `serialized state` share the same `Document`, as the entry for the page that was active when they were added.

Contiguous entries that differ just by their `URL`'s `fragments` also share the same `Document`.

Note

All entries that share the same `Document` (and that are therefore merely different states of one particular document) are contiguous by definition.

Each `Document` in a `browsing context` can also have a `latest entry`. This is the entry for that `Document` to which the `browsing context`'s `session history` was most recently traversed. When a `Document` is created, it initially has no `latest entry`.

User agents may `discard` the `Document` objects of entries other than the `current entry` that are not referenced from any script, reloading the pages fresh when the user or script navigates back to such pages. This specification does not specify when user agents should discard `Document` objects and when they should cache them.

Entries that have had their `Document` objects discarded must, for the purposes of the algorithms given below, act as if they had not. When the user or script navigates back or forwards to a page which has no in-memory DOM objects, any other entries that shared the same `Document` object with it must share the new object as well.

7.7.2 The `#history` interface

  void backward(any data, DOMString title, optional USVString url = null);
  void replaceState(any data, DOMString title, optional USVString url = null);
}
```

For web developers (non-normative)

window.**history.length**Returns the number of entries in the [joint session history](#).window.**history.scrollRestoration** [=value]Returns the [scroll restoration mode](#) of the current entry in the [session history](#).Can be set, to change the [scroll restoration mode](#) of the current entry in the [session history](#).window.**history.state**Returns the current [serialized state](#), serialized into an object.window.**history.go**(**delta**)Goes back or forward the specified number of steps in the [joint session history](#).

A zero delta will reload the current page.

If the delta is out of range, does nothing.

window.**history.back**()Goes back one step in the [joint session history](#).

If there is no previous page, does nothing.

window.**history.forward**()Goes forward one step in the [joint session history](#).

If there is no next page, does nothing.

window.**history.pushState**(**data**, **title** [, **url**])

Pushes the given data onto the session history, with the given title, and, if provided and not null, the given URL.

window.**history.replaceState**(**data**, **title** [, **url**])

Updates the current entry in the session history to have the given data, title, and, if provided and not null, URL.

The [joint session history](#) of a [top-level browsing context](#) is the union of all the [session histories](#) of all [browsing contexts](#) of all the [fully active document](#) objects that share that [top-level browsing context](#), with all the entries that are [current entries](#) in their respective [session histories](#) removed except for the [current entry of the joint session history](#).The [current entry of the joint session history](#) is the entry that most recently became a [current entry](#) in its [session history](#).Entries in the [joint session history](#) are ordered chronologically by the time they were added to their respective [session histories](#). Each entry has an index; the earliest entry has index 0, and the subsequent entries are numbered with consecutively increasing integers (1, 2, 3, etc).

Note

Since each [Document](#) in a [browsing context](#) might have a different [event loop](#), the actual state of the [joint session history](#) can be somewhat nebulous. For example, two sibling [iframe](#) elements could both [traverse](#) from one unique origin to another at the same time, so their precise order might not be well-defined; similarly, since they might only find out about each other later, they might disagree about the length of the [joint session history](#).

MDN

[History.length](#)

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy)12+Internet Explorer10+

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The [length](#) attribute of the [History](#) interface, on getting, must return the number of entries in the [top-level browsing context's](#) [joint session history](#). If this [History](#) object is associated with a [document](#) that is not [fully active](#), getting must instead throw a ["SecurityError" DOMException](#).

The actual entries are not accessible from script.

The [scrollRestoration](#) attribute of the [History](#) interface, on getting, must return the [scroll restoration mode](#) of the current entry in the [session history](#). On setting, the [scroll restoration mode](#) of the current entry in the [session history](#) must be set to the new value. If this [History](#) object is associated with a [document](#) that is not [fully active](#), both getting and setting must instead throw a ["SecurityError" DOMException](#).The [state](#) attribute of the [History](#) interface, on getting, must return the last value it was set to by the user agent. If this [History](#) object is associated with a [document](#) that is not [fully active](#), getting must instead throw a ["SecurityError" DOMException](#). Initially, its value must be null.

JSDOM

[History.length](#)

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy)12+Internet Explorer10+

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

When the [go\(delta\)](#) method is invoked:

1. Let [document](#) be this [History](#) object's associated [document](#).
2. If [document](#) is not [fully active](#), then throw a ["SecurityError" DOMException](#).
3. If [delta](#) is 0, then act as if the [location.reload\(\)](#) method was called, and return.
4. [Traverse the history by a delta](#) with [delta](#) and [document's](#) [browsing context](#).

When the [back\(\)](#) method is invoked:

1. Let [document](#) be this [History](#) object's associated [document](#).
2. If [document](#) is not [fully active](#), then throw a ["SecurityError" DOMException](#).
3. [Traverse the history by a delta](#) with -1 and [document's](#) [browsing context](#).

When the [forward\(\)](#) method is invoked:

1. Let [document](#) be this [History](#) object's associated [document](#).
2. If [document](#) is not [fully active](#), then throw a ["SecurityError" DOMException](#).
3. [Traverse the history by a delta](#) with +1 and [document's](#) [browsing context](#).

Each [top-level browsing context](#) has a [session history traversal queue](#), initially empty, to which [tasks](#) can be added.Each [top-level browsing context](#), when created, must begin running the following algorithm, known as the [session history event loop](#) for that [top-level browsing context](#), in parallel:

1. Wait until this [top-level browsing context's](#) [session history traversal queue](#) is not empty.
2. Pull the first [task](#) from this [top-level browsing context's](#) [session history traversal queue](#), and execute it.
3. Return to the first step of this algorithm.

The [session history event loop](#) helps coordinate cross-browsing-context transitions of the [joint session history](#): since each [browsing context](#) might, at any particular time, have a different [event loop](#) (this can happen if the user navigates from [example.com](#) to [shop.example](#)), transitions would otherwise have to involve cross-event-loop synchronization.To [traverse the history by a delta](#) given [delta](#) and [browsing context's](#) [source browsing context](#), the user agent must append a [task](#) to this [top-level browsing context's](#) [session history traversal queue](#), the [task](#) consisting of running the following steps:

1. If the index of the [current entry of the joint session history](#) plus [delta](#) is less than zero or greater than or equal to the number of items in the [joint session history](#), then return.
2. Let [specified entry](#) be the entry in the [joint session history](#) whose index is the sum of [delta](#) and the index of the [current entry of the joint session history](#).
3. Let [specified browsing context](#) be the [browsing context](#) of the [specified entry](#).
4. If [source browsing context](#) is not [allowed to navigate specified browsing context](#), then return.
5. If the [specified browsing context's](#) [active document's](#) [unload a document](#) algorithm is currently running, return.
6. [Queue a task](#) that consists of running the following substeps. The relevant [event loop](#) is that of the [specified browsing context's](#) [active document](#). The [task source](#) for the queued task is the [history traversal task source](#).
 1. If there is an ongoing attempt to navigate [specified browsing context](#) that has not yet [matured](#) (i.e. it has not passed the point of making its [document](#) the [active document](#)), then cancel that attempt to navigate the [browsing context](#).
 2. If the [specified browsing context's](#) [active document](#) is not the same [document](#) as the [document](#) of the [specified entry](#), then run these substeps:
 1. [Prompt to unload the active document of the specified browsing context](#). If the user [refused to allow the document to be unloaded](#), then return.
 2. [Unload the active document of the specified browsing context](#).
 3. [Traverse the history of the specified browsing context to the specified entry with the \[history-navigation flag\]\(#\)](#)

When the user navigates through a [browsing context](#), e.g. using a browser's back and forward buttons, the user agent must [traverse the history by a delta](#) with a delta equivalent to the action specified by the user and the browsing context being operated on.

1. Let `browsingContext` be `document`'s `browsingContext`.

2. If the `state push` flag is set, then:

1. Remove all the entries in `browsingContext`'s `session history` after the `current entry`. If the `current entry` is the last entry in the session history, then no entries are removed.

Note
This doesn't necessarily have to affect the user agent's user interface.

2. Remove any `links` queued by the `history traversal task source` that are associated with any `Document` objects in the `top-level browsing context`'s `document family`.

3. If appropriate, update the `current entry` to reflect any state that the user agent wishes to persist. The entry is then said to be an `entry with persisted user state`.

4. Add a `session history entry` entry to the session history, after the `current entry`, with:

- `newURL` as the `URL`;
- the `scroll restoration mode` of the current entry in the `session history` as the scroll restoration mode;
- `serializedData` as the `serialized state`, if it is given;
- `title` as the title, if it is given.

5. Update the `current entry` to be this newly added entry.

3. Otherwise, update the `current entry` in `browsingContext`'s `session history` so that:

- `newURL` is the entry's new `URL`;
- `serializedData` is the entry's new `serialized state`, if it is given; otherwise, the `current entry`'s current `serialized state` is kept;
- `title` is the entry's new title, if it is given; otherwise, the entry does not have a title;
- it represents a GET request, if it currently represents a non-GET request (e.g. it was the result of a POST submission).

4. Set `document`'s `URL` to `newURL`.

Note
Since this is neither a `navigational` of the `browsing context` nor a `history traversal`, it does not cause a `hashchange` event to be fired.

MDN

History/replaceState

Support in all current engines.

Firefox+ Safari+ Chrome5+

Opera11.5+Edge79+

Edge (Legacy)12+Internet Explorer10+

Firefox Android+ Safari iOS4.3+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android11.5+

The `replaceState(state, title, url)` method updates the state object, title, and optionally the `URL` of the `current entry` in the history.

When either of these methods is invoked, the user agent must run the following steps:

1. Let `document` be the unique `Document` object this `History` object is associated with.

2. If `document` is not `fully active`, throw a `"SecurityError"` `DOMException`.

3. Optionally, return. (For example, the user agent might disallow calls to these methods that are invoked on a timer, or from event listeners that are not triggered in response to a clear user action, or that are invoked in rapid succession.)

4. Let `targetRealm` be this `History` object's `relevant Realm`.

5. Let `serializedData` be `StructuredSerializeForStorage(data)`. Rethrow any exceptions.

6. Let `newURL` be the `URL` of the `current entry` in `browsingContext`'s `session history`.

7. If `url` is null, then:

1. Parse `url`, relative to the `relevant settings object` of this `History` object.

2. If that fails, then throw a `"SecurityError"` `DOMException`.

3. Set `newURL` to the resulting `URL record`.

4. Compare `newURL` to `document`'s `URL`. If any component of these two `URL records` differ other than the `path`, `query`, and `fragment` components, then throw a `"SecurityError"` `DOMException`.

5. If the `origin` of `newURL` is not `same origin` with the `origin` of `document`, and either the `path` or `query` components of the two `URL records` compared in the previous step differ, throw a `"SecurityError"` `DOMException`. (This prevents sandboxed content from spoofing other pages on the same origin.)

8. Run the `URL and history update steps` given document, `newURL`, `serializedData`, and `title`, with the `state push` flag set if the method invoked was the `pushState()` method.

9. Let `state` be `StructuredDeserialize(serializedData, targetRealm)`. If this throws an exception, catch it, ignore the exception, and set `state` to null.

10. Set `history.state` to `state`.

11. Set the `current entry`'s `document` object's `latest entry` to the `current entry`.

Note

The `title` is purely advisory. User agents might use the `title` in the user interface.

User agents may limit the number of state objects added to the session history per page. If a page hits the UA-defined limit, user agents must remove the entry immediately after the first entry for that `Document` object in the session history after having added the new entry. (Thus the state history acts as a FIFO buffer for eviction, but as a LIFO buffer for navigation.)

Example

Consider a game where the user can navigate along a line, such that the user is always at some coordinate, and such that the user can bookmark the page corresponding to a particular coordinate, to return to it later.

A static page implementing the `x=5` position in such a game could look like the following:

```
<!DOCTYPE HTML>
<!-- this is https://example.com/line?x=5 -->
<html>
<head>
<title>Line Game - 5</title>
<p>You are at coordinate 5 on the line.</p>
<p><a href="#x=6">Advance to 6</a> or<br/>
<a href="#x=4">Retreat to 4</a>?</p>
</head>
<body>
```

The problem with such a system is that each time the user clicks, the whole page has to be reloaded. Here instead is another way of doing it, using script:

```
<!DOCTYPE HTML>
<!-- this starts off as https://example.com/line?x=5 -->
<html>
<head>
<title>Line Game - 5</title>
<p>You are at coordinate <span id="coord">5</span> on the line.</p>
<p><a href="#" onclick="x(1); return false;">Advance to 6</a> or<br/>
<a href="#" onclick="x(-1); return false;">retreat to 4</a>?</p>
</head>
<script>
var currentPage = 5; // pre-filled by server
function x(d) {
  setupPage(currentPage + d);
  history.pushState(currentPage, document.title, '?x=' + currentPage);
}
onpopstate = function(event) {
  if(event.state) {
    currentPage = event.state;
  }
}
function setupPage(page) {
  currentPage = page;
  document.title = "Line Game - " + currentPage;
  document.getElementById("coord").textContent = currentPage;
  document.links[0].textContent = "Advance to " + (currentPage+1);
  document.links[1].textContent = "Retreat to " + (currentPage-1);
  document.links[1].textContent = "Retreat to " + (currentPage-1);
}
</script>
```

In systems without script, this still works like the previous example. However, users that do have script support can now navigate much faster, since there is no network access for the same experience. Furthermore, contrary to the experience the user would have with just a naïve script-based approach, bookmarking and navigating the session history still work.

In the example above, the `data` argument to the `pushState()` method is the same information as would be sent to the server, but in a more convenient form, so that the script doesn't have to parse the URL each time the user navigates.

Example

Applications might not use the same title for a `session history entry` as the value of the document's `title` element at that time. For example, here is a simple page that shows a block in the `title` element. Clearly, when navigating backwards to a previous state the user does not go back in time, and therefore it would be inappropriate to put the time in the session history title.

```
<!DOCTYPE HTML>
<!-- this starts off as https://example.com/line?x=5 -->
<html>
<head>
<title>Line /TITLE>
<SCRIPT>
setInterval(function () { document.title = 'Line - ' + new Date(); }, 1000);
var i = 1;
function inc() {
  document.title = i++;
}
</SCRIPT>
</head>
<body>
```

```

    i = newI;
    document.forms.F.I.value = newI;
  }
  </SCRIPT>
<BODY ONPOPSTATE="set(event.state)">
<FORM NAME=F>
  <INPUT NAME=I></INPUT> <INPUT VALUE="Increment" TYPE=BUTTON ONCLICK="inc()">
</FORM>

```

Example

Most applications want to use the same `scrollRestoration` value for all of their history entries. To achieve this they can set the `scrollRestoration` attribute as soon as possible (e.g., in the first `script` element in the document's `head` element) to ensure that any entry added to the history session gets the desired scroll restoration mode.

```

<head>
  <script>
    if ('scrollRestoration' in history)
      history.scrollRestoration = 'manual';
  </script>
</head>

```

7.7.3 Implementation notes for session history

This section is non-normative.

The `history` interface is not meant to place restrictions on how implementations represent the session history to the user.

For example, session history could be implemented in a tree-like manner, with each page having multiple "forward" pages. This specification doesn't define how the linear list of pages in the `history` object are derived from the actual session history as seen from the user's perspective.

Similarly, a page containing two `frames` has a `history` object distinct from the `frame's` `history` objects, despite the fact that typical Web browsers present the user with just one "Back" button, with a session history that interleaves the navigation of the two inner frames and the outer page.

Security: It is suggested that to avoid letting a page "hijack" the history navigation facilities of a UA by abusing `pushState()`, the UA provide the user with a way to jump back to the previous page (rather than just going back to the previous state). For example, the back button could have a drop down showing just the pages in the session history, and not showing any of the states. Similarly, an aural browser could have two "back" commands, one that goes back to the previous state, and one that jumps straight back to the previous page.

For both `pushState()` and `replaceState()`, user agents are encouraged to prevent abuse of these APIs via too-frequent calls or over-large state objects. As detailed above, the algorithm explicitly allows user agents to ignore any such calls when appropriate.

7.7.4 The `location` interface

DOM

Document/location

Support in all current engines.

Firefox 1+ Safari 1+ Chrome 1+

Window/location

Support in all current engines.

Firefox 1+ Safari 1+ Chrome 1+

Opera 3+ Edge 79+

Edge (Legacy) 12+ Internet Explorer 4+

Firefox Android 4+ Safari iOS 1+ Chrome Android 18+ WebView Android 1+ Samsung Internet 1.0+ Opera Android 10.1+

Each `window` object is associated with a unique instance of a `location` object, allocated when the `window` object is created.

⚠️ Warning!
The `location` exotic object is defined through a mishmash of IDL, invocation of JavaScript internal methods post-creation, and overridden JavaScript internal methods. Coupled with its scary security policy, please take extra care while implementing this excrescence.

To create a `location` object, run these steps:

1. Let `location` be a new `Location` [platform object](#).
2. Let `valueOf` be `location's` `relevant Realm`'s `[!Intrinsics][!%QoPProto_valueOf]`.
3. Perform ! `location[[DefineOwnProperty][@@protoPrototypeFor]]` (`[Value]: valueOf, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false).`
4. Perform ! `location[[DefineOwnProperty][@@protoPrototypeFor]]` (`[Value]: undefined, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false).`
5. Set the value of the `[!DefaultProperties]` internal slot of `location` to `location[[OwnPropertyKeys]]()`.
6. Return `location`.

Note

The addition of `valueOf` and `@@protoPrototypeFor` own data properties, as well as the fact that all of `location`'s IDL attributes are marked `[Unforgeable]`, is required by legacy code that consulted the `location` interface, or stringified it, to determine the `document URL`, and then used it in a security-sensitive way. In particular, the `valueOf`, `@@protoPrototypeFor`, and `[Unforgeable]` stringifier mitigations ensure that code such as `foo[location] = bar || location + ''` cannot be misdirected.

For web developers (non-normative)

`document : location [= value]`

Returns a `location` object with the current page's location.

Can be set, to navigate to another page.

The `document` object's `location` attribute's getter must return this `document` object's `relevant global object's` `Location` object, if this `document` object is `fully active`, and null otherwise.

The `Window` object's `location` attribute's getter must return this `Window` object's `location` object.

`Location` objects provide a representation of the `URL` of the `active document` of their `Document`'s `browsing context`, and allow the `current entry` of the `browsing context`'s session history to be changed, by adding or replacing entries in the `history` object.

```

ID([Exposed=Window])
interface Location { // But see also additional creation steps and overridden internal methods
  attribute String ancestorOrigins;
  attribute String host;
  attribute String hostname;
  attribute String port;
  attribute String path;
  attribute String search;
  attribute String hash;
  void assign(USVString url);
  void replaceState(USVString url);
  [Unforgeable, SameObject] readonly attribute DOMStringList ancestorOrigins;
}

```

For web developers (non-normative)

`location : string`

location `.href`

Returns the `location` object's URL.

Can be set, to navigate to the given URL.

location `.origin`

Returns the `location` object's URL's origin.

location `.protocol`

Returns the `location` object's URL's scheme.

location `.host`

Returns the `location` object's URL's host and port (if different from the default port for the scheme).

Can be set, to navigate to the same URL with a changed host and port.

location `.hostname`

Returns the `location` object's URL's host.

Can be set, to navigate to the same URL with a changed host.

location `.port`

Returns the `location` object's URL's port.

Can be set, to navigate to the same URL with a changed port.

location `.pathname`

Returns the `location` object's URL's path.

Can be set, to navigate to the same URL with a changed path.

location `.search`

Returns the `location` object's URL's query (includes leading "?" if non-empty).

<code>location.hash</code>	Returns the <code>location</code> object's URL's fragment (includes leading "# if non-empty). Can be set, to navigate to the same URL with a changed fragment (ignores leading "#").
<code>location.assign(url)</code>	Navigates to the given URL.
<code>location.replace(url)</code>	Removes the current page from the session history and navigates to the given URL.
<code>location.reload()</code>	Reloads the current page.
<code>location.ancestorOrigins</code>	Returns a <code>DOMStringList</code> object listing the origins of the ancestor <code>browsing contexts</code> , from the <code>parent browsing context</code> to the <code>top-level browsing context</code> .

A `Location` object has an associated `relevantDocument`, which is this `Location` object's `relevantGlobalObject`'s `browsingContext`'s `activeDocument`, if this `Location` object's `relevantGlobalObject`'s `browsingContext` is non-null, and null otherwise.

A `Location` object has an associated `url`, which is this `location` object's `relevantDocument`'s `URL`, if this `location` object's `relevantDocument` is non-null, and `about:blank` otherwise.

A `Location` object has an associated `ancestorOrigins` list. When a `Location` object is created, its `ancestorOrigins` list must be set to a `DOMStringList` object whose associated list is the `list` of strings that the following steps would produce:

1. Let `output` be a new `list` of strings.
2. Let `current` be the `browsingContext` of the `Document` with which this `Location` object is associated.
3. *Loop:* If `current` has no `parentBrowsingContext`, jump to the step labeled `end`.
4. Let `current` be `current`'s `parentBrowsingContext`.
5. Append the serialization of `current`'s `activeDocument`'s `origin` to `output`.
6. Return to the step labeled `loop`.
7. *End:* Return `output`.

A `Location` object has an associated `Location-object-setter-navigate` algorithm, which given a `url`, runs these steps:

1. If any of the following conditions are true, let `replacement` flag be `true`; otherwise, let it be `false`.
 - o This `Location` object's `relevantDocument` has `completelyLoaded`, or
 - o In the `task` in which the algorithm is running, an `activationBehavior` is currently being processed whose `click` event's `isTrusted` attribute is `true`, or
 - o In the `task` in which the algorithm is running, the event listener for a `click` event, whose `isTrusted` attribute is `true`, is being handled.
2. `Location-object-navigate`, given `url` and `replacement` flag.

To `Location-object-navigate`, given a `url` and `replacement` flag, run these steps:

1. The `sourceBrowsingContext` is the `responsibleBrowsingContext` specified by the `incumbentSettingsObject`.
 2. `Navigating the browsing context to url`, with the `exceptionsEnabled` flag set. Rethrow any exceptions.
- If the `replacement` flag is set or the `browsingContext's sessionHistory` contains only one `Document`, and that was the `about:blank Document` created when the `browsingContext` was created, then the navigation must be done with `replacementEnabled`.

MDN

`Location.href`

Support in all current engines.

Firefox22+SafariYesChromeYes

OperaYesFirefoxYes

Edge (Legacy)12+Internet ExplorerYes

Firefox Android22+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

The `href` attribute's getter must run these steps:

1. If this `location` object's `relevantDocument` is non-null and its `origin` is not `sameOriginDomain` with the `entrySettingsObject`'s `origin`, then throw a `"SecurityError" DOMException`.
2. Return this `location` object's `url` serialized.

The `href` attribute's setter must run these steps:

1. If this `location` object's `relevantDocument` is null, then return.
2. Parse the given value relative to the `entrySettingsObject`. If that failed, throw a `TypeError` exception.
3. `location-object-setter-navigate` to the resulting `URL record`.

Note

The `href` attribute setter intentionally has no security check.

MDN

`Location.origin`

Support in all current engines.

Firefox26+SafariYesChromeYes

Opera10+EdgeYes

Edge (Legacy)12+Internet Explorer11

Firefox Android26+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera Android?

The `origin` attribute's getter must run these steps:

1. If this `location` object's `relevantDocument` is non-null and its `origin` is not `sameOriginDomain` with the `entrySettingsObject`'s `origin`, then throw a `"SecurityError" DOMException`.
2. Return the `serialization` of this `location` object's `url`'s `origin`.

MDN

`Location.protocol`

Support in all current engines.

Firefox22+SafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet ExplorerYes

Firefox Android22+Safari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

The `protocol` attribute's getter must run these steps:

1. If this `location` object's `relevantDocument` is non-null and its `origin` is not `sameOriginDomain` with the `entrySettingsObject`'s `origin`, then throw a `"SecurityError" DOMException`.
2. Return this `location` object's `url`'s `scheme`, followed by ":".

The `protocol` attribute's setter must run these steps:

1. If the `location` object's `relevantDocument` is null, then return.
2. If this `location` object's `relevantDocument`'s `origin` is not `sameOriginDomain` with the `entrySettingsObject`'s `origin`, then throw a `"SecurityError" DOMException`.
3. Let `copyURL` be a copy of this `location` object's `url`.
4. Let `possibleFailure` be the result of `basicURL_parse` the given value, followed by ":"; with `copyURL` as `url` and `schemeStartState` as `stateOverride`.

Note

Because the URL parser ignores multiple consecutive colons, providing a value of "`https:`" (or even "`https::`") is the same as providing a value of "`https`".

5. If `possibleFailure` is failure, then throw a `"SyntaxError" DOMException`.

6. If `copyURL`'s `scheme` is not an `(HTTPS)` scheme, then terminate these steps.

7. `location-object-setter-navigate` to `copyURL`.

MDN

`Location.host`

Support in all current engines.

Firefox22+SafariYesChromeYes

The `ancestorOrigins` attribute's getter must run these steps:

1. If this `location` object's `relevant document` is null, then return an empty `list`.
2. If this `location` object's `relevant document`'s `origin` is not `same origin-domain` with the `entry settings object`'s `origin`, then throw a `"SecurityError"` `DOMException`.
3. Otherwise, return this `location` object's `ancestor origins list`.

⚠Warning!The details of how the `ancestorOrigins` attribute works are still controversial and might change. See issue #1918 for more information.As explained earlier, the `Location` exotic object requires additional logic beyond IDL for security purposes. The `Location` object must use the ordinary internal methods except where it is explicitly specified otherwise below.Also, every `Location` object has a `[[DefaultProperties]]` internal slot representing its own properties at time of its creation.**7.7.4.1 [[GetPrototypeOf]] ()**

1. If `! IsPlatformObjectSameOrigin(this)` is true, then return `! OrdinaryGetPrototypeOfOrThis`.
2. Return null.

7.7.4.2 [[SetPrototypeOf]] (V)

1. Return `! SetImmutablePrototype(this, V)`.

7.7.4.3 [[IsExtensible]] ()

1. Return true.

7.7.4.4 [[PreventExtensions]] (P)

1. Return false.

7.7.4.5 [[GetOwnProperty]] (P)

1. Let `desc` be ! `OrdinaryGetOwnProperty(this, P)`.
 2. If the value of the `[[DefaultProperties]]` internal slot of `this` contains `P`, then set `desc.[[Configurable]]` to true.
 3. Return `desc`.
 2. Let `property` be ! `CrossOriginGetOwnPropertyHelper(this, P)`.
 3. If `property` is not undefined, then return `property`.
 4. Return ? `CrossOriginPropertyFallback(P)`.

7.7.4.6 `[[DefineOwnProperty]](P, Desc)`

1. If ! `IsPlatformObjectSameOrigin(this)` is true, then:
 1. If the value of the `[[DefaultProperties]]` internal slot of `this` contains `P`, then return false.
 2. Return ? `OrdinaryDefineOwnProperty(this, P, Desc)`.

2. Throw a `"SecurityError"` `DOMException`.

7.7.4.7 `[[Get]](P, Receiver)`

1. If ! `IsPlatformObjectSameOrigin(this)` is true, then return ? `OrdinaryGet(this, P, Receiver)`.
 2. Return ? `CrossOriginGet(this, P, Receiver)`.

7.7.4.8 `[[Set]](P, V, Receiver)`

1. If ! `IsPlatformObjectSameOrigin(this)` is true, then return ? `OrdinarySet(this, P, Receiver)`.
 2. Return ? `CrossOriginSet(this, P, V, Receiver)`.

7.7.4.9 `[[Delete]](P)`

1. If ! `IsPlatformObjectSameOrigin(this)` is true, then return ? `OrdinaryDelete(this, P)`.
 2. Throw a `"SecurityError"` `DOMException`.

7.7.4.10 `[[OwnPropertyKey]]()`

1. If ! `IsPlatformObjectSameOrigin(this)` is true, then return ! `OrdinaryOwnPropertyKey(this)`.
 2. Return ? `CrossOriginOwnPropertyKey(this)`.

7.8 Browsing the Web

7.8.1 Navigating across documents

Certain actions cause the `browsingContext` to `navigate` to a new resource. A user agent may provide various ways for the user to explicitly cause a browsing context to navigate, in addition to those defined in this specification.

Example

For example, following a hyperlink, form submission, and the `window.open()` and `location.assign()` methods can all cause a browsing context to navigate.

Note

A resource has a URL, but that might not be the only information necessary to identify it. For example, a form submission that uses HTTP POST would also have the HTTP method and payload. Similarly, an `iframe` `sandbox` document needs to know the data it is to use.

Navigation always involves `sourceBrowsingContext`, which is the browsing context which was responsible for starting the navigation.

As explained in issue #130 the use of a browsing context as source might not be the correct architecture.

To navigate a browsing context `browsingContext` to a resource `resource`, optionally with an `exceptions enabled` flag, the user agent must run these steps:

- If `resource` is a `URL`, then set `resource` to a new `request` whose `url` is `resource`.
- If `resource` is a `request` and this is a reload-triggered navigation, then set `resource`'s `reload-navigation flag`.
- If the `sourceBrowsingContext` is not allowed to `navigate` `browsingContext`, then:
 - If the `exceptions enabled` flag is on, then throw a `"SecurityError"` `DOMException`.
 - Otherwise, the user agent may instead offer to open `resource` in a new `top-level browsing context` or in the `top-level browsing context` of the `sourceBrowsingContext`, at the user's option, in which case the user agent must `navigate` that designated `top-level browsing context` to `resource` as if the user had requested it independently.

Note

Doing so, however, can be dangerous, as it means that the user is overriding the author's explicit request to sandbox the content.

4. If there is a preexisting attempt to navigate `browsingContext`, and the `sourceBrowsingContext` is the same as `browsingContext`, and that attempt is currently running the `unload a document` algorithm, then return without affecting the preexisting attempt to navigate `browsingContext`.

5. If the `prompt to unload` algorithm is being run for the `activeDocument` of `browsingContext`, then return without affecting the `prompt to unload` algorithm.

6. If this is not a reload-triggered navigation, `resource`'s `url equals` `browsingContext's activeDocument's URL`, with exclude `fragments` flag set, and `resource's url's fragment` is non-null, then `navigate to that fragment`, with `replacement enabled` if this was invoked with `replacement enabled`, and return.

7. Let `activeDocumentNavigationOrigin` be the `origin` of the `activeDocument` of `browsingContext`.

8. Let `incumbentNavigationOrigin` be the `origin` of the `incumbentSettingsObject`, or if no `script` was involved, the `origin` of the `nodeDocument` of the element that initiated the `navigation`.

9. Cancel any pending but not yet `mature` attempt to navigate `browsingContext`, including canceling any instances of the `fetch` algorithm started by those attempts. If one of those attempts has already created and initialized a new `Document` object, abort that `Document` also. (Navigation attempts that have `matured` already have session history entries, and are therefore handled during the update the session history with the new page algorithm later.)

10. Prompt to unload the `activeDocument` of `browsingContext`. If the user refused to allow the document to be unloaded, then return.

If the instance of the `navigation` algorithm gets canceled while this step is running, the `prompt to unload` algorithm must nonetheless be run to completion.

11. Abort the `activeDocument` of `browsingContext`.

12. If `browsingContext` is a `childBrowsingContext`, then put it in the `delayingLoadEventsMode`.

The user agent must take this `childBrowsingContext` out of the `delayingLoadEventsMode` when this `navigation` algorithm later `matures`, or when it terminates (whether due to having run all the steps, or being canceled, or being aborted), whichever happens first.

13. Let `navigationType` be `"formSubmission"` if the `navigation` algorithm was invoked as a result of the `formSubmission algorithm`, and `"other"` otherwise.

14. Let `sandboxFlags` be the result of `determiningSandboxFlags` given `browsingContext`.

15. Return to whatever algorithm invoked the navigation steps and continue running these steps `in parallel`.

16. This is the step that attempts to obtain `resource`, if necessary. Jump to the first appropriate substep:

If `resource` is a `response`

Run `process a navigate response` with `null`, `resource`, `navigationType`, the `sourceBrowsingContext`, `browsingContext`, `sandboxFlags`, `incumbentNavigationOrigin`, and `activeDocumentNavigationOrigin`.

If `resource` is a `request` whose `url's scheme` is `"avascript"`

Queue a task, on the `DOM manipulation task source` and associated with the `activeDocument` of `browsingContext`, to run these steps:

1. Let `response` be the result of `executing a "avascript:URL" request` given `resource`, the `sourceBrowsingContext`, and `browsingContext`.

2. Run `process a navigate response` with `resource`, `response`, `navigationType`, the `sourceBrowsingContext`, `browsingContext`, `sandboxFlags`, `incumbentNavigationOrigin`, and `activeDocumentNavigationOrigin`.

Example

So for example a `avascript:URL` in an `href` attribute of an `a` element would only be evaluated when the link was `followed`, while such a URL in the `src` attribute of an `iframe` element would be evaluated in the context of the `iframe's nestedBrowsingContext` when the `iframe` is being set up. Once evaluated, its return value (if it was a string) would replace that `browsingContext's activeDocument`, thus also changing the corresponding `Window` object.

If `resource` is to be fetched using `"get"`, and there are `relevantApplicationCaches` that are identified by a URL with the `sameOrigin` as the URL in question, and that have this URL as one of their entries, excluding entries marked as `foreign`, and whose `mode` is `fast`, and the user agent is not in a mode where it will avoid using `applicationCaches`

Fetch resource from the `mostAppropriateApplicationCache` of those that match.

Example

For example, imagine an HTML page with an associated application cache displaying an image and a form, where the image is also used by several other application caches. If the user right-clicks on the image and chooses "View Image", then the user agent could decide to show the image from any of those caches, but it is likely that the most useful cache for the user would be the one that was used for the aforementioned HTML page. On the other hand, if the user submits the form, and the form does a POST submission, then the user agent will not use an application cache at all; the submission will be made to the network.

This still needs to be integrated with the Fetch standard. [FETCH]

If `resource` is a `request` whose `url's scheme` is a `fetch` scheme

Run `process a navigate fetch` given `resource`, the `sourceBrowsingContext`, `browsingContext`, `navigationType`, `sandboxFlags`, `incumbentNavigationOrigin`, and `activeDocumentNavigationOrigin`.

Otherwise, `resource` is a `request` whose `url's scheme` is neither `"avascript"` nor `"fetch"` scheme

Run `process a navigate URL scheme` given `resource's url` and `browsingContext`.

To process a `navigate fetch`, given a `request`, two `browsingContexts`, `sourceBrowsingContext` and `browsingContext`, a string `navigationType`, and two `origins`, `incumbentNavigationOrigin` and `activeDocumentNavigationOrigin`, run these steps:

1. Let `response` be null.

2. Set `request's client` to `sourceBrowsingContext's activeDocument's relevantSettingsObject.destination` to `"document"`, `mode` to `"navigate"`, `credentials mode` to `"include"`, `use-URL-credentials flag`, `redirect mode` to `"manual"`, and `replaces client id` to `browsingContext's activeDocument's relevantSettingsObject.id`.

3. If `browsingContext's container` is non-null and has a `browsingContext` scope `origin`, then set `request's origin` to that `browsingContext` scope `origin`.

4. Let `done` be false and `reservedEnvironment` be null.

5. While `done` is false:

1. Let `currentURL` be `response's location URL`, if `response` is not null, and `request's current URL` otherwise.

2. If `reservedEnvironment` is not null and `currentURL's origin` is not the `same` as `reservedEnvironment's creation URL's origin`, then:

1. Run the `environment discarding steps` for `reservedEnvironment`.

2. Set `reservedEnvironment` to null.

3. If `reservedEnvironment` is null, then set `reservedEnvironment` to a new `environment` whose `id` is a unique opaque string and `targetBrowsingContext` is `browsingContext`.

4. Set `reservedEnvironment's creation URL` to `currentURL`.

Note

The created environment's `active service worker` is set in the `Handle Fetch` algorithm during the fetch if the request URL matches a service worker registration. [SW]

5. Set `request's reserved client` to `reservedEnvironment`.

6. If the `Should navigation request of type from source in target be blocked by Content Security Policy?` algorithm returns `"blocked"` when executed upon `request`, `navigationType`, `sourceBrowsingContext`, and `browsingContext`, then set `response` to a `network error` and set `done` to true. [CSP]

1. If `response` is null, [fetch request](#).
 2. Otherwise, perform [HTTP redirect fetch](#) using `request` and `response`.
 3. Wait for the task on the [networking task source](#) to process `response` and set `response` to the result.
 4. If `response` does not have a [location URL](#), or the [location URL](#) is not a [URL](#) whose `scheme` is an [HTTP\(S\) scheme](#), then set `done` to true.

Note
 Navigation handles redirects manually as navigation is the only place in the web platform that cares for redirects to [mailto:](#) URLs and such.

6. If `response's location URL` is failure, then set `response` to a network error.
 7. Otherwise, if `response` has a [location URL](#) that is a [URL](#) whose `scheme` is "blob", "file", "filesystem", or "javascript", then set `response` to a network error.
 8. Otherwise, if `response` has a [location URL](#) that is a [URL](#) whose `scheme` is a [fetch scheme](#), then run [process a navigate fetch](#) with a new `request` whose `url` is `response's location URL`, `sourceBrowsingContext`, `browsingContext`, and `navigationType`.
 9. Otherwise, if `response` has a [location URL](#) that is a [URL](#), run the [process a navigate URL scheme](#) given `response's location URL`, `browsingContext`, and `browsingContext`.

10. **Fallback in pre-error mode:** If `response` was not fetched from an [application cache](#), and was to be fetched using "GET", and there are [relevant application caches](#) that are identified by a URL with the `same origin` as the URL in question, and that have this URL as one of their entries, excluding entries marked as [foreign](#), and whose `mode` is [prefetch](#), [online](#), and the user didn't cancel the navigation attempt during the earlier step, and `response` is either a network error or its `status` is not an `ok status`, then:
 Let `candidate` be the response identified by the URL in question from the [most appropriate application cache](#) of those that match.
 If `candidate` is not marked as [foreign](#), then the user agent must discard the failed load and instead continue along these steps using `candidate` as `response`. The user agent may indicate to the user that the original page load failed, and that the page used was a previously cached response.
 11. **Fallback for fallback entries:** If `response` was not fetched from an [application cache](#), and was to be fetched using "GET", and its `URL` matches the [fallback namespace](#) of one or more [relevant application caches](#), and the [most appropriate application cache](#) of those that match does not have an entry in its [online manifest](#) that has the `same origin` as `response's URL` and that is a [prefix match](#) for `response's URL`, and the user agent didn't cancel the navigation attempt during the earlier step, and `response` is either a network error or its `status` is not an `ok status`, then:
 Let `candidate` be the [fallback response](#) specified for the [fallback namespace](#) in question. If multiple application caches match, the user agent must use the fallback of the [most appropriate application cache](#) of those that match.
 If `candidate` is not marked as [foreign](#), then the user agent must discard the failed load and instead continue along these steps using `candidate` as `response`. The document's `URL`, if appropriate, will still be the originally requested URL, not the fallback URL, but the user agent may indicate to the user that the original page load failed, that the page used was a fallback response, and what the URL of the fallback response actually is.
 12. Run [process a navigate response](#) given `request`, `response`, `navigationType`, the `source browsing context`, `browsingContext`, `incumbentNavigationOrigin`, `activeDocumentNavigationOrigin`, and `reservedEnvironment`.

To process a [navigate response](#), given null or a `request` request, a `response` response, a string `navigationType`, two `browsingContext` source and `browsingContext`, a `sandboxFlags` set `sandboxFlags`, two `origins` `incumbentNavigationOrigin` and `activeDocumentNavigationOrigin`, and an optional `environment` `reservedEnvironment`, run these steps:

- If any of the following are true, then [display the inline content with an appropriate error shown to the user](#), with the newly created `document` object's `origin` set to a new `opaque origin`, run the [environment discarding steps](#) for `reservedEnvironment`, and return.
- `response` is a network error.
- TODO: Define X-Frame-Options processing here (tracked as [issue #1230](#)).
- The [Should navigation response to navigation request of type from source in target be blocked by Content Security Policy?](#) algorithm returns "blocked" when executed upon `request`, `response`, `navigationType`, `source`, and `browsingContext`. [\[CSP\]](#)

Note
 This is where the network errors defined and propagated by [Fetch](#), such as DNS or TLS errors, end up being displayed to users. [\[FETCH\]](#)

2. If `response's status` is 204 or 205, then return.

3. If `response` has an `Content-Disposition` header specifying the `attachment` disposition type, then handle it as a download and return.

4. Let `type` be the [computed type of response](#).

5. If the user agent has been configured to process resources of the given type using some mechanism other than rendering the content in a `browsing context`, then skip this step. Otherwise, if the type is one of the following types, jump to the appropriate entry in the following list, and process `response` as described there:

- an [HTML MIME type](#)
 Follow the steps given in the [HTML document](#) section providing `browsingContext`, `request`, `response`, `sandboxFlags`, `incumbentNavigationOrigin`, and `activeDocumentNavigationOrigin`. Once the steps have completed, return.
- an [XML MIME type](#) that is not an [explicitly supported XML MIME type](#)
 Follow the steps given in the [XML document](#) section providing `browsingContext`, `type`, `request`, `response`, `sandboxFlags`, `incumbentNavigationOrigin`, and `activeDocumentNavigationOrigin`. Once the steps have completed, return.
- a [JavaScript MIME type](#)
 a [JSON MIME type](#) that is not an [explicitly supported JSON MIME type](#)
 Follow the steps given in the [plain text file](#) section providing `browsingContext`, `type`, `request`, `response`, `sandboxFlags`, `incumbentNavigationOrigin`, and `activeDocumentNavigationOrigin`. Once the steps have completed, return.
- "[multipart/mixed-replace](#)"
 Follow the steps given in the [multipart/mixed-replace](#) section providing `browsingContext`, `type`, `request`, `response`, `sandboxFlags`, `incumbentNavigationOrigin`, and `activeDocumentNavigationOrigin`. Once the steps have completed, return.
- A supported image, video, or audio type
 Follow the steps given in the [media](#) section providing `browsingContext`, `type`, `request`, `response`, `sandboxFlags`, `incumbentNavigationOrigin`, and `activeDocumentNavigationOrigin`. Once the steps have completed, return.
- A type that will use an external application to render the content in `browsingContext`
 Follow the steps given in the [plugin](#) section providing `browsingContext`, `type`, `request`, `response`, `sandboxFlags`, `incumbentNavigationOrigin`, and `activeDocumentNavigationOrigin`. Once the steps have completed, return.

An [explicitly supported XML MIME type](#) is an [XML MIME type](#) for which the user agent is configured to use an external application to render the content (either a [plugin](#) rendering directly in `browsingContext`, or a separate application), or one for which the user agent has dedicated processing rules (e.g. a Web browser with a built-in Atom feed viewer would be said to explicitly support the [application/atom+xml](#) MIME type), or one for which the user agent has a dedicated handler.

An [explicitly supported JSON MIME type](#) is a [JSON MIME type](#) for which the user agent is configured to use an external application to render the content (either a [plugin](#) rendering directly in `browsingContext`, or a separate application), or one for which the user agent has dedicated processing rules, or one for which the user agent has a dedicated handler.

6. [Non-document content](#): If, given `type`, the new resource is to be handled by displaying some sort of inline content, e.g., a native rendering of the content or an error message because the specified type is not supported, then [display the inline content](#), and then return.

7. Otherwise, the document's `type` is such that the resource will not affect `browsingContext`, e.g., because the resource is to be handled by an external application or because it is an unknown type that will be processed as a download. [Process the resource appropriately](#).

To process a [navigate URL scheme](#), given a `URL` url and `browsingContext` `browsingContext`, run these steps:

- If `url` is to be handled using a mechanism that does not affect `browsingContext`, e.g., because `url's scheme` is handled externally, then [proceed with that mechanism instead](#).
- Otherwise, `url` is to be handled by displaying some sort of inline content, e.g., an error message because the specified scheme is not one of the supported protocols, or an inline prompt to allow the user to select a [registered handler](#) for the given scheme. [Display the inline content](#).

Note
 In the case of a registered handler being used, [navigate](#) will be invoked with a new URL.

When a resource is handled by passing its `URL` or data to an external software package separate from the user agent (e.g. handing a [mailto:](#) URL to a mail client, or a Word document to a word processor), user agents should attempt to mitigate the risk that this is an attempt to exploit the target software, e.g. by prompting the user to confirm that the `source browsingContext's activeDocument's origin` is to be allowed to invoke the specified software. In particular, if the [navigate](#) algorithm was invoked when `source browsingContext's [WindowProxy's [Window]] value` does not have [transient activation](#), the user agent should not invoke the external software package without prior user confirmation.

Example
 For example, there could be a vulnerability in the target software's URL handler which a hostile page would attempt to exploit by tricking a user into clicking a link.

To execute a [javascript: URL](#) request, given a `request` request and two `browsingContext` source and `browsingContext`, run these steps:

- Let `response` be a `response` whose `status` is 204.
- If both of the following are true:
 - `source's activeDocument's origin` is [same origin](#) with `browsingContext's activeDocument's origin`.
 As explained in [issue #2591](#) this step does not work and presents a security issue.
 - The [Should navigation request of type from source in target be blocked by Content Security Policy?](#) algorithm returns "Allowed" when executed upon `request`, "other", `source`, and `browsingContext`. [\[CSP\]](#)
- Let `urlString` be the result of running the [URL serializer](#) on `request's url`.
- Let `encodedScriptSource` be the result of removing the leading "javascript:" from `urlString`.
- Let `scriptSource` be the [UTF-8 decoding](#) of the [string percent decoding](#) of `encodedScriptSource`.
- Append `browsingContext's activeDocument's URL` to `request's URL list`.
- Let `settings` be `browsingContext's activeDocument's relevant settings object`.
- Let `baseURL` be `settings's API base URL`.
- Let `script` be the result of [creating a classic script](#) given `scriptSource`, `settings`, `baseURL`, and the [default classic script fetch options](#).
- Let `evaluationStatus` be the result of [running the classic script](#).
- Let `result` be undefined if `evaluationStatus` is an [empty completion](#) or `evaluationStatus[[Value]]` is empty, or `evaluationStatus[[Value]]` otherwise.
10. If `Type(result)` is String, then set `response` to a `response` whose `header list` consists of "`Content-Type`": "text/html" and "`Referer-Policy`": `settings's referer policy`, whose `body` is `result`, and whose `HTTPS state` is `settings's HTTPS state`.

The exact conversion between the JavaScript string `result` and the bytes that comprise a `response body` is not yet specified, pending further investigation into user agent behavior. See [issue #1129](#).

3. Return `response`.

In addition to the specific issues linked above, [javascipt:](#) URLs have a [dedicated label](#) on the issue tracker documenting various problems with their specification.

Some of the sections below, to which the above algorithm defers in certain cases, use the following steps to [create and initialize a Document object](#), given a `type` type, `content-type` `contentType`, a `request` request, a `response` response, a `browsingContext` `browsingContext`, a `sandboxFlags` set `sandboxFlags`, two `origins` `incumbentNavigationOrigin`, `activeDocumentNavigationOrigin`, and an optional `environment` `reservedEnvironment`:

1. Let `finalSandboxFlags` be the union of `sandboxFlags` and `response's forced sandboxFlags`.
2. Let `origin` be the result of [determining the origin](#) given `browsingContext`, `request's url`, `finalSandboxFlags`, `incumbentNavigationOrigin`, and `activeDocumentNavigationOrigin`.
3. Let `featurePolicy` be the result of [creating a feature policy from a response](#) given `browsingContext`, `origin`, and `response`. [\[FEATUREPOLICY\]](#)

Note
 The [creating a feature policy from a response](#) algorithm makes use of `origin`. If `document.domain` has been used for the `browsingContext container document`, then its `origin` cannot be `same origin-domain` with `>origin`, because these steps run before the `document` is created, so it cannot itself yet have used `document.domain`. Note that this means that Feature Policy checks are less permissive compared to doing a `same origin` check instead.
 See below for some examples of this in action.

4. If `browsingContext's` only entry in its `session history` is the `about:blank` `document`, that was added when `browsingContext` was `created`, and navigation is occurring with `replacementEnabled`, and that `document` has the `same origin` as `origin`, then do nothing.

5. Otherwise:

- 1. Let `agent` be the result of [obtaining a similar-origin window agent](#) given `origin` and `browsingContext's group`.
- 2. Let `realm execution context` be the result of [creating a new JavaScript realm](#) with the following customizations:
 - For the agent, use `agent`. This pointer is not yet defined in the JavaScript specification; see [issue #2629#1357](#).
 - For the global object, create a new `window` object.
 - For the global `this` binding, use `browsingContext's WindowProxy` object.
- 3. Set up a `window environment settings object` with `realm execution context` and `reservedEnvironment`, if present.

7. If `request` is non-null, then set `document's URL` to `request's current URL`.

8. Otherwise, set `document's URL` to `response's URL`.

9. Set `document's HTTPS state` to the `HTTPS state` of `response`.

10. Set `document's referrer policy` to the result of [parsing the 'Referrer-Policy' header of response](#). [REFERRERPOLICY]

11. Initialize a `document's CSP list` given `document`, `response`, and `request`. [CSP]

12. If `request` is non-null, then set `document's referrer` to the [serialization](#) of `request's referrer`, if `request's referrer` is a `URL record`, and the empty string otherwise.

Note
Per [Fetch](#) a `request's referrer` will be either a `URL record` or "`no-referrer`" at this point.

13. If `response` has a "`Referer`" header, then:

1. Let `value` be the [iogmorphic decoding](#) of the value of the header.

2. Run the [shared declarative refresh steps](#) with `document` and `value`.

We do not currently have a spec for how to handle multiple "`Referer`" headers. This is tracked as [issue #2900](#).

14. Return `document`.

Example

In this example, the child document is not allowed to use `PaymentRequest`, despite being `same-origin-domain` at the time the child document tries to use it. At the time the child document is initialized, only the parent document has set `document.domain`, and the child document has not.

```
<!-- https://foo.example.com/a.html -->
<!DOCTYPE html>
<script>
document.domain = 'example.com';
</script>
<iframe src=b.html></iframe>
<!-- https://bar.example.com/b.html -->
<!DOCTYPE html>
<script>
document.domain = 'example.com'; // This happens after the document is initialized
new PaymentRequest(); // Not allowed to use
</script>
```

Example

In this example, the child document is allowed to use `PaymentRequest`, despite not being `same-origin-domain` at the time the child document tries to use it. At the time the child document is initialized, none of the documents have set `document.domain` yet so `same-origin-domain` falls back to a normal `same-origin` check.

```
<!-- https://example.com/a.html -->
<!DOCTYPE html>
<script>
<!-- The child document is now initialized, before the script below is run. -->
document.domain = 'example.com';
</script>
<!-- https://example.com/b.html -->
<!DOCTYPE html>
<script>
new PaymentRequest(); // Allowed to use
</script>
```

Some of the sections below, which the above algorithm defers in certain cases, require the user agent to *update the session history with the new page*. When a user agent is required to do this, it must [queue a task](#) on the `networking task source`, associated with the `document` object of the `current entry` (not the new one), to run the following steps:

1. [Unload the document object of the current entry](#).

If this instance of the `navigate` algorithm is canceled while this step is running the `unload a document` algorithm, then the `unload a document` algorithm must be allowed to run to completion, but this instance of the `navigate` algorithm must not run beyond this step. (In particular, for instance, the cancellation of this algorithm does not abort any event dispatch or script execution occurring as part of unloading the document or its descendants.)

2. If the navigation was initiated for `entry update` of an entry

1. Replace the `browsingContext` of the entry being updated, and any other entries that referenced the same document as that entry, with the new `document`.

2. [Traverse the history](#) to the new entry.

If the navigation was initiated with a `URL` that [equals](#) the `browsingContext's active document's URL`,

1. Replace the `current entry` with a new entry representing the new resource and its `document` object, related state, and the default `scroll restoration mode` of "auto".

2. [Traverse the history](#) to the new entry.

Otherwise

1. Remove all the entries in the `browsingContext's session history` after the `current entry`. If the `current entry` is the last entry in the session history, then no entries are removed.

Note
This doesn't necessarily have to affect the user agent's user interface.

2. Append a new entry at the end of the `browsingContext` object representing the new resource and its `document` object, related state, and the default `scroll restoration mode` of "auto".

3. [Traverse the history](#) to the new entry. If the navigation was initiated with `replacement enabled`, then the traversal must itself be initiated with `replacement enabled`.

3. The `navigation algorithm` has now matured.

4. [Try to scroll to the fragment](#) for the `document`.

To try to scroll to the fragment for a `document`, perform the following steps [in parallel](#):

1. Wait for an implementation-defined amount of time. (This is intended to allow the user agent to optimize the user experience in the face of performance concerns.)

2. [Queue a task](#) on the `networking task source` to run these steps:

1. If document has no parser, or its parser has `stopped parsing`, or the user agent has reason to believe the user is no longer interested in scrolling to the `fragment`, then abort these steps.

2. [Scroll to the fragment](#) given in `document's URL`. If this does not find an indicated part of the document, then [try to scroll to the fragment](#) for `document`.

7.8.2 Page load processing model for HTML files

When an HTML document is to be loaded in a `browsing context`, provided `browsingContext, request, response, sandboxFlags, incumbentNavigationOrigin, and activeDocumentNavigationOrigin`, the user agent must [queue a task](#) on the `networking task source` to:

1. Let `document` be the result of [creating and initializing a document object](#) providing "`html`", "`text/html`", `request, response, browsingContext, sandboxFlags, incumbentNavigationOrigin, and activeDocumentNavigationOrigin`.

2. Create an `HTML parser` and associate it with the `document`. Each `task` that the `networking task source` places on the `task queue` while fetching runs must then fill the parser's `input byte stream` with the fetched bytes and cause the `HTML parser` to perform the appropriate processing of the input stream.

Note
The `input byte stream` converts bytes into characters for use in the `tokenizer`. This process relies, in part, on character encoding information found in the `real Content-Type metadata` of the resource; the computed type is not used for this purpose.

When no more bytes are available, the user agent must [queue a task](#) on the `networking task source` for the parser to process the implied EOF character, which eventually causes a `load` event to be fired.

After creating the `document` object, but before any script execution, certainly before the parser `stops`, the user agent must [update the session history with the new page](#).

Note

Application cache selection happens in the `HTML parser`.

7.8.3 Page load processing model for XML files

When faced with displaying an XML file inline, provided `browsingContext, request, response, sandboxFlags, incumbentNavigationOrigin, and activeDocumentNavigationOrigin`, user agents must follow the requirements defined in [XML and Namespaces in XML](#), [XML Media Types](#), [DOM](#), and other relevant specifications to [create and initialize a document object](#) providing "`xml`", `type, request, response, browsingContext, sandboxFlags, incumbentNavigationOrigin, and activeDocumentNavigationOrigin`. It must also create and a corresponding `XML parser` [[XML](#)] [[XMLNS](#)] [[RFC7303](#)] [[DOM](#)].

Note

At the time of writing, the XML specification community had not actually yet specified how XML and the DOM interact.

The actual HTTP headers and other metadata, not the headers as mutated or implied by the algorithms given in this specification, are the ones that must be used when determining the character encoding according to the rules given in the above specifications. Once the character encoding is established, the `document's character encoding` must be set to that character encoding.

If the `document element`, as parsed according to [XML](#), cited above, is found to be an `xml` element with an attribute `encoding`, whose value is not the empty string, then, as soon as the element is [inserted into the document](#), the user agent must `parse` the value of that attribute relative to that element's `node document`, and if that is successful, must apply the `URL serializer` algorithm to the `manifest URL` record with the `exclude fragment` set to obtain `manifest URL`, and then run the `application cache selection algorithm` with `manifest URL` as the manifest URL, passing in the newly-created `document`. Otherwise, if the attribute is absent, its value is the empty string, or parsing its value fails, then as soon as the `document element` is [inserted into the document](#), the user agent must run the `application cache selection algorithm` with no manifest, and passing in the `document`.

Note

Because the processing of the `manifest` attribute happens only once the `document element` is parsed, any URLs referenced by processing instructions before the `document element` (such as `<%! styleSheet%>`) PIs will be fetched from the network and cannot be cached.

Then, with the newly created `document`, the user agent must [update the session history with the new page](#). User agents may do this before the complete document has been parsed (thus achieving *incremental rendering*), and must do this before any scripts are to be executed.

Error messages from the parse process (e.g., XML namespace well-formedness errors) may be reported inline by mutating the `document`.

7.8.4 Page load processing model for text files

When a plain text document is to be loaded in a `browsing context`, provided `browsingContext, request, response, sandboxFlags, incumbentNavigationOrigin, and activeDocumentNavigationOrigin`, the user agent must [queue a task](#) on the `networking task source` to:

1. Let `document` be the result of [creating and initializing a document object](#) providing "`text`", "`text/html`", `request, response, browsingContext, sandboxFlags, incumbentNavigationOrigin, and activeDocumentNavigationOrigin`.

2. Create an `HTML parser` and associate it with the `document`. As it the tokenizer had emitted a start tag token with the tag name "`pre`" followed by a single U+00A0 LINE FEED (LF) character, and switch the `HTML parser`'s tokenizer to the `PLAINTEXT state`. Each `task` that the `networking task source` places on the `task queue` while fetching runs must then fill the parser's `input byte stream` with the fetched bytes and cause the `HTML parser` to perform the appropriate processing of the input stream.

The rules for how to convert the bytes of the plain text document into actual characters, and the rules for actually rendering the text to the user, are defined by the specifications for the `computed MIME type` of the resource (`type` in the `navigate` algorithm).

The `document's character encoding` must be set to the character encoding used to decode the document.

Upon creation of the `document` object, the user agent must run the `application cache selection algorithm` with no manifest, and passing in the newly-created `document`.

When no more bytes are available, the user agent must [queue a task](#) on the `networking task source` for the parser to process the implied EOF character, which eventually causes a `load` event to be fired.

After creating the `document` object, but potentially before the page has finished parsing, the user agent must [update the session history with the new page](#).

User agents may add content to the `head` element of the `document`, e.g., linking to a style sheet, providing script, or giving the document a `title`.

Note
In particular, if the user agent supports the `Format-Flowed` feature of RFC 3676 then the user agent would need to apply extra styling to cause the text to wrap correctly and to handle the quoting feature. This could be performed using, e.g., a CSS extension.

7.8.5 Page load processing model for multipart/* mixed replace resources

When a resource with the type `multipart/*;mixed-replace` is to be loaded in a `browsing context`, the user agent must parse the resource using the rules for multipart types. [RPC2046]

For each body part obtained from the resource, the user agent must run `process a navigate response` using the new body part and the same `browsing context`, with `replacement enabled` if a previous body part from the same resource resulted in a `creating and initializing a document object`, and otherwise using the same setup as the `navigate` attempt that caused this section to be invoked in the first place.

For the purposes of algorithms processing these body parts as if they were complete stand-alone resources, the user agent must act as if there were no more bytes for those resources whenever the boundary is reached.

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Note
Thus, `load` events (and for that matter `unload` events) do fire for each body part loaded.

7.8.6 Page load processing model for media

When an image, video, or audio resource is to be loaded in a *browsing context*, provided *browsingContext*, *request*, *response*, *sandboxFlags*, *incumbentNavigationOrigin*, and *activeDocumentNavigationOrigin*, the user agent should:

1. Let *document* be the result of *creating and initialize a document object* providing "html", *type*, *request*, *response*, *browsingContext*, *sandboxFlags*, *incumbentNavigationOrigin*, and *activeDocumentNavigationOrigin*.
2. Append an `html` element to *document*.
3. Append a `head` element to the `html` element.
4. Append a `body` element to the `html` element.
5. Append an element *host element* for the media, as described below, to the `body` element.
6. Set the appropriate attribute of the element *host element*, as described below, to the address of the image, video, or audio resource.

The element *host element* to create for the media is the element given in the table below in the second cell of the row whose first cell describes the media. The appropriate attribute to set is the one given by the third cell in that same row.

Type of media Element for the media Appropriate attribute

Image	<code>img</code>	<code>src</code>
Video	<code>video</code>	<code>src</code>
Audio	<code>audio</code>	<code>src</code>

Then, the user agent must act as if it had *stopped parsing*.

Upon creation of the `Document` object, the user agent must run the *application cache selection algorithm* with no manifest, and passing in the newly-created `Document`.

After creating the `Document` object, but potentially before the page has finished fully loading, the user agent must *update the session history with the new page*.

User agents may add content to the `head` element of the `Document`, or attributes to the element *host element*, e.g., to link to a style sheet, to provide a script, to give the document a `title`, or to make the media `autoplay`.

7.8.7 Page load processing model for content that uses plugins

When a resource that requires an external resource to be rendered is to be loaded in a *browsing context*, provided *browsingContext*, *request*, *response*, *sandboxFlags*, *incumbentNavigationOrigin*, and *activeDocumentNavigationOrigin*, the user agent should:

1. Let *document* be the result of *creating and initialize a document object* providing "html", *type*, *request*, *response*, *browsingContext*, *sandboxFlags*, *incumbentNavigationOrigin*, and *activeDocumentNavigationOrigin*.
2. Mark *document* as being a plugin *document*.
3. Append an `html` element to *document*.
4. Append a `head` element to the `html` element.
5. Append a `body` element to the `html` element.
6. Append an `embed` to the `body` element.
7. Set the `src` attribute of the `embed` element to the address of the resource.

Note
The term `plugin document` is used by *Content Security Policy* as part of the mechanism that ensures `iframes` can't be used to evade `plugin-type` directives. [CSP]

Then, the user agent must act as if it had *stopped parsing*.

Upon creation of the `Document` object, the user agent must run the *application cache selection algorithm* with no manifest, and passing in the newly-created `Document`.

After creating the `Document` object, but potentially before the page has finished fully loading, the user agent must *update the session history with the new page*.

User agents may add content to the `head` element of the `Document`, or attributes to the `embed` element, e.g., to link to a style sheet or to give the document a `title`.

Note
If the `document's active sandboxing flag set` has its `sandboxed plugins` browsing context flag set, the synthesized `embed` element will fail to render the content if the relevant plugin cannot be secured.

7.8.8 Page load processing model for inline content that doesn't have a DOM

When the user agent is to display a user agent page inline in a *browsing context*, the user agent should *create and initialize a Document object* providing "html", "text/html", null, null, *browsingContext*, an empty set, null, and null, and then either associate that `Document` with a custom rendering that is not rendered using the normal `Document` rendering rules, or mutate that `Document` until it represents the content the user agent wants to render.

Once the page has been set up, the user agent must act as if it had *stopped parsing*.

Upon creation of the `Document` object, the user agent must run the *application cache selection algorithm* with no manifest, passing in the newly-created `Document`.

After creating the `Document` object, but potentially before the page has been completely set up, the user agent must *update the session history with the new page*.

7.8.9 Navigating to a fragment

When a user agent is supposed to navigate to a `fragment`, optionally with `replacement enabled`, then the user agent must run the following steps:

1. If not with `replacement enabled`, then remove all the entries in the *browsing context's session history* after the `current entry`. If the `current entry` is the last entry in the session history, then no entries are removed.

Note
This doesn't necessarily have to affect the user agent's user interface.

2. Remove any `links` queued by the `history traversal task source` that are associated with any `Document` objects in the *top-level browsing context's document family*.
3. Append a new entry at the end of the `history` object representing the new resource and its `Document` object, related state, and `current entry's scroll restoration mode`. Its `URL` must be set to the address to which the user agent was *navigating*. The title must be left unset.
4. *Traverse the history* to the new entry, with `replacement enabled` if this was invoked with `replacement enabled`, and with the `non-blocking events flag` set. This will `scroll to the fragment` given in what is now the document's `URL`.

Note
If the scrolling fails because the relevant `ID` has not yet been parsed, then the original *navigation* algorithm will take care of the scrolling instead, as the last few steps of its *update the session history with the new page* algorithm.

When the user agent is required to *scroll to the fragment* and the indicated part of the document, if any, is *being rendered*, the user agent must either change the scrolling position of the document using the following algorithm, or perform some other action such that the indicated part of the document is brought to the user's attention. If there is no indicated part, or if the indicated part is not *being rendered*, then the user agent must do nothing. The aforementioned algorithm is as follows:

1. If there is no `indicated part of the document`, set the `document's target element` to null.

2. If the `indicated part of the document` is the top of the document, then

1. Set the `document's target element` to null.
2. *Scroll to the beginning of the document* for the `document`. [CSSOMVIEW]

3. Otherwise:

1. Let `target` be element that is the `indicated part of the document`.
2. Set the `document's target element` to `target`.
3. *Scroll target into view*, with `behavior` set to "auto", `block` set to "start", and `inline` set to "nearest". [CSSOMVIEW]
4. Run the `focusing steps` for `target`, with the `document's viewport` as the fallback `target`.
5. Move the `sequential focus navigation starting point` to `target`.

The indicated part of the document is the one that the `fragment`, if any, identifies. The semantics of the `fragment` in terms of mapping it to a node is defined by the specification that defines the `MIME type` used by the `Document` (for example, the processing of `fragments` for XML/MIME types is the responsibility of RFC7303). [RFC7303]

There is also a `target element` for each `Document`, which is used in defining the `target` pseudo-class and is updated by the above algorithm. It is initially null.

For HTML documents and [HTML MIME types], the following processing model must be followed to determine what the indicated part of the document is.

1. Let `fragment` be the document's `URL's fragment`.

2. If `fragment` is the empty string, then the indicated part of the document is the top of the document; return.

3. If `find a potential indicated element` with `fragment` returns non-null, then the return value is the indicated part of the document; return.

4. Let `fragmentBytes` be the result of `string-percent-decode fragment`.

5. Let `decodedFragment` be the result of running `UTF-8 decode without BOM` on `fragmentBytes`.

6. If `find a potential indicated element` with `decodedFragment` returns non-null, then the return value is the indicated part of the document; return.

7. If `decodedFragment` is an ASCII case-insensitive match for the string `top`, then the indicated part of the document is the top of the document; return.

8. There is no indicated part of the document.

To find a potential indicated element given a string `fragment`, run these steps:

1. If there is an element in the `document tree` that has an `ID` equal to `fragment`, then return the first such element in `tree order`.
2. If there is an `a` element in the `document tree` that has a `name` attribute whose value is equal to `fragment`, then return the first such element in `tree order`.
3. Return null.

The `task source` for the task mentioned in this section must be the `DOM manipulation task source`.

7.8.10 History traversal

To traverse the history to a `session history entry`, optionally with `replacement enabled`, optionally with the `non-blocking events flag`, and optionally with the `history-navigation flag`:

Note
This algorithm is not just invoked when explicitly going back or forwards in the session history — it is also invoked in other situations, for example when navigating a browsing context, as part of updating the session history with the new page.

1. If entry no longer holds a `Document` object, then:

1. Let `request` be a new `Request` whose `URL` is entry's `URL`.

2. If the `history-navigation flag` is set, then set `request's history-navigation flag`.

3. *Navigate the browsing context* to `request` to perform an `entry update` of `entry`. The navigation must be done using the same `source browsing context` as was used the first time `entry` was created. (This can never happen with `replacement enabled`.)

Note
The `navigate` algorithm reinvokes this "traverse" algorithm to complete the traversal, at which point `entry` holds a `Document` object.

Note
If the resource was obtained using a non-idempotent action, for example a POST form submission, or if the resource is no longer available, for example because the computer is now offline and the page wasn't cached, navigating to it again might not be possible. In this case, the navigation will result in a different page than previously; for example,

EXPAND

4. Return.
2. If the `currentEntry`'s title was not set by the `pushState()` or `replaceState()` methods, then set its title to the value returned by the `document.title` IDL attribute.
3. Otherwise, update the `currentEntry` in the `browsingContext`'s `history` object to reflect any state that the user agent wishes to persist. The entry is then said to be `anEntryWithPersistedUserState`.
4. If `entry` has a different `Document` object than the `currentEntry`, then run the following substeps:
 1. Remove any `Task`s queued by the `historyTraversalTaskSource` that are associated with any `Document` objects in the `top-level browsing context's document family`.
 2. If the `origin` of `entry's Document` object is not the `same` as the `origin` of the `currentEntry's Document` object, then run the following subsubsteps:
 1. The current `browsingContextName` must be stored with all the entries in the history that are associated with `Document` objects with the `sameOrigin` as the `activeDocument` and that are contiguous with the `currentEntry`.
 2. If the browsing context is a `top-level browsing context`, but not an `auxiliary browsing context`, then set the browsing context's `name` to the empty string.
 3. Set the `activeDocument` of the `browsingContext` to `entry's Document` object.
 4. If `entry` has a `browsingContextName`, then run the following subsubsteps:
 1. Set the browsing context's `browsingContextName` to `entry's browsingContextName`.
 2. Clear any `browsingContextNames` of all entries in the history that are associated with `Document` objects with the `sameOrigin` as the new `activeDocument` and that are contiguous with `entry`.
 5. If `entry's Document` object has any four controls whose `autoFillFieldNames` is `"text"`, invoke the `resetAlgorithm` of each of those elements.
 6. If the `currentDocumentReadiness` of `entry's Document` object is `"complete"`, then `queue a Task` to run the following subsubsteps:
 1. If the `Document's pageShowing` flag is true, then abort these steps.
 2. Set the `Document's pageShowing` flag to true.
 3. Run any session history document visibility change steps for `Document` that are defined by `other applicable specifications`.

Note

This is specifically intended for use by `Page Visibility` (`PAGEVIS`)

4. `Fire an event named pageShow at the Document object's relevantGlobalObject, using PageTransitionEvent, with the persisted attribute initialized to true, and legacyTargetOverride flag set.`
5. Set the document's `URL` to `entry's URL`.
6. If `entry` has a `URL` whose `fragment` differs from that of the `currentEntry`'s when compared in a `case-sensitive` manner, and the two share the same `Document` object, then let `hashChanged` be true, and let `oldURL` be the `currentEntry's URL` and `newURL` be `entry's URL`. Otherwise, let `hashChanged` be false.
7. If the traversal was initiated with `replacementEnabled`, remove the entry immediately before the `specifiedEntry` in the session history.
8. If `entry` is `anEntryWithPersistedUserState`, but its `URL`'s `fragment` is non-null, then `scroll to the fragment`.
9. Set the `currentEntry` to `entry`.

10. Let `targetRealm` be the `currentRealmRecord`.

11. If `entry` has `serializedState`, then let `state` be `StructuredDeserialize`(`entry's serializedState`, `targetRealm`). If this throws an exception, catch it, ignore the exception, and let `state` be null.

12. Otherwise, let `state` be null.

13. Set `history.state` to `state`.

14. Let `stateChanged` be true if `entry's Document` object has a `latestEntry`, and that entry is not `entry`; otherwise let it be false.

15. Set `entry's Document` object's `latestEntry` to `entry`.

16. If the `nonBlockingEventsFlag` is not set, then run the following substeps `immediately`. Otherwise, the `non-blocking events flag` is set; `queue a Task` to run the following substeps instead.

1. If `stateChanged` is true, then `fire an event` named `popState` at the `Document` object's `relevantGlobalObject`, using `PopStateEvent`, with the `state` attribute initialized to `state`.

2. If `entry` is `anEntryWithPersistedUserState`, then the user agent may `restorePersistedUserState` and update aspects of the document and its rendering.

3. If `hashChanged` is true, then `fire an event` named `hashChange` at the `browsingContext's Window` object, using `HashChangeEvent`, with the `oldURL` attribute initialized to `oldURL` and the `newURL` attribute initialized to `newURL`.

The `taskSource` for the tasks mentioned above is the `DOMManipulationTaskSource`.

7.8.10.1 Persisted user state restoration

When the user agent is to `restorePersistedUserState` from a history entry, it must run the following steps immediately:

1. If the entry has a `scrollRestorationMode`, let `scrollRestoration` be that. Otherwise let `scrollRestoration` be `"auto"`.
2. If `scrollRestoration` is `"manual"`, then the user agent should not restore the scroll position for the `Document` or any of its scrollable regions, with the exception of any `childBrowsingContexts` of `Document's browsingContext` whose scroll restoration is controlled by their own history entry's `scrollRestorationMode`; otherwise, it may do so.
3. Optionally, update other aspects of the document and its rendering, for instance values of form fields, that the user agent had previously recorded.

Note

This can even include updating the `dir` attribute of `Textarea` elements or `Input` elements whose `type` attribute is in either the `Text` state or the `Search` state, if the persisted state includes the directionality of user input in such controls.

Note

Not restoring the scroll position by user agent does not imply that the scroll position will be left at any particular value (e.g., `(0,0)`). The actual scroll position depends on the navigation type and the user agent's particular caching strategy. So web applications cannot assume any particular scroll position but rather are urged to set it to what they want it to be.

7.8.10.2 The `PopStateEvent` interface**MDN****PopStateEvent**

Support in all current engines.

Firefox 4+ Safari iOS 5+ Chrome Android 18+ WebView Android Yes Samsung Internet 1.0+ Opera Android Yes

```
IDL Exposed=Window, Constructor(DOMString type, optional PopStateEventInit eventInitDict = {})
```

```
interface PopStateEvent : Event {
```

```
  readonly attribute any state;
```

```
} dictionary PopStateEventInit : EventInit {
```

```
  any state = null;
```

```
}
```

For web developers (non-normative)

`event.state` Returns a copy of the information that was provided to `pushState()` or `replaceState()`.

The `state` attribute must return the value it was initialized to. It represents the context information for the event, or null, if the state represented is the initial state of the `Document`.

7.8.10.3 The `HashChangeEvent` interface**MDN****HashChangeEvent**

Support in all current engines.

Firefox 3.6+ Safari 5+ Chrome 5+

Opera 10.6+ Edge 79+

Edge (Legacy) 12+ Internet Explorer 8+

Firefox Android 4+ Safari iOS 5+ Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android 1+

```
IDL Exposed=Window, Constructor(DOMString type, optional HashChangeEventInit eventInitDict = {})
```

```
interface HashChangeEvent : Event {
```

```
  readonly attribute USVString oldURL;
```

```
  readonly attribute USVString newURL;
```

```
} dictionary HashChangeEventInit : EventInit {
```

```
  USVString oldURL = "";
```

```
  USVString newURL = "";
```

```
}
```

For web developers (non-normative)

`event.oldURL` Returns the `URL` of the `sessionHistoryEntry` that was previously current.

`event.newURL` Returns the `URL` of the `sessionHistoryEntry` that is now current.

MDN**HashChangeEvent.oldURL**

Support in all current engines.

Firefox 6+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer No

The `oldURL` attribute must return the value it was initialized to. It represents context information for the event, specifically the URL of the [session history entry](#) that was traversed from.

MDN
[HashChangeEvent/newURL](#)

Support in all current engines.

Firefox6+ Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer No

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `newURL` attribute must return the value it was initialized to. It represents context information for the event, specifically the URL of the [session history entry](#) that was traversed to.

7.8.10.4 The `PageTransitionEvent` interface

MDN

[PageTransitionEvent](#)

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer Yes

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

```
IDL Exports = [Unforgeable]
Constructor (DOMString type, optional PageTransitionEventInit eventInitDict = {})

interface PageTransitionEvent : Event {
  readonly attribute boolean persisted;
};

dictionary PageTransitionEventInit : EventInit {
  boolean persisted = false;
};
```

For web developers (non-normative)

`event.persisted`

For the `pageshow` event, returns false if the page is newly being loaded (and the `load` event will fire). Otherwise, returns true.

For the `pagehide` event, returns false if the page is going away for the last time. Otherwise, returns true, meaning that (if nothing conspires to make the page unsalvageable) the page might be reused if the user navigates back to this page.

Things that can cause the page to be unsalvageable include:

- Listening for `beforeunload` events
- Having `unload` events
- Having `iframe`s that are not salvageable
- Active `Websocket` objects
- Aborting a `document`

MDN

[PageTransitionEvent/persisted](#)

Support in all current engines.

Firefox Yes Safari Yes Chrome Yes

Opera Yes Edge Yes

Edge (Legacy) 12+ Internet Explorer 11

Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

The `persisted` attribute must return the value it was initialized to. It represents the context information for the event.

7.8.11 Unloading documents

A `document` has a *salvageable* state, which must initially be true, a *fired unload* flag, which must initially be false, and a *page showing* flag, which must initially be false. The `page showing` flag is used to ensure that scripts receive `pageshow` and `pagehide` events in a consistent manner (e.g. that they never receive two `pagehide` events in a row without an intervening `pageshow`, or vice versa).

Event loops have a *termination nesting level* counter, which must initially be 0.

To prompt to *unload*, given a `document` object `document` and optionally a *recursiveFlag*, run these steps:

1. Increase the `event loop's termination nesting level` by 1.
2. Increase the `document's ignore-opens-during-unload counter` by 1.
3. Let `event` be the result of *creating an event* using `beforeUnload@event`.
4. Initialize `event.type` attribute to `beforeunload` and its `cancelable` attribute true.
5. Dispatch `Dispatch` event at `document's relevant global object`.
6. Decrease the `event loop's termination nesting level` by 1.
7. If any event listeners were triggered by the earlier *dispatch* step, then set `document's salvageable` state to false.
8. If `document's active sandboxing flag set` does not have its `sandboxed modules flag` set, and the `returnValue` attribute of the `event` object is not the empty string, or if the event was canceled, then the user agent may ask the user to confirm that they wish to *unload* the document.

Note
The message shown to the user is not customizable, but instead determined by the user agent. In particular, the actual value of the `returnValue` attribute is ignored.

The user agent is encouraged to avoid asking the user for confirmation if it judges that doing so would be annoying, deceptive, or pointless. A simple heuristic might be that if the user has not interacted with the document, the user agent would not ask for confirmation before unloading it.

If the user agent asks the user for confirmation, it must `prompt` while waiting for the user's response.

If the user did not confirm the page navigation, then the user agent *refused to allow the document to be unloaded*.

9. If the *recursiveFlag* is not set, then:

1. Let `descendants` be the *list of the descendant browsing contexts* of `document`.
2. For each `browsingContext` in `descendants`:
 1. `Prompt to unload` `browsingContext's active document` with the *recursiveFlag* set. If the user *refused to allow the document to be unloaded*, then the user implicitly also *refused to allow document to be unloaded*: `break`.
 2. If the `salvageable` state of `browsingContext's active document` is false, then set the `salvageable` state of `document` to false.

10. Decrease the `document's ignore-opens-during-unload counter` by 1.

To *unload a document*, optionally given a *recursiveFlag*:

1. Increase the `event loop's termination nesting level` by one.
2. Increase `document's ignore-opens-during-unload counter` by one.
3. If `document's page showing` flag is false, then jump to the step labeled *unload event* below (i.e. skip firing the `pagehide` event and don't rerun the *unloading document visibility change steps*).
4. Set `document's page showing` flag to false.
5. `Fire an event named` `pagehide` `at document's relevant global object`, using `PageTransitionEvent`, with the `persisted` attribute initialized to true if `document's salvageable` state is true, and false otherwise, and legacy `target override` flag set.
6. Run any *unloading document visibility change steps* for `document` that are defined by *other applicable specifications*.

Note
This is specifically intended for use by *Page Visibility*. [PAGEVIS]

7. *Unload event*: If `document's first unload` flag is false, then `fire an event named` `unload` `at document's relevant global object`, with legacy `target override` flag set.

8. Decrease the `event loop's termination nesting level` by one.

9. If any event listeners were triggered by the earlier *unload event* step, then set `document's salvageable` state to false and set `document's fired unload` flag to true.

10. Run any *unloading document cleanup steps* for `document` that are defined by this specification and *other applicable specifications*.

11. If the *recursiveFlag* is not set, then:

1. Let `descendants` be the *list of the descendant browsing contexts* of `document`.
2. For each `browsingContext` in `descendants`:
 1. `Unload the active document` of `browsingContext` with the *recursiveFlag* set.
 2. If the `salvageable` state of the `active document` of `browsingContext` is false, then set the `salvageable` state of `document` to false also.

3. If `document's salvageable` state is false, then `discard document`.

12. Decrease `document's ignore-opens-during-unload counter` by one.

This specification defines the following *unloading document cleanup steps*. Other specifications can define more. Given a `document`, `document`:

1. Let `window` be `document's relevant global object`.

2. For each `WebSocket` object `webSocket` whose `relevant global object` is `window`, `make disappear` `webSocket`.

If this affected any `WebSocket` objects, then set `document's salvageable` state to false.

3. If `document's salvageable` state is false, then:

1. For each `EventSource` object `eventSource` whose `relevant global object` is equal to `window`, `forcibly close` `eventSource`.
2. Empty `window's list of active timers`.

7.8.11.1 The `beforeUnload` interface

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

```
interface BeforeUploadEvent {
  attribute DOMString returnValue;
}
```

Note
There are no `BeforeUploadEvent`-specific initialization methods.

The `BeforeUploadEvent` interface is a legacy interface which allows [prompting to upload](#) to be controlled not only by canceling the event, but by setting the `returnValue` attribute to a value besides the empty string. Authors should use the `preventDefault()` method, or other means of canceling events, instead of using `returnValue`. The `returnValue` attribute controls the process of [prompting to upload](#). When the event is created, the attribute must be set to the empty string. On getting, it must return the last value it was set to. On setting, the attribute must be set to the new value.

Note
`this` attribute is a `DOMString` only for historical reasons. Any value besides the empty string will be treated as a request to ask the user for confirmation.

7.8.12 Aborting a document load

To abort a [document](#):

1. Abort the [active documents](#) of every [child browsing context](#). If this results in any of those [document](#) objects having their `savagable` state set to false, then set [document](#)'s `savagable` state to false also.
2. Cancel any instances of the `fetch` algorithm in the context of [document](#), discarding any [tasks queued](#) for them, and discarding any further data received from the network for them. If this resulted in any instances of the `fetch` algorithm being canceled or any [queued tasks](#) or any network data getting discarded, then set [document](#)'s `savagable` state to false.
3. If [document](#) has an [active parser](#), then:
 1. Set [document](#)'s `active parser was aborted` to true.
 2. [Abort that parse](#).
 3. Set [document](#)'s `savagable` state to false.

User agents may allow users to explicitly invoke the [abort a document](#) algorithm for a [document](#). If the user does so, then, if that [document](#) is an [active document](#), the user agent should [queue a task](#) to [fire an event](#) named `abort` at that [document](#) object's [relevant global object](#) before invoking the [abort](#) algorithm.

To stop [document loading](#) given a [document](#) object [document](#), run these steps:

1. If [document](#) is not an [active document](#), then return.
2. Let [browsingContext](#) be [document](#)'s [browsing context](#).
3. If there is an existing attempt to [navigate](#) [browsingContext](#) and that attempt is not currently running the [unload a document](#) algorithm, then cancel that [navigation](#).
4. [Abort document](#).

7.9 Offline Web applications

Firefox Android 4+ Safari iOS 3.2+Chrome Android 4+WebView Android 4+Samsung Internet 1.0+Opera Android 11+

This feature is in the process of being removed from the Web platform. (This is a long process that takes many years.) Using any of the offline Web application features at this time is highly discouraged. Use service workers instead. [\(SW\)](#)

7.9.1 Introduction

This section is non-normative.

In order to enable users to continue interacting with Web applications and documents even when their network connection is unavailable — for instance, because they are traveling outside of their ISP's coverage area — authors can provide a manifest which lists the files that are needed for the Web application to work offline and which causes the user's browser to keep a copy of the files for use offline.

To illustrate this, consider a simple clock applet consisting of an HTML page "`clock1.html`", a CSS style sheet "`clock.css`", and a JavaScript script "`clock.js`".

Before adding the manifest, these three files might look like this:

```
<!-- clock1.html -->
<!DOCTYPE HTML>
<html>
  <head>
    <meta charset="utf-8">
    <title>Clock</title>
    <script src="clock.js"></script>
    <link rel="stylesheet" href="clock.css">
  </head>
  <body>
    <p>The time is: <output id="clock"></output></p>
  </body>
</html>

CSS/* clock.css */
output { font: 2em sans-serif; }

/* clock.js */
setInterval(function () {
  document.getElementById("clock").value = new Date();
}, 1000);
```

If the user tries to open the "`clock1.html`" page while offline, though, the user agent (unless it happens to have it still in the local cache) will fail with an error.

The author can instead provide a manifest of the three files, say "`clock.appcache`".

```
CACHE MANIFEST
clock.html
clock.css
clock.js
```

With a small change to the HTML file, the manifest (served as [text/cache-manifest](#)) is linked to the application:

```
<!-- clock.html -->
<!DOCTYPE HTML>
<html manifest="clock.appcache">
  <head>
    <meta charset="utf-8">
    <title>Clock</title>
    <script src="clock.js"></script>
    <link rel="stylesheet" href="clock.css">
  </head>
  <body>
    <p>The time is: <output id="clock"></output></p>
  </body>
</html>
```

Now, if the user goes to the page, the browser will cache the files and make them available even when the user is offline.

Note

Authors are encouraged to include the main page in the manifest also, but in practice the page that referenced the manifest is automatically cached even if it isn't explicitly mentioned.

Note

With the exception of "no-store" directive, HTTP cache headers and restrictions on caching pages served over TLS (encrypted, using [https://](#)) are overridden by manifests. Thus, pages will not expire from an application cache before the user agent has updated it, and even applications served over TLS can be made to work offline.

[View this example online.](#)

7.9.1.1 Supporting offline caching for legacy applications

This section is non-normative.

The application cache feature works best if the application logic is separate from the application and user data, with the logic (markup, scripts, style sheets, images, etc) listed in the manifest and stored in the application cache, with a finite number of static HTML pages for the application, and with the application and user data stored in Web Storage or a client-side Indexed Database, updated dynamically using Web Sockets, [WebRTC](#), server-sent events, or some other similar mechanism.

This model results in a fast experience for the user: the application immediately loads, and fresh data is obtained as fast as the network will allow it (possibly while stale data shows).

Legacy applications, however, tend to be designed so that the user data and the logic are mixed together in the HTML, with each operation resulting in a new HTML page from the server.

Example

For example, consider a news application. The typical architecture of such an application, when not using the application cache feature, is that the user fetches the main page, and the server returns a dynamically-generated page with the current headlines and the user interface logic mixed together.

A news application designed for the application cache feature, however, would instead have the main page just consist of the logic, and would then have the main page fetch the data separately from the server, e.g. using [XMLHttpRequest](#).

The mixed-content model does not work well with the application cache feature: since the content is cached, it would result in the user always seeing the stale data from the previous time the cache was updated.

While there is no way to make the legacy model work as fast as the separated model, it can at least be retrofitted for offline use using the [prefer-online application cache mode](#). To do so, list all the static resources used by the HTML page you want to have work offline in an [application cache manifest](#), use the `manifest` attribute to select that manifest from the HTML file, and then add the following line at the bottom of the manifest:

```
HTTP/1.1
prefer-online
NETWORK:
*
```

This causes the [application cache](#) to only be used for [master entries](#) when the user is offline, and causes the application cache to be used as an atomic HTTP cache (essentially pinning resources listed in the manifest), while allowing all resources not listed in the manifest to be accessed normally when the user is online.

7.9.1.2 Events summary

This section is non-normative.

When the user visits a page that declares a manifest, the browser will try to update the cache. It does this by fetching a copy of the manifest and, if the manifest has changed since the user agent last saw it, redownloading all the resources it mentions and caching them anew.

As this is going on, a number of events get fired on the [applicationCache](#) object to keep the script updated as to the state of the cache update, so that the user can be notified appropriately. The events are as follows:

Event name	Interface	Fired when...	Next events
<code>checking</code>	<code>Event</code>	The user agent is checking for an update, or attempting to download the manifest for the first time. This is always the first event in the sequence.	<code>updateerror</code>
<code>noupdate</code>	<code>Event</code>	The manifest hadn't changed.	Last event in sequence.
<code>downloading</code>	<code>Event</code>	The user agent has found an update and is fetching it, or is downloading the resources listed by the manifest for the first time.	<code>progress</code>
<code>progress</code>	<code>ProgressEvent</code>	The user agent is downloading resources listed by the manifest. The event object's <code>total</code> attribute returns the total number of files to be downloaded. The event object's <code>loaded</code> attribute returns the number of files processed so far.	<code>error</code>
<code>cached</code>	<code>Event</code>	The resources listed in the manifest have been downloaded, and the application is now cached.	<code>updateready</code>

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Event name	Interface	Fired when...	Next events
obsolete	Event	The manifest was found to have become a 404 or 410 page, so the application cache is being deleted. The manifest was a 404 or 410 page, so the attempt to cache the application has been aborted.	Last event in sequence.
error	Event	The manifest hadn't changed, but the page referencing the manifest failed to download properly. A fatal error occurred while fetching the resources listed in the manifest. The manifest changed while the update was being run.	Last event in sequence. The user agent will try fetching the files again momentarily.
These events are cancellable; their default action is for the user agent to show download progress information. If the page shows its own update UI, canceling the events will prevent the user agent from showing redundant progress information.			
7.9.2 Application caches			
An <i>application cache</i> is a set of cached resources consisting of:			
• One or more resources (including their out-of-band metadata, such as HTTP headers, if any), identified by URLs, each falling into one (or more) of the following categories:			
Master entries			
Note These are documents that were added to the cache because a browsing context was navigated to that document and the document indicated that this was its cache, using the <code>manifest</code> attribute.			
The manifest			
Note This is the resource corresponding to the URL that was given in a master entry's <code>html</code> element's <code>manifest</code> attribute. The manifest is fetched and processed during the application cache download process . All the <i>master entries</i> have the <i>same origin</i> as the manifest.			
Explicit entries			
Note These are the resources that were listed in the cache's <code>manifest</code> in an explicit section .			
Fallback entries			
Note These are the resources that were listed in the cache's <code>manifest</code> in a fallback section .			
Explicit entries and Fallback entries can be marked as <i>foreign</i> , which means that they have a <code>manifest</code> attribute but that it doesn't point at this cache's <code>manifest</code> .			
Note A URL in the list can be flagged with multiple different types, and thus an entry can end up being categorized as multiple entries. For example, an entry can be a manifest entry and an explicit entry at the same time, if the manifest is listed within the manifest.			
• Zero or more <i>fallback namespaces</i> , each of which is mapped to a fallback entry .			
Note These are URLs used as prefix match patterns for resources that are to be fetched from the network if possible, or to be replaced by the corresponding fallback entry if not. Each namespace URL has the <i>same origin</i> as the manifest.			
• Zero or more URLs that form the <i>online safelist namespaces</i> .			
Note These are used as prefix match patterns , and declare URLs for which the user agent will ignore the application cache, instead fetching them normally (i.e. from the network or local HTTP cache as appropriate).			
• An online safelist wildcard flag , which is either <i>open</i> or <i>blocking</i> .			
Note The <i>open</i> state indicates that any URL not listed as cached is to be implicitly treated as being in the online safelist namespaces ; the <i>blocking</i> state indicates that URLs not listed explicitly in the manifest are to be treated as unavailable.			
• A <i>cache mode flag</i> , which is either in the <i>fast</i> state or the <i>prefer-online</i> state.			
Each application cache has a <i>completeness flag</i> , which is either <i>complete</i> or <i>incomplete</i> .			
An <i>application cache group</i> is a group of application caches , identified by the absolute URL of a resource <code>manifest</code> which is used to populate the caches in the group.			
An application cache is <i>newer</i> than another if it was created after the other (in other words, application caches in an application cache group have a chronological order).			
Only the newest application cache in an application cache group can have its completeness flag set to <i>incomplete</i> ; the others are always all <i>complete</i> .			
Each application cache group has an <i>update status</i> , which is one of the following: <i>idle</i> , <i>checking</i> , <i>downloading</i> .			
A <i>relevant application cache</i> is an application cache that is the <i>newest</i> in its group to be <i>complete</i> .			
Each application cache group has a <i>list of pending master entries</i> . Each entry in this list consists of a resource and a corresponding Document object. It is used during the application cache download process to ensure that new master entries are cached even if the application cache download process was already running for their application cache group when they were loaded.			
An application cache group can be marked as <i>obsolete</i> , meaning that it must be ignored when looking at what application cache groups exist.			
A <i>cache host</i> is a Document object.			
Each cache host has an associated ApplicationCache object.			
Each cache host initially is not associated with an application cache , but can become associated with one early during the page load process, when steps in the parser and in the navigation sections cause cache selection to occur.			
Multiple application caches in different application cache groups can contain the same resource, e.g. if the manifests all reference that resource. If the user agent is to select an application cache from a list of relevant application caches that contain a resource, the user agent must use the application cache that the user most likely wants to see the resource from, taking into account the following:			
• which application cache was most recently updated, • which application cache was being used to display the resource from which the user decided to look at the new resource, and • which application cache the user prefers.			
A URL matches a <i>fallback namespace</i> if there exists a relevant application cache whose <code>manifest</code> 's URL has the <i>same origin</i> as the URL in question, and that has a <code>fallback namespace</code> that is a prefix match for the URL being examined. If multiple fallback namespaces match the same URL, the longest one is the one that matches. A URL looking for a fallback namespace can match more than one application cache at a time, but only matches one namespace in each cache.			
Example If a manifest https://example.com/app1/manifest declares that https://example.com/resources/images is a fallback namespace, and the user navigates to https://example.com:80/resources/images/cat.png , then the user agent will decide that the application cache identified by https://example.com/app1/manifest contains a namespace with a match for that URL.			
7.9.3 The cache manifest syntax			
7.9.3.1 Some sample manifests			
This section is non-normative.			
Example			
This example manifest requires two images and a style sheet to be cached and safelists a CGI script.			
CACHE MANIFEST # the above line is required			
# this is a comment			
# there can be as many of these anywhere in the file			
# they are all treated as comments			
# comments can have spaces before them			
# but must be alone on the line			
# blank lines are ignored too			
# these are files that need to be cached they can either be listed			
# first, or a "CACHE:" header could be put before them, as is done			
# here is an example			
# images/sound-icon.png			
# images/background.png			
# this file has to be put on its own line			
# here is a file for the online safelist -- it isn't cached, and			
# referenced to this file will bypass the cache, always hitting the			
# network (or trying to, if the user is offline).			
#NETWORK: #online			
# here is another set of files to cache, this time just the CSS file.			
CACHE: style/default.css			
It could equally well be written as follows:			
CACHE MANIFEST #NETWORK: #online #CACHE: #style/default.css #images/sound-icon.png #images/background.png			
Example			
Offline application cache manifests can use absolute paths or even absolute URLs:			
CACHE MANIFEST /main/home /main/app.js /style.css /settings/app.js https://img.example.com/logo.png https://img.example.com/icon.png https://img.example.com/cross.png			
Example			
The following manifest defines a catch-all error page that is displayed for any page on the site while the user is offline. It also specifies that the online safelist wildcard flag is <i>open</i> , meaning that accesses to resources on other sites will not be blocked. (Resources on the same site are already not blocked because of the catch-all fallback namespace.)			
So long as all pages on the site reference this manifest, they will get cached locally as they are fetched, so that subsequent hits to the same page will load the page immediately from the cache. Until the manifest is changed, those pages will not be fetched from the server again. When the manifest changes, then all the files will be redownloaded.			
Subresources, such as style sheets, images, etc, would only be cached using the regular HTTP caching semantics, however.			
CACHE MANIFEST #FALLBACK: #offline.html #NETWORK: *			
7.9.3.2 Writing cache manifests			
Manifests must be served using the application-cache-MIME-type . All resources served using the application-cache-MIME-type must follow the syntax of application cache manifests as described in this section.			
► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.			
EXPAND			

An application cache manifest is a text file, whose text is encoded using UTF-8. Data in application cache manifests is line-based. Newlines must be represented by U+00A LINE FEED (LF) characters, U+00D CARRIAGE RETURN (CR) characters, or U+00D CARRIAGE RETURN (CR) U+00A LINE FEED (LF) pairs. [\[ENCODING\]](#)

Note
This is a [willful violation](#) of RFC 2046, which requires all `<text/*>` types to only allow CRLF line breaks. This requirement, however, is outdated: the use of CR, LF and CRLF line breaks is commonly supported and indeed sometimes CRLF is *not* supported by text editors. [\[RFC2046\]](#)

The first line of an application cache manifest must consist of the string "CACHE", a single U+020 SPACE character, the string "MANIFEST", and either a U+020 SPACE character, a U+009 CHARACTER TABULATION (tab) character, a U+00A LINE FEED (LF) character, or a U+00D CARRIAGE RETURN (CR) character. The first line may optionally be preceded by a U+FEFF BYTE ORDER MARK (BOM) character. If any other text is found on the first line, it is ignored.

Subsequent lines, if any, must all be one of the following:

A blank line

Blank lines must consist of zero or more U+020 SPACE and U+009 CHARACTER TABULATION (tab) characters only.

A comment

Comment lines must consist of zero or more U+020 SPACE and U+009 CHARACTER TABULATION (tab) characters, followed by a single U+023 NUMBER SIGN character (#), followed by zero or more characters other than U+00A LINE FEED (LF) and U+00D CARRIAGE RETURN (CR) characters.

Note
Comments need to be on a line on their own. If they were to be included on a line with a URL, the "#" would be mistaken for part of a [fragment](#).

A section header

Section headers change the current section. There are four possible section headers:

CACHE:
Switches to the [explicit section](#).

FALLBACK:
Switches to the [fallback section](#).

NETWORK:
Switches to the [online safelist section](#).

SETTINGS:
Switches to the [settings section](#).

Section header lines must consist of zero or more U+020 SPACE and U+009 CHARACTER TABULATION (tab) characters, followed by one of the names above (including the U+03A COLON character (:)) followed by zero or more U+020 SPACE and U+009 CHARACTER TABULATION (tab) characters.

Ironically, by default, the current section is the [explicit section](#).

Data for the current section

The format that data lines must take depends on the current section.

When the current section is the [explicit section](#), data lines must consist of zero or more U+020 SPACE and U+009 CHARACTER TABULATION (tab) characters, a [valid URL string](#) identifying a resource other than the manifest itself, and then zero or more U+020 SPACE and U+009 CHARACTER TABULATION (tab) characters.

When the current section is the [fallback section](#), data lines must consist of zero or more U+020 SPACE and U+009 CHARACTER TABULATION (tab) characters, a [valid URL string](#) identifying a resource other than the manifest itself, one or more U+020 SPACE and U+009 CHARACTER TABULATION (tab) characters, another [valid URL string](#) identifying a resource other than the manifest itself, and then zero or more U+020 SPACE and U+009 CHARACTER TABULATION (tab) characters.

When the current section is the [online safelist section](#), data lines must consist of zero or more U+020 SPACE and U+009 CHARACTER TABULATION (tab) characters, either a single U+02A ASTERISK character (*) or a [valid URL string](#) identifying a resource other than the manifest itself, and then zero or more U+020 SPACE and U+009 CHARACTER TABULATION (tab) characters.

When the current section is the [settings section](#), data lines must consist of zero or more U+020 SPACE and U+009 CHARACTER TABULATION (tab) characters, a [setting](#), and then zero or more U+020 SPACE and U+009 CHARACTER TABULATION (tab) characters.

Currently only one [setting](#) is defined:

The cache mode setting
This consists of the string "`prefer-online`". It sets the [cache mode](#) to `prefer-online`. (The [cache mode](#) defaults to `fast`.)

Within a [settings section](#), each [setting](#) must occur no more than once.

Manifests may contain sections more than once. Sections may be empty.

URLs that are to be fallback pages associated with [fallback namespaces](#), and those namespaces themselves, must be given in [fallback sections](#), with the namespace being the first URL of the data line, and the corresponding fallback page being the second URL. All the other pages to be cached must be listed in [explicit sections](#).

[Fallback namespaces](#) and [fallback entries](#) must have the [same origin](#) as the manifest itself. [Fallback namespaces](#) must also be in the same path as the manifest's URL.

[Fallback namespaces](#) must not be listed more than once.

Namespaces that the user agent is to put into the [online safelist](#) must all be specified in [online safelist sections](#). (This is needed for any URL that the page is intending to use to communicate back to the server.) To specify that all URLs are automatically safelisted in this way, a U+02A ASTERISK character (*) may be specified as one of the URLs.

Authors should not include namespaces in the [online safelist](#) for which another namespace in the [online safelist](#) is a [prefix match](#).

[Relative URLs](#) must be given relative to the manifest's own URL. All URLs in the manifest must have the same [scheme](#) as the manifest itself (either explicitly or implicitly, through the use of [relative URLs](#)). [\[URL\]](#)

URLs in manifests must not have [fragments](#) (i.e. the U+023 NUMBER SIGN character #) allowed in URLs in manifests).

[Fallback namespaces](#) and namespaces in the [online safelist](#) are matched by [prefix match](#).

7.9.3.3 Parsing cache manifests

When a user agent is to *parse a manifest*, it means that the user agent must run the following steps:

1. [UTF-8 decode](#) the byte stream corresponding with the manifest to be parsed.

Note
The [UTF-8 decode](#) algorithm strips a leading BOM, if any.

2. Let [base URL](#) be the [absolute URL](#) representing the manifest.

3. Apply the [URL parser](#) to [base URL](#) and let [manifest path](#) be the [path](#) component thus obtained.

4. Remove all the characters in [manifest path](#) after the last U+002F SOLIDUS character (/), if any. (The first character and the last character in [manifest path](#) after this step will both be slashes, the URL path separator character.)

5. Apply the [URL parser](#) steps to [base URL](#), so that the components from its [URI record](#) can be used by the subsequent steps of this algorithm.

6. Let [explicit URLs](#) be an initially empty list of [absolute URLs](#) for [explicit entries](#).

7. Let [fallback URLs](#) be an initially empty mapping of [fallback namespaces](#) to [absolute URLs](#) for [fallback entries](#).

8. Let [online safelist namespaces](#) be an initially empty list of [absolute URLs](#) for an [online safelist](#).

9. Let [online safelist wildcard flag](#) be `blocking`.

10. Let [cache mode flag](#) be `fast`.

11. Let [input](#) be the decoded text of the manifest's byte stream.

12. Let [position](#) be a pointer into [input](#), initially pointing at the first character.

13. If the characters starting from [position](#) are "CACHE", followed by a U+020 SPACE character, followed by "MANIFEST", then advance [position](#) to the next character after those. Otherwise, this isn't a cache manifest; return with a failure while checking for the magic signature.

14. If the character at [position](#) is neither a U+020 SPACE character, a U+009 CHARACTER TABULATION (tab) character, U+00A LINE FEED (LF) character, nor a U+00D CARRIAGE RETURN (CR) character, then this isn't a cache manifest; return with a failure while checking for the magic signature.

15. This is a cache manifest. The algorithm cannot fail beyond this point (though bogus lines can get ignored).

16. [Collect a sequence of code points](#) that are not U+00A LINE FEED (LF) or U+00D CARRIAGE RETURN (CR) characters from [input](#) given [position](#), and ignore those characters. (Extra text on the first line, after the signature, is ignored.)

17. Let [mode](#) be "explicit".

18. [Start of line](#): If [position](#) is past the end of [input](#), then jump to the last step. Otherwise, [collect a sequence of code points](#) that are U+00A LINE FEED (LF), U+00D CARRIAGE RETURN (CR), U+020 SPACE, or U+009 CHARACTER TABULATION (tab) characters from [input](#) given [position](#).

19. Now, [collect a sequence of code points](#) that are not U+00A LINE FEED (LF) or U+00D CARRIAGE RETURN (CR) characters from [input](#) given [position](#), and let the result be [line](#).

20. Drop any trailing U+020 SPACE and U+009 CHARACTER TABULATION (tab) characters at the end of [line](#).

21. If [line](#) is the empty string, then jump back to the step labeled [start of line](#).

22. If the first character in [line](#) is a U+023 NUMBER SIGN character (#), then jump back to the step labeled [start of line](#).

23. If [line](#) equals "CACHE:" (the word "CACHE" followed by a U+03A COLON character (:)), then set [mode](#) to "explicit" and jump back to the step labeled [start of line](#).

24. If [line](#) equals "FALLBACK:" (the word "FALLBACK" followed by a U+03A COLON character (:)), then set [mode](#) to "fallback" and jump back to the step labeled [start of line](#).

25. If [line](#) equals "NETWORK:" (the word "NETWORK" followed by a U+03A COLON character (:)), then set [mode](#) to "online safelist" and jump back to the step labeled [start of line](#).

26. If [line](#) equals "SETTINGS:" (the word "SETTINGS" followed by a U+03A COLON character (:)), then set [mode](#) to "settings" and jump back to the step labeled [start of line](#).

27. If [line](#) ends with a U+00A COLON character (:), then set [mode](#) to "unknown" and jump back to the step labeled [start of line](#).

28. This is either a data line or it is syntactically incorrect.

29. Let [position](#) be a pointer into [line](#), initially pointing at the start of the string.

30. Let [tokens](#) be a list of strings, initially empty.

31. While [position](#) doesn't point past the end of [line](#):

1. Let [current token](#) be an empty string.

2. While [position](#) doesn't point past the end of [line](#) and the character at [position](#) is neither a U+020 SPACE nor a U+009 CHARACTER TABULATION (tab) character, add the character at [position](#) to [current token](#) and advance [position](#) to the next character in [input](#).

3. Add [current token](#) to the [tokens](#) list.

4. While [position](#) doesn't point past the end of [line](#) and the character at [position](#) is either a U+020 SPACE or a U+009 CHARACTER TABULATION (tab) character, advance [position](#) to the next character in [input](#).

32. Process [tokens](#) as follows:

If [mode](#) is "explicit"

Let [uriRecord](#) be the result of [parsing](#) the first item in [tokens](#) with [base URL](#); ignore the rest.

If [uriRecord](#) is failure, then jump back to the step labeled [start of line](#).

If [uriRecord](#) has a different [scheme](#) component than [base URL](#) (the manifest's URL), then jump back to the step labeled [start of line](#).

Let [new URL](#) be the result of applying the [URL serializer](#) algorithm to [uriRecord](#), with the [exclude fragment](#) flag set.

Add [new URL](#) to the [explicit URLs](#).

If [mode](#) is "fallback"

Let [part one](#) be the first token in [tokens](#), and let [part two](#) be the second token in [tokens](#).

Let [uriRecordOne](#) be the result of [parsing](#) [part one](#) with [base URL](#).

Let [uriRecordTwo](#) be the result of [parsing](#) [part two](#) with [base URL](#).

If the `origin` of either `uriRecordOne` or `uriRecordTwo` is not `same-origin` with the manifest's URL, `origin`, then jump back to the step labeled `start of line`.
 Let `part one path` be the `path` component of `uriRecordOne`.
 If `manifest path` is not a `prefix match` for `part one path`, then jump back to the step labeled `start of line`.
 Let `part one` be the result of applying the `URL serializer` algorithm to `uriRecordOne`, with the `exclude fragment` flag set.
 Let `part two` be the result of applying the `URL serializer` algorithm to `uriRecordTwo`, with the `exclude fragment` flag set.
 If `part one` is already in the `fallback URLs` mapping as a `fallback namespace`, then jump back to the step labeled `start of line`.
 Otherwise, add `part one` to the `fallback URLs` mapping as a `fallback namespace`, mapped to `part two` as the `fallback entry`.

If `mode` is "online safelist"
 If the first item in `tokens` is a U+002A ASTERISK character (*), then set `online safelist wildcard flag` to `open` and jump back to the step labeled `start of line`.
 Otherwise, let `uriRecord` be the result of `parsing` the first item in `tokens` with `base URL`.
 If `uriRecord` is failure, then jump back to the step labeled `start of line`.
 If `uriRecord` has a different `scheme` component than `base URL` (the manifest's URL), then jump back to the step labeled `start of line`.
 Let `new URL` be the result of applying the `URL serializer` algorithm to `uriRecord`, with the `exclude fragment` flag set.
 Add `new URL` to the `online safelist namespaces`.
 If `mode` is "settings"
 If `tokens` contains a single token, and that token is a `case-sensitive` match for the string "prefer-online", then set `cache mode flag` to `prefer-online` and jump back to the step labeled `start of line`.
 Otherwise, the line is an unsupported setting; do nothing; the line is ignored.

If `mode` is "unknown"
 Do nothing. The line is ignored.

33. Jump back to the step labeled `start of line`. (That step jumps to the next, and last, step when the end of the file is reached.)

34. Return the `explicit URLs` list, the `fallback URLs` mapping, the `online safelist namespaces`, the `online safelist wildcard flag`, and the `cache mode flag`.

Note

The resource that declares the manifest (with the `manifest` attribute) will always get taken from the cache, whether it is listed in the cache or not, even if it is listed in an `online safelist namespace`.
 If a resource is listed in the `explicit section` or as a `fallback entry` in the `fallback section`, the resource will always be taken from the cache, regardless of any other matching entries in the `fallback namespaces` or `online safelist namespaces`.
 When a `fallback namespace` and an `online safelist namespace` overlap, the `online safelist namespace` has priority.
 The `online safelist wildcard flag` is applied last, only for URLs that match neither the `online safelist namespace` nor the `fallback namespace` and that are not listed in the `explicit section`.

7.9.4 Downloading or updating an application cache

When the user agent is required (by other parts of this specification) to start the `application cache download process` for an `absolute URL`, purported to identify a `manifest`, or for an `application cache group`, potentially given a particular `cache host`, and potentially given a `master` resource, the user agent must run the steps below. These steps are always run `in parallel` with the `event loop tasks`.

Some of these steps have requirements that only apply if the user agent `shows caching progress`. Support for this is optional. Caching progress UI could consist of a progress bar or message panel in the user agent's interface, or an overlay, or something else. Certain events fired during the `application cache download process` allow the script to override the display of such an interface. (Such events are delayed until after the `load` event has fired.) The goal of this is to allow Web applications to provide more seamless update mechanisms, hiding from the user the mechanics of the application cache mechanism. User agents may display user interfaces independent of this, but are encouraged to not show prominent update progress notifications for applications that cancel the relevant events.

The `application cache download process` steps are as follows:

1. Optionally, wait until the permission to start the `application cache download process` has been obtained from the user and until the user agent is confident that the network is available. This could include doing nothing until the user explicitly opts-in to caching the site, or could involve prompting the user for permission. The algorithm might never get past this point. (This step is particularly intended to be used by users running on severely space-constrained devices or in highly privacy-sensitive environments).
2. Atomically, so as to avoid race conditions, perform the following substeps:
 1. Pick the appropriate substeps:
 If these steps were invoked with an `absolute URL`, purported to identify a `manifest`
 Let `manifest URL` be that `absolute URL`.
 If there is no `application cache group` identified by `manifest URL`, then create a new `application cache group` identified by `manifest URL`. Initially, it has no `application caches`. One will be created later in this algorithm.
 If these steps were invoked with a `application cache group`
 Let `manifest URL` be the `absolute URL` of the `manifest` used to identify the `application cache group` to be updated.
 If that `application cache group` is `obsolete`, then abort this instance of the `application cache download process`. This can happen if another instance of this algorithm found the manifest to be 404 or 410 while this algorithm was waiting in the first step above.
 2. Let `cache group` be the `application cache group` identified by `manifest URL`.
 3. If these steps were invoked with a `master` resource, then add the resource, along with the resource's `document`, to `cache group's list of pending master entries`.
 4. If these steps were invoked with a `cache host`, and the `status` of `cache group` is `checking` or `downloading`, then `queue a post-load task` to run these steps:
 1. Let `showProgress` be the result of `fire an event named "checking"` at the `ApplicationCache` singleton of that `cache host`, with the `cancelable` attribute initialized to true.
 2. If `showProgress` is true and the user agent `shows caching progress`, then display some sort of user interface indicating to the user that the user agent is checking to see if it can download the application.
 5. If these steps were invoked with a `cache host`, and the `status` of `cache group` is `downloading`, then also `queue a post-load task` to run these steps:
 1. Let `showProgress` be the result of `fire an event named "downloading"` at the `ApplicationCache` singleton of that `cache host`, with the `cancelable` attribute initialized to true.
 2. If `showProgress` is true and the user agent `shows caching progress`, then display some sort of user interface indicating to the user that the application is being downloaded.
 6. If the `status` of the `cache group` is either `checking` or `downloading`, then abort this instance of the `application cache download process`, as an update is already in progress.
 7. Set the `status` of `cache group` to `checking`.
 8. For each `cache host` associated with an `application cache` in `cache group`, `queue a post-load task` run these steps:
 1. Let `showProgress` be the result of `fire an event named "checking"` at the `ApplicationCache` singleton of the `cache host`, with the `cancelable` attribute initialized to true.
 2. If `showProgress` is true and the user agent `shows caching progress`, then display some sort of user interface indicating to the user that the user agent is checking for the availability of updates.

Note

The remainder of the steps run `in parallel`.

If `cache group` already has an `application cache` in it, then this is an `upgrade attempt`. Otherwise, this is a `cache attempt`.

3. If this is a `cache attempt`, then this algorithm was invoked with a `cache host`; `queue a post-load task` to run these steps:

1. Let `showProgress` be the result of `fire an event named "checking"` at the `ApplicationCache` singleton of that `cache host`, with the `cancelable` attribute initialized to true.
2. If `showProgress` is true and the user agent `shows caching progress`, then display some sort of user interface indicating to the user that the user agent is checking for the availability of updates.

4. Let `request` be a new `request` whose `url` is `manifest URL`, `client` is null, `destination` is the empty string, `referrer` is "no-referrer", `synchronous flag` is set, `credentials mode` is "include", and whose `use-URL-credentials flag` is set.

5. **Fetching the manifest:** Let `manifest` be the result of `fetching request`. HTTP caching semantics should be honored for this request.

Parse `manifest's body` according to the `rules for parsing manifests`, obtaining a list of `explicit entries`, `fallback entries` and the `fallback namespaces` that map to them, entries for the `online safelist`, and values for the `online safelist wildcard flag` and the `cache mode flag`.

Note

The `MIME type` of the resource is ignored — it is assumed to be `text/cache-manifest`. In the future, if new manifest formats are supported, the different types will probably be distinguished on the basis of the file signatures (for the current format, that is the "CACHE MANIFEST" string at the top of the file).

6. If **fetching the manifest** fails due to a 404 or 410 response status, then run these substeps:

1. Mark `cache group` as `obsolete`. This `cache group` no longer exists for any purpose other than the processing of `document` objects already associated with an `application cache` in the `cache group`.
2. Let `task list` be an empty list of `tasks`.

3. For each `cache host` associated with an `application cache` in `cache group`, create a `task` to run these steps and append it to `task list`:

1. Let `showProgress` be the result of `fire an event named "error"` (not `obsolete!`) at the `ApplicationCache` singleton of the `document` for this entry, if there still is one, with the `cancelable` attribute initialized to true.
2. If `showProgress` is true and the user agent `shows caching progress`, then display some sort of user interface indicating to the user that the application is no longer available for offline use.

4. For each entry in `cache group's list of pending master entries`, create a `task` to run these steps and append it to `task list`:

1. Let `showProgress` be the result of `fire an event named "error"` (not `obsolete!`) at the `ApplicationCache` singleton of the `document` for this entry, if there still is one, with the `cancelable` attribute initialized to true.
2. If `showProgress` is true and the user agent `shows caching progress`, then display some sort of user interface indicating to the user that the user agent failed to save the application for offline use.

5. If `cache group` has an `application cache` whose `completeness flag` is `incomplete`, then discard that `application cache`.

6. If appropriate, remove any user interface indicating that an update for this cache is in progress.

7. Let the `status` of `cache group` be `idle`.

8. For each `task` in `task list`, `queue that task as a post-load task`.

9. Abort the `application cache download process`.

7. Otherwise, if **fetching the manifest** fails in some other way (e.g. the server returns another 4xx or 5xx response, or there is a DNS error, or the connection times out, or the user cancels the download, or the parser for manifests fails when checking the magic signature), or if the server returned a redirect, then run the `cache failure steps`. (HTTP)

8. If this is an `upgrade attempt` and the newly downloaded `manifest` is byte-for-byte identical to the manifest found in the `newest application cache` in `cache group`, or the response status is 304, then run these substeps:

1. Let `cache` be the `newest application cache` in `cache group`.
2. Let `task list` be an empty list of `tasks`.

3. For each entry in `cache group's list of pending master entries`, wait for the resource for this entry to have either completely downloaded or failed.

If the download failed (e.g. the server returns a 4xx or 5xx response, or there is a DNS error, the connection times out, or the user cancels the download), or if the resource is labeled with the "no-store" cache directive, then create a `task` to run these steps and append it to `task list`:

1. Let `showProgress` be the result of `fire an event named "error"` at the `ApplicationCache` singleton of the `document` for this entry, if there still is one, with the `cancelable` attribute initialized to true.

2. If `showProgress` is true and the user agent `shows caching progress`, then display some sort of user interface indicating to the user that the user agent failed to save the application for offline use.

Otherwise, associate the `document` for this entry with `cache`; store the resource for this entry in `cache`, if it's not already there, and categorize its entry as a `master entry`. If applying the `URL parser` algorithm to the resource's `URL` results in a `URL record` that has a non-null `fragment` component, the `URL` used for the entry in `cache` must instead be the `absolute URL` obtained from applying the `URL serializer` algorithm to the `URL record` with the `exclude fragment` flag set (application caches never include `fragments`).

1. Let `showProgress` be the result of `firing an event` named `update` at the `ApplicationCache` singleton of the `cache host`, with the `cancellable` attribute initialized to true.
2. If `showProgress` is true and the user agent `shows caching progress`, then display some sort of user interface indicating to the user that the application is up to date.
3. Empty `cache group's list of pending master entries`.
4. If appropriate, remove any user interface indicating that an update for this cache is in progress.
5. Let the `status` of `cache group` be `idle`.
6. For each `task` in `task list`, `queue task as a post-load task`.
7. Abort the `application cache download process`.
9. Let `new cache` be a newly created `application cache` in `cache group`. Set its `completeness flag` to `incomplete`.
10. For each entry in `cache group's list of pending master entries`, associate the `Document` for this entry with `new cache`.
11. Set the `status` of `cache group` to `downloading`.
12. For each `cache host` associated with an `application cache` in `cache group`, `queue a post-load task` to run these steps:
 1. Let `showProgress` be the result of `firing an event` named `download` at the `ApplicationCache` singleton of the `cache host`, with the `cancellable` attribute initialized to true.
 2. If `showProgress` is true and the user agent `shows caching progress`, then display some sort of user interface indicating to the user that a new version is being downloaded.
13. Let `file list` be an empty list of URLs with flags.
14. Add all the URLs in the list of `explicit entries` obtained by parsing `manifest` to `file list`, each flagged with "explicit entry".
15. Add all the URLs in the list of `fallback entries` obtained by parsing `manifest` to `file list`, each flagged with "fallback entry".
16. If this is an `upgrade attempt`, then add all the URLs of `master entries` in `newest application cache` in `cache group` whose `completeness flag` is `complete` to `file list`, each flagged with "master entry".
17. If any URL is in `file list` more than once, then merge the entries into one entry for that URL, that entry having all the flags that the original entries had.
18. For each URL in `file list`, run the following steps. These steps may be run in parallel for two or more of the URLs at a time. If, while running these steps, the `ApplicationCache` object's `shorten` method `sends a signal` to this instance of the `application cache download process` algorithm, then run the `cache failure steps` instead.
 1. If the resource URL being processed was flagged as neither an "explicit entry" nor a "fallback entry", then the user agent may skip this URL.
19. Note This is intended to allow user agents to expire resources not listed in the manifest from the cache. Generally, implementers are urged to use an approach that expires lesser-used resources first.
20. For each `cache host` associated with an `application cache` in `cache group`, `queue a progress post-load task` to run these steps:
 1. Let `showProgress` be the result of `firing an event` named `progress` at the `ApplicationCache` singleton of the `cache host`, using `ProgressEvent`, with the `cancellable` attribute initialized to true, the `lengthComputable` attribute initialized to true, the `total` attribute initialized to the number of files in `file list`, and the `loaded` attribute initialized to the number of files in `file list` that have been either downloaded or skipped so far. [XHR]
 2. If `showProgress` is true and the user agent `shows caching progress`, then display some sort of user interface indicating to the user that a file is being downloaded in preparation for updating the application.
21. Let `request` be a new `request` whose `url` is `URL`, `client` is null, `destination` is the empty string, `origin` is `manifest URL's origin`, `referrer` is "`no-referrer`", `synchronous flag` is set, `credentials mode` is "`include`", `use-URL-credentials flag` is set, and `redirect mode` is "`manual`".
22. `Fetch request`. If this is an `upgrade attempt`, then use the `newest application cache` in `cache group` as an HTTP cache, and honor HTTP caching semantics (such as expiration, ETags, and so forth) with respect to that cache. User agents may also have other caches in place that are also honored.
23. If the previous step fails (e.g. the server returns a 4xx or 5xx response, or there is a DNS error, or the connection times out, or the user cancels the download), or if the server returned a redirect, or if the resource is labeled with the "`no-store`" cache directive, then run the first appropriate step from the following list: [HTTP]
24. If the URL being processed was flagged as an "explicit entry" or a "fallback entry"
 1. If these steps are being run in parallel for any other URLs in `file list`, then abort this algorithm for those other URLs. Run the `cache failure steps`.
25. Note Redirects are fatal because they are either indicative of a network problem (e.g. a captive portal); or would allow resources to be added to the cache under URLs that differ from any URL that the networking model will allow access to, leaving orphan entries; or would allow resources to be stored under URLs different than their true URLs. All of these situations are bad.
26. If the error was a 404 or 410 HTTP response
If the resource was labeled with the "`no-store`" cache directive
 Skip this resource. It is dropped from the cache.
Otherwise
 Copy the resource and its metadata from the `newest application cache` in `cache group` whose `completeness flag` is `complete`, and act as if that was the fetched resource, ignoring the resource obtained from the network.
User agents may warn the user of these errors as an aid to development.
27. Note These rules make errors for resources listed in the manifest fatal, while making it possible for other resources to be removed from caches when they are removed from the server, without errors, and making non-manifest resources survive server-side errors.
28. Note Except for the "`no-store`" directive, HTTP caching rules that would cause a file to be expired or otherwise not cached are ignored for the purposes of the `application cache download process`.
29. Otherwise, the fetching succeeded. Store the resource in the `new cache`.
30. If the user agent is not able to store the resource (e.g. because of quota restrictions), the user agent may prompt the user or try to resolve the problem in some other manner (e.g. automatically pruning content in other caches). If the problem cannot be resolved, the user agent must run the `cache failure steps`.
31. If the URL being processed was flagged as an "explicit entry" in `file list`, then categorize the entry as an `explicit entry`.
32. If the URL being processed was flagged as a "fallback entry" in `file list`, then categorize the entry as a `fallback entry`.
33. If the URL being processed was flagged as an "master entry" in `file list`, then categorize the entry as a `master entry`.
34. As an optimization, if the resource is an HTML or XML file whose `document element` is an `html` element with a `manifest` attribute whose value doesn't match the manifest URL of the application cache being processed, then the user agent should mark the entry as being `foreign`.
35. For each `cache host` associated with an `application cache` in `cache group`, `queue a progress post-load task` to run these steps:
 1. Let `showProgress` be the result of `firing an event` named `progress` at the `ApplicationCache` singleton of the `cache host`, using `ProgressEvent`, with the `cancellable` attribute initialized to true, the `lengthComputable` attribute initialized to true, and the `total` and `loaded` attributes initialized to the number of files in `file list`. [XHR]
 2. If `showProgress` is true and the user agent `shows caching progress`, then display some sort of user interface indicating to the user that all the files have been downloaded.
36. Store the list of `fallback namespaces`, and the URLs of the `fallback entries` that they map to, in `new cache`.
37. Store the URLs that form the new `online safest` in `new cache`.
38. Store the value of the new `online safest wildcard flag` in `new cache`.
39. Store the value of the new `cache mode` flag in `new cache`.
40. For each entry in `cache group's list of pending master entries`, wait for the resource for this entry to have either completely downloaded or failed.
41. If the download failed (e.g. the server returns a 4xx or 5xx response, or there is a DNS error, the connection times out, or the user cancels the download), or if the resource is labeled with the "`no-store`" cache directive, then run these substeps:
 1. Unassociate the `Document` for this entry from `new cache`.
 2. `Queue a post-load task` to run these steps:
 1. Let `showProgress` be the result of `firing an event` named `error` at the `ApplicationCache` singleton of the `Document` for this entry, if there still is one, with the `cancellable` attribute initialized to true.
 2. If `showProgress` is true and the user agent `shows caching progress`, then display some sort of user interface indicating to the user that the user agent failed to save the application for offline use.
42. If this is a `cache attempt` and this entry is the last entry in `cache group's list of pending master entries`, then run these further substeps:
 1. Discard `cache group` and its only `application cache`, `new cache`.
 2. If appropriate, remove any user interface indicating that an update for this cache is in progress.
 3. Abort the `application cache download process`.
 4. Otherwise, remove this entry from `cache group's list of pending master entries`.
43. Otherwise, store the resource for this entry in `new cache`, if it isn't already there, and categorize its entry as a `master entry`.
44. Let `request` be a new `request` whose `url` is `manifest URL`, `client` is null, `destination` is the empty string, `origin` is "`no-referrer`", `synchronous flag` is set, `credentials mode` is "`include`", and whose `use-URL-credentials flag` is set.
45. Let `second manifest` be the result of `fetching request`. HTTP caching semantics should again be honored for this request.
46. Note Since caching can be honored, authors are encouraged to avoid setting the `cache headers` on the manifest in such a way that the user agent would simply not contact the network for this second request; otherwise, the user agent would not notice if the cache had changed during the cache update process.
47. If the previous step failed for any reason, or if the fetching attempt involved a redirect, or if `second manifest` and `manifest` are not byte-for-byte identical, then schedule a rerun of the entire algorithm with the same parameters after a short delay, and run the `cache failure steps`.
48. Otherwise, store `manifest` in `new cache`, if it's not there already, and categorize its entry as `the manifest`.
49. Set the `completeness flag` of `new cache` to `complete`.
50. Let `task list` be an empty list of `tasks`.
51. If this is a `cache attempt`, then for each `cache host` associated with an `application cache` in `cache group`, create a `task` to run these steps and append it to `task list`:
 1. Let `showProgress` be the result of `firing an event` named `cached` at the `ApplicationCache` singleton of the `cache host`, with the `cancellable` attribute initialized to true.
 2. If `showProgress` is true and the user agent `shows caching progress`, then display some sort of user interface indicating to the user that the application has been cached and that they can now use it offline.
52. Otherwise, it is an `upgrade attempt`. For each `cache host` associated with an `application cache` in `cache group`, create a `task` to run these steps and append it to `task list`:
 1. Let `showProgress` be the result of `firing an event` named `updateready` at the `ApplicationCache` singleton of the `cache host`, with the `cancellable` attribute initialized to true.
 2. If `showProgress` is true and the user agent `shows caching progress`, then display some sort of user interface indicating to the user that a new version is available and that they can activate it by reloading the page.
53. If appropriate, remove any user interface indicating that an update for this cache is in progress.
54. Set the `update status` of `cache group` to `idle`.
55. For each `task` in `task list`, `queue task as a post-load task`.
56. The `cache failure steps` are as follows:
 1. Let `task list` be an empty list of `tasks`.
 2. For each entry in `cache group's list of pending master entries`, run the following further substeps. These steps may be run in parallel for two or more entries at a time.
 1. Wait for the resource for this entry to have either completely downloaded or failed.
 2. Unassociate the `Document` for this entry from its `application cache`, if it has one.
 3. Create a `task` to run these steps and append it to `task list`:

2. If `showProgress` is true and the user agent `shows caching progress`, then display some sort of user interface indicating to the user that the user agent failed to save the application for offline use.
3. For each `cache host` still associated with an `application cache` in `cache group`, create a `task` to run these steps and append it to `task list`.
 1. Let `showProgress` be the result of `fireng an event` named `error` at the `ApplicationCache` singleton of the `cache host`, with the `cancellable` attribute initialized to true.
 2. If `showProgress` is true and the user agent `shows caching progress`, then display some sort of user interface indicating to the user that the user agent failed to save the application for offline use.
4. Empty `cache group's` `list of pending master entries`.
5. If `cache group` has an `application cache` whose `completeness flag` is `incomplete`, then discard that `application cache`.
6. If appropriate, remove any user interface indicating that an update for this cache is in progress.
7. Let the `status` of `cache group` be `idle`.
8. If this was a `cache attempt`, discard `cache group` altogether.
9. For each `task` in `task list`, `queue the task as a post-load task`.
10. Abort the `application cache download process`.

Attempts to fetch resources as part of the `application cache download process` may be done with cache-defeating semantics, to avoid problems with stale or inconsistent intermediary caches.

User agents may invoke the `application cache download process`, in the background, for any `application cache group`, at any time (with no `cache host`). This allows user agents to keep caches primed and to update caches even before the user visits a site.

Each `document` has a list of `pending application cache download process tasks` that is used to delay events fired by the algorithm above until the document's `load` event has fired. When the `document` is created, the list must be empty.

When the steps above say to `queue a post-load task`, where `task` is a `task` that dispatches an event on a target `ApplicationCache` object target, the user agent must run the appropriate steps from the following list:

If `target's node document` is ready for post-load tasks

`Queue the task.`

Otherwise

Add task to target's `node document`'s list of `pending application cache download process tasks`.

When the steps above say to `queue a progress post-load task`, where `task` is a `task` that dispatches an event on a target `ApplicationCache` object target, the user agent must run the following steps:

1. If there is a `task` in `target's node document`'s list of `pending application cache download process tasks` that is labeled as a `progress task`, then remove that task from the list.
2. Label task as a `progress task`.
3. `Queue a post-load task task.`

The `task source` for these `tasks` is the `networking task source`.

7.9.5 The application cache selection algorithm

When the `application cache selection algorithm` algorithm is invoked with a `document` and optionally a manifest URL, the user agent must run the first applicable set of steps from the following list:

If there is a `manifest URL`, and `document` was loaded from an `application cache`, and the URL of the `manifest` of that cache's `application cache group` is not the same as `manifest URL`

Mark the entry for the resource from which `document` was taken in the `application cache` from which it was loaded as `foreign`.

Restart the current navigation from the top of the `navigation algorithm`, undoing any changes that were made as part of the initial load (changes can be avoided by ensuring that the step to `update the session history with the new page` is only ever completed after this `application cache selection algorithm` is run, though this is not required).

Note

The navigation will not result in the same resource being loaded, because "foreign" entries are never picked during navigation.

User agents may notify the user of the inconsistency between the cache manifest and the document's own metadata, to aid in application development.

If `document` was loaded from an `application cache`, and that `application cache` still exists (it is not now `obsolete`)

Associate `document` with the `application cache` from which it was loaded. Invoke, in the background, the `application cache download process` for that `application cache`'s `application cache group`, with `document` as the `cache host`.

If `document` was loaded using `GET`, and, there is a `manifest URL`, and `manifest URL` has the `same origin` as `document`

Invoke, in the background, the `application cache download process` for `manifest URL`, with `document` as the `cache host` and with the resource from which `document` was parsed as the `master` resource.

If there are `relevant application caches` that are identified by a URL with the `same origin` as the URL of `document`, and that have this URL as one of their entries, excluding entries marked as `foreign`, then the user agent should use the `most appropriate application cache` of those that match as an HTTP cache for any subresource loads. User agents may also have other caches in place that are also honored.

Otherwise

The `Document` is not associated with any `application cache`.

If there was a `manifest URL`, the user agent may report to the user that it was ignored, to aid in application development.

7.9.6 Changes to the networking model

If "AppCache" is not removed as a feature this section needs to be integrated into the Fetch standard.

When a `cache host` is associated with an `application cache` whose `completeness flag` is `complete`, any and all loads for resources related to that `cache host` other than those for `child browsing contexts` must go through the following steps instead of immediately invoking the mechanisms appropriate to that resource's scheme:

1. If the resource is not to be fetched using the `GET` method, or if applying the `URL parser` algorithm to both its `URL` and the `application cache's manifest`'s `URL` results in two `URL records` with different `scheme` components, then fetch the resource normally and return.
2. If the resource's `URL` is a `master entry`, the `manifest`, an `explicit entry`, or a `fallback entry` in the `application cache`, then get the resource from the cache (instead of fetching it), and return.
3. If there is an entry in the `application cache's online safestlist` that has the `same origin` as the resource's `URL` and that is a `prefix match` for the resource's `URL`, then fetch the resource normally and return.
4. If the resource's `URL` has the `same origin` as the `manifest`'s `URL`, and there is a `fallback namespace` in the `application cache` that is a `prefix match` for the resource's `URL`, then:
 - Fetch the resource normally. If this results in a redirect to another `origin` (indicative of a captive portal), or a `4xx` or `5xx` status code, or if there were network errors (but not if the user canceled the download), then instead get, from the cache, the resource of the `fallback entry` corresponding to the `fallback namespace`. Return.
 - If the `application cache's online safestlist wildcard flag` is `open`, then fetch the resource normally and return.
6. Fail the resource load as if there had been a generic network error.

Note
The above algorithm ensures that so long as the `online safestlist wildcard flag` is `blocking`, resources that are not present in the `manifest` will always fail to load (at least, after the `application cache` has been primed the first time), making the testing of offline applications simpler.

7.9.7 Expiring application caches

As a general rule, user agents should not expire application caches, except on request from the user, or after having been left unused for an extended period of time.

Application caches and cookies have similar implications with respect to privacy (e.g. if the site can identify the user when providing the cache, it can store data in the cache that can be used for cookie resurrection). Implementors are therefore encouraged to expose application caches in a manner related to HTTP cookies, allowing caches to be expunged together with cookies and other origin-specific data.

Example

For example, a user agent could have a "delete site-specific data" feature that clears all cookies, application caches, local storage, databases, etc, from an origin all at once.

7.9.8 Disk space

User agents should consider applying constraints on disk usage of `application caches`, and care should be taken to ensure that the restrictions cannot be easily worked around using subdomains.

User agents should allow users to see how much space each domain is using, and may offer the user the ability to delete specific `application caches`.

For predictability, quotas should be based on the uncompressed size of stored data.

Note

How quotas are presented to the user is not defined by this specification. User agents are encouraged to provide features such as allowing a user to indicate that certain sites are trusted to use more than the default quota, e.g. by presenting a non-modal user interface while a cache is being updated, or by having an explicit safestlist in the user agent's configuration.

7.9.9 Security concerns with offline applications caches

This section is non-normative.

The main risk introduced by offline application caches is that an injection attack can be elevated into persistent site-wide page replacement. This attack involves using an injection vulnerability to upload two files to the victim site. The first file is an application cache manifest consisting of just a fallback entry pointing to the second file, which is an HTML page whose manifest is declared as that first file. Once the user has been directed to that second file, all subsequent accesses to any file covered by the given fallback namespace while either the user or the site is offline will instead show that second file. Targeted denial-of-service attacks or cookie bombing attacks (where the client is made to send so many cookies that the server refuses to process the request) can be used to ensure that the site appears offline.

To mitigate this, manifests can only specify fallbacks that are in the same path as the manifest itself. This means that a content injection upload vulnerability in a particular directory on a server can only be escalated to a take-over of that directory and its subdirectories. If there is no way to inject a file into the root directory, the entire site cannot be taken over.

If a site has been attacked in this way, simply removing the offending manifest might eventually clear the problem, since the next time the manifest is updated, a `404` error will be seen, and the user agent will clear the cache. "Eventually" is the key word here, however; while the attack on the user or server is ongoing, such that connections from an affected user to the affected site are blocked, the user agent will simply assume that the user is offline and will continue to use the hostile manifest. Unfortunately, if a cookie bombing attack has also been used, merely removing the manifest is insufficient; in addition, the server has to be configured to return a `404` or `410` response instead of the `413 "Request Entity Too Large"` response.

TLS does not inherently protect a site from this attack, since the attack relies on content being served from the server itself. Not using application caches also does not prevent this attack, since the attack relies on an attacker-provided manifest.

7.9.10 Application cache API

```
IDL([SecureContext,
Exposed=Window])
interface ApplicationCache : EventTarget {
  // update status
  const unsigned short NOLOADING = 0;
  const unsigned short DOWNLOADING = 1;
  const unsigned short UPDATING = 2;
  const unsigned short COMPLETE = 3;
  const unsigned short OBSOLETE = 4;
  readonly attribute unsigned short status;

  // update()
  void abort();
  void swapCache();
  void update();

  // events
  attribute EventHandler onchecking;
  attribute EventHandler onerror;
  attribute EventHandler onupdateready;
  attribute EventHandler ondownloading;
  attribute EventHandler onobsolete;
  attribute EventHandler oncached;
  attribute EventHandler onobsolete;
};

For web developers (non-normative)
cache = window . applicationCache
```

`cache.status`
Returns the current status of the application cache, as given by the constants defined below.

`cache.update()`
Invokes the [application cache download process](#).
Throws an `"invalidstateerror"` `DOMException` if there is no application cache to update.
Calling this method is not usually necessary, as user agents will generally take care of updating [application caches](#) automatically.
The method can be useful in situations such as long-lived applications. For example, a Web mail application might stay open in a browser tab for weeks at a time. Such an application could want to test for updates each day.

`cache.abort()`
 Cancels the [application cache download process](#).
This method is intended to be used by Web application showing their own caching progress UI, in case the user wants to stop the update (e.g. because bandwidth is limited).

`cache.swapCache()`
Switches to the most recent application cache, if there is a newer one. If there isn't, throws an `"invalidstateerror"` `DOMException`.
This does not cause previously-loaded resources to be reloaded; for example, images do not suddenly get reloaded and style sheets and scripts do not get reparsed or reevaluated. The only change is that subsequent requests for cached resources will obtain the newer copies.
The `updateReady` event will fire before this method can be called. Once it fires, the Web application can, at its leisure, call this method to switch the underlying cache to the one with the more recent updates. To make proper use of this, applications have to be able to bring the new features into play; for example, reloading scripts to enable new features.
An easier alternative to `swapCache()` is just to reload the entire page at a time suitable for the user, using `location.reload()`.

There is a one-to-one mapping from `cache.hosts` to `ApplicationCache` objects. The `applicationCache` attribute on `Window` objects must return the `ApplicationCache` object associated with the `Window` object's `activeDocument`.

Note
A `Document` has an associated `ApplicationCache` object even if that `cache.host` has no actual `applicationCache`.

The `status` attribute, on getting, must return the current state of the `applicationCache` that the `ApplicationCache` object's `cache.host` is associated with, if any. This must be the appropriate value from the following list:

`UNCACHED` (numeric value 0)

The `ApplicationCache` object's `cache.host` is not associated with an `applicationCache` at this time.

`IDLE` (numeric value 1)

The `ApplicationCache` object's `cache.host` is associated with an `applicationCache` whose `applicationCacheGroup.updateStatus` is `idle`, and that `applicationCache` is the `newest` cache in its `applicationCacheGroup`, and the `applicationCacheGroup` is not marked as `obsolete`.

`CHECKING` (numeric value 2)

The `ApplicationCache` object's `cache.host` is associated with an `applicationCache` whose `applicationCacheGroup.updateStatus` is `checking`.

`DOWNLOADING` (numeric value 3)

The `ApplicationCache` object's `cache.host` is associated with an `applicationCache` whose `applicationCacheGroup.updateStatus` is `downloading`.

`UPDATEREADY` (numeric value 4)

The `ApplicationCache` object's `cache.host` is associated with an `applicationCache` whose `applicationCacheGroup.updateStatus` is `idle`, and whose `applicationCacheGroup` is not marked as `obsolete`, but that `applicationCache` is not the `newest` cache in its group.

`OBSCOLETE` (numeric value 5)

The `ApplicationCache` object's `cache.host` is associated with an `applicationCache` whose `applicationCacheGroup` is marked as `obsolete`.

If the `update()` method is invoked, the user agent must invoke the `applicationCache.downloadProcess`, in the background, for the `applicationCacheGroup` of the `applicationCache` with which the `ApplicationCache` object's `cache.host` is associated, but without giving that `cache.host` to the algorithm. If there is no such `applicationCache`, or if its `applicationCacheGroup` is marked as `obsolete`, then the method must throw an `"invalidstateerror"` `DOMException`.

If the `abort()` method is invoked, the user agent must send a signal to the current `applicationCache.downloadProcess` for the `applicationCacheGroup` of the `applicationCache` with which the `ApplicationCache` object's `cache.host` is associated, if any. If there is no such `applicationCache`, or it does not have a current `applicationCache.downloadProcess`, then do nothing.

If the `swapCache()` method is invoked, the user agent must run the following steps:

1. Check that `ApplicationCache` object's `cache.host` is associated with an `applicationCache`. If it is not, then throw an `"invalidstateerror"` `DOMException`.
2. Let `cache` be the `applicationCache` with which the `ApplicationCache` object's `cache.host` is associated. (By definition, this is the same as the one that was found in the previous step.)
3. If `cache's applicationCacheGroup` is marked as `obsolete`, then unassociate the `ApplicationCache` object's `cache.host` from `cache` and return. (Resources will now load from the network instead of the cache.)
4. Check that there is an application cache in the same `applicationCacheGroup` as `cache` whose `completeness` flag is `complete` and that is `newer` than `cache`. If there is not, then throw an `"invalidstateerror"` `DOMException`.
5. Let `new cache` be the `newest` application cache in the same `applicationCacheGroup` as `cache` whose `completeness` flag is `complete`.
6. Unassociate the `ApplicationCache` object's `cache.host` from `cache` and instead associate it with `new cache`.

The following are the `event handlers` (and their corresponding `event handler event types`) that must be supported, as `event handler IDL attributes`, by all objects implementing the `ApplicationCache` interface:

Event handler Event handler event type

`oncanceling` `canceling`
`onerror` `error`
`onobsolete` `obsolete`
`ondownload` `downloading`
`onprogress` `progress`
`onupdateready` `updateready`
`onattached` `attached`
`onobsolete` `obsolete`

7.9.11 Browser state

Support: online-statusChrome for Android 8.1+|Chrome 14+|iOS Safari 4.2+|Safari 5+|Firefox 41+|Samsung Internet 4+|Edge 12+|UC Browser for Android 12.12+|IE 9+|Opera 15+|Opera Mini None|Firefox for Android 68+

Firefox, Android 4.4+Safari iOS 6.2+|Chrome Android 18+|WebView Android 1+|Samsung Internet 1.0+|Opera Android 10.1+

The `navigator.online` attribute must return false if the user agent will not contact the network when the user follows links or when a script requests a remote page (or knows that such an attempt would fail), and must return true otherwise.

When the value that would be returned by the `navigator.online` attribute of a `Window` or `WorkerGlobalScope` changes from true to false, the user agent must `queue a task` to `fire an event` named `offline` at the `Window` or `WorkerGlobalScope` object.

On the other hand, when the value that would be returned by the `navigator.online` attribute of a `Window` or `WorkerGlobalScope` changes from false to true, the user agent must `queue a task` to `fire an event` named `online` at the `Window` or `WorkerGlobalScope` object.

The `task source` for these `tasks` is the `networking_task_source`.

Note

This attribute is inherently unreliable. A computer can be connected to a network without having Internet access.

Example

In this example, an indicator is updated as the browser goes online and offline.

```
<!DOCTYPE HTML>
<html lang="en">
<head>
  <title>online status</title>
</head>
<body>
  <script>
    function updateIndicator() {
      document.getElementById('indicator').textContent = navigator.onLine ? 'online' : 'offline';
    }
  </script>
</body>
<body onload="updateIndicator()" ononline="updateIndicator()" onoffline="updateIndicator()">
  <p>The network is: <span id="indicator">(state unknown)</span>

8.1 Scripting

8.1.1 Introduction

Various mechanisms can cause author-provided executable code to run in the context of a document. These mechanisms include, but are probably not limited to:

- Processing of `<script>` elements.
- Navigating to [same-origin URLs](#).
- Event handlers, whether registered through the DOM using `addEventListener()`, by explicit `event handler content attributes`, by `event handler IDL attributes`, or otherwise.
- Processing of technologies like SVG that have their own scripting features.

8.1.2 Enabling and disabling scripting

Scripting is enabled in a [browsing context](#) when all of the following conditions are true:

- The user agent supports scripting.
- The user has not disabled scripting for this [browsing context](#) at this time. (User agents may provide users with the option to disable scripting globally, or in a finer-grained manner, e.g., on a per-origin basis.)
- The [browsing context's active document's active sandboxed flag set](#) does not have its [sandboxed scripts browsing context flag](#) set.

Scripting is disabled in a [browsing context](#) when any of the above conditions are false (i.e. when scripting is not enabled).

Scripting is enabled for a node if the node's `node document's browsing context` is non-null, and `scripting is enabled` in that [browsing context](#).

Scripting is disabled for a node if there is no such [browsing context](#), or if `scripting is disabled` in that [browsing context](#).

8.1.3 Processing model

8.1.3.1 Definitions

A `script` is one of two possible `structs`. All scripts have:

A `settings object`

An [environment settings object](#), containing various settings that are shared with other `scripts` in the same context.

A `record`

Either a `Script Record`, for `classic script`; a `Source Text Module Record`, for `module script`; or null. In the former two cases, it represents a parsed script; null represents a failure parsing.

A `parse error`

A JavaScript value, which has meaning only if the `record` is null, indicating that the corresponding script source text could not be parsed.

An `error to rethrow`

A JavaScript value representing an error that will prevent evaluation from succeeding. It will be re-thrown by any attempts to `run` the script.

Note

Since this exception value is provided by the JavaScript specification, we know that it is never null, so we use null to signal that no error has occurred.

Fetch options

A `script fetch options`, containing various options related to fetching this script or `module scripts` that it imports.

A base URL

A base [URL](#) used for `resolving module specifiers`. This will either be the URL from which the script was obtained, for external scripts, or the [document base URL](#) of the containing document, for inline scripts.

A `classic script` is a type of `script` that has the following additional item:

A muted errors boolean

A boolean which, if true, means that error information will not be provided for errors in this script. This is used to mute errors for cross-origin scripts, since that can leak private information.

A `module script` is another type of `script`. It has no additional items.

The `active script` is determined by the following algorithm:

1. Let record be `GetActiveScriptOrModule()`.
2. If record is null, return null.
3. Return record.[[HostDefined]].

Note

The `active script` concept is so far only used by the `import()` feature, to determine the [base URL](#) to use for resolving relative module specifiers.

An environment is an object that identifies the settings of a current or potential execution environment. An [environment](#) has the following fields:

An id

An opaque string that uniquely identifies the [environment](#).

A creation URL

A [URL record](#) that represents the location of the resource with which the [environment](#) is associated.

Note

In the case of an [environment settings object](#), this URL might be distinct from the [environment settings object's responsible document's URL](#), due to mechanisms such as `history.pushState()`.

A target browsing context

Null or a target [browsing context](#) for a [navigation request](#).

An active service worker

Null or a [service worker](#) that [controls](#) the [environment](#).

An execution ready flag

A flag that indicates whether the environment setup is done. It is initially unset.

Specifications may define `environment discarding steps` for environments. The steps take an [environment](#) as input.

Note

The `environment discarding steps` are run for only a select few environments: the ones that will never become execution ready because, for example, they failed to load.

An environment settings object is an [environment](#) that additionally specifies algorithms for:

A realm execution context

A [JavaScript execution context](#) shared by all `script`s that use this settings object, i.e. all scripts in a given [JavaScript realm](#). When we `run a classic script` or `run a module script`, this execution context becomes the top of the [JavaScript execution context stack](#), on top of which another execution context specific to the script in question is pushed. (This setup ensures `ParseScript` and `Source Text Module Record's Evaluate` know which Realm to use.)

A module map

A `module map` that is used when importing JavaScript modules.

A responsible browsing context

A [browsing context](#) that is assigned responsibility for actions taken by the scripts that use this [environment settings object](#).

Example

When a script creates and navigates a new top-level [browsing context](#), the `opener` attribute of the new [browsing context's Window](#) object will be set to the [responsible browsing context's WindowProxy](#) object.

A responsible event loop

An [event loop](#) that is used when it would not be immediately clear what event loop to use.

A responsible document

A [document](#) that is assigned responsibility for actions taken by the scripts that use this [environment settings object](#).

Example

For example, the `URL` of the [responsible document](#) is used to set the `URL` of the [document](#) after it has been reset using `document.open()`.

If the [responsible event loop](#) is not a [window event loop](#), then the [environment settings object](#) has no [responsible document](#).

An API URL character encoding

A character encoding used to encode URLs by APIs called by scripts that use this [environment settings object](#).

An API base URL

A `URL` used by APIs called by scripts that use this [environment settings object](#) to `parse URLs`.

An origin

An [origin](#) used in security checks.

An HTTPS state

An [HTTPS state value](#) representing the security properties of the network channel used to deliver the resource with which the [environment settings object](#) is associated.

A referrer policy

The default [referrer policy](#) for `fetches` performed using this [environment settings object](#) as a `request client`. [REFERRERPOLICY]

An [environment settings object](#) also has an [outstanding rejected promises weak set](#) and an [about-to-be-notified rejected promises list](#), used to track [unhandled promise rejections](#). The [outstanding rejected promises weak set](#) must not create strong references to any of its members, and implementations are free to limit its size, e.g. by removing old entries from it when new ones are added.

8.1.3.2 Fetching scripts

This section introduces a number of algorithms for fetching scripts, taking various necessary inputs and resulting in `classic` or `module scripts`.

`Script.fetch options` is a `struct` with the following items:

cryptographic nonce

integrity metadata

The [integrity metadata](#) used for the initial fetch

parser metadata

The [parser metadata](#) used for the initial fetch and for fetching any imported modules

credentials mode

The [credentials mode](#) used for the initial fetch (for [module scripts](#)) and for fetching any imported modules (for both [module scripts](#) and [classic scripts](#))

referrer policy

The [referrer policy](#) used for the initial fetch and for fetching any imported modules

Note

Recall that via the [import\(\)](#) feature, [classic scripts](#) can import [module scripts](#).

The default [classic script fetch options](#) are a [script fetch options](#) whose [cryptographic nonce](#) is the empty string, [integrity metadata](#) is the empty string, [parser metadata](#) is "not-parsed-inserted", [credentials mode](#) is "same-origin", and [referrer policy](#) is the empty string.

Given a [request](#) request and a [script fetch options](#) options, we define:

Set up the classic script request

Set requests [cryptographic nonce metadata](#) to options's [cryptographic nonce](#), its [integrity metadata](#) to options's [integrity metadata](#), its [parser metadata](#) to options's [parser metadata](#), and its [referrer policy](#) to options's [referrer policy](#).

Set up the module script request

Set requests [cryptographic nonce metadata](#) to options's [cryptographic nonce](#), its [integrity metadata](#) to options's [integrity metadata](#), its [parser metadata](#) to options's [parser metadata](#), its [credentials mode](#) to options's [credentials mode](#), and its [referrer policy](#) to options's [referrer policy](#).

For any given [script fetch options](#) options, the descendant [script fetch options](#) are a new [script fetch options](#) whose [items](#) all have the same values, except for the [integrity metadata](#), which is instead the empty string.

The algorithms below can be customized by optionally supplying a custom [perform the fetch](#) hook, which takes a [request](#) and an [is-top-level](#) flag. The algorithm must complete with a [response](#) (which may be a [network error](#)), either synchronously (when using [fetch a classic worker-imported script](#)) or asynchronously (otherwise). The [is-top-level](#) flag will be set for all [classic-script](#) fetches, and for the initial fetch when [fetching an external module script graph](#), [fetching a module worker script graph](#), or [fetching an import\(\) module script graph](#), but not for the fetches resulting from [import](#) statements encountered throughout the graph.

Note

By default, not supplying the [perform the fetch](#) will cause the below algorithms to simply [fetch](#) the given [request](#), with algorithm-specific customizations to the [request](#) and validations of the resulting [response](#).

To layer your own customizations on top of these algorithm-specific ones, supply a [perform the fetch](#) hook that modifies the given [request](#), [fetches it](#), and then performs specific validations of the resulting [response](#) (completing with a [network error](#) if the validations fail).

The hook can also be used to perform more subtle customizations, such as keeping a cache of [responses](#) and avoiding performing a [fetch](#) at all.

Note

[Service Workers](#) is an example of a specification that runs these algorithms with its own options for the hook. [SW]

Now for the algorithms themselves.

To [fetch a classic script](#) given a [url](#), a [settings object](#), some [options](#), a [CORS setting](#), and a [character encoding](#), run these steps. The algorithm will asynchronously complete with either null (on failure) or a new [classic script](#) (on success).

1. Let [request](#) be the result of [creating a potential-CORS request](#) given [url](#), "script", and [CORS setting](#).
2. Set [request's client](#) to [settings object](#).
3. *Set up the classic script request* given [request](#) and [options](#).
4. If the caller specified custom steps to [perform the fetch](#), perform them on [request](#), with the [is-top-level](#) flag set. Return from this algorithm, and when the custom [perform the fetch](#) steps complete with [response response](#), run the remaining steps.

Otherwise, [fetch request](#). Return from this algorithm, and run the remaining steps as part of the fetch's [process response](#) for the [response response](#).

Note

[response](#) can be either [CORS-same-origin](#) or [CORS-cross-origin](#). This only affects how error reporting happens.

5. Let [response](#) be [response's unsafe response](#).
6. If [response's type](#) is "error", or [response's status](#) is not an [ok status](#), asynchronously complete this algorithm with null, and abort these steps.

7. If [response's Content-Type metadata](#), if any, specifies a character encoding, and the user agent supports that encoding, then set [character encoding](#) to that encoding (ignoring the passed-in value).

8. Let [source text](#) be the result of [decoding response's body](#) to Unicode, using [character encoding](#) as the fallback encoding.

Note

[The decode algorithm overrides character encoding](#) if the file contains a BOM.

9. Let [muted errors](#) be true if [response](#) was [CORS-cross-origin](#), and false otherwise.

10. Let [script](#) be the result of [creating a classic script](#) given [source text](#), [settings object](#), [response's url](#), [options](#), and [muted errors](#).

11. Asynchronously complete this algorithm with [script](#).

To [fetch a classic worker-imported script](#) given a [url](#), a [fetch client settings object](#), a [destination](#), and a [script settings object](#), run these steps. The algorithm will asynchronously complete with either null (on failure) or a new [classic script](#) (on success).

1. Let [request](#) be a new [request](#) whose [url](#) is [url](#), [client](#) is [fetch client settings object](#), [destination](#) is [destination](#), [mode](#) is "same-origin", [credentials mode](#) is "same-origin", [parser metadata](#) is "not parser-inserted", and whose [use-URL-credentials](#) flag is set.
2. If the caller specified custom steps to [perform the fetch](#), perform them on [request](#), with the [is-top-level](#) flag set. Return from this algorithm, and when the custom [perform the fetch](#) steps complete with [response response](#), run the remaining steps.

Otherwise, [fetch request](#). Return from this algorithm, and run the remaining steps as part of the fetch's [process response](#) for the [response response](#).

3. Let [response](#) be [response's unsafe response](#).

4. If [response's type](#) is "error", or [response's status](#) is not an [ok status](#), asynchronously complete this algorithm with null, and abort these steps.

5. Let [source text](#) be the result of [UTF-8 decoding response's body](#).

6. Let [script](#) be the result of [creating a classic script](#) using [source text](#), [script settings object](#), [response's url](#), and the [default classic script fetch options](#).

7. Asynchronously complete this algorithm with [script](#).

To [fetch a classic script](#) given a [url](#) and a [settings object](#), run these steps. The algorithm will synchronously complete with a [classic script](#) on success, or throw an exception on failure.

1. Let [request](#) be a new [request](#) whose [url](#) is [url](#), [client](#) is [settings object](#), [destination](#) is "script", [parser metadata](#) is "not parser-inserted", [synchronous flag](#) is set, and whose [use-URL-credentials](#) flag is set.
2. If the caller specified custom steps to [perform the fetch](#), perform them on [request](#), with the [is-top-level](#) flag set. Let [response](#) be the result.

Otherwise, [fetch request](#), and let [response](#) be the result.

Note

Unlike other algorithms in this section, the fetching process is synchronous here. Thus any [perform the fetch](#) steps will also finish their work synchronously.

3. Let [response](#) be [response's unsafe response](#).

4. If any of the following conditions are met, throw a "[NetworkError](#)" [DOMException](#):

- o [response's type](#) is "error"
- o [response's status](#) is not an [ok status](#)
- o The result of [extracting a MIME type](#) from [response's header list](#) is not a [JavaScript MIME type](#)

5. Let [source text](#) be the result of [UTF-8 decoding response's body](#).

6. Let [muted errors](#) be true if [response](#) was [CORS-cross-origin](#), and false otherwise.

7. Let [script](#) be the result of [creating a classic script](#) given [source text](#), [settings object](#), [response's url](#), the [default classic script fetch options](#), and [muted errors](#).

8. Return [script](#).

To [fetch an external module script graph](#) given a [url](#), a [settings object](#), and some [options](#), run these steps. The algorithm will asynchronously complete with either null (on failure) or a [module script](#) (on success).

1. [Fetch a single module script](#) given [url](#), [settings object](#), "script", [options](#), [settings object](#), "client", and with the [top-level module fetch](#) flag set. If the caller of this algorithm specified custom [perform the fetch](#) steps, pass those along as well. Wait until the algorithm asynchronously completes with [result](#).
2. If [result](#) is null, asynchronously complete this algorithm with null, and abort these steps.

3. Let [visited set](#) be « [url](#) ».

4. [Fetch the descendants of and link result](#) given [settings object](#), [destination](#), and [visited set](#). When this asynchronously completes with [final result](#), asynchronously complete this algorithm with [final result](#).

To [fetch an import\(\) module script graph](#) given a [specifier](#), a [base URL](#), a [settings object](#), and some [options](#), run these steps. The algorithm will asynchronously complete with either null (on failure) or a [module script](#) (on success).

1. Let [url](#) be the result of [resolving a module specifier](#) given [base URL](#) and [specifier](#).
2. If [url](#) is failure, then asynchronously complete this algorithm with null, and abort these steps.

3. [Fetch a single module script](#) given [url](#), [settings object](#), "script", [options](#), [settings object](#), "client", and with the [top-level module fetch](#) flag set. If the caller of this algorithm specified custom [perform the fetch](#) steps, pass those along as well. Wait until the algorithm asynchronously completes with [result](#).

4. If [result](#) is null, asynchronously complete this algorithm with null, and abort these steps.

5. Let [visited set](#) be « [url](#) ».

6. [Fetch the descendants of and link result](#) given [settings object](#), [destination](#), and [visited set](#). When this asynchronously completes with [final result](#), asynchronously complete this algorithm with [final result](#).

To [fetch a modulepreload module script graph](#) given a [url](#), a [destination](#), a [settings object](#), and some [options](#), run these steps. The algorithm will asynchronously complete with either null (on failure) or a [module script](#) (on success), although it will perform optional steps even after completing.

1. [Fetch a single module script](#) given [url](#), [settings object](#), "script", [options](#), [settings object](#), "client", and with the [top-level module fetch](#) flag set. Wait until algorithm asynchronously completes with [result](#).
2. Asynchronously complete this algorithm with [result](#), but do not abort these steps.

3. Optionally, perform the following steps:

1. Let [visited set](#) be « [url](#) ».

2. [Fetch the descendants of and link result](#) given [settings object](#), [destination](#), and [visited set](#).

Note
Generally, performing these steps will be beneficial for performance, as it allows pre-loading the modules that will invariably be requested later, via algorithms such as [fetch an external module script graph](#) that fetch the entire graph. However, user agents might wish to skip them in bandwidth-constrained situations, or situations where the relevant fetches are already in flight.

To [fetch an inline module script graph](#) given a [source text](#), a [base URL](#), a [settings object](#), and [options](#), run these steps. The algorithm will asynchronously complete with either null (on failure) or a [module script](#) (on success).

1. Let [script](#) be the result of [creating a module script](#) using [source text](#), [settings object](#), [base URL](#), and [options](#).
2. If [script](#) is null, asynchronously complete this algorithm with null, and abort these steps.

4. **Fetch the descendants of and link script**, given `settings object`, the destination “script”, and `visited set`. When this asynchronously completes with `final result`, asynchronously complete this algorithm with `final result`.

To fetch a module worker script graph given a `url`, a `fetch client settings object`, a `destination`, a `credentials mode`, and a `module map settings object`, run these steps. The algorithm will asynchronously complete with either null (on failure) or a `module script` (on success).

1. Let `options` be a `script fetch options` whose `cryptographic nonce` is the empty string, `integrity metadata` is the empty string, `parser metadata` is “not-parsed-inserted”, `credentials mode` is `credentials mode`, and `referrer policy` is the empty string.

2. **Fetch a single module script** given `url`, `fetch client settings object`, `destination`, `options`, `module map settings object`, “client”, and with the top-level `module fetch` flag set. If the caller of this algorithm specified custom `perform the fetch` steps, pass those along as well. Wait until the algorithm asynchronously completes with `result`.

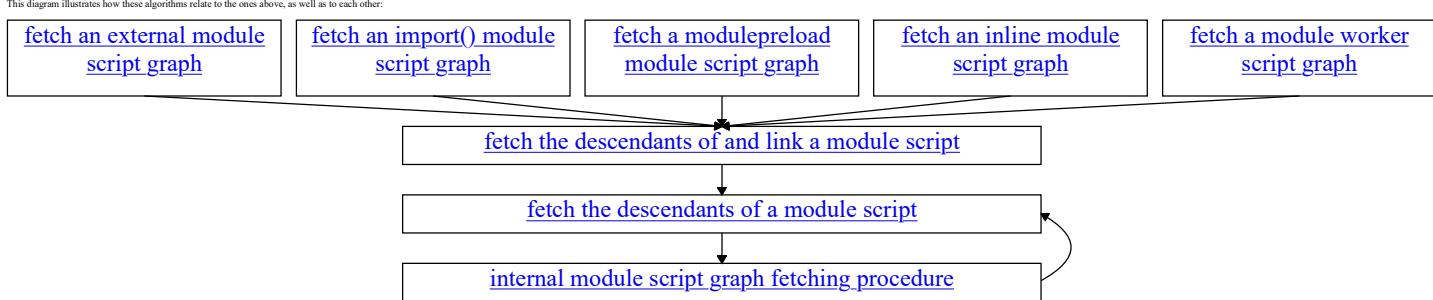

3. If `result` is null, asynchronously complete this algorithm with null, and abort these steps.

4. Let `visited set` be `< url >`.

5. **Fetch the descendants of and link result** given `fetch client settings object`, `destination`, and `visited set`. When this asynchronously completes with `final result`, asynchronously complete this algorithm with `final result`.

The following algorithms are meant for internal use by this specification only as part of `fetching an external module script graph` or other similar concepts above, and should not be used directly by other specifications.

This diagram illustrates how these algorithms relate to the ones above, as well as to each other:

To fetch the descendants of and link a module script `module script`, given a `fetch client settings object`, a `destination`, and a `visited set`, run these steps. The algorithm will asynchronously complete with either null (on failure) or with `module script` (on success).

1. **Fetch the descendants of module script**, given `fetch client settings object`, `destination`, and `visited set`.

2. Return from this algorithm, and run the following steps when `fetching the descendants of a module script` asynchronously completes with `result`.

3. If `result` is null, then asynchronously complete this algorithm with `result`.

Note

In this case, there was an error fetching one or more of the descendants. We will not attempt to link.

4. Let `parse error` be the result of `finding the first parse error` given `result`.

5. If `parse error` is null, then:

1. Let `record` be `result's record`.
2. Perform `record Link`.

Note

This step will recursively call `Link` on all of the module's unlinked dependencies.

If this throws an exception, set `result's error to rethrow` to that exception.

6. Otherwise, set `result's error to rethrow` to `parse error`.

7. Asynchronously complete this algorithm with `result`.

To fetch the descendants of a module script `module script`, given a `fetch client settings object`, a `destination`, and a `visited set`, run these steps. The algorithm will asynchronously complete with either null (on failure) or with `module script` (on success).

1. If `module script's record` is null, then asynchronously complete this algorithm with `module script` and abort these steps.

2. Let `record` be `module script's record`.

3. If `record` is not a `CyclicModuleRecord`, or if `record[[RequestedModules]]` is `empty`, asynchronously complete this algorithm with `module script`.

4. Let `urls` be a new empty `list`.

5. **For each** string requested of `record[[RequestedModules]]`,

1. Let `url` be the result of `resolving a module specifier` given `module script's base URL` and `requested`.
2. Assert: `url` is never failure, because `resolving a module specifier` must have been `previously successful` with these same two arguments.

3. If `visited set` does not `contain url`, then:

1. `Append url to urls`.
2. `Append url to visited set`.

6. Let `options` be the `descendant script fetch options` for `module script's fetch options`.

7. Assert: `options` is not null, as `module script` is a `module script`.

8. **For each** `url` in `urls`, perform the `internal module script graph fetching procedure` given `url`, `fetch client settings object`, `destination`, `options`, `module script's settings object`, `visited set`, and `module script's base URL`. If the caller of this algorithm specified custom `perform the fetch` steps, pass those along while performing the `internal module script graph fetching procedure`.

These invocations of the `internal module script graph fetching procedure` should be performed in parallel to each other.

If any of the invocations of the `internal module script graph fetching procedure` asynchronously complete with null, asynchronously complete this algorithm with null, aborting these steps.

Otherwise, wait until all of the `internal module script graph fetching procedure` invocations have asynchronously completed. Asynchronously complete this algorithm with `module script`.

To perform the `internal module script graph fetching procedure` given a `url`, a `fetch client settings object`, a `destination`, some `options`, a `module map settings object`, a `visited set`, and a `referrer`, perform these steps. The algorithm will asynchronously complete with either null (on failure) or a `module script` (on success).

1. Assert: `visited set` `contains url`.

2. **Fetch a single module script** given `url`, `fetch client settings object`, `destination`, `options`, `module map settings object`, `referrer`, and with the top-level `module fetch` flag unset. If the caller of this algorithm specified custom `perform the fetch` steps, pass those along while `fetching a single module script`.

3. Return from the algorithm, and run the following steps when `fetching a single module script` asynchronously completes with `result`:

4. If `result` is null, asynchronously complete this algorithm with null, and abort these steps.

5. **Fetch the descendants of result** given `fetch client settings object`, `destination`, and `visited set`.

6. When the appropriate algorithm asynchronously completes with `final result`, asynchronously complete this algorithm with `final result`.

To fetch a single module script, given a `url`, a `fetch client settings object`, a `destination`, some `options`, a `module map settings object`, a `referrer`, and a top-level `module fetch` flag, run these steps. The algorithm will asynchronously complete with either null (on failure) or a `module script` (on success).

1. Let `moduleMap` be `module map settings object's module map`.

2. If `moduleMap[url]` is “fetching”, wait `in parallel` until that entry's value changes, then `queue a task` on the `networking task source` to proceed with running the following steps.

3. If `moduleMap[url]` exists, asynchronously complete this algorithm with `moduleMap[url]`, and abort these steps.

4. **Set** `moduleMap[url]` to “fetching”.

5. Let `request` be a new `request` whose `url` is `url`, `destination` is `destination`, `mode` is “cors”, `referrer` is `referrer`, and `client` is `fetch client settings object`.

6. If `destination` is “worker” or “sharedworker” and the top-level `module fetch` flag is set, then set `request's mode` to “same-origin”.

7. **Set up the module script request** given `request` and `options`.

8. If the caller specified custom steps to `perform the fetch`, perform them on `request`, setting the `is top-level` flag if the top-level `module fetch` flag is set. Return from this algorithm, and when the custom `perform the fetch` steps complete with `response response`, run the remaining steps.

Otherwise, `fetch request`. Return from this algorithm, and run the remaining steps as part of the fetch's `process response` for the `response response`.

Note

`response` is always `CORS-same-origin`.

9. If any of the following conditions are met, `set moduleMap[url]` to null, asynchronously complete this algorithm with null, and abort these steps:

- o `response's type` is “error”
- o `response's status` is not an `ok status`
- o The result of `extracting a MIME type` from `response's header list` is not a `JavaScript MIME type`

Note

For historical reasons, `fetching a classic script` does not include MIME type checking. In contrast, module scripts will fail to load if they are not of a correct MIME type.

10. Let `source text` be the result of `LTE-8 decoding response's body`.

11. Let `module script` be the result of `creating a module script` given `source text`, `module map settings object`, `response's url`, and `options`.

12. **Set** `moduleMap[url]` to `module script`, and asynchronously complete this algorithm with `module script`.

Note

It is intentional that the `module map` is keyed by the `request URL`, whereas the `base URL` for the `module script` is set to the `response URL`. The former is used to deduplicate fetches, while the latter is used for URL resolution.

To find the first `parse error` given a root `moduleScript` and an optional `discoveredSet`:

1. Let `moduleMap` be `moduleScript's settings object's module map`.

2. If `discoveredSet` was not given, let it be an empty `set`.

3. **Append** `moduleScript` to `discoveredSet`.

4. If `moduleScript's record` is null, then return `moduleScript's parse error`.

6. Let `childURLs` be the `list` obtained by calling `resolve a module specifier` once for each item of `childSpecifiers`, given `moduleScript's baseURL`, and that item. (None of these will ever fail, as otherwise `moduleScript` would have been marked as itself having a parse error.)

7. Let `childModules` be the `list` obtained by `getting each value` in `moduleMap` whose key is given by an item of `childURLs`.

8. **For each** `childModule` of `childModules`:

 1. Assert: `childModule` is a `module script` (i.e., it is not "`fetching`" or null); by now all `module scripts` in the graph rooted at `moduleScript` will have successfully been fetched.

 2. If `discoveredSet` already `contains` `childModule`, `continue`.

 3. Let `childParseError` be the result of `finding the first parse error` given `childModule` and `discoveredSet`.

 4. If `childParseError` is not null, return `childParseError`.

 5. Return null.

8.1.3.3 Creating scripts

To create a `classic script`, given a `JavaScript string` `source`, an `environment settings object` `settings`, a `URL` `baseURL`, some `script fetch options` `options`, and an optional `muted errors` boolean:

1. If `muted errors` was not provided, let it be false.

2. If `scripting is disabled` for `settings's responsible browsing context`, then set `source` to the empty string.

3. Let `script` be a new `classic script` that this algorithm will subsequently initialize.

4. Set `script's settings object` to `settings`.

5. Set `script's baseURL` to `baseURL`.

6. Set `script's fetch options` to `options`.

7. Set `script's muted errors` to `muted errors`.

8. Set `script's parse error` and `error to rethrow` to null.

9. Let `result` be `ParseScript(source, settings's Realm, script)`.

Note

Passing `script` as the last parameter here ensures `result.[[HostDefined]]` will be `script`.

10. If `result` is a `list` of errors, then:

 1. Set `script's parse error` and its `error to rethrow` to `result[0]`.

 2. Return `script`.

11. Set `script's record` to `result`.

12. Return `script`.

To create a `module script`, given a `JavaScript string` `source`, an `environment settings object` `settings`, a `URL` `baseURL`, and some `script fetch options` `options`:

1. If `scripting is disabled` for `settings's responsible browsing context`, then set `source` to the empty string.

2. Let `script` be a new `module script` that this algorithm will subsequently initialize.

3. Set `script's settings object` to `settings`.

4. Set `script's baseURL` to `baseURL`.

5. Set `script's fetch options` to `options`.

6. Set `script's parse error` and `error to rethrow` to null.

7. Let `result` be `ParseModule(source, settings's Realm, script)`.

Note

Passing `script` as the last parameter here ensures `result.[[HostDefined]]` will be `script`.

8. If `result` is a `list` of errors, then:

 1. Set `script's parse error` to `result[0]`.

 2. Return `script`.

9. **For each** `string requested of result.[[RequestedModules]]`:

 1. Let `url` be the result of `resolving a module specifier` given `script's baseURL` and `requested`.

 2. If `url` is failure, then:

 1. Let `error` be a new `TypeError` exception.

 2. Set `script's parse error` to `error`.

 3. Return `script`.

Note

This step is essentially validating all of the requested module specifiers. We treat a module with unresolvable module specifiers the same as one that cannot be parsed; in both cases, a syntactic issue makes it impossible to ever contemplate linking the module later.

10. Set `script's record` to `result`.

11. Return `script`.

8.1.3.4 Calling scripts

To run a `classic script` given a `classic script` `script` and an optional `rethrow errors` boolean:

1. If `rethrow errors` is not given, let it be false.

2. Let `settings` be the `settings object` of `script`.

3. `Check if we can run script` with `settings`. If this returns "do not run" then return `NormalCompletion(empty)`.

4. `Prepare to run script` given `settings`.

5. Let `evaluationStatus` be null.

6. If `script's error to rethrow` is not null, then set `evaluationStatus` to `Completion { [[Type]]: throw, [[Value]]: script's error to rethrow, [[Target]]: empty }`.

7. Otherwise, set `evaluationStatus` to `ScriptEvaluation(script's record)`.

If `ScriptEvaluation` does not complete because the user agent has `aborted the running script`, leave `evaluationStatus` as null.

8. If `evaluationStatus` is an `abrupt completion`, then:

 1. If `rethrow errors` is true and `script's muted errors` is false, then:

 1. `Clean up after running script` with `settings`.

 2. Rethrow `evaluationStatus.[[Value]]`.

 2. If `rethrow errors` is true and `script's muted errors` is true, then:

 1. `Clean up after running script` with `settings`.

 2. Throw a "`RuntimeError`" `DOMException`.

 3. Otherwise, `rethrow errors` is false. Perform the following steps:

 1. `Report the exception` given by `evaluationStatus.[[Value]]` for `script`.

 2. `Clean up after running script` with `settings`.

 3. Return `evaluationStatus`.

9. `Clean up after running script` with `settings`.

10. If `evaluationStatus` is a normal completion, then return `evaluationStatus`.

11. If we've reached this point, `evaluationStatus` was left as null because the script was `aborted prematurely` during evaluation. Return `Completion { [[Type]]: throw, [[Value]]: a new "QuotaExceededError" DOMException, [[Target]]: empty }`.

To run a `module script` given a `module script` `script`, with an optional `rethrow errors` boolean:

1. If `rethrow errors` is not given, let it be false.

2. Let `settings` be the `settings object` of `script`.

3. `Check if we can run script` with `settings`. If this returns "do not run" then return `NormalCompletion(empty)`.

4. `Prepare to run script` given `settings`.

5. Let `evaluationStatus` be null.

6. If `script's error to rethrow` is not null, then set `evaluationStatus` to `Completion { [[Type]]: throw, [[Value]]: script's error to rethrow, [[Target]]: empty }`.

7. Otherwise:

 1. Let `record` be `script's record`.

 2. Set `evaluationStatus` to `record.Evaluate()`.

Note

This step will recursively evaluate all of the module's dependencies.

If `Evaluate` fails to complete as a result of the user agent `aborting the running script`, then set `evaluationStatus` to `Completion { [[Type]]: throw, [[Value]]: a new "QuotaExceededError" DOMException, [[Target]]: empty }`.

8. If `evaluationStatus` is an `abrupt completion`, then:

 1. If `rethrow errors` is true, rethrow the exception given by `evaluationStatus.[[Value]]`.

 2. Otherwise, `report the exception` given by `evaluationStatus.[[Value]]` for `script`.

9. `Clean up after running script` with `settings`.

The steps to check if we can run script with an `environment settings object` settings are as follows. They return either "run" or "do not run".

1. If the `global object` specified by `settings` is a `window` object whose `document` object is not `fully active`, then return "do not run".
2. If `scripting is disabled` for the `responsible browsing context` specified by `settings`, then return "do not run".
3. Return "run".

The steps to prepare to run script with an `environment settings object` settings are as follows:

1. Push `settings's realm execution context` onto the `JavaScript execution context stack`; it is now the `running JavaScript execution context`.
2. Add `settings` to the currently running `task's script evaluation environment settings object set`.

The steps to clean up after running script with an `environment settings object` settings are as follows:

1. Assert: `settings's realm execution context` is the `running JavaScript execution context`.
2. Remove `settings's realm execution context` from the `JavaScript execution context stack`.
3. If the `JavaScript execution context stack` is now empty, perform a microtask checkpoint. (If this runs scripts, these algorithms will be invoked reentrantly.)

Note

These algorithms are not invoked by one script directly calling another, but they can be invoked reentrantly in an indirect manner, e.g. if a script dispatches an event which has event listeners registered.

The running script is the `script` in the `[[HostDefined]]` field in the `ScriptOrModule` component of the `running JavaScript execution context`.

8.1.3.5 Realms, settings objects, and global objects

A `global object` is a JavaScript object that is the `[[GlobalObject]]` field of a `JavaScript realm`.

Note

In this specification, all `JavaScript realms` are created with `global objects` that are either `window` or `WorkerGlobalScope` objects.

There is always a 1-to-1-to-1 mapping between `JavaScript realms`, `global objects`, and `environment settings objects`:

- A `JavaScript realm` has a `[[HostDefined]]` field, which contains the `Realm's settings object`.
- A `JavaScript realm` has a `[[GlobalObject]]` field, which contains the `Realm's global object`.
- Each `global object` in this specification is created during the `creation` of a corresponding `JavaScript realm`, known as the `global object's Realm`.
- Each `global object` in this specification is created alongside a corresponding `environment settings object`, known as its `relevant settings object`.
- An `environment settings object's realm execution context`'s Realm component is the `environment settings object's Realm`.
- An `environment settings object's Realm` then has a `[[GlobalObject]]` field, which contains the `environment settings object's global object`.

To create a new `JavaScript realm`, optionally with instructions to create a global object or a global `this` binding (or both), the following steps are taken:

1. Perform `InitializeHostDefinedRealm()` with the provided customizations for creating the global object and the global `this` binding.

2. Let `realm execution context` be the `running JavaScript execution context`.

Note
This is the `JavaScript execution context` created in the previous step.

3. Remove `realm execution context` from the `JavaScript execution context stack`.

4. Return `realm execution context`.

When defining algorithm steps throughout this specification, it is often important to indicate what `JavaScript realm` is to be used—or, equivalently, what `global object` or `environment settings object` is to be used. In general, there are at least four possibilities:

Entry

This corresponds to the script that initiated the currently running script action: i.e., the function or script that the user agent called into when it called into author code.

Incumbent

This corresponds to the most-recently-entered author function or script on the stack, or the author function or script that originally scheduled the currently-running callback.

Current

This corresponds to the currently-running function object, including built-in user-agent functions which might not be implemented as JavaScript. (It is derived from the `current JavaScript realm`.)

Relevant

Every `platform object` has a `relevant Realm`, which is roughly the `JavaScript realm` in which it was created. When writing algorithms, the most prominent `platform object` whose `relevant Realm` might be important is the `this` value of the currently-running function object. In some cases, there can be other important `relevant Realms`, such as those of any arguments.

Note how the `entry`, `incumbent`, and `current` concepts are usable without qualification, whereas the `relevant` concept must be applied to a particular `platform object`.

Example

Consider the following pages, with `a.html` being loaded in a browser window, `b.html` being loaded in an `iframe` as shown, and `c.html` and `d.html` omitted (they can simply be empty documents):

```
<!-- a.html -->
<!DOCTYPE html>
<html lang="en">
<title>Entry page</title>
<iframe src="b.html"></iframe>
<button onclick="frames[0].hello()">Hello</button>

<-- b.html -->
<!DOCTYPE html>
<html lang="en">
<title>Incumbent page</title>
<iframe src="c.html" id="c"></iframe>
<iframe src="d.html" id="d"></iframe>

<script>
const c = document.querySelector("#c");
const d = document.querySelector("#d");
window.hello = () => {
  c.print.call(d);
}
</script>
```

Each page has its own `browsing context`, and thus its own `JavaScript realm`, `global object`, and `environment settings object`.

When the `print()` method is called in response to pressing the button in `a.html`, then:

- The `entry Realm` is that of `a.html`.
- The `incumbent Realm` is that of `b.html`.
- The `current Realm` is that of `c.html` (since it is the `print()` method from `c.html` whose code is running).
- The `relevant Realm` of the object on which the `print()` method is being called is that of `d.html`.

⚠Warning!

The `incumbent` and `entry` concepts should not be used in new specifications, as they are excessively complicated and unintuitive to work with. We are working to remove almost all existing uses from the platform: see issue #1430 for `incumbent`, and issue #1431 for `entry`.

In general, web platform specifications should use the `relevant` concept, applied to the object being operated on (usually the `this` value of the current method). This mismatches the JavaScript specification, where `current` is generally used as the default (e.g. in determining the `JavaScript realm` whose `Array` constructor should be used to construct the result in `Array.prototype.map`). But this inconsistency is so embedded in the platform that we have to accept it going forward.

Example

One reason why the `relevant` concept is generally a better default choice than the `current` concept is that it is more suitable for creating an object that is to be persisted and returned multiple times. For example, the `navigator.getBattery()` method creates promises in the `relevant Realm` for the `Navigator` object on which it is invoked. This has the following impact: **[BATTERY]**

```
<!-- outer.html -->
<!DOCTYPE html>
<html lang="en">
<title>Outer Realm demo: outer page</title>
<script>
function doTest() {
  const promise = navigator.getBattery().call(frames[0].navigator);
  console.log(promise instanceof Promise); // logs false
  console.log(promise instanceof frames[0].Promise); // logs true
  frames[0].hello();
}
</script>
<iframe src="inner.html" onload="doTest()"></iframe>

<-- inner.html -->
<!DOCTYPE html>
<html lang="en">
<title>Inner Realm demo: inner page</title>
<script>
function hello() {
  const hello = navigator.getBattery();
  console.log(promise instanceof Promise); // logs true
  console.log(promise instanceof parent.Promise); // logs false
}
</script>
```

If the algorithm for the `getBattery()` method had instead used the `current Realm`, all the results would be reversed. That is, after the first call to `getBattery()` in `outer.html`, the `Navigator` object in `inner.html` would be permanently storing a `Promise` object created in `outer.html`'s `JavaScript realm`, and calls like that inside the `hello()` function would then return a promise from the "wrong" realm. Since this is undesirable, the algorithm instead uses the `relevant Realm`, giving the sensible results indicated in the comments above.

The rest of this section deals with formally defining the `entry`, `incumbent`, `current`, and `relevant` concepts.

8.1.3.5.1 entry

The process of `calling script` will push or pop `realm execution contexts` onto the `JavaScript execution context stack`, interspersed with other `execution contexts`.

With this in hand, we define the `entry execution context` to be the most recently pushed item in the `JavaScript execution context stack` that is a `realm execution context`. The `entry Realm` is the `entry execution context`'s Realm component.

Then, the `entry settings object` is the `environment settings object` of the `entry Realm`.

Similarly, the `entry global object` is the `global object` of the `entry Realm`.

8.1.3.5.2 incumbent

All `JavaScript execution contexts` must contain, as part of their code evaluation state, a `skip-when-determining-incumbent` counter value, which is initially zero. In the process of `preparing to run a callback` and `cleaning up after running a callback`, this value will be incremented and decremented.

Every `event loop` has an associated `backup incumbent settings object stack`, initially empty. Roughly speaking, it is used to determine the `incumbent settings object` when no author code is on the stack, but author code is responsible for the current algorithm having been run in some way. The process of `preparing to run a callback` and `cleaning up after running a callback` manipulate this stack. **[WEBIDL]**

To prepare to run a callback with an `environment settings object` settings:

1. Push settings onto the `backup incumbent settings object stack`.
2. Let `context` be the `topmost script-having execution context`.
3. If `context` is not null, increment `context's skip-when-determining-incumbent counter`.

To clean up after running a callback with an `environment settings object` settings:

1. Let `context` be the `topmost script-having execution context`.

Note
This will be the same as the `topmost script-having execution context` inside the corresponding invocation of `prepare to run a callback`.

2. If `context` is not null, decrement `context's skip-when-determining-incumbent counter`.
3. Assert: the topmost entry of the `backup incumbent settings object stack` is `settings`.
4. Remove settings from the `backup incumbent settings object stack`.

Here, the `topmost script-having execution context` is the topmost entry of the `JavaScript execution context stack` that has a non-null `ScriptOrModule component`, or null if there is no such entry in the `JavaScript execution context stack`.

With all this in place, the `incumbent settings object` is determined as follows:

1. Let `context` be the `topmost script-having execution context`.
2. If `context` is null, or if `context's skip-when-determining-incumbent counter` is greater than zero, then:
 1. Assert: the `backup incumbent settings object stack` is not empty.

Note
This assert would fail if you try to obtain the `incumbent settings object` from inside an algorithm that was triggered neither by `calling scripts` nor by Web IDL `invoking` a callback. For example, it would trigger if you tried to obtain the `incumbent settings object` inside an algorithm that ran periodically as part of the `event loop`, with no involvement of author code. In such cases the `incumbent` concept cannot be used.

2. Return the topmost entry of the `backup incumbent settings object stack`.

3. Return `context's Realm component's settings object`.

Then, the `incumbent Realm` is the `Realm` of the `incumbent settings object`.

Similarly, the `incumbent global object` is the `global object` of the `incumbent settings object`.

The following series of examples is intended to make it clear how all of the different mechanisms contribute to the definition of the `incumbent` concept:

Example

Consider the following very simple example:

```
<!DOCTYPE html>
<html></html>
<script>
  new frames[0].MessageChannel();
</script>
```

When the `MessageChannel()` constructor looks up the `incumbent settings object` to use as the `owner` of the new `MessagePort` objects, the `topmost script-having execution context` will be that corresponding to the `script` element: it was pushed onto the `JavaScript execution context stack` as part of `ScriptEvaluation` during the `run a classic script` algorithm. Since there are no Web IDL callback invocations involved, the context's `skip-when-determining-incumbent counter` is zero, so it is used to determine the `incumbent settings object`: the result is the `environment settings object` of `window`.

In this example, the `environment settings object` of `frames[0]` is not involved at all. It is the `current settings object`, but the `MessageChannel()` constructor cares only about the `incumbent`, not `current`.

Example

Consider the following more complicated example:

```
<!DOCTYPE html>
<html></html>
<script>
  const bound = frames[0].postMessage.bind(frames[0], "some data", "*");
  bound.setTimeout(bound);
</script>
```

There are two interesting `environment settings objects` here: that of `window`, and that of `frames[0]`. Our concern is: what is the `incumbent settings object` at the time that the algorithm for `postMessage()` executes?

It should be that of `window`, to capture the intuitive notion that the author script responsible for causing the algorithm to happen is executing in `window`, not `frames[0]`. Another way of capturing the intuition here is that invoking algorithms asynchronously (in this case via `setTimeout()`) should not change the `incumbent` concept.

Let us now explain how the steps given above give us our intuitively-desired result of `window's relevant settings object`.

When `bound` is converted to a Web IDL callback type, the `incumbent settings object` is that corresponding to `window` (in the same manner as in our simple example above). Web IDL stores this as the resulting callback value's `callback context`.

When the `task` posted by `postMessage()` executes, the algorithm for that task uses Web IDL to `invoke` the stored callback value. Web IDL in turn calls the above `prepare to run a callback` algorithm. This pushes the stored `callback context` onto the `backup incumbent settings object stack`. At this time (inside the timer task) there is no author code on the stack, so the `topmost script-having execution context` is null, and nothing gets its `skip-when-determining-incumbent counter` incremented.

Invoking the callback then calls `bound`, which in turn calls the `postMessage()` method of `frames[0]`. When the `postMessage()` algorithm looks up the `incumbent settings object`, there is still no author code on the stack, since the `bound` function just directly calls the built-in `method`. So the `topmost script-having execution context` will be null: the `JavaScript execution context stack` only contains an execution context corresponding to `postMessage()`, with no `ScriptEvaluation` context or similar below it.

This is where we fall back to the `backup incumbent settings object stack`. As noted above, it will contain as its topmost entry the `relevant settings object` of `window`. So that is what is used as the `incumbent settings object` while executing the `postMessage()` algorithm.

Example

Consider this final, even more convoluted example:

```
<-- a.html -->
<!DOCTYPE html>
<html></html>
<button>click me!</button>
<iframe></iframe>
<script>
  const bound = frames[0].location.assign.bind(frames[0].location, "https://example.com/");
  bound.QUERYSELECTOR("button").addEventListener("click", bound);
</script>

<-- b.html -->
<!DOCTYPE html>
<html><a href="a.html"></a></html>
<script>
  const iframe = document.querySelector("iframe");
  iframe.onload = function() {
    iframe.contentWindow.document.querySelector("button").click();
  };
</script>
```

Again there are two interesting `environment settings objects` in play: that of `a.html`, and that of `b.html`. When the `location.assign()` method triggers the `location object navigate` algorithm, what will be the `incumbent settings object`? As before, it should intuitively be that of `a.html`: the `click` listener was originally scheduled by `a.html`, so even if something involving `b.html` causes the listener to fire, the `incumbent` responsible is that of `a.html`.

The callback setup is similar to the previous example: when `bound` is converted to a Web IDL callback type, the `incumbent settings object` is that corresponding to `a.html`, which is stored as the callback's `callback context`.

When the `click` method is called inside `b.html`, it dispatches a `click` event on the button that is inside `a.html`. This time, when the `prepare to run a callback` algorithm executes as part of event dispatch, there is author code on the stack: the `topmost script-having execution context` is that of the `onLoad` function, whose `skip-when-determining-incumbent counter` goes incremented. Additionally, `a.html's environment settings object` (stored as the `eventHandler's callback context`) is pushed onto the `backup incumbent settings object stack`.

Now, when the `location object navigate` algorithm looks up the `incumbent settings object`, the `topmost script-having execution context` is still that of the `onLoad` function (due to the fact we are using a bound function as the callback). Its `skip-when-determining-incumbent counter` value is one, however, so we fall back to the `backup incumbent settings object stack`. This gives us the `environment settings object` of `a.html`, as expected.

Note that this means that even though it is the `iframe` inside `a.html` that navigates, it is `a.html` itself that is used as the `source browsing context`, which determines among other things the `request client`. This is perhaps the only justifiable use of the `incumbent` concept on the web platform; in all other cases the consequences of using it are simply confusing and we hope to one day switch them to use `current` or `relevant` as appropriate.

8.1.3.5.3 Current

The JavaScript specification defines the `current Realm Record`, sometimes abbreviated to the “current Realm”. [\[JAVASCRIPT\]](#)

Then, the `current settings object` is the `environment settings object` of the `current Realm Record`.

Similarly, the `current global object` is the `global object` of the `current Realm Record`.

8.1.3.5.4 Relevant

The `relevant Realm` for a `platform object` is the value of `[it] [Realm]`.

Then, the `relevant settings object` for a `platform object` is the `environment settings object` of the `relevant Realm` for `o`.

Similarly, the `relevant global object` for a `platform object` is the `global object` of the `relevant Realm` for `o`.

8.1.3.6 Killing scripts

Although the JavaScript specification does not account for this possibility, it's sometimes necessary to *abort a running script*. This causes any `ScriptEvaluation` or `Source Text Module Record Evaluate` invocations to cease immediately, emptying the `JavaScript execution context stack` without triggering any of the normal mechanisms like `finally` blocks. [\[JAVASCRIPT\]](#)

User agents may impose resource limitations on scripts, for example CPU quotas, memory limits, total execution time limits, or bandwidth limitations. When a script exceeds a limit, the user agent may either throw a `"quotaExceededError"` `DOMException`, `abort the script` without an exception, prompt the user, or throttle script execution.

Example

For example, the following script never terminates. A user agent could, after waiting for a few seconds, prompt the user to either terminate the script or let it continue.

```
<script>
  while (true) { /* loop */ }
</script>
```

User agents are encouraged to allow users to disable scripting whenever the user is prompted either by a script (e.g. using the `window.alert()` API) or because of a script's actions (e.g. because it has exceeded a time limit).

If scripting is disabled while a script is executing, the script should be terminated immediately.

User agents may allow users to specifically disable scripts just for the purposes of closing a `browsing context`.

Example

For example, the prompt mentioned in the example above could also offer the user with a mechanism to just close the page entirely, without running any `unload` event handlers.

8.1.3.7 Integration with the JavaScript job queue

The JavaScript specification defines the `JavaScript Job` and `job queue` abstractions in order to specify certain invariants about how promise operations execute with a clean `JavaScript execution context stack` and in a certain order. However, as of the time of this writing the definition of `EnqueueJob` in that specification is not sufficiently flexible to integrate with HTML as a host environment. [\[JAVASCRIPT\]](#)

Note
This is not strictly true. It is in fact possible, by taking liberal advantage of the many “implementation defined” sections of the algorithm, to contort it to our purposes. However, the end result is a mass of messy indirection and workarounds that essentially bypasses the job queue infrastructure entirely, albeit in a way that is technically sanctioned within the bounds of implementation-defined behavior. We do not take this path, and instead introduce the following `willful violation`.

As such, user agents must instead use the following definition in place of that in the JavaScript specification. These ensure that the promise jobs enqueued by the JavaScript specification are properly integrated into the user agent's `event loops`.

The `willful violation` occurs from the `JavaScript execution context stack` and based on the `event loop`.

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

8.1.3.7.3 `EnqueueJob(name, job, arguments)`

When the JavaScript specification says to call the `EnqueueJob` abstract operation, the following algorithm must be used in place of JavaScript's `EnqueueJob`:

1. Assert: `queueName` is `"PromiseJobs"`. (`"scriptJobs"` must not be used by user agents.)
2. Let `job settings` be some appropriate `environment settings object`.
3. Let `incumbent settings` be the `incumbent setting object`.
4. Let `active script` be the `active script`.
5. Let `script execution context` be null.
6. If `active script` is not null, set `script execution context` to a new `JavaScript execution context`, with its Function field set to null, its Realm field set to `active script's settings object's Realm`, and its `ScriptOrModule` set to `active script's record`.

Note

As seen below, this is used in order to propagate the current `active script` forward to the time when the job is executed.

Example

A case where `active script` is non-null, and saving it in this way is useful, is the following:

```
Promise.resolve("import './example.mjs'").then(eval);
```

Without this step (and the steps below that use it), there would be no `active script` when the `import()` expression is evaluated, since `eval()` is a built-in function that does not originate from any particular `script`.

With this step in place, the `active script` is propagated from the above code into the job, allowing `import()` to use the original script's `base URL` appropriately.

Example

`active script` can be null if the user clicks on the following button:

```
<button onclick="Promise.resolve('import './example.mjs'').then(eval)">>click me</button>
```

In this case, the JavaScript function for the `event handler` will be created by the `get the current value of the event handler` algorithm, which creates a function with null [[ScriptOrModule]] value. Thus, when the promise machinery calls `EnqueueJob`, there will be no `active script` to pass along.

As a consequence, this means that when the `import()` expression is evaluated, there will still be no `active script`. Fortunately that is handled by our implementations of `HostResolveImportedModule` and `HostImportModuleDynamically`, by falling back to using the `current settings object's API base URL`.

7. *Queue a microtask*, on `job settings's responsible event loop`, to perform the following steps:

1. Check if we can run `script` with `job settings`. If this returns "do not run" then return.

2. Prepare to run `script` with `job settings`.

Note

This affects the `entry` concept while the job runs.

3. Prepare to run a `callback` with `incumbent settings`.

Note

This affects the `incumbent` concept while the job runs.

4. If `script execution context` is not null, then push `script execution context` onto the `JavaScript execution context stack`.

Note

As explained above, this affects the `active script` while the job runs.

5. Let `result` be the result of performing the abstract operation specified by `job`, using the elements of `arguments` as its arguments.

6. If `script execution context` is not null, then pop `script execution context` from the `JavaScript execution context stack`.

7. Clean up after running a `callback` with `incumbent settings`.

Clean up after running script with job settings

8. Clean up after running `script` with `job settings`.

9. If `result` is an `abrupt completion`, then report the exception given by `result.[[Value]]`.

8.1.3.8 Integration with the JavaScript module system

The JavaScript specification defines a syntax for modules, as well as some host-agnostic parts of their processing model. This specification defines the rest of their processing model: how the module system is bootstrapped, via the `script` element with `type` attribute set to "module", and how modules are fetched, resolved, and executed. [\[JAVASCRIPT\]](#)

Note

Although the JavaScript specification speaks in terms of "scripts" versus "modules", in general this specification speaks in terms of `classic scripts` versus `module scripts`, since both of them use the `script` element.

For web developers (non-normative)

`modulePromise = import(moduleSpecifier)`

Returns a promise for the module namespace object for the `module script` identified by `specifier`. This allows dynamic importing of module scripts at runtime, instead of statically using the `import` statement form. The specifier will be `resolved` relative to the `active script's base URL`.

The returned promise will be rejected if an invalid specifier is given, or if a failure is encountered while `fetched` or `evaluating` the resulting module graph.

This syntax can be used inside both `classic` and `module scripts`. It thus provides a bridge into the module-script world, from the classic-script world.

`url = import_.meta_.url`

Returns the `active module script's base URL`.

This syntax can only be used inside `module scripts`.

A `module map` is a map of `URL records` to values that are either a `module script`, null (used to represent failed fetches), or a placeholder value "`fetching`". `Module maps` are used to ensure that imported JavaScript modules are only fetched, parsed, and evaluated once per `Document` or `Worker`.

Example

Since `module maps` are keyed by URL, the following code will create three separate entries in the `module map`, since it results in three different URLs:

```
import "https://example.com/module1.mjs";
import "https://example.com/module1.mjs#map-buster";
import "https://example.com/module1.mjs?dshash=true";
```

That is, URL `queries` and `fragments` can be varied to create distinct entries in the `module map`; they are not ignored. Thus, three separate fetches and three separate module evaluations will be performed.

In contrast, the following code would only create a single entry in the `module map`, since after applying the `URL parser` to these inputs, the resulting `URL records` are equal:

```
import "https://example.com/module1.mjs";
import "https://example.com/module2.mjs";
import "https://example.com/module1.mjs";
import "https://example.com/module2.mjs";
```

So in this second example, only one fetch and one module evaluation will occur.

Note that this behavior is the same as how `shared workers` are keyed by their parsed `constructor.url`.

To resolve a module specifier given a `URL`, `base URL` and a `JavaScript string` specifier, perform the following steps. It will return either a `URL record` or failure.

1. Apply the `URL parser` to `specifier`. If the result is not failure, return the result.
2. If `specifier` does not start with the character U+002F SOLIDUS (/), the two-character sequence U+002E FULL STOP, U+002F SOLIDUS (/), or the three-character sequence U+002E FULL STOP, U+002E FULL STOP, U+002F SOLIDUS (/..), return failure.

Note

This restriction is in place so that in the future we can allow custom module loaders to give special meaning to "bare" import specifiers, like `import "jquery"` or `import "web/crypto"`. For now any such imports will fail, instead of being treated as relative URLs.

3. Return the result of applying the `URL parser` to `specifier` with `base URL` as the base URL.

Example

The following are valid module specifiers according to the above algorithm:

- <https://example.com/apples.mjs>
- <http://example.com/pears.js> (becomes <http://example.com/pears.js> as step 1 parses with no base URL)
- `/scratches/mjs.cgi`
- `..lychees`
- `/limes.jsx`
- `data:text/javascript,export default 'grapes';`
- `blob:https://whatwg.org/d03802f2-case=46ff-4a2f-87db0456f6f`

The following are valid module specifiers according to the above algorithm, but will invariably cause failures when they are `fetched`:

- `javascript:import default 'artichokes';`
- `data:text/plain,export default 'kale';`
- `about:legumes`
- `wss://example.com/cecely`

The following are not valid module specifiers according to the above algorithm:

- `https://eggplant/h/c`
- `pumpkins.js`
- `tomato`
- `..zucchini.mjs`
- `..lyam.ws`

8.1.3.8.1 `HostResolveImportedModule(referencingScriptOrModule, specifier)`

JavaScript contains an implementation-defined `HostResolveImportedModule` abstract operation. User agents must use the following implementation: [\[JAVASCRIPT\]](#)

1. Let `settings object` be the `current settings object`.
2. Let `base URL` be `settings object's API base URL`.
3. If `referencingScriptOrModule` is not null, then:
 1. Let `referencing script` be `referencingScriptOrModule.[[HostDefined]]`.
 2. Set `settings object` to referencing `script's settings object`.
 3. Set `base URL` to referencing `script's base URL`.

`referencingScriptOrModule` is not usually null, but will be so for event handlers per the [get the current value of the event handler](#) algorithm. For example, given:

```
<button onclick="import('./foo.js')>Click me</button>
```

If a `click` event occurs, then at the time the `import` expression runs, `GetActiveScriptOrModule` will return null, which will be passed to this abstract operation when `HostResolveImportedModule` is called by `FinishDynamicImport`.

4. Let `moduleMap` be `settings` object's `module map`.
5. Let `url` be the result of [resolving a module specifier](#) given base `URL` and `specifier`.
6. Assert: `url` is never failure, because [resolving a module specifier](#) must have been previously successful with these same two arguments (either [while creating the corresponding module script](#), or in `HostImportModuleDynamically`).
7. Let resolved module `script` be `moduleMap[url]`. (This entry must [exist](#) for us to have gotten to this point.)
8. Assert: resolved module `script` is a `module script` (i.e., is not null or "fetching").
9. Assert: resolved module `script`'s `record` is not null.
10. Return [resolved module](#) `script`'s `record`.

8.1.2.8 `HostImportModuleDynamically(referencingScriptOrModule, specifier, promiseCapability)`

JavaScript contains an implementation-defined `HostImportModuleDynamically` abstract operation. User agents must use the following implementation: [\[JAVASCRIPT\]](#)

1. Let `settings` object be the [current settings object](#).
2. Let `base URL` be settings object's [API base URL](#).
3. Let `fetch options` be the [default classic script fetch options](#).
4. If `referencingScriptOrModule` is not null, then:
 1. Let `referencing script` be `referencingScriptOrModule`[[HostDefined]].
 2. Set `settings` object to `referencing script`'s `settings` object.
 3. Set `base URL` to `referencing script`'s `base URL`.
 4. Set `fetch options` to the [descendant script fetch options](#) for `referencing script`'s `fetch options`.

Note
As explained above for `HostResolveImportedModule`, in the common case, `referencingScriptOrModule` is non-null.

5. [Fetch an import](#) (module script graph) given `specifier`, `base URL`, `settings` object, and `fetch options`. Wait until the algorithm asynchronously completes with `result`.

6. If `result` is null, then:

1. Let `completion` be `Completion` { [[Type]]: throw, [[Value]]: a new `TypeError`, [[Target]]: empty }.
2. Perform `FinishDynamicImport`(`referencingScriptOrModule`, `specifier`, `promiseCapability`, `completion`).
3. Return.

7. [Run the module script](#) `result`, with the `rethrow errors` boolean set to true.

8. If running the module script throws an exception, then perform `FinishDynamicImport`(`referencingScriptOrModule`, `specifier`, `promiseCapability`, the thrown exception completion).

9. Otherwise, perform `FinishDynamicImport`(`referencingScriptOrModule`, `specifier`, `promiseCapability`, `NormalCompletion`(undefined)).

10. Return undefined.

8.1.2.8.3 `HostGetImportMetaProperties(moduleRecord)`

OMN

Reference-Statements/import.meta

Support in all current engines.

Firefox62+ Safari11.1+ Chrome64+

OpenS1+ Edge79+

Edge (Legacy) No Internet Explorer No

Firefox Android62+ Safari iOS12+ Chrome Android64+ WebView Android64+ Samsung Internet9.0+ Opera Android47+

The `import.meta` proposal contains an implementation-defined `HostGetImportMetaProperties` abstract operation. User agents must use the following implementation: [\[JSIMPORTMETA\]](#)

1. Let `module script` be `moduleRecord`[[HostDefined]].
2. Let `urlString` be `module script`'s `base URL`, `serialized`.
3. Return a `Record` { [[Key]]: "url", [[Value]]: `urlString` }.

8.1.2.9 Integration with the JavaScript agent formalism

JavaScript defines the concept of an `agent`. This section gives the mapping of that language-level concept on to the web platform.

JavaScript is expected to define `agents` in more detail, in particular that `realm` have a pointer to their agent. See [tc39/ecma262 issue #1357](#). The algorithms which allocate new realms that belong to `similar-origin window agents` include this pointer. For other realms, the following section describes the relationship.

Note

Conceptually, the `agent` concept is an architecture-independent, idealized "thread" in which JavaScript code runs. Such code can involve multiple globals/`realm`s that can synchronously access each other, and thus needs to run in a single execution thread.

Two `window` objects having the same `agent` does not indicate they can directly access all objects created in each other's realms. They would have to be `same origin`; see [IsPlatformObjectSameOrigin](#).

To create a `similar-origin` `window` agent:

1. Let `signifier` be a new unique internal value.
2. Let `candidateExecution` be a new `candidate execution`.
3. Return a new `agent` whose [[CanBlock]] is true, [[Signifier]] is `signifier`, [[CandidateExecution]] is `candidateExecution`, and [[IsLockFree1]], [[IsLockFree2]], and [[LittleEndian]] are set at the implementation's discretion.

Note

All global objects that use this agent all have a similar `origin` and are allocated via the `obtain similar-origin window agent` algorithm.

In addition to the above definition for `similar-origin window agent`, until such a time that this standard has a better handle on lifetimes, it defines the following other types of `agents` that user agents must allocate at the appropriate time.

Dedicated worker agent

An `agent` whose [[CanBlock]] is true and whose set of `realm`s consists of a single `DedicatedWorkerGlobalScope` object's `Realm`.

Shared worker agent

An `agent` whose [[CanBlock]] is true and whose set of `realm`s consists of a single `SharedWorkerGlobalScope` object's `Realm`.

Service worker agent

An `agent` whose [[CanBlock]] is false and whose set of `realm`s consists of a single `ServiceWorkerGlobalScope` object's `Realm`.

Worker agent

An `agent` whose [[CanBlock]] is false and whose set of `realm`s consists of a single `WorkerGlobalScope` object's `Realm`.

Note

Although a given `worker` can have multiple realms, each such realm needs its own agent, as each realm can be executing code independently and at the same time as the others.

The relevant agent for a `platform object` `platformObject` is the `agent` whose set of `realm`s contains `platformObject`'s `relevant Realm`.

Note

The agent equivalent of the `current Realm` Record is the `surrounding agent`.

8.1.2.10 Integration with the Java Script agent cluster formalism

JavaScript also defines the concept of an `agent cluster`, which this standard maps to the web platform using the `can share memory with` equivalence relation detailed below, as well as explicit allocation of `similar-origin window agents` to agent clusters. On the web platform, an `agent cluster` consists of all `agents` in the same equivalence class with respect to the `can share memory with` equivalence relation.

The `agent cluster` concept is crucial for defining the JavaScript memory model, and in particular among which `agents` the backing data of `SharedArrayBuffer` objects can be shared.

Note
Conceptually, the `agent cluster` concept is an architecture-independent, idealized "process boundary" that groups together multiple "threads" (`agents`). The `agent clusters` defined by the specification are generally more restrictive than the actual process boundaries implemented in user agents. By enforcing these idealized divisions at the specification level, we insure that web developers see interoperable behavior with regard to shared memory, even in the face of varying and changing user agent process models.

The following defines the allocation of the `agent clusters` of `similar-origin window agents`:

A `scheme-and-registrable-domain` is a `tuple` of a `scheme` and a `domain`.

An `agent cluster key` is an `origin` or a `scheme-and-registrable-domain`.

To obtain an `agent cluster key`, given an `origin` `origin`, run these steps:

1. If `origin` is an `opaque origin`, then return `origin`.
2. If `origin`'s `host`'s `registrable domain` is null, then return `origin`.
3. Return `(origin's scheme, origin's host's registrable domain)`.

To obtain a `similar-origin window agent`, given an `origin` `origin` and `browsing context group` `group`, run these steps:

1. Let `clusterKey` be the result of `obtaining an agent cluster key` given `origin`.
2. Let `agentCluster` be the result of `obtaining a browsing context agent cluster` with `group` and `clusterKey`.
3. Return the single `similar-origin window agent` contained in `agentCluster`.

To obtain a `browsing context agent cluster`, given a `browsing context group` `group` and `agent cluster key` `key`, run these steps:

1. If `group's agent cluster key` does not exist, then:

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

1. Let `agentCluster` be a new `agent_cluster`.
2. Add the result of `creating a similar-origin window agent` to `agentCluster`.
3. Set `group's agent_cluster_map[key]` to `agentCluster`.
2. Return `group's agent_cluster_map[key]`.

Note

This means that there is only one `similar-origin window agent` per browsing context agent cluster. (However, other types of agents might be in the same cluster, if they `can_share_memory_with` the `similar-origin window agent`.)

The allocation of other types of agents to clusters is done via the following `can_share_memory` with equivalence relation. Until such a time that this standard has a better handle on the lifetimes of those sorts of agents, user agents must allocate new agent clusters, or reuse ones created via `obtain a browsing context agent cluster`, in order to ensure that there is one agent cluster for each equivalence class of `can_share_memory`.

A `similar-origin window agent`, `dedicated worker agent`, `shared worker agent`, or `service worker agent`, `agent`, `can_share_memory` with any `dedicated worker agent` whose single `realm`'s `global object`'s `owner set` contains an item whose `relevant agent` is `agent`.

Note

"`Item`" is used above as an `owner set` can contain `Document` objects.

A `similar-origin window agent` `agent` `can_share_memory` with any `worker agent` whose single `realm`'s `global object`'s `relevant agent` is `agent`.

In addition, any `agent A` `can_share_memory` with:

- `A`,
- any `agent B` such that `B` `can_share_memory` with `A`, and
- any `agent B` such that there exists an `agent C`, where `A` `can_share_memory` with `C` and `C` `can_share_memory` with `B`.

Example

The following pairs of global objects are each within the same `agent cluster`, and thus can use `SharedArrayBuffer` instances to share memory with each other:

- A `window` object and a dedicated worker it created.
- A worker (of any type) and a dedicated worker it created.
- A `window` object and the `window` object of an `iframe` element that `A` created that could be `same origin-domain` with `A`.
- A `window` object and a `same origin-domain` `window` object that opened it.
- A `window` object and a worker that it created.

The following pairs of global objects are *not* within the same `agent cluster`, and thus cannot share memory:

- A `window` object and a shared worker it created.
- A worker (of any type) and a shared worker it created.
- A `window` object and a service worker it created.
- A `window` object and the `window` object of an `iframe` element that `A` created that cannot be `same origin-domain` with `A`.
- Any two `window` objects whose `browsing contexts` do not have a non-null `openers` or `ancestor` relationship. This holds even if the two `window` objects are `same origin`.

8.13.11 Runtime script errors

In various scenarios, the user agent can report an exception by firing an `error` event at the `window`. If this event is not canceled, then the error is considered not handled, and can be reported to the developer console.

When the user agent is required to *report an error* for a particular `script` with a particular position `line:col`, using a particular target `target`, it must run these steps, after which the error is either *handled* or *not handled*:

1. If `target` is `in_error_reporting_mode`, then return; the error is *not handled*.
2. Let `target` be *in error reporting mode*.

3. Let `message` be a user-agent-defined string describing the error in a helpful manner.

4. Let `errorValue` be the value that represents the error: in the case of an uncaught exception, that would be the value that was thrown; in the case of a JavaScript error that would be an `Error` object. If there is no corresponding value, then the null value must be used instead.

5. Let `wrString` be the result of applying the `URL serializer` to the `URL record` that corresponds to the resource from which `script` was obtained.

Note

The resource containing the script will typically be the file from which the `document` was parsed, e.g. for inline `<script>` elements or `<event handler content attributes>`, or the JavaScript file that the script was in, for external scripts. Even for dynamically-generated scripts, user agents are strongly encouraged to attempt to keep track of the original source of a script. For example, if an external script uses the `document.write()` API to insert an inline `<script>` element during parsing, the URL of the resource containing the script would ideally be reported as being the external script, and the line number might ideally be reported as the line with the `document.write()` call or where the string passed to that call was first constructed. Naturally, implementing this can be somewhat non-trivial.

Note
User agents are similarly encouraged to keep careful track of the original line numbers, even in the face of `document.write()` calls mutating the document as it is parsed, or `<event handler content attributes>` spanning multiple lines.

6. If `script's muted_errors` is true, then set `message` to "Script error.", `wrString` to the empty string, `line` to 0, and `errorValue` to null.

7. Let `notHandled` be the result of `firing an event named error at target, using ErrorEvent, with the cancelable attribute initialized to true, the message attribute initialized to message, the filename attribute initialized to wrString, the lineno attribute initialized to line, the colno attribute initialized to col, and the error attribute initialized to errorValue`.

8. Let `target` no longer be `in error reporting mode`.

9. If `notHandled` is false, then the error is *handled*. Otherwise, the error is *not handled*.

Note

Returning true in an event handler cancels the event per the `event handler processing algorithm`.

8.13.11.1 Runtime script errors in documents

When the user agent is to *report an exception* `E`, the user agent must *report the error* for the relevant `script`, with the problematic position (line number and column number) in the resource containing the script, using the `global object` specified by the script's `settings object` as the target. If the error is still *not handled* after this, then the error may be reported to a developer console.

8.13.11.2 The `error` interface**ErrorEvent**

Support in all current engines.

FirefoxYesSafariYesChrome10+

Opera11+Edge79+

Edge (Legacy)YesInternet ExplorerYes

```
FirefoxAndroidYesSafariiOSYesChrome Android18+WebView AndroidYesSamsung Internet1.0+Opera Android11+
IDL[Exposed=(Window,Worker)]
interface ErrorEvent : Event {
  optional DOMString message;
  optional unsigned long lineno;
  optional unsigned long colno;
  optional any error;
};

dictionary ErrorEventInit : EventInit {
  DOMString message = "";
  unsigned long lineno = 0;
  unsigned long colno = 0;
  any error = null;
};
```

The `message` attribute must return the value it was initialized to. It represents the error message.

The `filename` attribute must return the value it was initialized to. It represents the `URL` of the script in which the error originally occurred.

The `lineno` attribute must return the value it was initialized to. It represents the line number where the error occurred in the script.

The `colno` attribute must return the value it was initialized to. It represents the column number where the error occurred in the script.

The `error` attribute must return the value it was initialized to. Where appropriate, it is set to the object representing the error (e.g., the exception object in the case of an uncaught DOM exception).

8.13.12 Unhandled promise rejections**Window/rejectionhandled_event**

Support in all current engines.

In addition to synchronous `rejecting script errors`, scripts may experience asynchronous promise rejections, tracked via the `unhandledrejection` and `rejectionhandled` events.

Support: unhandledrejection Chrome for Android 81+Chrome 49+iOS Safari 11.3+Safari 11+Firefox 69+Samsung Internet 5.0+Edge 79+UC Browser for Android 12.12+IE NoneOpera 36+Opera Mini NoneFirefox for Android None

Source: caniuse.com

When the user agent is to *notify about rejected promises* on a given `environment settings object`, it must run these steps:

1. Let `list` be a copy of `settings object's about-to-be-notified rejected promises list`.

3. Clear settings object's `about-to-be-notified rejected promises list`.

4. Queue a task on the DOM manipulation task source to run the following substep:

1. For each promise *p* in *list*:
 1. If *p*'s [[PromisedHandled]] internal slot is true, continue to the next iteration of the loop.
 2. Let *notHandled* be the result of `fire an event named unhandledrejection at settings object's global object`, using `PromiseRejectionEvent`, with the `cancelable` attribute initialized to true, the `promise` attribute initialized to *p*, and the `reason` attribute initialized to the value of *p*'s [[PromiseResult]] internal slot.
 3. If *notHandled* is false, then the promise rejection is `handled`. Otherwise, the promise rejection is `not handled`.
 4. If *p*'s [[PromisedHandled]] internal slot is false, add *p* to settings object's `outstanding rejected promises weak set`.

This algorithm results in promise rejections being marked as `handled` or `not handled`. These concepts parallel `handled` and `not handled` script errors. If a rejection is still `not handled` after this, then the rejection may be reported to a developer console.

K.1.12.1 `HostPromiseRejectionTracker(promise, operation)`

JavaScript contains an implementation-defined `HostPromiseRejectionTracker(promise, operation)` abstract operation. User agents must use the following implementation: [\[JAVASCRIPT\]](#)

1. Let *script* be the `running script`.
2. If *script*'s `muted errors` is true, terminate these steps.
3. Let *settings object* be *script*'s `settings object`.
4. If *operation* is `"reject"`,

1. Add promise to *settings object's* `about-to-be-notified rejected promises list`.

5. If *operation* is `"handle"`,

1. If *settings object's* `about-to-be-notified rejected promises list` contains *promise*, then remove *promise* from that list and return.

2. If *settings object's* `outstanding rejected promises weak set` does not contain *promise*, then return.

3. Remove *promise* from *settings object's* `outstanding rejected promises weak set`.

4. Queue a task on the DOM manipulation task source to fire an event named `rejectionhandled` at *settings object's* `global object`, using `PromiseRejectionEvent`, with the `promise` attribute initialized to *promise*, and the `reason` attribute initialized to the value of *promise*'s [[PromiseResult]] internal slot.

K.1.13 `HostEnsureCanCompileString(callerRealm, calleeRealm)`

JavaScript contains an implementation-defined `HostEnsureCanCompileString(callerRealm, calleeRealm)` abstract operation. User agents must use the following implementation: [\[JAVASCRIPT\]](#)

1. Perform ? `EnsureCSPDoesNotBlockStringCompilation(callerRealm, calleeRealm)`. [CSP]

8.1.4 Event loops

8.1.4.1 Definitions

To coordinate events, user interaction, scripts, rendering, networking, and so forth, user agents must use *event loops* as described in this section. Each `agent` has an associated *event loop*.

Note

In the future, this standard hopes to define exactly when *event loops* can be created or reused.

A *window event loop* is the *event loop* used by *similar-origin window agents*. User agents may share an *event loop* across *similar-origin window agents*.

This specification does not currently describe how to handle the complications arising from *navigating* between *similar-origin window agents*. E.g., when a *browsing context* *navigates* from <https://example.com> to <https://shop.example.com>.

A *worker event loop* is the *event loop* used by *dedicated worker agents*, *shared worker agents*, and *service worker agents*. There must be one *worker event loop* per such `agent`.

A *worker event loop* is the *event loop* used by *workerlet agents*.

As detailed in [issue #4213](#) the situation for workerlets is more complicated.

An *event loop* has one or more *task queues*. A *task queue* is a *set of tasks*.

Note

Task queues are *sets*, not *queues*, because step one of the event loop processing model grabs the first *Runnable task* from the chosen queue, instead of *dequeueing* the first task.

Note

The `microtask queue` is not a *task queue*.

Tasks encapsulate algorithms that are responsible for such work as:

Events

Dispatching an `Event` object at a particular `EventTarget` object is often done by a dedicated task.

Note

Not all events are dispatched using the `task queue`; many are dispatched during other tasks.

Parsing

The `HTML_parser` tokenizing one or more bytes, and then processing any resulting tokens, is typically a task.

Callbacks

Calling a callback is often done by a dedicated task.

Using a resource

When an algorithm `fetchez` a resource, if the fetching occurs in a non-blocking fashion then the processing of the resource once some or all of the resource is available is performed by a task.

Reacting to DOM manipulation

Some elements have tasks that trigger in response to DOM manipulation, e.g. when that element is `inserted into the document`.

Steps
A series of steps specifying the work to be done by the task.A **source**
One of the [task sources](#), used to group and serialize related tasks.A **document**
A [agent](#) associated with the task, or null for tasks that are not in a [window event loop](#).A [script evaluation environment settings object set](#)
A [set](#) of [environment settings objects](#) used for tracking script evaluation during the task.A **task** is **runnable** if its **document** is either null or **fully active**.Per its [source](#) field, each [task](#) is defined as coming from a specific [task source](#). For each [event loop](#), every [task source](#) must be associated with a specific [task queue](#).**Note**
Essentially, [task sources](#) are used within standards to separate logically-different types of tasks, which a user agent might wish to distinguish between. [Task queues](#) are used by user agents to coalesce task sources within a given [event loop](#).**Example**
For example, a user agent could have one [task queue](#) for mouse and key events (to which the [user interaction task source](#) is associated), and another to which all other [task sources](#) are associated. Then, using the freedom granted in the initial step of the [event loop processing model](#), it could give keyboard and mouse events preference over other tasks three-quarters of the time, keeping the interface responsive but not starving other task queues. Note that in this setup, the processing model still enforces that the user agent would never process events from any one [task source](#) out of order.Each [event loop](#) has a **currently running task**, which is either a [task](#) or null. Initially, this is null. It is used to handle reentrancy.Each [event loop](#) has a **microtask queue**, which is a [queue](#) of [microtasks](#), initially empty. A [microtask](#) is a colloquial way of referring to a [task](#) that was created via the [queue a microtask](#) algorithm.Each [event loop](#) has a **performing a microtask checkpoint** boolean, which is initially false. It is used to prevent reentrant invocation of the [perform a microtask checkpoint](#) algorithm.**8.1.4.2 Queueing tasks**To [queue a task](#) on a [task source](#) source, which performs a series of steps [steps](#), optionally given an event loop [event loop](#) and a document [document](#):

1. If [event loop](#) was not given, set [event loop](#) to the [implied event loop](#).
2. If [document](#) was not given, set [document](#) to the [implied document](#).
3. Let [task](#) be a new [task](#).
4. Set [task's steps](#) to [steps](#).
5. Set [task's source](#) to [source](#).
6. Set [task's document](#) to [document](#).
7. Set [task's script evaluation environment settings object set](#) to an empty [set](#).
8. Let [queue](#) be the [task queue](#) to which [source](#) is associated on [event loop](#).
9. [Append](#) [task](#) to [queue](#).

To [queue an element task](#) on a [task source](#) source, with an element [element](#) and a series of steps [steps](#):

1. Let [document](#) be [element's node document](#).
2. Let [event loop](#) be [document's relevant realm's](#) corresponding [agent's event loop](#).
3. [Queue a task](#) given [source](#), [event loop](#), [document](#), and [steps](#).

To [queue a microtask](#) which performs a series of steps [steps](#), optionally given an event loop [event loop](#) and a document [document](#):

1. If [event loop](#) was not given, set [event loop](#) to the [implied event loop](#).
2. If [document](#) was not given, set [document](#) to the [implied document](#).
3. Let [microtask](#) be a new [task](#).
4. Set [microtask's steps](#) to [steps](#).
5. Set [microtask's source](#) to the [microtask task source](#).
6. Set [microtask's document](#) to [document](#).
7. Set [task's script evaluation environment settings object set](#) to an empty [set](#).
8. [Enqueue](#) [task](#) on [event loop's microtask queue](#).

Note
It is possible for a [microtask](#) to be moved to a regular [task queue](#); if, during its initial execution, it [spins the event loop](#). This is the only case in which the [source](#), [document](#), and [script evaluation environment settings object set](#) of the [microtask](#) are consulted; they are ignored by the [perform a microtask checkpoint](#) algorithm.The [implied event loop](#) when queuing a task is the one that can deduced from the context of the calling algorithm. This is generally unambiguous, as most specification algorithms only ever involve a single [agent](#) (and thus a single [event loop](#)). The exception is algorithms involving or specifying cross-agent communication (e.g., between a window and a worker); for those cases, the [implied event loop](#) concept must not be relied upon and specifications must explicitly provide an [event loop](#) when [queuing a task](#) or [microtask](#).The [implied document](#) when queuing a task on an [event loop event loop](#) is determined as follows:

1. If [event loop](#) is not a [window event loop](#), then return null.
2. If the task is being queued in the context of an element, then return the element's [node document](#).
3. If the task is being queued in the context of a [browsing context](#), then return the browsing context's [active document](#).
4. If the task is being queued by or for a [script](#), then return the script's [settings object's responsible document](#).
5. Assert: this step is never reached, because one of the previous conditions must be true. Really?

Both [implied event loop](#) and [implied document](#) are vaguely-defined and have a lot of action-at-a-distance. Perhaps we can come up with a more explicit architecture, while still avoiding all callers needing to explicitly specify the event loop and document.**8.1.4.3 Processing model**An [event loop](#) must continually run through the following steps for as long as it exists:

1. Let [taskQueue](#) be one of the [event loop's task queues](#), chosen in a user-agent-defined manner, with the constraint that the chosen task queue must contain at least one [runnable task](#). If there is no such task queue, then jump to the [microtasks](#) step below.

Note
Remember that the [microtask queue](#) is not a [task queue](#), so it will not be chosen in this step. However, a [task queue](#) to which the [microtask task source](#) is associated might be chosen in this step. In that case, the [task](#) chosen in the next step was originally a [microtask](#), but it got moved as part of [spinning the event loop](#).

2. Let [oldestTask](#) be the first [runnable task](#) in [taskQueue](#), and [remove](#) it from [taskQueue](#).
3. Set the [event loop's currently running task](#) to [oldestTask](#).
4. Let [taskStartTime](#) be the current high resolution time.
5. Perform [oldestTask's steps](#).
6. Set the [event loop's currently running task](#) back to null.

Microtasks: Perform a microtask checkpoint.

7. Now let be the [current high resolution time](#) (HRT).

9. Report the [task's duration](#) by performing the following steps:

1. Let [top-level browsing contexts](#) be an empty [set](#).
2. For each [environment settings object](#) settings of [oldestTask's script evaluation environment settings object set](#), [append](#) setting's [top-level browsing context](#) to [top-level browsing contexts](#).
3. [Report long tasks](#), passing in [taskStartTime](#), now (the end time of the task), [top-level browsing contexts](#), and [oldestTask](#).

10. Update the rendering: if this is a [window event loop](#), then:

1. Let [docs](#) be the list of [document](#) objects associated with the [event loop](#) in question, sorted arbitrarily except that the following conditions must be met:
 - Any [browsing context](#) B whose [browsing context's container document](#) is A must be listed after A in the list.
 - If there are two documents A and B whose [browsing contexts](#) are both [child browsing contexts](#) whose [container documents](#) are another [document](#) C, then the order of A and B in the list must match the [shadow-including tree order](#) of their respective [browsing context containers](#) in C's [node tree](#).

In the steps below that iterate over [docs](#), each [browsing context](#) must be processed in the order it is found in the list.**Rendering opportunities:** If there are [browsing contexts](#) [browsingContexts](#) for which the user agent believes updating the rendering would have no visible effect and which possess no [document](#) objects whose [browsing context](#) is in [browsingContexts](#).A [browsing context](#) has a [rendering opportunity](#) if the user agent is currently able to present the contents of the [browsing context](#) to the user, accounting for hardware refresh rate constraints and user agent throttling for performance reasons, but considering content presentable even if it's outside the viewport.**Browsing context rendering opportunities** are determined based on hardware constraints such as display refresh rates and other factors such as page performance or whether the page is in the background. Rendering opportunities typically occur at regular intervals.**Note**
This specification does not mandate any particular model for selecting rendering opportunities. But for example, if the browser is attempting to achieve a 60Hz refresh rate, then rendering opportunities occur at a maximum of every 60th of a second (about 16.7ms). If the browser finds that a [browsing context](#) is not able to sustain this rate, it might drop to a more sustainable 30 rendering opportunities per second for that [browsing context](#), rather than occasionally dropping frames. Similarly, if a [browsing context](#) is not visible, the user agent might decide to drop that page to a much slower 4 rendering opportunities per second, or even less.**Unnecessary rendering:** If there are [browsing contexts](#) [browsingContexts](#) for which the user agent believes updating the rendering would have no visible effect and which possess no [document](#) objects with a non-empty map of [animation frame callbacks](#), then remove from [docs](#) all [document](#) objects whose [browsing context](#) is in [browsingContexts](#). Invoke the [mark paint timing](#) algorithm for each [browsing context](#) removed.**If there are** [browsing contexts](#) [browsingContexts](#) for which the user agent believes it's preferable to skip updating the rendering for other reasons, then remove from [docs](#) all [document](#) objects whose [browsing context](#) is in [browsingContexts](#).**Note**The step labeled **Rendering opportunities** prevents the user agent from updating the rendering when it is unable to present new content to the user (there's no [rendering opportunity](#)).The step labeled **Unnecessary rendering** prevents the user agent from updating the rendering when there's no new content to draw.This step enables the user agent to prevent the steps below from running for other reasons, for example, to ensure certain [tasks](#) are executed immediately after each other, with only [microtask checkpoints](#) interleaved (and without, e.g., [animation frame callbacks](#) interleaved). Concretely, a user agent might wish to coalesce timer callbacks together, with no intermediate rendering updates.5. For each [fully active document](#) in [docs](#), [flush autofocus candidates](#) for that [document](#) if its [browsing context](#) is a [top-level browsing context](#).6. For each [fully active document](#) in [docs](#), [run the resize steps](#) for that [document](#), passing in [now](#) as the timestamp. [\[CSSOMVIEW\]](#)7. For each [fully active document](#) in [docs](#), [run the scroll steps](#) for that [document](#), passing in [now](#) as the timestamp. [\[CSSOMVIEW\]](#)8. For each [fully active document](#) in [docs](#), [evaluate media queries and report changes](#) for that [document](#), passing in [now](#) as the timestamp. [\[CSSOMVIEW\]](#)9. For each [fully active document](#) in [docs](#), [update animations and send events](#) for that [document](#), passing in [now](#) as the timestamp. [\[WEBANIMATIONS\]](#)10. For each [fully active document](#) in [docs](#), [run the fullscreen steps](#) for that [document](#), passing in [now](#) as the timestamp. [\[FULLSCREEN\]](#)11. For each [fully active document](#) in [docs](#), [run the animation frame callbacks](#) for that [document](#), passing in [now](#) as the timestamp.

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

13. Invoke the [mark paint timing](#) algorithm for each [document](#) object in *docs*.
14. For each [fully active document](#) in *docs*, update the rendering or user interface of that [document](#) and its [browsing context](#) to reflect the current state.
11. If all of the following are true:
- this is a [window event loop](#)
 - there is no task in the event loop's task queue whose document is [fully active](#)
 - the event loop's microtask queue is empty
 - none of the [browsing contexts](#) have a [rendering opportunity](#)

then for each [browsing context](#), run the steps in the [start an idle period](#) algorithm, passing the [Window](#) associated with that [browsing context](#). [\[REQUESTIDLECALLBACK\]](#)

12. Report the duration of the [update the rendering](#) step by performing the following steps:

1. Let [rendering end time](#) be the [current high resolution time](#) (HRT).
2. Let [top-level browsing contexts](#) be the set of all [top-level browsing contexts](#) of all [fully active documents](#) in *docs*.
3. [Report long tasks](#), passing in *now* (repurposed as meaning the beginning of the [update the rendering](#) step), [rendering end time](#), and [top-level browsing contexts](#).

13. If this is a [worker event loop](#), then:

1. If this [event loop's agent's single realm's global object](#) is a supported [PromiseReacterGlobalScope](#) and the user agent believes that it would benefit from having its rendering updated at this time, then:
 1. Let *now* be the [current high resolution time](#) (HRT)
 2. [Run the animation frame callbacks](#) for that [PromiseReacterGlobalScope](#), passing *now* as the timestamp.
3. Update the rendering of that dedicated worker to reflect the current state.

Note

Similar to the notes for [updating the rendering in a window event loop](#), a user agent can determine the rate of rendering in the dedicated worker.

2. If there are no tasks in the [event loop's task queue](#) and the [WorkerGlobalScope](#) object's [closing](#) flag is true, then destroy the [event loop](#), aborting these steps, resuming the [run a worker](#) steps described in the [Web workers](#) section below.

When a user agent is to *perform a microtask checkpoint*:

1. If the [event loop's performing a microtask checkpoint](#) is true, then return.

2. Set the [event loop's performing a microtask checkpoint](#) to true.

3. While the [event loop's microtask queue](#) is not [empty](#):

1. Let [oldestMicrotask](#) be the result of [dequeue](#) from the [event loop's microtask queue](#).

2. Set the [event loop's currently running task](#) to [oldestMicrotask](#).

3. Run [oldestMicrotask](#).

Note

This might involve invoking scripted callbacks, which eventually calls the [clean up after running script](#) steps, which call this [perform a microtask checkpoint](#) algorithm again, which is why we use the [performing a microtask checkpoint](#) flag to avoid reentrancy.

4. Set the [event loop's currently running task](#) back to null.

4. For each [environment settings object](#) whose [responsible event loop](#) is this [event loop](#), [notify about rejected promises](#) on that [environment settings object](#).

5. [Cleanup Indexed Database transactions](#).

6. Set the [event loop's performing a microtask checkpoint](#) to false.

When an algorithm running [in parallel](#) is to *await a stable state*, the user agent must [queue a microtask](#) that runs the following steps, and must then stop executing (execution of the algorithm resumes when the microtask is run, as described in the following steps):

1. Run the algorithm's [synchronous section](#).

2. Resumes execution of the algorithm [in parallel](#), if appropriate, as described in the algorithm's steps.

Note

Steps in [synchronous sections](#) are marked with .

Algorithm steps that say to *spin the event loop until a condition goal* is met are equivalent to substituting in the following algorithm steps:

1. Let *task* be the [event loop's currently running task](#).

Note

task could be a [microtask](#).

2. Let *task source* be *task's source*.

3. Let *old stack* be a copy of the [JavaScript execution context stack](#).

4. Empty the [JavaScript execution context stack](#).

5. [Perform a microtask checkpoint](#).

Note

If *task* is a [microtask](#) this step will be a no-op due to [performing a microtask checkpoint](#) being true.

6. [In parallel](#):

1. Wait until the condition *goal* is met.

2. [Queue a task](#) on *task source* to:
 1. Replace the [JavaScript execution context stack](#) with *old stack*.

2. Perform any steps that appear after this [spin the event loop](#) instance in the original algorithm.

Note

This resumes *task*.

7. Stop *task*, allowing whatever algorithm that invoked it to resume.

Note

This causes the [event loop's main set of steps](#) or the [perform a microtask checkpoint](#) algorithm to continue.

Note

Unlike other algorithms in this and other specifications, which behave similar to programming-language function calls, [spin the event loop](#) is more like a macro, which saves typing and indentation at the usage site by expanding into a series of steps and operations.

Example

An algorithm whose steps are:

1. Do something.
2. [Spin the event loop](#) until awesomeness happens.
3. Do something else.

is a shorthand which, after "macro expansion", becomes

1. Do something.
2. Let *old stack* be a copy of the [JavaScript execution context stack](#).

3. Empty the [JavaScript execution context stack](#).

4. [Perform a microtask checkpoint](#).

5. [In parallel](#):

1. Wait until awesomeness happens.

2. [Queue a task](#) on the *task source* in which "do something" was done to:
 1. Replace the [JavaScript execution context stack](#) with *old stack*.

2. Do something else.

Example

Here is a more full example of the substitution, where the event loop is spun from inside a task that is queued from work in parallel. The version using [spin the event loop](#):

1. [In parallel](#):

1. Do parallel thing 1.

2. [Queue a task](#) on the [DOM manipulation task source](#) to:
 1. Do task thing 1.

2. [Spin the event loop](#) until awesomeness happens.

3. Do task thing 2.

3. Do parallel thing 2.

The fully expanded version:

1. [In parallel](#):

1. Do parallel thing 1.

2. Let *old stack* be null.

3. [Queue a task](#) on the [DOM manipulation task source](#) to:
 1. Do task thing 1.

2. Set *old stack* to a copy of the [JavaScript execution context stack](#).

3. Empty the [JavaScript execution context stack](#).

4. Wait until awesomeness happens.
5. [Queue a task](#) on the [DOM manipulation task source](#):
 1. Replace the [JavaScript execution context stack](#) with *old stack*.
 2. Do task thing 2.
6. Do parallel thing 2.

Some of the algorithms in this specification, for historical reasons, require the user agent to pause while running a [task](#) until a condition *goal* is met. This means running the following steps:

1. If necessary, update the rendering or user interface of any [document](#) or [browsing context](#) to reflect the current state.
2. Wait until the condition *goal* is met. While a user agent has a paused [task](#), the corresponding [event loop](#) must not run further [tasks](#), and any script in the currently running [task](#) must block. User agents should remain responsive to user input while paused, however, albeit in a reduced capacity since the [event loop](#) will not be doing anything.

⚠ Warning!

[Pausing](#) is highly detrimental to the user experience, especially in scenarios where a single [event loop](#) is shared among multiple documents. User agents are encouraged to experiment with alternatives to [pausing](#), such as [spinning the event loop](#) or even simply proceeding without any kind of suspended execution at all, insofar as it is possible to do so while preserving compatibility with existing content. This specification will happily change if a less-drastic alternative is discovered to be web-compatible.

In the interim, implementers should be aware that the variety of alternatives that user agents might experiment with can change subtle aspects of [event loop](#) behavior, including [task](#) and [microtask](#) timing. Implementations should continue experimenting even if doing so causes them to violate the exact semantics implied by the [pause](#) operation.

8.1.4.4 Generic task sources

The following [task sources](#) are used by a number of mostly unrelated features in this and other specifications.

The [DOM manipulation task source](#)

This [task source](#) is used for features that react to DOM manipulations, such as things that happen in a non-blocking fashion when an element is [inserted into the document](#).

The [user interaction task source](#)

This [task source](#) is used for features that react to user interaction, for example keyboard or mouse input.

Events sent in response to user input (e.g. [click](#) events) must be fired using [tasks queued](#) with the [user interaction task source](#). ([UIFVENTS](#))

The [networking task source](#)

This [task source](#) is used for features that trigger in response to network activity.

The [history traversal task source](#)

This [task source](#) is used to queue calls to [history.back\(\)](#) and similar APIs.

8.1.4.5 Dealing with the event loop from other specifications

Writing specifications that correctly interact with the [event loop](#) can be tricky. This is compounded by how this specification uses concurrency-model-independent terminology, so we say things like "[event loop](#)" and "[in parallel](#)" instead of using more familiar model-specific terms like "main thread" or "on a background thread".

By default, specification text generally runs on the [event loop](#). This falls out from the formal [event loop processing model](#), in that you can eventually trace most algorithms back to a [task queued](#) there.

Example

The algorithm steps for any JavaScript method will be invoked by author code calling that method. And author code can only be run via queued tasks, usually originating somewhere in the [script processing model](#).

From this starting point, the overriding guideline is that any work a specification needs to perform that would otherwise block the [event loop](#) must instead be performed [in parallel](#) with it. This includes (but is not limited to):

- performing heavy computation;
- displaying a user-facing prompt;
- performing operations which could require involving outside systems (i.e. "going out of process").

The next complication is that, in algorithm sections that are [in parallel](#), you must not create or manipulate objects associated to a specific [JavaScript realm](#), [global](#), or [environment settings object](#). (Stated in more familiar terms, you must not directly access main-thread artifacts from a background thread.) Doing so would create data races observable to JavaScript code, since after all, your algorithm steps are running [in parallel](#) to the Java code.

You can, however, manipulate specification-level data structures and values from [Infra](#), as those are realm-agnostic. They are never directly exposed to JavaScript without a specific conversion taking place (often via [Web IDL](#)). ([INFRA](#)) ([WEBIDL](#))

To affect the world of observable JavaScript objects, then, you must [queue a task](#) to perform any such manipulations. This ensures your steps are properly interleaved with respect to other things happening on the [event loop](#). Furthermore, you must choose a [task source](#) when [queuing a task](#); this governs the relative order of your steps versus others. If you are unsure which [task source](#) to use, pick one of the [generic task sources](#) that sounds most applicable.

Most invocations of [queue a task](#) use the [implied event loop](#), i.e., the one that is obvious from context. That is because it is very rare for algorithms to be invoked in contexts involving multiple event loops. (Unlike contexts involving multiple global objects, which happen all the time!) So unless you are writing a specification which, e.g., deals with manipulating [workers](#), you can omit this argument when [queueing a task](#).

Putting this all together, we can provide a template for a typical algorithm that needs to do work asynchronously:

1. Do any synchronous setup work, while still on the [event loop](#). This may include converting [realm](#)-specific JavaScript values into realm-agnostic specification-level values.
2. Perform a set of potentially-expensive steps [in parallel](#), operating entirely on realm-agnostic values, and producing a realm-agnostic result.
3. [Queue a task](#), on a specified [task source](#), to convert the realm-agnostic result back into observable effects on the observable world of JavaScript objects on the [event loop](#).

Example

The following is an algorithm that "encrypts" a passed-in [list](#) of [scalar value strings](#) *input*, after parsing them as URLs:

1. Let *urls* be an empty [list](#).
2. [For each](#) [string](#) of *input*:
 1. Let *parsed* be the result of [parsing string](#) relative to the [current settings object](#).
 2. If *parsed* is failure, return a promise rejected with a [SyntaxError](#) [DOMException](#).
 3. Let *serialized* be the result of applying the [URL serializer](#) to *parsed*.
 4. [Append](#) *serialized* to *urls*.
3. Let *realm* be the [current Realm Record](#).
4. Let *p* be a new promise.
5. Run the following steps [in parallel](#):
 1. Let *encryptedURLs* be an empty [list](#).
 2. [For each](#) [url](#) of *urls*:
 1. Wait 100 milliseconds, so that people think we're doing heavy-duty encryption.
 2. Let *encrypted* be a new [JavaScript string](#) derived from *url*, whose *n*th [code unit](#) is equal to *url*'s *n*th [code unit](#) plus 13.
 3. [Append](#) *encrypted* to *encryptedURLs*.
 3. [Queue a task](#), on the [networking task source](#), to perform the following steps:
 1. Let *array* be the result of [converting](#) *encryptedURLs* to a JavaScript array, in *realm*.
 2. Resolve *p* with *array*.
6. Return *p*.

Here are several things to notice about this algorithm:

- It does its URL parsing up front, on the [event loop](#), before going to the [in parallel](#) steps. This is necessary, since parsing depends on the [current settings object](#), which would no longer be current after going [in parallel](#).
- Alternately, it could have saved a reference to the [current settings object](#)'s [API base URL](#) and used it during the [in parallel](#) steps; that would have been equivalent. However, we recommend instead doing as much work as possible up front, as this example does. Attempting to save the correct values can be error prone; for example, if we'd saved just the [current settings object](#), instead of its [API base URL](#), there would have been a potential race.
- It implicitly passes a [list](#) of [JavaScript strings](#) from the initial steps to the [in parallel](#) steps. This is OK, as both [lists](#) and [JavaScript strings](#) are realm-agnostic.
- It performs "expensive computation" (waiting for 100 milliseconds per input URL) during the [in parallel](#) steps, thus not blocking the main [event loop](#).
- Promises, as observable JavaScript objects, are never created and manipulated during the [in parallel](#) steps. *p* is created before entering those steps, and then is manipulated during a [task](#) that is [queued](#) specifically for that purpose.
- The creation of a JavaScript array object also happens during the queued task, and is careful to specify which realm it creates the array in since that is no longer obvious from context.

On these last two points, see also [w3ctag/promises-guide issue #52](#), [brycam/webidl issue #135](#), and [brycam/webidl issue #371](#), where we are still mulling over the subtleties of the above promise-resolution pattern.

Another thing to note is that, in the event this algorithm was called from a Web IDL-specified operation taking a [sequence<USVString>](#), there was an automatic conversion from [realm](#)-specific JavaScript objects provided by the author as input, into the realm-agnostic [sequence<USVString>](#) Web IDL type, which we then treat as a [list](#) of [scalar value strings](#). So depending on how your specification is structured, there may be other implicit steps happening on the main [event loop](#) that play a part in this whole process of getting you ready to go [in parallel](#).

8.1.5 Events

8.1.5.1 Event handlers

MDN

[Events/Event_handlers](#)

Many objects can have [event handlers](#) specified. These act as non-capture [event listeners](#) for the object on which they are specified. ([DOM](#))

An [event handler](#) is a [struct](#) with two [items](#):

- a [value](#), which is either null, a callback object, or an [internal raw uncompiled handler](#). The [eventHandler](#) callback function type describes how this is exposed to scripts. Initially, an [event handler](#)'s [value](#) must be set to null.
- a [listener](#), which is either null or an [event listener](#) responsible for running the [event handler processing algorithm](#). Initially, an [event handler](#)'s [listener](#) must be set to null.

Event handlers are exposed in two ways.

The first way, common to all event handlers, is as an [event handler IDL attribute](#).

The second way is as an [event handler content attribute](#). Event handlers on [HTML_element](#)s and some of the event handlers on [Window](#) objects are exposed in this way.

For both of these two ways, the [event handler](#) is exposed through a name, which is a string that always starts with "`on`" and is followed by the name of the event for which the handler is intended.

Most of the time, the object that exposes an [event handler](#) is the same as the object on which the corresponding [event listener](#) is added. However, the [body](#) and [frameSet](#) elements expose several [event handlers](#) that act upon the element's [Window](#) object, if one exists. In either case, we call the object an [event handler](#) acts upon the [target](#) of that [event handler](#).

To determine the target of an event handler, given an [EventTarget](#) object *eventTarget* on which the [event handler](#) is exposed, and an [event handler name](#), *name*, the following steps are taken:

1. If *eventTarget* is not a [body](#) element or a [frameSet](#) element, then return *eventTarget*.

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

2. If `name` is not the name of an attribute member of the `WindowEventHandlers` interface mixin and the `Window`-reflecting `body` element `event handler set` does not contain `name`, then return `eventTarget`.

3. If `eventTarget's node document` is not an `active document`, then return null.

Note

This could happen if this object is a `body` element without a corresponding `Window` object, for example.

Note

This check does not necessarily prevent `body` and `frameset` elements that are not the `body` element of their `node document` from reaching the next step. In particular, a `body` element created in an `active document` (perhaps with `document.createElement()`) but not `connected` will also have its corresponding `Window` object as the `target` of several `event handlers` exposed through it.

4. Return `eventTarget's node document's relevant global object`.

Each `eventTarget` object that has one or more `event handlers` specified has an associated `event handler map`, which is a `Map` of strings representing `names` of `event handlers` to `event handlers`.

When an `eventTarget` object that has one or more `event handlers` specified is created, its `event handler map` must be initialized such that it contains an `empty` for each `event handler` that has that object as `target`, with `items` in those `event handlers` set to their initial values.

Note

The order of the `entries` of `event handler map` could be arbitrary. It is not observable through any algorithms that operate on the map.

Note

`Entries` are not created in the `event handler map` of an object for `event handlers` that are merely exposed on that object, but have some other object as their `targets`.

An `event handler IDL attribute` is an IDL attribute for a specific `event handler`. The name of the IDL attribute is the same as the `name` of the `event handler`.

The getter of an `event handler IDL attribute` with name `name`, when called, must run these steps:

1. Let `eventTarget` be the result of `determining the target of an event handler` given this object and `name`.
2. If `eventTarget` is null, then return null.
3. Return the result of `getting the current value of the event handler` given `eventTarget` and `name`.

The setter of an `event handler IDL attribute` with name `name`, when called, must run these steps:

1. Let `eventTarget` be the result of `determining the target of an event handler` given this object and `name`.
2. If `eventTarget` is null, then return.
3. If the given value is null, then `deactivate an event handler` given `eventTarget` and `name`.
4. Otherwise:
 1. Let `handlerMap` be `eventTarget's event handler map`.
 2. Let `eventHandler` be `handlerMap[name]`.
 3. Set `eventHandler's value` to the given value.
 4. `Activate an event handler` given `eventTarget` and `name`.

Note

Certain `event handler IDL attributes` have additional requirements, in particular the `congruence` attribute of `MessagePort` objects.

An `event handler content attribute` is a content attribute for a specific `event handler`. The name of the content attribute is the same as the `name` of the `event handler`.

`Event handler content attributes`, when specified, must contain valid JavaScript code which, when parsed, would match the `FunctionBody` production after `automatic semicolon insertion`.

The following `attribute change steps` are used to synchronize between `event handler content attributes` and `event handlers` (DOM)

1. If `namespace` is not null, or `localName` is not the name of an `event handler content attribute` on `element`, then return.
2. Let `eventTarget` be the result of `determining the target of an event handler` given `element` and `localName`.
3. If `eventTarget` is null, then return.
4. If `value` is null, then `deactivate an event handler` given `eventTarget` and `localName`.
5. Otherwise:
 1. If the `Should element's inline behavior be blocked by Content Security Policy?` algorithm returns "Blocked" when executed upon `element`, "script attribute", and `value`, then return: [CSP]
 2. Let `handlerMap` be `eventTarget's event handler map`.
 3. Let `eventHandler` be `handlerMap[localName]`.
 4. Let `location` be the script location that triggered the execution of these steps.
 5. Set `eventHandler's value` to the `internal raw uncompiled handler value/location`.
 6. `Activate an event handler` given `eventTarget` and `localName`.

Note

For the DOM Standard, these steps are run even if `oldValue` and `value` are identical (setting an attribute to its current value), but not if `oldValue` and `value` are both null (removing an attribute that doesn't currently exist). [DOM]

To deactivate an `event handler` given an `EventTarget` object `eventTarget` and a string `name` that is the `name` of an `event handler`, run these steps:

1. Let `handlerMap` be `eventTarget's event handler map`.
2. Let `eventHandler` be `handlerMap[name]`.
3. Set `eventHandler's value` to null.
4. Let `listener` be `eventHandler's listener`.
5. If `listener` is not null, then `remove an event listener` with `eventTarget` and `listener`.
6. Set `eventHandler's listener` to null.

To erase all `event listeners` and `handlers` given an `EventTarget` object `eventTarget`, run these steps:

1. If `eventTarget` has an associated `event handler map`, then for each `name` → `eventHandler` of `eventTarget's associated event handler map`, `deactivate an event handler` given `eventTarget` and `name`.
2. `Remove all event listeners` given `eventTarget`.

Note

This algorithm is used to define `document.open()`.

To activate an `event handler` given an `EventTarget` object `eventTarget` and a string `name` that is the `name` of an `event handler`, run these steps:

1. Let `handlerMap` be `eventTarget's event handler map`.
2. Let `eventHandler` be `handlerMap[name]`.
3. If `eventHandler's listener` is not null, then return.
4. Let `callback` be the result of creating a Web IDL `EventListener` instance representing a reference to a function of one argument that executes the steps of `the event handler processing algorithm`, given `eventTarget`, `name`, and its argument.

The `EventListener's callback context` can be arbitrary; it does not impact the steps of `the event handler processing algorithm`. [DOM]

Note

The `callback` is emphatically not the `event handler` itself. Every event handler ends up registering the same `callback`, the algorithm defined below, which takes care of invoking the right code, and processing the code's return value.

5. Let `listener` be a new `event listener` whose `type` is the `event handler` `event type` corresponding to `eventHandler` and `callback` is `callback`.

Note

To be clear, an `event listener` is different from an `EventListener`.

6. `Add an event listener` with `eventTarget` and `listener`.

7. Set `eventHandler's listener` to `listener`.

Note

The event listener registration happens only if the `event handler's value` is being set to non-null, and the `event handler` is not already activated. Since listeners are called in the order they were registered, assuming no `deactivation` occurred, the order of event listeners for a particular event type will always be:

1. the event listeners registered with `addEventListener()` before the first time the `event handler's value` was set to non-null
2. then the `callback` to which it is currently set, if any
3. and finally the event listeners registered with `addEventListener()` after the first time the `event handler's value` was set to non-null.

Example

This example demonstrates the order in which event listeners are invoked. If the button in this example is clicked by the user, the page will show four alerts, with the text "ONE", "TWO", "THREE", and "FOUR" respectively.

```
<button id="test">Start Demo</button>
<script>
var button = document.getElementById("test");
button.addEventListener("click", function () { alert("ONE") }, false);
button.addEventListener("click", function () { alert("TWO") }, false); // event handler listener is registered here
button.addEventListener("click", function () { alert("THREE") }, false);
button.onclick = function () { alert("TWO") };
button.addEventListener("click", function () { alert("FOUR") }, false);
</script>
```

However, in the following example, the event handler is `deactivated` after its initial activation (and its event listener is removed), before being reactivated at a later time. The page will show five alerts with "ONE", "TWO", "THREE", "FOUR", and "FIVE" respectively, in order.

```
<button id="test">Start Demo</button>
<script>
var button = document.getElementById("test");
button.addEventListener("click", function () { alert("ONE") }, false);
button.addEventListener("click", function () { alert("TWO") }, false); // event handler is activated here
button.addEventListener("click", function () { alert("THREE") }, false); // but deactivated here
button.onclick = null;
button.addEventListener("click", function () { alert("TWO") });
button.onclick = function () { alert("FOUR") }; // re-activated here
button.addEventListener("click", function () { alert("FIVE") }, false);
</script>
```

Note

The interfaces implemented by the event object do not influence whether an `event handler` is triggered or not.

The `event handler processing algorithm` for an `EventTarget` object `eventTarget`, a string `name` representing the `name` of an `event handler`, and an `event` object `event` is as follows:

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

1. Let `callback` be the result of [getting the current value of the event handler](#) given `eventTarget` and `name`.

2. If `callback` is null, then return.

3. Let [special error event handling](#) be true if `event` is an `ErrorEvent` object, `event's type` is `error`, and `event's currentTarget` implements the `WindowOrWorkerGlobalScope` mixin. Otherwise, let [special error event handling](#) be false.

4. Process the `Event` object `event` as follows:

If [special error event handling](#) is true

`Invoke callback` with five arguments, the first one having the value of `event's message` attribute, the second having the value of `event's lineno` attribute, the third having the value of `event's colno` attribute, the fourth having the value of `event's error` attribute, and with the `callback this value` set to `event's currentTarget`. Let `return value` be the callback's return value. [\[WEBIDL\]](#)

Otherwise

`Invoke callback` with one argument, the value of which is the `Event` object `event`, with the `callback this value` set to `event's currentTarget`. Let `return value` be the callback's return value. [\[WEBIDL\]](#)

If an exception gets thrown by the callback, end these steps and allow the exception to propagate. (It will propagate to the `DOM event dispatch logic`, which will then [report the exception](#).)

5. Process `return value` as follows:

If `event` is a `BeforeUnloadEvent` object and `event's type` is `beforeunload`

Note
In this case, the `event handler IDL attribute`'s type will be `OnBeforeUnloadEventHandler`, so `return value` will have been coerced into either null or a `DOMString`.

If `return value` is not null, then:

1. Set `event's canceled flag`.
2. If `event's returnValue` attribute's value is the empty string, then set `event's returnValue` attribute's value to `return value`.

If [special error event handling](#) is true

If `return value` is true, then set `event's canceled flag`.

Otherwise

If `return value` is false, then set `event's canceled flag`.

Note
If we've gotten to this "Otherwise" clause because `event's type` is `beforeunload` but `event` is not a `BeforeUnloadEvent` object, then `return value` will never be false, since in such cases `return value` will have been coerced into either null or a `DOMString`.

The `EventHandler` callback function type represents a callback used for event handlers. It is represented in Web IDL as follows:

```
IDLInterface<EventHandler>
callback OnErrorEventHandlerNull = any (Event event);
typedef OnErrorEventHandlerNull? OnErrorEventHandlers;
```

Note
In JavaScript, any `Function` object implements this interface.

Example

For example, the following document fragment:

```
<body onload="alert(this)" onclick="alert(this)">
```

leads to an alert saying "[object Window]" when the document is loaded, and an alert saying "[object HTMLElement]" whenever the user clicks something in the page.

Note

The return value of the function affects whether the event is canceled or not: as described above, if the return value is false, the event is canceled.

There are two exceptions in the platform, for historical reasons:

- The `onerror` handlers on global objects, where returning `true` cancels the event
- The `onbeforeunload` handler, where returning any non-null and non-undefined value will cancel the event.

For historical reasons, the `onerror` handler has different arguments:

```
IDLInterface<ErrorHandler>
callback OnErrorEventHandlerNull = any (Event event, optional DOMString source, optional unsigned long lineno, optional unsigned long colno, optional any error);
typedef OnErrorEventHandlerNull? OnErrorEventHandlers;
```

Example

```
window.onerror = (message, source, lineno, colno, error) => ( ... );
```

Similarly, the `onbeforeunload` handler has a different return value:

```
IDLInterface<ErrorHandler>
callback OnBeforeUnloadEventHandlerNull = any (Event event);
typedef OnBeforeUnloadEventHandlerNull? OnBeforeUnloadEventHandlers;
```

An [internal raw uncompiled handler](#) is a tuple with the following information:

- An uncompiled script body
- A location where the script body originated, in case an error needs to be reported

When the user agent is to get the current value of the event handler given an `EventTarget` object `eventTarget` and a string `name` that is the `name` of an `event handler`, it must run these steps:

1. Let `handlerMap` be `eventTarget's event handler map`.
2. Let `eventHandler` be `handlerMap[name]`.
3. If `eventHandler's value` is an [internal raw uncompiled handler](#), then:
 1. If `eventTarget` is an element, then let `element` be `eventTarget`, and `document` be `element's node document`. Otherwise, `eventTarget` is a `Window` object, let `element` be null, and `document` be `eventTarget's associated document`.
 2. If `scripting is disabled` for `document`, then return null.
 3. Let `body` be the uncompiled script body in `eventHandler's value`.
 4. Let `location` be the location where the script body originated, as given by `eventHandler's value`.
 5. If `element` is not null and `element` has a `form owner`, let `form owner` be that `form owner`. Otherwise, let `form owner` be null.
 6. Let `settings object` be the relevant `settings object` of `document`.
 7. If `body` is not parseable as `FunctionBody` or if parsing detects an `early error`, then follow these substeps:
 1. Set `eventHandler's value` to null.

Note
This does not deactivate the event handler, which additionally removes the event handler's `listener` (if present).

2. Report the `error` for the appropriate `script` and with the appropriate position (line number and column number) given by `location`, using `settings object's global object`. If the error is still `not handled` after this, then the error may be reported to a developer console.
3. Return null.

8. Push `settings object's realm execution context` onto the `JavaScript execution context stack`; it is now the running `JavaScript execution context`.

Note
This is necessary so the subsequent invocation of `OrdinaryFunctionCreate` takes place in the correct `JavaScript Realm`.

9. Let `function` be the result of calling `OrdinaryFunctionCreate`, with arguments:

```
functionPrototype %FunctionPrototype%
ParameterList
  If eventHandler is an error or event handler of a Window object
    Let the function have five arguments, named event, source, lineno, colno, and error.
  Otherwise
    Let the function have a single argument called event.
Body
  The result of parsing body above.
thisMode
  non-lexical-this
Scope
  1. Let realm be settings object's Realm.
  2. Let scope be realm.[[GlobalEnv]].
  3. If eventHandler is an element's event handler, then set scope to NewObjectEnvironment(document, scope).
  (Otherwise, eventHandler is a Window object's event handler)
  4. If form owner is not null, then set scope to NewObjectEnvironment(form owner, scope).
  5. If element is not null, then set scope to NewObjectEnvironment(element, scope).
  6. Return scope.
```
10. Remove `settings object's realm execution context` from the `JavaScript execution context stack`.
11. Set `function.[[ScriptOrModule]]` to null.

Note

This is done because the default behavior, of associating the created function with the nearest `script` on the stack, can lead to path-dependent results. For example, an event handler which is first invoked by user interaction would end up with null `[ScriptOrModule]` (since then this algorithm would be first invoked when the `active script` is null), whereas one that is first invoked by dispatching an event from script would have its `[ScriptOrModule]` set to that script.

Instead, we just always set `[ScriptOrModule]` to null. This is more intuitive anyway; the idea that the first script which dispatches an event is somehow responsible for the event handler code is dubious.

In practice, this only affects the resolution of relative URLs via `import()`, which consult the `base URL` of the associated script. Nulling out `[ScriptOrModule]` means that `HostResolveImportedModule` and `HostImportModuleDynamically` will fall back to the `current settings object's API base URL`.

12. Set `eventHandler's value` to the result of creating a Web IDL `EventHandler` callback function object whose object reference is `function` and whose `callback context` is `settings object`.
4. Return `eventHandler's value`.

The following are the [event handlers](#) (and their corresponding [event handler event types](#)) that must be supported by all [HTML elements](#), as both [event handler content attributes](#) and [event handler IDL attributes](#); and that must be supported by all [Document](#) and [Window](#) objects, as [event handler IDL attributes](#):

8.1.5.3 Event firing

```

Certain operations and methods are defined as firing events on elements. For example, the `click()` method on the `HTMLElement` interface is defined as firing a `click` event on the element. ([UI EVENTS](#))

Firing a synthetic mouse event named `@target`, with an optional `not trusted` flag, means running these steps:

- Let `event` be the result of *creating an event* using `mouseEvent`.
- Initialize `event`'s `type` attribute to `e`.
- Initialize `event`'s `bubbles` and `cancelable` attributes to true.
- Set `event`'s `composed` flag.
- If the `not trusted` flag is set, initialize `event`'s `isTrusted` attribute to false.
- Initialize `event`'s `ctrlKey`, `shiftKey`, `altKey`, and `metaKey` attributes according to the current state of the key input device, if any (false for any keys that are not available).
- Initialize `event`'s `view` attribute to `target`'s `nodeDocument's` `Window` object, if any, and null otherwise.
- `event`'s `getModifierState()` method is to return values appropriately describing the current state of the key input device.
- Return the result of *firing event at target*.

Firing a `click` event at target means `firing a synthetic mouse event named click` at target.

8.2 The `WindowOrWorkerGlobalScope` mixin

MDN

`WindowOrWorkerGlobalScope`

Support in all current engines.

Firefox1+SafariYesChrome4+

OperaYesEdge79+

Edge (Legacy)12+Internet ExplorerYes

Firefox, Android4+Safari iOSYesChrome Android18+WebView AndroidYesSamsung Internet1.0+Opera AndroidYes

The `WindowOrWorkerGlobalScope` mixin is for use of APIs that are to be exposed on `Window` and `WorkerGlobalScope` objects.

Note

Other standards are encouraged to further extend it using `partial interface mixin WindowOrWorkerGlobalScope { ... }` along with an appropriate reference.

```

IDLtypedef (DOMString or Function) TimerHandler;
interface mixin WindowOrWorkerGlobalScope {
    (Replaceable) readonly attribute USVString origin;
    base64 utility function;
    DOMString localStorage attribute USVString;
    Bytestring localStorage attribute DOMString;
    // timers
    long settimeout(TimerHandler handler, optional long timeout = 0, any... arguments);
    void clearTimeout(optional long handle = 0);
    void clearInterval(optional long handle = 0, optional long timeout = 0, any... arguments);
    void clearInterval(optional long handle = 0);
    // microtask queueing
    void queueMicrotask(VoidFunction callback);
    // ImageBitmap
    Promise<ImageBitmap> createImageBitmap(ImageBitmapSource image, optional ImageBitmapOptions options = {});
    Promise<ImageBitmap> createImageBitmap(ImageBitmapSource image, long sx, long sy, long sw, long sh, optional ImageBitmapOptions options = {});
    Window includes WindowWorkerGlobalScope;
    WorkerGlobalScope includes WorkerGlobalScope;
    WorkerGlobalScope includes WindowOrWorkerGlobalScope;
}

For web developers (non-normative)
origin = self . origin
    Returns the global object's origin, serialized as string.

```

Example

Developers are strongly encouraged to use `self.origin` over `location.origin`. The former returns the `origin` of the environment, the latter of the URL of the environment. Imagine the following script executing in a document on <https://stargate.example/>:

```

var frame = document.createElement("iframe");
frame.onload = function() {
    var framewin = frame.contentWindow;
    framewin.location.origin // "null"
    console.log(framewin.origin) // "https://stargate.example"
}
document.body.appendChild(frame)

```

`self.origin` is a more reliable security indicator.

MDN

`WindowOrWorkerGlobalScope/origin`

Firefox54+SafariNoChrome59+

OperaNoEdge79+

Edge (Legacy)NoInternet ExplorerNo

Firefox, Android54+Safari iOSNoChrome Android59+WebView Android59+Samsung Internet7.0+Opera AndroidNo

The `origin` attribute's getter must return this object's `elevated settings object's` `origin_serialized`.

8.3 Base64 utility methods

MDN

Support: atob-btoaChrome for Android 81+Chrome 4+iOS Safari 3.2+Safari 3.1+Firefox 2+Samsung Internet 4+Edge 12+UC Browser for Android 12.12+IE 10+Opera 10.6+Opera Mini all+Firefox for Android 68+

Source: [caniuse.com](#)

The `atob()` and `btoa()` methods allow developers to transform content to and from the base64 encoding.

Note

In these APIs, for mnemonic purposes, the "b" can be considered to stand for "binary", and the "a" for "ASCII". In practice, though, for primarily historical reasons, both the input and output of these functions are Unicode strings.

For web developers (non-normative)

`result = self . atob (data)`

Takes the input data, in the form of a Unicode string containing only characters in the range U+0000 to U+00FF, each representing a binary byte with values 0x00 to 0xFF respectively, and converts it to its base64 representation, which it returns.

Throws an "`InvalidCharacterError`" `DOMException` exception if the input string contains any out-of-range characters.

`result = self . btoa (data)`

Takes the input data, in the form of a Unicode string containing base64-encoded binary data, decodes it, and returns a string consisting of characters in the range U+0000 to U+00FF, each representing a binary byte with values 0x00 to 0xFF respectively, corresponding to that binary data.

Throws an "`InvalidCharacterError`" `DOMException` if the input string is not valid base64 data.

MDN

`WindowOrWorkerGlobalScope/btoa`

Support in all current engines.

Firefox1+Safari3+Chrome4+

Opera10.5+Edge79+

Edge (Legacy)12+Internet Explorer10+

Firefox Android4+Safari iOS1+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android11+

The `atob(data)` method must throw an "`invalidCharacterError`" `DOMException` if `data` contains any character whose code point is greater than U+00FF. Otherwise, the user agent must convert `data` to a byte sequence whose *n*th byte is the eight-bit representation of the *n*th code point of `data`, and then must apply `forgiving-base64 encode` to that byte sequence and return the result.

OMN

[WindowOrWorkerGlobalScope.atob](#)

Support in all current engines.

Firefox1+Safari3+Chrome4+

Opera10.5+Edge79+

Edge (Legacy)12+Internet Explorer10+

Firefox Android4+Safari iOS1+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android11+

The `atob(data)` method, when invoked, must run the following steps:

1. Let `decodedData` be the result of running `forgiving-base64 decode` on `data`.
2. If `decodedData` is failure, then throw an "`invalidCharacterError`" `DOMException`.
3. Return `decodedData`.

8.4 Dynamic markup insertion

Note

APIs for dynamically inserting markup into the document interact with the parser, and thus their behavior varies depending on whether they are used with [HTML documents](#) (and the [HTML parser](#)) or [XML documents](#) (and the [XML parser](#)).

`Document` objects have a `throw-on-dynamic-markup-insertion counter`, which is used in conjunction with the `create an element for the token` algorithm to prevent `custom element constructors` from being able to use `document.open()`, `document.close()`, and `document.write()` when they are invoked by the parser. Initially, the counter must be set to zero.

8.4.1 Opening the input stream

For web developers (non-normative)

`document = document.open()`

Causes the `Document` to be replaced in-place, as if it was a new `Document` object, but reusing the previous object, which is then returned.

The resulting `Document` has an HTML parser associated with it, which can be given data to parse using `document.write()`.

The method has no effect if the `Document` is still being parsed.

Throws an "`invalidStateError`" `DOMException` if the `Document` is an [XML document](#).

Throws an "`invalidStateError`" `DOMException` if the parser is currently executing a `custom element constructor`.

`window = document.open(url, name, features)`

Works like the `window.open()` method.

`Document` objects have an `ignore-opens-during-unload counter`, which is used to prevent scripts from invoking the `document.open()` method (directly or indirectly) while the document is [being unloaded](#). Initially, the counter must be set to zero.

`Document` objects have an active parser `was_aborted` boolean, which is used to prevent scripts from invoking the `document.open()` and `document.write()` methods (directly or indirectly) after the document's `active_parser` has been aborted. It is initially false.

The `document open steps`, given a `document`, are as follows:

1. If `document` is an [XML document](#), then throw an "`invalidStateError`" `DOMException`.
2. If `document`'s `throw-on-dynamic-markup-insertion counter` is greater than 0, then throw an "`invalidStateError`" `DOMException`.
3. Let `entryDocument` be the [entry global object's associated document](#).
4. If `document`'s `origin` is not same `origin` to `entryDocument`'s `origin`, then throw a "`SecurityError`" `DOMException`.
5. If `document` has an `active_parser` whose `script nesting level` is greater than 0, then return `document`.

Note
This basically causes `document.open()` to be ignored when it's called in an inline script found during parsing, while still letting it have an effect when called from a non-parser task such as a timer callback or event handler.

6. Similarly, if `document`'s `ignore-opens-during-unload counter` is greater than 0, then return `document`.

Note
This basically causes `document.open()` to be ignored when it's called from a `beforeunload`, `pagehide`, or `unload` event handler while the `Document` is being unloaded.

7. If `document`'s `active_parser was aborted` is true, then return `document`.

Note
This notably causes `document.open()` to be ignored if it is called after a `navigate` has started, but only during the initial parse. See [issue #4723](#) for more background.

8. If `document`'s `browsing context` is non-null and there is an existing attempt to `navigate` `document`'s `browsing context`, then `stop_document_loading` given `document`.

[Issue #4477](#) looks into the distinction between an ongoing instance of the `navigate` algorithm versus tasks to `navigate` that are still queued. For the purpose of implementing this step, both an ongoing instance of the `navigate` algorithm and tasks queued to `navigate` should be counted towards "an existing attempt to `navigate`," at least until that issue is resolved.

9. For each `shadow-including inclusive descendant` node of `document`, `erase all event listeners and handlers` given `node`.

10. If `document` is the `associated document` of `document`'s `relevant global object`, then `erase all event listeners and handlers` given `document`'s `relevant global object`.

11. `Replace all` with null within `document`, without firing any mutation events.

12. If `document` is `fully_seeing`, then:

1. Let `newURL` be a copy of `entryDocument`'s `URL`.
2. If `entryDocument` is not `document`, then set `newURL`'s `fragment` to null.

3. Run the `URL and history update steps` with `document` and `newURL`.

13. If `document`'s `frame load in progress` flag is set, then set `document`'s `mute_iframe_load` flag.

14. Set `document` to `no-quirks mode`.

15. Create a new [HTML parser](#) and associate it with `document`. This is a `script-created parser` (meaning that it can be closed by the `document.open()` and `document.close()` methods, and that the tokenizer will wait for an explicit call to `document.close()` before emitting an end-of-file token). The encoding `confidence` is `irrelevant`.

16. Set the `current_document.readiness` of `document` to `*loading*`.

17. Finally, set the `insertion point` to point at just before the end of the `input stream` (which at this point will be empty).

18. Return `document`.

Note

The `document open steps` do not affect whether a `Document` is ready for post-load tasks or completely loaded.

OMN

[Document.open](#)

Support in all current engines.

FirefoxYesSafariYesChrome45+

OperaYesEdge79+

Edge (Legacy)12+Internet ExplorerYes

Firefox AndroidYesSafari iOSYesChrome Android45+WebView Android45+Samsung Internet5.0+Opera AndroidYes

The `open(unused1, unused2)` method must return the result of running the `document open steps` with this `Document` object.

Note
The `unused1` and `unused2` arguments are ignored, but kept in the IDL to allow code that calls the function with one or two arguments to continue working. They are necessary due to Web IDL [overload resolution algorithm](#) rules, which would throw a `TypeError` exception for such calls had the arguments not been there. [hycam/webidl issue #581](#) investigates changing the algorithm to allow for their removal. ([WEBIDL](#))

The `open(url, name, features)` method must run these steps:

1. If this `Document` object is not an `active_document`, then throw an "`invalidAccessError`" `DOMException`.
2. Return the result of running the `window open steps` with `url`, `name`, and `features`.

8.4.2 Closing the input stream

For web developers (non-normative)

`document.close()`

Closes the input stream that was opened by the `document.open()` method.

Throws an "`invalidStateError`" `DOMException` if the `Document` is an [XML document](#).

Throws an "`invalidStateError`" `DOMException` if the parser is currently executing a `custom element constructor`.

OMN

[Document.close](#)

Support in all current engines.

FirefoxYesSafariYesChrome45+

OperaYesEdge79+

Edge (Legacy)12+Internet Explorer?

[Issue #4477](#) looks into the distinction between an ongoing instance of the `navigate` algorithm versus tasks to `navigate` that are still queued. For the purpose of implementing this step, both an ongoing instance of the `navigate` algorithm and tasks queued to `navigate` should be counted towards "an existing attempt to `navigate`," at least until that issue is resolved.

The `close()` method must run the following steps:

- If the `document` object is an `XMLDocument`, then throw an `"InvalidStateError"` `DOMException`.
- If the `document` object's `throw-on-dynamic-markup-insertion-counter` is greater than zero, then throw an `"InvalidStateError"` `DOMException`.
- If there is no `script-created parser` associated with the document, then return.
- Insert an `explicit "EOF"` character at the end of the parser's `input stream`.
- If there is a `pending parsing-blocking script`, then return.
- Run the tokenizer, processing resulting tokens as they are emitted, and stopping when the tokenizer reaches the `explicit "EOF"` character or `goes the event loop`.

8.4.3 `document.write()`

For web developers (non-normative)

`document.write(text...)`

In general, adds the given string(s) to the `document`'s input stream.

⚠️ Warning!

This method has very idiosyncratic behavior. In some cases, this method can affect the state of the `HTML parser` while the parser is running, resulting in a DOM that does not correspond to the source of the document (e.g. if the string written is the string "`<plaintext>`" or "`<!-->`"). In other cases, the call can clear the current page first, as if `document.open()` had been called. In yet more cases, the method is simply ignored, or throws an exception. User agents are explicitly allowed to avoid executing `script` elements inserted via this method. And to make matters even worse, the exact behavior of this method can in some cases be dependent on network latency, which can lead to failures that are very hard to debug. **For all these reasons, use of this method is strongly discouraged.**

Throws an `"InvalidStateError"` `DOMException` when invoked on `XML documents`.

Throws an `"InvalidStateError"` `DOMException` if the parser is currently executing a `custom element constructor`.

`Document` objects have an `ignore-destructive-writes counter`, which is used in conjunction with the processing of `script` elements to prevent external scripts from being able to use `document.write()` to blow away the document by implicitly calling `document.open()`. Initially, the counter must be set to zero.

The `document.write` steps, given a `Document` object `document` and a string `input`, are as follows:

- If `document` is an `XMLDocument`, then throw an `"InvalidStateError"` `DOMException`.
- If `document`'s `throw-on-dynamic-markup-insertion-counter` is greater than 0, then throw an `"InvalidStateError"` `DOMException`.
- If `document`'s `active_parser` was aborted is true, then return.
- If the `insertion_point` is undefined, then:
 - If `document`'s `ignore-opens-during-unload counter` is greater than 0 or `document`'s `ignore-destructive-writes counter` is greater than 0, then return.
 - Run the `document.open` steps with `document`.
- Insert `input` into the `input stream` just before the `insertion point`.
- If there is no `pending parsing-blocking script`, have the `HTML parser` process `input`, one code point at a time, processing resulting tokens as they are emitted, and stopping when the tokenizer reaches the insertion point or when the processing of the tokenizer is aborted by the tree construction stage (this can happen if a `script` end tag token is emitted by the tokenizer).

Note

If the `document.write()` method was called from script executing inline (i.e. executing because the parser parsed a set of `script` tags), then this is a `recurrent invocation of the parser`. If the `parser pause flag` is set, the tokenizer will abort immediately and no HTML will be parsed, per the tokenizer's `parser.pause flag check`.

MDN

Document/write

Support in all current engines.

Firefox1+ Safari1+ Chrome1+ Chorme1+

Opera3+ Edge79+

Edge (Legacy)12+ Internet Explorer4+

Firfox Android4+ Safari iOS1+ Chrome Android18+ WebView Android1+ Samsung Internet1.0+ Opera Android10.1+

The `document.write(...)` method, when invoked, must run the `document.write steps` with this `document` object and a string that is the concatenation of all arguments passed.

8.4.4 `document.writeln()`

For web developers (non-normative)

`document.writeln(text...)`

Adds the given string(s) to the `document`'s input stream, followed by a newline character. If necessary, calls the `open()` method implicitly first.

Throws an `"InvalidStateError"` `DOMException` when invoked on `XML documents`.

Throws an `"InvalidStateError"` `DOMException` if the parser is currently executing a `custom element constructor`.

MDN

Documentwriteln

Support in all current engines.

FireFoxYes SafariYes Chrome45+

OperaYes Edge79+

Edge (Legacy)12+ Internet Explorer?

Firfox AndroidYes Safari iOSYes Chrome Android45+ WebView Android45+ Samsung Internet5.0+ Opera Android45+

The `document.writeln(...)` method, when invoked, must run the `document.write steps` with this `document` object and a string that is the concatenation of all arguments passed and U+000A LINE FEED.

8.5 DOM parsing

The `DOMParser` interface allows authors to create new `Document` objects by parsing strings, as either HTML or XML.

For web developers (non-normative)

`parser = new DOMParser()`

Constructs a new `DOMParser` object.

`document = parser.parseFromString(string, type)`

Parses `string` using either the HTML or XML parser, according to `type`, and returns the resulting `Document`; `type` can be `"text/html"` (which will invoke the HTML parser), or any of `"text/xml"`, `"application/xml"`, `"application/xhtml+xml"`, or `"image/svg+xml"` (which will invoke the XML parser).

For the XML parser, if `string` can be parsed, then the returned `document` will contain elements describing the resulting error.

Note that `script` elements are not evaluated during parsing, and the resulting document's `encoding` will always be `UTF-8`.

Values other than the above for `type` will cause a `parseError` exception to be thrown.

Note

The design of `DOMParser`, as a class that needs to be constructed and then have its `parseFromString` method called, is an unfortunate historical artifact. If we were designing this functionality today it would be a standalone function.

```
IDI[IExposedWindow]
interface DOMParser {
  [Constructable]
  [Exposed(Windows)]
  (NewObject) Document parseFromString(DOMString string, DOMParserSupportedType type);
}

enum DOMParserSupportedType {
  "text/html",
  "text/xml",
  "application/xml",
  "application/xhtml+xml",
  "image/svg+xml"
}
```

The `DOMParser()` constructor steps are to do nothing.

The `parseFromString(string, type)` method steps are:

- Let `document` be a new `Document`, whose `content_type` is `type` and `url` is this's `relevant global object's associated document`'s `URL`.

Note

The document's `encoding` will be left as its default, of `UTF-8`. In particular, any XML declarations or `meta` elements found while parsing `string` will have no effect.

- Switch on `type`:

1. Set `document`'s `type` to `"html"`.

2. Create an `HTML parser` parser, associated with `document`.

3. Place `string` into the `input stream` for `parser`. The encoding `confidence` is `irrelevant`.

4. Start `parser` and let it run until it has consumed all the characters just inserted into the `input stream`.

Note

This might mutate the document's `node`.

Note

Since `document` does not have a `browsing context`, `scripting is disabled`.

Otherwise

- Create an `XML parser` parse, associated with `document`, and with `XML scripting support disabled`.

2. Parse `string` using `parser`.

3. If the previous step resulted in an XML well-formedness or XML namespace well-formedness error, then:

1. Assert: `document` has no child nodes.

2. Let `root` be the result of `creating an element` given `document`, `"paisajericoz"`, and `"http://www.mozilla.org/newlayout/xml/parserericoz.xml"`.

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

4. [Append](#) root to document.

3. Return document.

8.6 Timers

The `setTimeout()` and `setInterval()` methods allow authors to schedule timer-based callbacks.

For web developers (non-normative)

`handle = self.setTimeout(handler [, timeout [, arguments...]])`

Schedules a timeout to run `handler` after `timeout` milliseconds. Any `arguments` are passed straight through to the `handler`.

`handle = self.setInterval(code [, timeout])`

Schedules a timeout to compile and run `code` after `timeout` milliseconds.

`self.clearTimeout(handle)`

Cancels the timeout set with `setTimeout()` or `setInterval()` identified by `handle`.

`handle = self.setInterval(handler [, timeout [, arguments...]])`

Schedules a timeout to run `handler` every `timeout` milliseconds. Any `arguments` are passed straight through to the `handler`.

`handle = self.setInterval(code [, timeout])`

Schedules a timeout to compile and run `code` every `timeout` milliseconds.

`self.clearInterval(handle)`

Cancels the timeout set with `setInterval()` or `setTimeout()` identified by `handle`.

Note

Timers can be nested; after five such nested timers, however, the interval is forced to be at least four milliseconds.

Note

This API does not guarantee that timers will run exactly on schedule. Delays due to CPU load, other tasks, etc, are to be expected.

Objects that implement the `WindowOrWorkerGlobalScope` mixin have a *list of active timers*. Each entry in this lists is identified by a number, which must be unique within the list for the lifetime of the object that implements the `WindowOrWorkerGlobalScope` mixin.

The `clearTimeout()` and `clearInterval()` methods must clear the entry identified as `handle` from the `list of active timers` of the `WindowOrWorkerGlobalScope` object on which the method was invoked, if any, where `handle` is the argument passed to the method. (If `handle` does not identify an entry in the `list of active timers` of the `WindowOrWorkerGlobalScope` object on which the method was invoked, the method does nothing.)

Note

Because `clearTimeout()` and `clearInterval()` clear entries from the same list, either method can be used to clear timers created by `setTimeout()` or `setInterval()`.

The timer initialization steps, which are invoked with some method arguments, a `method context`, a `repeat` flag which can be true or false, and optionally (and only if the `repeat` flag is true) a previous `handle`, are as follows:

1. Let `method context proxy` be `method context` if that is a `WorkerGlobalScope` object, or else the `WindowProxy` that corresponds to `method context`.

2. If `previous handle` was provided, let `handle` be `previous handle`; otherwise, let `handle` be a user-agent-defined integer that is greater than zero that will identify the timeout to be set by this call in the `list of active timers`.

3. If `previous handle` was not provided, add an entry to the `list of active timers` for `handle`.

4. Let `callerRealm` be the `current Realm Record`, and `calleeRealm` be `method context's JavaScript realm`.

5. Let `initiating script` be the `active script`.

6. Assert: `initiating script` is not null, since this algorithm is always called from some script.

7. Let `task` be a `task` that runs the following substeps:

1. If the entry for `handle` in the `list of active timers` has been cleared, then abort these steps.

If the first method argument is a [Function](#)
 Invoke the [Function](#). Use the third and subsequent method arguments (if any) as the arguments for invoking the [Function](#). Use [method context](#) proxy as the [callback this value](#).
 Otherwise
 1. Perform `HostEnsureCanCompileString(callerRealm, calleeRealm)`. If this throws an exception, catch it, [report the exception](#), and abort these steps.
 2. Let `script source` be the first method argument.
 3. Let `settings object` be `method context's environment settings object`.
 4. Let `base URL` be initiating script's `base URL`.
 5. Let `fetch options` be a `script fetch options` whose `cryptographic nonce` is *initiating script's fetch options' cryptographic nonce*, `integrity metadata` is the empty string, `parser metadata` is "not-parsed-inserted", `credentials mode` is *initiating script's fetch options' credentials mode*, and `referrer policy` is *initiating script's fetch options' referrer policy*.
 Note
 The effect of these options ensures that the string compilation done by `setTimeOut()` and `setInterval()` behaves equivalently to that done by `setTimeout()`. That is, `module script` fetches via `import()` will behave the same in both contexts.
 6. Let `script` be the result of `creating a classic script` given `script source`, `settings object`, `base URL`, and `fetch options`.
 7. [Run the classic script](#) `script`.
 3. If the `repeat` flag is true, then call [timer initialization steps](#) again, passing them the same method arguments, the same `method context`, with the `repeat` flag still set to true, and with the `previous handle` set to `handler`.
 8. Let `timeout` be the second method argument.
 9. If the currently running `task` is a task that was created by this algorithm, then let `nesting level` be the `task's timer nesting level`. Otherwise, let `nesting level` be zero.
 Note
 The task's `timer nesting level` is used both for nested calls to `setTimeout()`, and for the repeating timers created by `setInterval()`. (Or, indeed, for any combination of the two.) In other words, it represents nested invocations of this algorithm, not of a particular method.
 10. If `timeout` is less than 0, then set `timeout` to 0.
 11. If `nesting level` is greater than 5, and `timeout` is less than 4, then set `timeout` to 4.
 12. Increment `nesting level` by one.
 13. Let `task's timer nesting level` be `nesting level`.
 14. Return `handle`, and then continue running this algorithm [in parallel](#).
 15. If `method context` is a `Window` object, wait until the `document` associated with `method context` has been [fully active](#) for a further `timeout` milliseconds (not necessarily consecutively).
 Otherwise, `method context` is a `WorkerGlobalScope` object; wait until `timeout` milliseconds have passed with the worker not suspended (not necessarily consecutively).
 16. Wait until any invocations of this algorithm that had the same `method context`, that started before this one, and whose `timeout` is equal to or less than this one's, have completed.
 Note
 Argument conversion as defined by Web IDL (for example, invoking `toString()` methods on objects passed as the first argument) happens in the algorithms defined in Web IDL, before this algorithm is invoked.
Example
 So for example, the following rather silly code will result in the log containing "ONE TWO".

```
var log = '';
function logger(s) { log += s + ' ' }

setTimeOut(toString: function () {
  setTimeOut("logger('ONE')", 100);
  return "logger('TWO')";
}, 100);
```

 17. Optionally, wait a further user-agent defined length of time.
 Note
 This is intended to allow users to pad timeouts as needed to optimize the power usage of the device. For example, some processors have a low-power mode where the granularity of timers is reduced; on such platforms, user agents can slow timers down to fit this schedule instead of requiring the processor to use the more accurate mode with its associated higher power usage.
 18. [Queue the task](#).

Note
 Once the task has been processed, if the `repeat` flag is false, it is safe to remove the entry for `handle` from the [list of active timers](#) (there is no way for the entry's existence to be detected past this point, so it does not technically matter one way or the other).

The `task source` for these `tasks` is the `timer task source`.

Example
 To run tasks of several milliseconds back to back without any delay, while still yielding back to the browser to avoid starving the user interface (and to avoid the browser killing the script for hogging the CPU), simply queue the next timer before performing work:

```
function doExpensiveWork() {
  var done = false;
  // ...
  // This part of the function takes up to five milliseconds
  // // set done to true if we're done
  // ...
  // return done;
}

function rescheduleWork() {
  var handle = setTimeOut(rescheduleWork, 0); // preschedule next iteration
  if (doExpensiveWork())
    clearTimeOut(handle); // clear the timeout if we don't need it
}

function scheduleWork() {
  setTimeOut(rescheduleWork, 0);
}
scheduleWork(); // queues a task to do lots of work
```

8.7 Microtask queuing

MDN

[WindowOrWorkerGlobalScope/queueMicrotask](#)

Support in all current engines

Firefox69+Safari12.1+Chrome71+

Opera58+Edge79+

Edge (Legacy)NoInternet ExplorerNo

Firefox Android/NoSafari iOS12.2+Chrome Android71+WebView Android71+Samsung Internet10.0+Opera Android50+

For web developers (non-normative)

`self.queueMicrotask(callback)`

Queues a microtask to run the given callback.

The `queueMicrotask(callback)` method must [queue a microtask](#) to [invoke](#) `callback`, and if `callback` throws an exception, [report the exception](#).

The `queueMicrotask()` method allows authors to schedule a callback on the [microtask queue](#). This allows their code to run after the currently-executing `task` has run to completion and the [JavaScript execution context stack](#) is empty, but without yielding control back to the [event loop](#), as would be the case when using, for example, `setTimeout(f, 0)`.

Authors ought to be aware that scheduling a lot of microtasks has the same performance downsides as running a lot of synchronous code. Both will prevent the browser from doing its own work, such as rendering or scrolling. In many cases, `requestAnimationFrame()` or `requestIdleCallback()` is a better choice. In particular, if the goal is to run code before the next rendering cycle, that is the purpose of `requestAnimationFrame()`.

As can be seen from the following examples, the best way of thinking about `queueMicrotask()` is as a mechanism for rearranging synchronous code, effectively placing the queued code immediately after the current task's worth of non-queued JavaScript.

Example

The most common reason for using `queueMicrotask()` is to create consistent ordering, even in the cases where information is available synchronously, without introducing undue delay.

For example, consider a custom element firing a `load` event, that also maintains an internal cache of previously-loaded data. A naive implementation might look like:

```
Element.prototype.loadData = function(url) {
  if (!this._cache[url])
    this._setData(this._cache[url]);
  this.dispatchEvent(new Event("load"));
  else
    fetch(url).then(res => res.arrayBuffer()).then(data => {
      this._cache[url] = data;
      this._setData(data);
      this.dispatchEvent(new Event("load"));
    });
}
```

This naive implementation is problematic, however, in that it causes users to experience inconsistent behavior. For example, code such as

```
element.addEventListener("load", () => console.log("loaded"));
element.addEventListener("load", () => console.log("loaded"));
element.loadData();
console.log("?"');
```

will sometimes log "1,2, loaded" (if the data needs to be fetched), and sometimes log "1, loaded, 2" (if the data is already cached). Similarly, after the call to `loadData()`, it will be inconsistent whether or not the data is set on the element.

To get a consistent ordering, `queueMicrotask()` can be used:

```
Element.prototype.loadData = function(url) {
  if (!this._cache[url])
    queueMicrotask(() => {
      this._setData(this._cache[url]);
      this.dispatchEvent(new Event("load"));
    });
  else
    fetch(url).then(res => res.arrayBuffer()).then(data => {
      this._cache[url] = data;
      this._setData(data);
      this.dispatchEvent(new Event("load"));
    });
}
```

By essentially rearranging the queued code to be after the currently-executing task, this ensures a consistent ordering and update of the element's state.

```
const queuedToSend = [];

function sendData(data) {
  queuedToSend.push(data);

  if (queuedToSend.length === 1) {
    const stringToSend = JSON.stringify(queuedToSend);
    queuedToSend.length = 0;
    fetch("/endpoint", stringToSend);
  }
}

With this architecture, multiple subsequent calls to sendData() within the same turn of the event loop will be batched together into one fetch() call, but with no intervening event loop tasks preempting the fetch (as would have happened with similar code that instead used setInterval()).
```

8.8 User prompts

8.8.1 Simple dialogs

For web developers (non-normative)

`window.alert(message)`

Displays a modal alert with the given message, and waits for the user to dismiss it.

`result = window.confirm(message)`

Displays a modal OK/Cancel prompt with the given message, waits for the user to dismiss it, and returns true if the user clicks OK and false if the user clicks Cancel.

`result = window.prompt(message [, default])`

Displays a modal text control prompt with the given message, waits for the user to dismiss it, and returns the value that the user entered. If the user cancels the prompt, then returns null instead. If the second argument is present, then the given value is used as a default.

Note

Logic that depends on `tasks` or `microtasks`, such as `media elements` loading their `media data`, are stalled when these methods are invoked.

To *optionally truncate a simple dialog string s*, return either s itself or some string derived from s that is shorter. User agents should not provide UI for displaying the elided portion of s, as this makes it too easy for abusers to create dialogs of the form "Important security alert! Click 'Show More' for full details!".

Note
For example, a user agent might want to only display the first 100 characters of a message. Or, a user agent might replace the middle of the string with "...". These types of modifications can be useful in limiting the abuse potential of unnaturally large, trustworthy-looking system dialogs.

MDN

Window.alert

Support in all current engines.

Firefox1+Safari1+Chrome1+

The `prompt(message, default)` method, when invoked, must run the following steps:

- If the `event loop's termination nesting level` is nonzero, optionally return null.
- If the `active sandboxing flag` set of this `Window` object's `associated document` has the `sandboxed modals` flag set, then return.
- Optionally, return null. (For example, the user agent might give the user the option to ignore all prompts, and would thus abort at this step whenever the method was invoked.)
- Set `message` to the result of `optionally truncating` `message`.
- Set `message` to the result of `normalizing newlines` given `message`.
- Set `default` to the result of `optionally truncating` `default`.
- Show `message` to the user, treating U+000A LF as a line break, and ask the user to either respond with a string value or abort. The response must be defaulted to the value given by `default`.
- `Pause` while waiting for the user's response.
- If the user aborts, then return null; otherwise, return the string that the user responded with.

8.8.2 Printing

MDN

Window/print

Support in all current engines.

Firefox1+Safari1.1+Chrome1+

Opera6+Edge79+

Edge (Legacy)12+Internet Explorer5+

Firefox AndroidNoSafari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android10.1+

For web developers (non-normative)

`window.print()`

Prompts the user to print the page.

When the `print()` method is invoked, if the `document` is `ready for post-load tasks`, then the user agent must run the `printing steps`. Otherwise, the user agent must only set the `print when loaded` flag on the `document`.

User agents should also run the `printing steps` whenever the user asks for the opportunity to `obtain a physical form` (e.g. printed copy), or the representation of a physical form (e.g. PDF copy), of a document.

The `printing steps` are as follows:

Example	For instance, a kiosk browser could silently ignore any invocations of the <code>print()</code> method.
Example	For instance, a browser on a mobile device could detect that there are no printers in the vicinity and display a message saying so before continuing to offer a "save to PDF" option.
2.	If the <code>active sandboxing flag set</code> of this <code>Window</code> object's <code>associated Document</code> has the <code>sandboxed modal</code> flag set, then return.
Note	If the printing dialog is blocked by a <code>Document</code> 's sandbox, then neither the <code>beforeprint</code> nor <code>afterprint</code> events will be fired.
3.	The user agent must <code>fire an event</code> named <code>beforeprint</code> at the <code>relevant global object</code> of the <code>Document</code> that is being printed, as well as any <code>child browsing contexts</code> in it.
Example	The <code>beforeprint</code> event can be used to annotate the printed copy, for instance adding the time at which the document was printed.
4.	The user agent should offer the user the opportunity to <code>obtain a physical form</code> (or the representation of a physical form) of the document. The user agent may wait for the user to either accept or decline before returning; if so, the user agent must <code>pause</code> while the method is waiting. Even if the user agent doesn't wait at this point, the user agent must use the state of the relevant documents as they are at this point in the algorithm if and when it eventually creates the alternate form.
5.	The user agent must <code>fire an event</code> named <code>afterprint</code> at the <code>relevant global object</code> of the <code>Document</code> that is being printed, as well as any <code>child browsing contexts</code> in it.
Example	The <code>afterprint</code> event can be used to revert annotations added in the earlier event, as well as showing post-printing UI. For instance, if a page is walking the user through the steps of applying for a home loan, the script could automatically advance to the next step after having printed a form or other.

8.9 System state and capabilities

8.9.1 The `navigator` object

OMN	
Navigator	
Support in all current engines.	
Firefox1+Safari1+Chrome1+	
Opera3+Edge79+	
Edge (Legacy)12+Internet Explorer4+	
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android10.1+	
OMN	
Window.navigator	
Support in all current engines.	
Firefox1+Safari1+Chrome1+	
Opera3+Edge79+	
Edge (Legacy)12+Internet Explorer4+	
Firefox Android4+Safari iOS1+Chrome Android18+WebView Android1+Samsung Internet1.0+Opera Android10.1+	

The `navigator` attribute of the `Window` interface must return an instance of the `Navigator` interface, which represents the identity and state of the user agent (the client), and allows Web pages to register themselves as potential protocol handlers:

```
IDL [Exposed=Window]
interface Navigator {
  // Note: any interface implementing this interface also implement the interfaces given below
};

Navigator includes NavigatorID;
Navigator includes NavigatorLanguage;
Navigator includes NavigatorOnLine;
Navigator includes NavigatorPlatform;
Navigator includes NavigatorCookies;
Navigator includes NavigatorPlugins;
Navigator includes NavigatorConcurrencyHardware;
```

This interface mixins are defined separately so that `WorkerNavigator` can re-use parts of the `navigator` interface.

8.9.1.1 Client identification

OMN	
Navigator	
Support in all current engines.	
FirefoxYesSafariYesChromeYes	
OperaYesEdgeYes	
Edge (Legacy)12+Internet ExplorerYes	
Firefox AndroidYes Safari iOSYes Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidYes	
OMN	
NavigatorID	
readonly attribute DOMString appCodeName; // constant "Mozilla" readonly attribute DOMString appName; // constant "Netscape" readonly attribute DOMString appVersion; readonly attribute DOMString platform; readonly attribute DOMString productSub; [Exposed=Window] readonly attribute DOMString product; [Exposed=Window] readonly attribute DOMString vendor; [Exposed=Window] readonly attribute DOMString vendorSub; // constant "" };	

In certain cases, despite the best efforts of the entire industry, Web browsers have bugs and limitations that Web authors are forced to work around.

This section defines a collection of attributes that can be used to determine, from script, the kind of user agent in use, in order to work around these issues.

The user agent has a *navigator compatibility mode*, which is either *Chrome*, *Gecko*, or *WebKit*.

Note

The `navigator compatibility mode` constrains the `NavigatorID` interface to the combinations of attribute values and presence of `paintEnabled()` and `open()` that are known to be compatible with existing Web content.

Client detection should always be limited to detecting known current versions; future versions and unknown versions should always be assumed to be fully compliant.

For web developers (non-normative)

```
self.navigator.appName
  Returns the string "Mozilla".
self.navigator.appName
  Returns the string "Netscape".
self.navigator.userAgent
  Returns the version of the browser.
self.navigator.platform
  Returns the name of the platform.
self.navigator.product
  Returns the string "Gecko".
window.navigator.productSub
  Returns either the string "20030107", or the string "20100101".
self.navigator.userAgent
  Returns the complete "User-Agent" header.
window.navigator.vendor
  Returns either the empty string, the string "Apple Computer, Inc.", or the string "Google Inc.".
window.navigator.vendorSub
  Returns the empty string.

[Navigator/vendorSub](#)

Support in all current engines.

FirefoxYes SafariYes ChromeYes

Opera15+ EdgeYes

Edge (Legacy)12+ Internet ExplorerYes

Firefox AndroidYes Safari iOSYes Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera Android14+

Must return the empty string.

If the `navigator compatibility mode` is `Gecko`, then the user agent must also support the following partial interface:

```
IDLPartial Interface mixin NavigatorID {
    [Exposed=Window] boolean taintEnabled(); // constant false
    [Exposed=Window] readonly attribute DOMString userAgent;
}
```

The `taintEnabled()` method must return `false`.

The `userAgent` attribute's getter must return either the empty string or a string representing the platform on which the browser is executing, e.g. "Windows NT 10.0; Win64; x64", "Linux x86_64".

Any information in this API that varies from user to user can be used to profile the user. In fact, if enough such information is available, a user can actually be uniquely identified. For this reason, user agent implementers are strongly urged to include as little information in this API as possible.

8.9.1.2 Language preferences

MDN

[NavigatorLanguage](#)

Support in all current engines.

Firefox1+Safari1+Chrome1+

Opera4+Edge79+

Edge (Legacy)12+ Internet Explorer11

```
IDLInterface mixin NavigatorLanguage {
  readonly attribute DOMString language;
  readonly attribute FrozenArray<DOMString> languages;
};
```

For web developers (non-normative)

`self.navigator.language`

Returns a language tag representing the user's preferred language.

`self.navigator.languages`

Returns an array of language tags representing the user's preferred languages, with the most preferred language first.

The most preferred language is the one returned by `navigator.language`.

Note

A `languagechange` event is fired at the `Window` or `WorkerGlobalScope` object when the user agent's understanding of what the user's preferred languages are changes.

`language`

MDN

`NavigatorLanguage.languages`

Support in all current engines.

Firefox+1+Safari+1+Chrome+18+WebView+Android+1+Samsung+Internet+1.0+Opera+Android+10.1+

Must return a valid BCP 47 language tag representing either a `plausible language` or the user's most preferred language. [BCP47]

`languages`

MDN

`NavigatorLanguage.languages`

Support in all current engines.

Firefox+32+Safari+11+Chrome+32+

Opera+24+Edge+79+

Edge (Legacy)+12+Internet Explorer+11

Firefox+Android+4+Safari+iOS+Chrome+Android+32+WebView+Android+4.3+Samsung+Internet+2.0+Opera+Android+24+

Must return a `frozen array` of valid BCP 47 language tags representing either one or more `plausible languages`, or the user's preferred languages, ordered by preference with the most preferred language first. The same object must be returned until the user agent needs to return different values, or values in a different order. [BCP47]

Whenever the user agent needs to make the `navigator.languages` attribute of a `Window` or `WorkerGlobalScope` object return a new set of language tags, the user agent must `queue a task` to `fire an event` named `languagechange` at the `Window` or `WorkerGlobalScope` object and wait until that task begins to be executed before actually returning a new value.

The `task source` for this `task` is the `DOM manipulation task source`.

To determine a `plausible language`, the user agent should bear in mind the following:

Any information in this API that varies from user to user can be used to profile or identify the user.

If the user is not using a service that obfuscates the user's point of origin (e.g. the Tor anonymity network), then the value that is least likely to distinguish the user from other users with similar origins (e.g. from the same IP address block) is the language used by the majority of such users. [TOR]

If the user is using an anonymizing service, then the value "`en-US`" is suggested; if all users of the service use that same value, that reduces the possibility of distinguishing the users from each other.

To avoid introducing any more fingerprinting vectors, user agents should use the same list for the APIs defined in this function as for the HTTP `'Accept-Language'` header.

8.9.1.3 Custom scheme handlers: the `registerProtocolHandler()` method

[

Support: registerProtocolHandlerChrome for Android NonChrome 13+iOS Safari NonSafari NonFirefox 3+Samsung Internet NoneEdge 79+UC Browser for Android NonIE NonOpera 11.6+Opera Mini NonFirefox for Android None

Source: [caniuse.com](#)

MDN

`Navigator/registerProtocolHandler`

Firefox+3+Safari?Chrome+13+

Opera+11.6+Edge+79+

Edge (Legacy)?NoInternet Explorer?

Firefox+Android+4+Safari+iOS+Chrome+Android+Yes+WebView+Android+No+Samsung+Internet+Yes+Opera+Android?

```
IDLInterface mixin NavigatorContentUtils {
  [SecureContext] void registerProtocolHandler(DOMString scheme, USVString url, DOMString title);
  [SecureContext] void unregisterProtocolHandler(DOMString scheme, USVString url);
};
```

The `registerProtocolHandler()` method allows Web sites to register themselves as possible handlers for particular schemes. For example, an online telephone messaging service could register itself as a handler of the `psa` scheme, so that if the user clicks on such a link, they are given the opportunity to use that web site. [SMS]

For web developers (non-normative)

`window.navigator.registerProtocolHandler(scheme, url, title)`

Registers a handler for the given scheme, at the given URL, with the given title.

The string "`*`" in the URL is used as a placeholder for where to put the URL of the content to be handled.

Throws a `"SecurityError"` `PDMException` if the user agent blocks the registration (this might happen if trying to register as a handler for "http", for instance).

Throws a `"SyntaxError"` `PDMException` if the "`*`" string is missing in the URL.

User agents may, within the constraints described in this section, do whatever they like when the method is called. A UA could, for instance, prompt the user and offer the user the opportunity to add the site to a shortlist of handlers, or make the handlers their default, or cancel the request. UAs could provide such a UI through modal UI or through a non-modal transient notification interface. UAs could also simply silently collect the information, providing it only when relevant to the user.

User agents should keep track of which sites have registered handlers (even if the user has declined such registrations) so that the user is not repeatedly prompted with the same request.

The arguments to the method have the following meanings and corresponding implementation requirements. The requirements that involve throwing exceptions must be processed in the order given below, stopping at the first exception thrown. (So the exceptions for the first argument take precedence over the exceptions for the second argument.)

scheme

A scheme, such as "`mailto`" or "`web-auth`". The scheme must be compared in an `ASCII case-insensitive` manner by user agents for the purposes of comparing with the scheme part of URLs that they consider against the list of registered handlers.

The `scheme` value, if it contains a colon (as in "`mailto:*`"), will never match anything, since schemes don't contain colons.

If the `registerProtocolHandler()` method is invoked with a scheme that is neither a `safelisted scheme` nor a scheme whose value starts with the substring "`web-`" and otherwise contains only `ASCII lower alphas`, and whose length is at least five characters (including the "`web-`" prefix), the user agent must throw a `"SecurityError"` `PDMException`.

The following schemes are the `safelisted schemes`:

- bitcoin
- geo
- im
- irc
- ircs
- https
- mailto
- sms
- news
- nntp
- sftp
- shttp
- ssh
- smsto
- ssh
- tel
- teln
- telnet
- vbscript
- wsd
- xmpp

Note

This list can be changed. If there are schemes that ought to be added, please send feedback.

Note

This list excludes any schemes that could reasonably be expected to be supported inline, e.g. in an `iframe`, such as `http` or (more theoretically) `gopher`. If those were supported, they could potentially be used in man-in-the-middle attacks, by replacing pages that have frames with such content with content under the control of the protocol handler. If the user agent has native support for the schemes, this could further be used for cookie-theft attacks.

url

A string used to build the `URL` of the page that will handle the requests.

User agents must throw a `"SyntaxError"` `PDMException` if the `url` argument passed to one of these methods does not contain the exact literal string "`*`".

User agents must throw a `"SyntaxError"` `PDMException` if `parseing` the `url` argument relative to the `relevant settings object` of this `NavigatorContentUtils` object is not successful.

Note

The `resulting URL` string would by definition not be a `valid URL string` as it would include the string "`*`" which is not a valid component in a URL.

User agents must throw a `"SecurityError"` `PDMException` if the `resulting URL` record has an `origin` that differs from the `origin` specified by the `relevant settings object` of this `NavigatorContentUtils` object.

Note

This is forcibly the case if the `url` placeholder is in the scheme, host, or port parts of the URL.

The `resulting URL` string is the `proto-URL`. It identifies the handler for the purposes of the methods described below.

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

`registerProtocolHandler()` method was invoked, and then `navigate` an appropriate `browsing context` to the resulting URL.

To get the escaped version of the `absolute URL` of the content in question, the user agent must replace every character in that `absolute URL`, that is not a character in the URL `default encode set` with the result of `UTF-8 percent encoding` that character.

Example

```
If the user had visited a site at https://example.com/ that made the following call:  
navigator.registerProtocolHandler("web-soup", "soup?url=%s", "SoupWeb")  
...and then, much later, while visiting https://www.example.net/, clicked on a link such as:  
Download our Chicken Kiwi soup!  
...then the UA might navigate to the following URL:  
https://example.com/soup?url=web-soup;chicken=%C3%A9AFw1  
This site could then do whatever it is that it does with soup (synthesize it and ship it to the user, or whatever).
```

title

A descriptive title of the handler, which the UA might use to remind the user what the site in question is.

This section does not define how the pages registered by this method are used, beyond the requirements on how to process the `url` value (see above). To some extent, the [processing model for navigating across documents](#) defines some cases where these methods are relevant, but in general UAs may use this information wherever they would otherwise consider handing content to native plugins or helper applications.

In addition to the registration method, there is also a method for unregistering handlers.

For web developers (non-normative)
`window.navigator.unregisterProtocolHandler(scheme, url)`
Unregisters the handler given by the arguments.

The `unregisterProtocolHandler()` method must unregister the handler described by the two arguments to the method, where the first argument gives the scheme and the second gives the string used to build the `URL` of the page that will handle the requests.

The first argument must be compared to the schemes for which custom protocol handlers are registered in an [ASCII case-insensitive](#) manner to find the relevant handlers.

The second argument must be preprocessed as described below, and if that is successful, must then be matched against the `proto-URLs` of the relevant handlers to find the described handler.

The second argument must be preprocessed as follows:

1. If the string does not contain the substring "%s", then return. There's no matching handler.
2. Parse the string relative to the `relevantSettingsObject` of this `NavigatorContentUtils` object. If this fails, then throw a `"SyntaxError"` `DOMException`.
3. If the resulting `URL` record's `origin` is not the `same origin` as the `origin` of the `relevantSettingsObject` of this `NavigatorContentUtils` object, then throw a `"SecurityError"` `DOMException`.
4. Return the `resultingURLString` as the result of preprocessing the argument.

8.5.1.1 Security and privacy

Custom scheme handlers can introduce a number of concerns, in particular privacy concerns.

Hijacking all Web usage. User agents should not allow schemes that are key to its normal operation, such as an [\(HTTPS\)scheme](#), to be rerouted through third-party sites. This would allow a user's activities to be trivially tracked, and would allow user information, even in secure connections, to be collected.

Hijacking defaults. User agents are strongly urged to not automatically change any defaults, as this could lead the user to send data to remote hosts that the user is not expecting. New handlers registering themselves should never automatically cause those sites to be used.

Registration spamming. User agents should consider the possibility that a site will attempt to register a large number of handlers, possibly from multiple domains (e.g., by redirecting through a series of pages each on a different domain, and each registering a handler for `wab+span`: — analogous practices abusing other web browser features have been used by pornography Web sites for many years). User agents should gracefully handle such hostile attempts, protecting the user.

Misleading titles. User agents should not rely wholly on the `title` argument to the method when presenting the registered handlers to the user, since sites could easily lie. For example, a site `hostile.example.net` could claim that it was registering the "Cuddly Bear Happy Scheme Handler". User agents should therefore use the handler's origin in any UI along with any title.

Hostile handler metadata. User agents should protect against typical attacks against strings embedded in their interface, for example ensuring that markup or escape characters in such strings are not executed, that null bytes are properly handled, that over-long strings do not cause crashes or buffer overruns, and so forth.

Leaking private data. Web page authors may reference a custom scheme handler using URL data considered private. They might do so with the expectation that the user's choice of handler points to a page inside the organization, ensuring that sensitive data will not be exposed to third parties. However, a user may have registered a handler pointing to an external site, resulting in a data leak to that third party. Implementors might wish to consider allowing administrators to disable custom handlers on certain subdomains, content types, or schemes.

Leaking credentials. User agents must never send username or password information in the URLs that are escaped and included sent to the handler sites. User agents may even avoid attempting to pass to Web-based handlers the URLs of resources that are known to require authentication to access, as such sites would be unable to access the resources in question without prompting the user for credentials themselves (a practice that would require the user to know whether to trust the third-party handler, a decision many users are unable to make or even understand).

Interface interference. User agents should be prepared to handle intentionally long arguments to the methods. For example, if the user interface exposed consists of an "accept" button and a "deny" button, with the "accept" binding containing the name of the handler, it's important that a long name not cause the "deny" button to be pushed off the screen.

8.9.1.4 Cookies

```
IDLInterface mixin NavigatorCookieControl {
  [readonly] attribute boolean cookieEnabled;
};
```

For web developers (non-normative)
`window.navigator.cookieEnabled`
Returns false if setting a cookie will be ignored, and true otherwise.

  readonly attribute Plugin? hiddenPlugin;
};

For web developers (non-normative)
window.navigator.plugins.refresh() [refresh]

Updates the lists of supported plugins and MIME types for this page, and reloads the page if the lists have changed.

window.navigator.plugins.length
Returns the number of plugins, represented by Plugin objects, that the user agent reports.

plugin = window.navigator.plugins.item(index)
window.navigator.plugins[index]
Returns the specified Plugin object.

plugin = window.navigator.plugins.item(name)
window.navigator.plugins[name]
Returns the Plugin object for the plugin with the given name.

window.navigator.mimeTypes.length
Returns the number of MIME types, represented by MimeType objects, supported by the plugins that the user agent reports.

MimeType = window.navigator.mimeTypes.item(index)
window.navigator.mimeTypes[index]
Returns the specified MimeType object.

MimeType = window.navigator.mimeTypes.item(name)
window.navigator.mimeTypes[name]
Returns the MimeType object for the given MIME type.

plugin.name
Returns the plugin's name.

plugin.description
Returns the plugin's description.

plugin.filename
Returns the plugin library's filename, if applicable on the current platform.

plugin.length
Returns the number of MIME types, represented by MimeType objects, supported by the plugin.

MimeType = plugin.item(index)
plugin[index]
Returns the specified MimeType object.

MimeType = plugin.item(name)
plugin[name]
Returns the MimeType object for the given MIME type.

MimeType.type
Returns the MIME type.

MimeType.description
Returns the MIME type's description.

MimeType.suffixes
Returns the MIME type's typical file extensions, in a comma-separated list.

MimeType.enabledPlugin
Returns the Plugin object that implements this MIME type.

window.navigator.javaEnabled()
Returns true if there's a plugin that supports the MIME type "application/x-java-vm".

```

AMDN**NavigatorPlugins/plugins**

Support in one engine only.

Firefox?Safari?ChromeYes

Opera?EdgeYes

Edge (Legacy)NoInternet Explorer?

Firefox Android?Safari iOS?Chrome AndroidYesWebView AndroidYesSamsung InternetYesOpera Android?

The `navigator.plugins` attribute must return a PluginArray object.**AMDN****NavigatorPlugins/mimeTypes**

Support in one engine only.

Firefox?Safari?ChromeYes

Opera?EdgeYes

Edge (Legacy)NoInternet Explorer?

Firefox Android?Safari iOS?Chrome AndroidYesWebView AndroidYesSamsung InternetYesOpera Android?

The `navigator.mimeTypes` attribute must return a MimeTypeArray object.A PluginArray object represents none, some, or all of the plugins supported by the user agent, each of which is represented by a Plugin object. Each of these Plugin objects may be hidden plugins. A hidden plugin can't be enumerated, but can still be inspected by using its name.**Note**

The fewer plugins are represented by the PluginArray object, and of those, the more that are hidden, the more the user's privacy will be protected. Each exposed plugin increases the number of bits that can be derived for fingerprinting. Hiding a plugin helps, but unless it is an extremely rare plugin, it is likely that a site attempting to derive the list of plugins can still determine whether the plugin is supported or not by probing for it by name (the names of popular plugins are widely known). Therefore not exposing a plugin at all is preferred. Unfortunately, many legacy sites use this feature to determine, for example, which plugin to use to play video. Not exposing any plugins at all might therefore not be entirely private.

The PluginArray objects created by a user agent must not be live. The set of plugins represented by the objects must not change once an object is created, except when it is updated by the refresh() method.Each plugin represented by a PluginArray can support a number of MIME types. For each such plugin, the user agent must pick one or more of these MIME types to be those that are explicitly supported.**Note**

The explicitly supported MIME types of a plugin are those that are exposed through the Plugin and MimeTypeArray interfaces. As with plugins themselves, any variation between users regarding what is exposed allows sites to fingerprint users. User agents are therefore encouraged to expose the same MIME types for all users of a plugin, regardless of the actual types supported... at least, within the constraints imposed by compatibility with legacy content.

The supportedPropertyIndices of a PluginArray object are the numbers from zero to the number of non-hidden plugins represented by the object, if any.The length attribute must return the number of non-hidden plugins represented by the object.The item() method of a PluginArray object must return null if the argument is not one of the object's supportedPropertyIndices, and otherwise must return the result of running the following steps, using the method's argument as index:

1. Let list be the Plugin objects representing the non-hidden plugins represented by the PluginArray object.
2. Sort list alphabetically by the name of each Plugin.
3. Return the indexth entry in list.

NoteIt is important for privacy that the order of plugins not leak additional information, e.g., the order in which plugins were installed.

The `supportedPropertyNames` of a `PluginArray` object are the values of the `name` attributes of all the `Plugin` objects represented by the `PluginArray` object.

The `namedItem()` method of a `PluginArray` object must return null if the argument is not one of the object's `supportedPropertyNames`, and otherwise must return the `Plugin` object, of those represented by the `PluginArray` object, that has a `name` equal to the method's argument.

The `refresh()` method of the `PluginArray` object of a `navigator` object, when invoked, must check to see if any `plugins` have been installed or reconfigured since the user agent created the `PluginArray` object. If so, and the method's argument is true, then the user agent must act as if the `location.reload()` method was called instead. Otherwise, the user agent must update the `PluginArray` object and `MimeTypeArray` object created for attributes of that `navigator` object, and the `Plugin` and `MimeType` objects created for those `PluginArray` and `MimeTypeArray` objects, using the same `Plugin` objects for cases where the `name` is the same, and the same `MimeType` objects for cases where the `type` is the same, and creating new objects for cases where there were no matching objects immediately prior to the `refresh()` call. Old `Plugin` and `MimeType` objects must continue to return the same values that they had prior to the update, though naturally now the data is stale and may appear inconsistent (for example, an old `MimeType` entry might list as its `enabledPlugin` a `Plugin` object that no longer lists that `MimeType` as a supported `MimeType`).

A `MimeTypeArray` object represents the `MIME types explicitly supported` by `plugins` supported by the user agent, each of which is represented by a `MimeType` object.

The `MimeTypeArray` objects created by a user agent must not be `live`. The set of MIME types represented by the objects must not change once an object is created, except when it is updated by the `PluginArray` object's `refresh()` method.

The `supportedPropertyIndices` of a `MimeTypeArray` object are the numbers from zero to the number of `MIME types explicitly supported` by non-hidden `plugins` represented by the corresponding `PluginArray` object, if any.

The `length` attribute must return the number of `MIME types explicitly supported` by non-hidden `plugins` represented by the corresponding `PluginArray` object, if any.

The `item()` method of a `MimeTypeArray` object must return null if the argument is not one of the object's `supportedPropertyIndices`, and otherwise must return the result of running the following steps, using the method's argument as `index`:

1. Let `list` be the `MimeType` objects representing the `MIME types explicitly supported` by non-hidden `plugins` represented by the corresponding `PluginArray` object, if any.
2. Sort `list` alphabetically by the `type` of each `MimeType`.
3. Return the `index`th entry in `list`.

Note
It is important for privacy that the order of MIME types not leak additional information, e.g., the order in which plugins were installed.

The `supportedPropertyNames` of a `MimeTypeArray` object are the values of the `type` attributes of all the `MimeType` objects represented by the `MimeTypeArray` object.

The `namedItem()` method of a `MimeTypeArray` object must return null if the argument is not one of the object's `supportedPropertyNames`, and otherwise must return the `MimeType` object that has a `type` equal to the method's argument.

A `Plugin` object represents a `plugin`. It has several attributes to provide details about the plugin, and can be enumerated to obtain the list of `MIME types` that it `explicitly supports`.

The `Plugin` objects created by a user agent must not be `live`. The set of MIME types represented by the objects, and the values of the objects' attributes, must not change once an object is created, except when updated by the `PluginArray` object's `refresh()` method.

The reported `MIME types` for a `Plugin` object are the `MIME types explicitly supported` by the corresponding `plugin` when this object was last created or updated by `PluginArray.refresh()`, whichever happened most recently.

The `supportedPropertyIndices` of a `Plugin` object are the numbers from zero to the number of reported `MIME types`.

The `length` attribute must return the number of reported `MIME types`.

The `item()` method of a `Plugin` object must return null if the argument is not one of the object's `supportedPropertyIndices`, and otherwise must return the result of running the following steps, using the method's argument as `index`:

1. Let `list` be the `MimeType` objects representing the reported `MIME types`.
2. Sort `list` alphabetically by the `type` of each `MimeType`.
3. Return the `index`th entry in `list`.

Note
It is important for privacy that the order of MIME types not leak additional information, e.g., the order in which plugins were installed.

The `supportedPropertyNames` of a `Plugin` object are the values of the `type` attributes of the `MimeType` objects representing the reported `MIME types`.

The `namedItem()` method of a `Plugin` object must return null if the argument is not one of the object's `supportedPropertyNames`, and otherwise must return the `MimeType` object that has a `type` equal to the method's argument.

The `name` attribute must return the `plugin`'s name.

The `description` and `filename` attributes must return user-agent-defined (or, in all likelihood, `plugin`-defined) strings. In each case, the same string must be returned each time, except that the strings returned may change when the `PluginArray.refresh()` method updates the object.

If the values returned by the `description` or `filename` attributes vary between versions of a `plugin`, they can be used both as a fingerprinting vector and, even more importantly, as a trivial way to determine what security vulnerabilities a `plugin` (and thus a browser) may have. It is thus highly recommended that the `description` attribute just return the same value as the `name` attribute, and that the `filename` attribute return the empty string.

If the values returned by the `description` or `suffixes` attributes vary between versions of a `plugin`, they can be used both as a fingerprinting vector and, even more importantly, as a trivial way to determine what security vulnerabilities a `plugin` (and thus a browser) may have. It is thus highly recommended that the `description` attribute just return the same value as the `type` attribute, and that the `suffixes` attribute return the empty string.

Commas in the `suffixes` attribute are interpreted as separating subsequent filename extensions, as in "hts,html".

The `enabledPlugin` attribute must return the `Plugin` object that represents the `plugin` that `explicitly supported` the `MIME type` that this `MimeType` object represents when this object was last created or updated by `PluginArray.refresh()`, whichever happened most recently.

`NavigatorPlugins.javaEnabled`

Support in one engine only.

`Firefox?Safari?Chrome?Yes`

`Opera?Edge?Yes`

`Edge?Legacy?NoInternet Explorer?No`

The `navigator.javaEnabled()` method must return true if the user agent supports a `plugin` that supports the `MIME type` "application/x-java-vm"; otherwise it must return false.

}
```

An `ImageBitmap` object represents a bitmap image that can be painted to a canvas without undue latency.

The exact judgement of what is undue latency of this is left up to the implementer, but in general if making use of the bitmap requires network I/O, or even local disk I/O, then the latency is probably undue; whereas if it only requires a blocking read from a GPU or system RAM, the latency is probably acceptable.

For web developers (non-normative)

```
promise = self.createImageBitmap(image[, options])
```

```
promise = self.createImageBitmap(image, sx, sy, sw, sh[, options])
```

If no `ImageBitmap` object can be constructed, for example because the provided `image` data is not actually an image, then the promise is rejected instead.

If `x`, `y`, `sw`, and `sh` arguments are provided, the source image is cropped to the given pixels, with any pixels missing in the original replaced by `transparent black`. These coordinates are in the source image's pixel coordinate space, *not* in `CSS pixels`.

If `options` is provided, the `ImageBitmap` object's bitmap data is modified according to `options`. For example, if the `premultiplyAlpha` option is set to "`premultiplied`", the `bitmapData`'s color channels are premultiplied by its alpha channel.

Rejects the promise with an "`invalidStateError`" `DOMException` if the source image is not in a valid state (e.g., an `img` element that hasn't loaded successfully), an `ImageBitmap` object whose `[IDetached]` internal slot value is true, an `ImageData` object whose `data` attribute value's `[ViewedArrayBuffer]` internal slot is detached, or a `Blob` whose data cannot be interpreted as a bitmap image.

Rejects the promise with a "`syntaxError`" `DOMException` if the script is not allowed to access the image data of the source image (e.g. a `video` that is `CORS-cross-origin`, or a `canvas` being drawn on by a script in a worker from another `origin`).

`ImageBitmap.close()`
Releases `ImageBitmap`'s underlying `bitmapData`.

`ImageBitmap.width`
Returns the `intrinsic width` of the image, in `CSS pixels`.

`ImageBitmap.height`
Returns the `intrinsic height` of the image, in `CSS pixels`.

An `ImageBitmap` object whose `[IDetached]` internal slot value is false always has associated `bitmapData`, with a width and a height. However, it is possible for this data to be corrupted. If an `ImageBitmap` object's media data can be decoded without errors, it is said to be *fully decodable*.

An `ImageBitmap` object's bitmap has an `origin-clean` flag, which indicates whether the bitmap is tainted by content from a different `origin`. The flag is initially set to true and may be changed to false by the steps of `createImageBitmap()`.

`ImageBitmap` objects are *serializable objects* and *transferable objects*.

Their `serialization steps`, given `value` and `serialized`, are:

1. If `value's origin-clean` flag is not set, then throw a "`syntaxError`" `DOMException`.
2. Set `serialized.[[BitmapData]]` to a copy of `value's bitmapData`.

Their `deserialization steps`, given `serialized` and `value`, are:

1. Set `value's bitmapData` to `serialized.[[BitmapData]]`.

Their `transfer steps`, given `value` and `dataHolder`, are:

1. If `value's origin-clean` flag is not set, then throw a "`syntaxError`" `DOMException`.
2. Set `dataHolder.[[BitmapData]]` to `value's bitmapData`.
3. Unset `value's bitmapData`.

Their `transfer-receiving steps`, given `dataHolder` and `value`, are:

1. Set `value's bitmapData` to `dataHolder.[[BitmapData]]`.

The `createImageBitmap(image, options)` and `createImageBitmap(image sx, sy, sw, sh, options)` methods, when invoked, must run these steps:

...

Support: `createImageBitmap` Chrome for Android 81+Chrome 59+iOS Safari NoneSafari NoneFirefox (limited) 42+Samsung Internet 6.2+Edge 79+UC Browser for Android 12.12+IE NonOpera 46+Opera Mini NoneFirefox for Android (limited) 68+

Source: caniuse.com

1. Let `p` be a new promise.
2. If either `sw` or `sh` is given and is 0, then return `p` rejected with a "`syntaxError`".
3. If either `options's resizeWidth` or `options's resizeHeight` is present and is 0, then return `p` rejected with an "`invalidStateError`" `DOMException`.
4. **Check the usability of the `image` argument.** If this throws an exception or returns `bad`, then return `p` rejected with an "`invalidStateError`" `DOMException`.
5. Let `imageBitmap` be a new `ImageBitmap` object.
6. Switch on `image`:

[img](#) [SVG image](#)

1. If `image`'s media data has no `intrinsic dimensions` (e.g., it's a vector graphic with no specified content size) and either `options's resizeWidth` or `options's resizeHeight` is not present, then return `p` rejected with an "`invalidStateError`" `DOMException`.
2. If `image`'s media data has no `intrinsic dimensions` (e.g., it's a vector graphics with no specified content size), it should be rendered to a bitmap of the size specified by the `resizeWidth` and the `resizeHeight` options.
3. Set `imageBitmap's bitmapData` to a copy of `image`'s media data, [cropped to the source rectangle with formatting](#). If this is an animated image, `imageBitmap's bitmapData` must only be taken from the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation.
4. If the `origin` of `image`'s image is not `sameOrigin` with `entrySettings object's origin`, then set the `origin-clean` flag of `imageBitmap`'s bitmap to false.
5. Run this step **in parallel**:

1. Resolve `p` with `imageBitmap`.

[video](#)

1. If `image`'s `networkState` attribute is `NETWORK_EMPTY`, then return `p` rejected with an "`invalidStateError`" `DOMException`.
2. Set `imageBitmap's bitmapData` to a copy of the frame at the `current playback position`, at the `media` resource's `intrinsic width` and `intrinsic height` (i.e., after any aspect-ratio correction has been applied), [cropped to the source rectangle with formatting](#).
3. If the `origin` of `image`'s video is not `sameOrigin` with `entrySettings object's origin`, then set the `origin-clean` flag of `imageBitmap`'s bitmap to false.
4. Run this step **in parallel**:

1. Resolve `p` with `imageBitmap`.

[audio](#)

1. Set `imageBitmap's bitmapData` to a copy of `image`'s `bitmapData`, [cropped to the source rectangle with formatting](#).
2. Set the `origin-clean` flag of `imageBitmap`'s bitmap to the same value as the `origin-clean` flag of `image`'s bitmap.
3. Run this step **in parallel**:

1. Resolve `p` with `imageBitmap`.

[blob](#)

Run these step **in parallel**:

1. Let `imageData` be the result of reading `image`'s data. If an `error occurs during reading of the object`, then reject `p` with an "`invalidStateError`" `DOMException` and abort these steps.
2. Apply the `image sniffing rules` to determine the file format of `imageData`, with MIME type of `image` (as given by `image's type` attribute) giving the official type.
3. If `imageData` is not in a supported image file format (e.g., it's not an image at all), or if `imageData` is corrupted in some fatal way such that the image dimensions cannot be obtained (e.g., a vector graphic with no intrinsic size), then reject `p` with an "`invalidStateError`" `DOMException` and abort these steps.
4. Set `imageBitmap's bitmapData` to `imageData`, [cropped to the source rectangle with formatting](#). If this is an animated image, `imageBitmap's bitmapData` must only be taken from the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation.
5. Resolve `p` with `imageBitmap`.

[ImageData](#)

1. Let `buffer` be `image's data` attribute value's `[ViewedArrayBuffer]` internal slot.
2. If `isDetachedBuffer(buffer)` is true, then return `p` rejected with an "`invalidStateError`" `DOMException`.
3. Set `imageBitmap's bitmapData` to `image`'s image data, [cropped to the source rectangle with formatting](#).
4. Run this step **in parallel**:

1. Resolve `p` with `imageBitmap`.

[ImageBitmap](#)

1. Set `imageBitmap's bitmapData` to a copy of `image`'s `bitmapData`, [cropped to the source rectangle with formatting](#).
2. Set the `origin-clean` flag of `imageBitmap`'s bitmap to the same value as the `origin-clean` flag of `image`'s bitmap.
3. Run this step **in parallel**:

1. Resolve `p` with `imageBitmap`.

7. Return `p`.

When the steps above require that the user agent *crop bitmap data to the source rectangle with formatting*, the user agent must run the following steps:

1. Let `input` be the `bitmapData` being transformed.
2. If `sw`, `sh` and `sh` are specified, let `sourceRectangle` be a rectangle whose corners are the four points $(x, y), (x+sw, y), (x+sw, y+sh), (x, y+sh)$. Otherwise let `sourceRectangle` be a rectangle whose corners are the four points $(0, 0), (\text{width of } input, 0), (\text{width of } input, \text{height of } input), (0, \text{height of } input)$.

Note
If either `sw` or `sh` are negative, then the top-left corner of this rectangle will be to the left or above the (x, y) point.

3. Clip `sourceRectangle` to the dimensions of `input`.

4. Let `outputWidth` be determined as follows:

If the `sourceWidth` member of `sourceRectangle` is zeroed

If the `resizeWidth` member of `options` is not specified, but the `resizeHeight` member is specified
 the width of `sourceRectangle`, times the value of the `resizeHeight` member of `options`, divided by the height of `sourceRectangle`, rounded up to the nearest integer
 If neither `resizeWidth` nor `resizeHeight` are specified
 the width of `sourceRectangle`

5. Let `outputHeight` be determined as follows:

If the `resizeHeight` member of `options` is specified
 the value of the `resizeHeight` member of `options`
 If the `resizeHeight` member of `options` is not specified, but the `resizeWidth` member is specified
 the height of `sourceRectangle`, times the value of the `resizeWidth` member of `options`, divided by the width of `sourceRectangle`, rounded up to the nearest integer
 If neither `resizeWidth` nor `resizeHeight` are specified
 the height of `sourceRectangle`

6. Place `input` on an infinite `transparent black` grid plane, positioned so that its top left corner is at the origin of the plane, with the `x`-coordinate increasing to the right, and the `y`-coordinate increasing down, and with each pixel in the `input` image data occupying a cell on the plane's grid.

7. Let `output` be the rectangle on the plane denoted by `sourceRectangle`.

8. Scale `output` to the size specified by `outputWidth` and `outputHeight`. The user agent should use the value of the `resizeQuality` option to guide the choice of scaling algorithm.

9. If the value of the `imageOrientation` member of `options` is `"flip"`, `output` must be flipped vertically, disregarding any image orientation metadata of the source (such as EXIF metadata), if any. [EXIF]

Note
 If the value is `"none"`, no extra step is required.

10. If `image` is an `img` element or a `blob` object, let `val` be the value of the `colorSpaceConversion` member of `options`, and then run these substeps:

1. If `val` is `"default"`, the color space conversion behavior is implementation-specific, and should be chosen according to the color space that the implementation uses for drawing images onto the canvas.
2. If `val` is `"none"`, `output` must be decoded without performing any color space conversions. This means that the image decoding algorithm must ignore color profile metadata embedded in the source data as well as the display device color profile.

Note
 The native color space of `canvas` is currently unspecified, but this is expected to change in the future.

11. Let `val` be the value of `premultipliedAlpha` member of `options`, and then run these substeps:

1. If `val` is `"default"`, the alpha premultiplication behavior is implementation-specific, and should be chosen according to implementation deemed optimal for drawing images onto the canvas.
2. If `val` is `"premultiplied"`, the `output` that is not premultiplied by alpha must have its color components multiplied by alpha and that is premultiplied by alpha must be left untouched.
3. If `val` is `"none"`, the `output` that is not premultiplied by alpha must be left untouched and that is premultiplied by alpha must have its color components divided by alpha.

12. Return `output`.

Some objects include the `AnimationFrameProvider` interface mixin.

```
IDLCallback FrameRequestCallback = void (DOMHighResTimeStamp time);
interface mixin AnimationFrameProvider {
  unsigned long requestAnimationFrame(FrameRequestCallback callback);
  void cancelAnimationFrame(unsigned long handle);
}
Window includes AnimationFrameProvider;
DocumentWorkerGlobalScope includes AnimationFrameProvider;
```

Each `AnimationFrameProvider` object also has a `targer` object that stores the provider's internal state. It is defined as follows:

If the `AnimationFrameProvider` object is a `Window`:

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

If the `AnimationFrameProvider` is a `DedicatedWorkerGlobalScope`
 The `DedicatedWorkerGlobalScope`

Each `target object` has a map of animation frame callbacks, which is an `ordered map` that must be initially empty, and an `animation frame callback identifier`, which is a number that must initially be zero.

An `AnimationFrameProvider provider` is considered `supported` if any of the following hold:

- `provider` is a `Window`.
- `provider's owner set` contains a `Document` object.
- Any of the `DedicatedWorkerGlobalScope` objects in `provider's owner set` are `supported`.

The `requestAnimationFrame(callback)` method must run the following steps:

1. If this `AnimationFrameProvider` is not `supported`, then throw a `"NotSupportedError"` `DOMException`.
2. Let `target` be this `AnimationFrameProvider`'s `target object`.
3. Increment `target`'s `animation frame callback identifier` by one, and let `handle` be the result.
4. Let `callbacks` be `target`'s map of animation frame callbacks.
5. `Set callbacks[handle]` to `callback`.
6. Return `handle`.

MDN

[Window.cancelAnimationFrame](#)

Support in all current engines.

Firefox23+Safari6.1+ChromeYes

Opera15+EdgeYes

Edge (Legacy)12+Internet Explorer10+

Firefox Android23+Safari iOS7+Chrome AndroidYesWebView AndroidYesSamsung InternetYesOpera Android14+

The `cancelAnimationFrame(handle)` method must run the following steps:

1. If this `AnimationFrameProvider` is not `supported`, then throw a `"NotSupportedError"` `DOMException`.
2. Let `callbacks` be this `AnimationFrameProvider`'s `target object`'s map of animation frame callbacks.
3. `Remove callbacks[handle]`.

To run the animation frame callbacks for a `target object` target with a timestamp `now`:

1. Let `callbacks` be `target`'s map of animation frame callbacks.
2. Let `callbackHandles` be the result of `getting the keys` of `callbacks`.
3. **For each** `handle` in `callbackHandles`, if `handle exists` in `callbacks`:
 1. Let `callback` be `callbacks[handle]`.
 2. `Remove callbacks[handle]`.
 3. `Invoke` `callback`, passing `now` as the only argument, and if an exception is thrown, `report the exception`.

Example

```
inside workers, requestAnimationFrame() can be used together with an OffscreenCanvas transferred from a canvas element. First, in the document, transfer control to the worker:
const offscreenCanvas = document.createElementById("c").transferControlToOffscreen();
worker.postMessage(offscreenCanvas, [offscreenCanvas]);

Then, in the worker, the following will draw a rectangle moving from left to right:
let ctx, pos = 0;
function draw() {
  ctx.clearRect(0, 0, 100, 100);
  ctx.fillRect(pos, 0, 10, 10);
  requestAnimationFrame(draw);
}

self.onmessage = function(ev) {
  const transferredCanvas = ev.data;
  ctx = transferredCanvas.getContext("2d");
  draw();
}
;
```

9 Communication

9.1 The `MessageEvent` interface

Messages in [server-sent events](#), [Web sockets](#), [cross-document messaging](#), [channel messaging](#), and [broadcast channels](#) use the `MessageEvent` interface for their `message` events:

9.2.1 Introduction

*This section is non-normative.*To enable servers to push data to Web pages over HTTP or using dedicated server-push protocols, this specification introduces the `EventSource` interface.Using this API consists of creating an `EventSource` object and registering an event listener.

```
var source = new EventSource('updates.cgi');
source.onmessage = function (event) {
  alert(event.data);
};
```

On the server-side, the script ("updates.cgi" in this case) sends messages in the following form, with the `text/event-stream` MIME type:

```
data: This is the first message.
data: This is the second message, it
data: has two lines.
data: This is the third message.
```

Authors can separate events by using different event types. Here is a stream that has two event types, "add" and "remove":

```
event: add
data: 73857293
event: remove
data: 2153
event: add
data: 113411
```

The script to handle such a stream would look like this (where `addHandler` and `removeHandler` are functions that take one argument, the event):

```
var source = new EventSource('updates.cgi');
source.addEventListener('add', addHandler, false);
source.addEventListener('remove', removeHandler, false);
```

The default event type is "message".

Event streams are always decoded as UTF-8. There is no way to specify another character encoding.

Event stream requests can be redirected using HTTP 301 and 307 redirects as with normal HTTP requests. Clients will reconnect if the connection is closed; a client can be told to stop reconnecting using the HTTP 204 No Content response code.

Using this API rather than emulating it using `XMLHttpRequest` or an `iframe` allows the user agent to make better use of network resources in cases where the user agent implementer and the network operator are able to coordinate in advance. Amongst other benefits, this can result in significant savings in battery life on portable devices. This is discussed further in the section below on [connectionless push](#).

9.2.2 The `EventSource` interface

MDN

`EventSource`

Support in all current engines.

Firefox6+Safari5+Chrome6+

Opera11+Edge79+

Edge (Legacy)NoInternet ExplorerNo

Firefox Android4.5+Safari iOS5+Chrome Android1.8+WebView Android3.7+Samsung Internet1.0+Opera Android11+

```
IDL:[Exposed=(Window,Worker)]
interface EventSource : EventTarget {
  attribute EventHandler<Event> onerror;
  attribute URL url;
  attribute Object withCredentials;
  readonly attribute unsigned long readyState;
  const unsigned short CONNECTING = 0;
  const unsigned short OPEN = 1;
  const unsigned short CLOSING = 2;
  readonly attribute unsigned short readyState;
};

attribute EventHandler onopen;
attribute EventHandler onmessage;
attribute EventHandler onerror;
void close();
}
```

```
dictionary EventSourceInit {
  boolean withCredentials = false;
};
```

Each `EventSource` object has the following associated with it:

- A `url` (a [URL record](#)). Set during construction.
- A `request`. This must initially be null.
- A `reconnection time`, in milliseconds. This must initially be a user-agent-defined value, probably in the region of a few seconds.
- A `last event ID string`. This must initially be the empty string.

Apart from `url` these are not currently exposed on the `EventSource` object.

For web developers (non-normative)

```
source = new EventSource(url, {withCredentials: true});
```

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

url is a string giving the [URL](#) that will provide the event stream.

Setting `withCredentials` to true will set the [credentials mode](#) for connection requests to *url* to "include".

```
source .close()
Aborts instances of the fetch algorithm started for this EventSource object, and sets the readyState attribute to CLOSED.
source .url
Returns the URL providing the event stream.
source .withCredentials
Returns true if the credentials mode for connection requests to the URL providing the event stream is set to "include", and false otherwise.
source .readyState
Returns the state of this EventSource object's connection. It can have the values described below.
```

9.2.3 Processing model

The resource indicated in the argument to the `EventSource` constructor is fetched when the constructor is run.

As data is received, the `task` queued by the `networking task source` to handle the data must act as follows.

HTTP 200 OK responses with a `'Content-Type'` header specifying the type `'text/event-stream'`, ignoring any `MIME-type` parameters, must be processed line by line as described below.

When a successful response with a supported `MIME-type` is received, such that the user agent begins parsing the contents of the stream, the user agent must `announce the connection`.

The `task` that the `networking task source` places on the `task queue` once fetching for such a resource (with the correct `MIME-type`) has completed must cause the user agent to `reestablish the connection in parallel`. This applies whether the connection is closed gracefully or unexpectedly (but does not apply when fetching is canceled by the user agent, e.g., in response to `window.stop()`, since in those cases the final `task` is actually discarded). It doesn't apply for the error conditions listed below except where explicitly specified.

HTTP 200 OK responses that have a `Content-Type` specifying an unsupported type, or that have no `Content-Type` at all, must cause the user agent to `fail the connection`.

Network errors that prevents the connection from being established in the first place (e.g. DNS errors), should cause the user agent to `reestablish the connection in parallel`, unless the user agent knows that to be futile, in which case the user agent may `fail the connection`.

Any other HTTP response code not listed here, as well as the cancellation of the fetch algorithm by the user agent (e.g. in response to `window.stop()` or the user canceling the network connection manually) must cause the user agent to `fail the connection`.

When a user agent is to `announce the connection`, the user agent must `queue a task` which, if the `readyState` attribute is set to a value other than `CLOSED`, sets the `readyState` attribute to `OPEN` and `fires an event` named `open` at the `EventSource` object.

When a user agent is to `reestablish the connection`, the user agent must run the following steps. These steps are run in parallel, not as part of a `task`. (The tasks that it queues, of course, are run like normal tasks and not themselves in parallel.)

1. Queue a task to run the following steps:

1. If the `readyState` attribute is set to `CLOSED`, abort the task.

2. Set the `readyState` attribute to `CONNECTING`.

3. `Fire an event` named `error` at the `EventSource` object.

2. Wait a delay equal to the reconnect time of the event source.

3. Optionally, wait some more. In particular, if the previous attempt failed, then user agents might introduce an exponential backoff delay to avoid overloading a potentially already overloaded server. Alternatively, if the operating system has reported that there is no network connectivity, user agents might wait for the operating system to announce that the network connection has returned before retrying.

4. Wait until the aforementioned task has run, if it has not yet run.

5. Queue a task to run the following steps:

1. If the `EventSource` object's `readyState` attribute is not set to `CONNECTING`, return.

2. Let `request` be the `EventSource` object's `request`.

3. If the `EventSource` object's `lastEventID` string is not the empty string, set `"Last-Event-ID": lastEventID` in `request's header list`.

4. `Fetch` `request` and process the response obtained in this fashion, if any, as described earlier in this section.

When a user agent is to `fail the connection`, the user agent must `queue a task` which, if the `readyState` attribute is set to a value other than `CLOSED`, sets the `readyState` attribute to `CLOSED` and `fires an event` named `error` at the `EventSource` object. Once the user agent has `failed the connection`, it does not attempt to reconnect!

The `task source` for any `task`s that are queued by `EventSource` objects is the `remote event task source`.

9.2.4 Parsing an event stream

This event stream format's `MIME-type` is `'text/event-stream'`.

The event stream format is as described by the `stream` production of the following ABNF. The character set for which is Unicode. [ABNF]

```
stream      = [ b0n ] *event
event      = *( comment / field ) end-of-line
comment    = *( space / U+000D CARRIAGE RETURN (CR)
field      = 1#name-char [ colon [ space ] *any-char ] end-of-line
end-of-line = *( cr lf / cr / lf )

; characters
if          = %x000A ; U+000A LINE FEED (LF)
cr          = %x000D ; U+000D CARRIAGE RETURN (CR)
space       = %x0020 ; U+0020 SPACE
colon       = %x003A ; U+003A COLON (:)
b0n        = %x0000-007F BYTES EXCLUDING MARKS
name-char   = %x0000-007F / %x00B0-00C9 / %x00D0-10FFFF
any-char    = %x0000-007F / %x00B0-00C9 / %x00D0-10FFFF
; a scalar value other than U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR)
```

Event streams in this format must always be encoded as UTF-8. [ENCODING]

Lines must be separated by either a U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair, a single U+000A LINE FEED (LF) character, or a single U+000D CARRIAGE RETURN (CR) character.

Since connections established to remote servers for such resources are expected to be long-lived, UAs should ensure that appropriate buffering is used. In particular, while line buffering with lines are defined to end with a single U+000A LINE FEED (LF) character is safe, block buffering or line buffering with different expected line endings can cause delays in event dispatch.

9.2.5 Interpreting an event stream

Streams must be decoded using the `UTF-8 decode` algorithm.

The `UTF-8 decode` algorithm strips one leading UTF-8 Byte Order Mark (BOM), if any.

The stream must then be parsed by reading everything line by line, with a U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair, a single U+000A LINE FEED (LF) character, or a single U+000D CARRIAGE RETURN (CR) character, and a single U+000D CARRIAGE RETURN (CR) character not preceded by a U+000D CARRIAGE RETURN (CR) character, and a single U+000D CARRIAGE RETURN (CR) character followed by a U+000A LINE FEED (LF) character being the ways in which a line can end.

When a stream is parsed, a `data` buffer, an `eventType` buffer, and a `lastEventID` buffer must be associated with it. They must be initialized to the empty string.

Lines must be processed, in the order they are received, as follows:

If the line is empty (a blank line):

`Dispatch the event`, as defined below.

If the line starts with a U+003A COLON character (:)

Ignore the line.

If the line contains a U+003A COLON character (:)

Collect the characters on the line before the first U+003A COLON character (:), and let `field` be that string.

Collect the characters on the line after the first U+003A COLON character (:), and let `value` be that string. If `value` starts with a U+0020 SPACE character, remove it from `value`.

`Process the field` using the steps described below, using `field` as the field name and `value` as the field value.

Otherwise, the string is not empty but does not contain a U+003A COLON character (:)

`Process the field` using the steps described below, using the whole line as the field name, and the empty string as the field value.

Once the end of the file is reached, any pending data must be discarded. (If the file ends in the middle of an event, before the final empty line, the incomplete event is not dispatched.)

The steps to `process the field` given a field name and a field value depend on the field name, as given in the following list. Field names must be compared literally, with no case folding performed.

If the field name is "event"

Set the `eventType` buffer to field value.

If the field name is "data"

Append the field value to the `data` buffer, then append a single U+000A LINE FEED (LF) character to the `data` buffer.

If the field name is "id"

If the field value does not contain U+0000 NULL, then set the `lastEventID` buffer to the field value. Otherwise, ignore the field.

If the field name is "retry"

If the field value consists of only `ASCII digits`, then interpret the field value as an integer in base ten, and set the event stream's `reconnection time` to that integer. Otherwise, ignore the field.

Otherwise

The field is ignored.

When the user agent is required to `dispatch the event`, the user agent must process the `data` buffer, the `eventType` buffer, and the `lastEventID` buffer using steps appropriate for the user agent.

For Web browsers, the appropriate steps to `dispatch the event` are as follows:

1. Set the `lastEventID` string of the event source to the value of the `lastEventID` buffer. The buffer does not get reset, so the `lastEventID` string of the event source remains set to this value until the next time it is set by the server.

2. If the `data` buffer is an empty string, set the `data` buffer and the `eventType` buffer to the empty string and return.

3. If the `data` buffer's last character is a U+000A LINE FEED (LF) character, then remove the last character from the `data` buffer.

4. Let `event` be the result of `creating an event` using `messageEvent`, in the `relevant Realm` of the `EventSource` object.

5. Initialize `event's type` attribute to `event`, its `data` attribute to `data`, its `eventType` attribute to the `generalization` of the `origin` of the event stream's final URL (i.e., the URL after redirects), and its `lastEventID` attribute to the `lastEventID` string of the event source.

6. If the `event type` buffer has a value other than the empty string, change the `type` of the newly created event to equal the value of the `event type` buffer.

7. Set the `data` buffer and the `event type` buffer to the empty string.

8. `Queue a task` which, if the `readyState` attribute is set to a value other than `CLOSED`, dispatches the newly created event at the `EventSource` object.

If an event doesn't have an "id" field, but an earlier event did set the event source's `lastEventId`, then the event's `lastEventId` field will be set to the value of whatever the last seen "id" field was.

For other user agents, the appropriate steps to `dispatch the event` are implementation dependent, but at a minimum they must set the `data` and `event type` buffers to the empty string before returning.

Example

The following event stream, once followed by a blank line:

```
data: 9800
data: 2
data: 10
...would cause an event message with the interface MessageEvent to be dispatched on the eventSource object. The event's data attribute would contain the string "THREE\n2\n10" (where "\n" represents a newline).
```

This could be used as follows:

```
var stocks = new EventSource("https://stocks.example.com/ticker.php");
stocks.onmessage = function(event) {
  var data = event.data.split("\n");
  updateStocks(data[0], data[1], data[2]);
};

...where updateStocks() is a function defined as:
function updateStocks(symbol, delta, value) { ... }

...or some such.
```

Example

The following stream contains four blocks. The first block has just a comment, and will fire nothing. The second block has two fields with names "data" and "id" respectively; an event will be fired for this block, with the data "first event", and will then set the last event ID to "1" so that if the connection died between this block and the next, the server would be sent a `lastEventId` header with the value "1". The third block fires an event with data "second event", and also has an "id" field, this time with no value, which resets the last event ID to the empty string (meaning no `lastEventId` header will now be sent in the event of a reconnection being attempted). Finally, the last block just fires an event with the data "third event" (with a single leading space character). Note that the last still has to end with a blank line, the end of the stream is not enough to trigger the dispatch of the last event.

```
/* test stream
data: first event
id: 1
data:second event
id:
data: third event
```

Example

The following stream fires two events:

```
data
data
data:
data:

The first block fires events with the data set to the empty string, as would the last block if it was followed by a blank line. The middle block fires an event with the data set to a single newline character. The last block is discarded because it is not followed by a blank line.
```

Example

The following stream fires two identical events:

```
data:test
data: test
```

This is because the space after the colon is ignored if present.

9.2.6 Authoring notes

Legacy proxy servers are known to, in certain cases, drop HTTP connections after a short timeout. To protect against such proxy servers, authors can include a comment line (one starting with a '#' character) every 15 seconds or so.

Authors wishing to relate event source connections to each other or to specific documents previously served might find that relying on IP addresses doesn't work, as individual clients can have multiple IP addresses (due to having multiple proxy servers) and individual IP addresses can have multiple clients (due to sharing a proxy server). It is better to include a unique identifier in the document when it is served and then pass that identifier as part of the URL when the connection is established.

Authors are also cautioned that HTTP chunking can have unexpected negative effects on the reliability of this protocol, in particular if the chunking is done by a different layer unaware of the timing requirements. If this is a problem, chunking can be disabled for serving event streams.

Clients that support HTTP's per-server connection limitation might run into trouble when opening multiple pages from a site if each page has an `EventSource` to the same domain. Authors can avoid this using the relatively complex mechanism of using unique domain names per connection, or by allowing the user to enable or disable the `EventSource` functionality on a per-page basis, or by sharing a single `EventSource` object using a `shared worker`.

9.2.7 Connectionless push and other features

User agents running in controlled environments, e.g. browsers on mobile handsets tied to specific carriers, may offload the management of the connection to a proxy on the network. In such a situation, the user agent for the purposes of conformance is considered to include both the handset software and the network proxy.

Example

For example, a browser on a mobile device, after having established a connection, might detect that it is on a supporting network and request that a proxy server on the network take over the management of the connection. The timeline for such a situation might be as follows:

1. Browser connects to a remote HTTP server and requests the resource specified by the author in the `EventSource` constructor.
2. The server sends occasional messages.
3. In between two messages, the browser detects that it is idle except for the network activity involved in keeping the TCP connection alive, and decides to switch to sleep mode to save power.
4. The browser disconnects from the server.
5. The browser connects to a proxy on the network, and requests that the service, a "push proxy", maintain the connection instead.
6. The "push proxy" service contacts the remote HTTP server and requests the resource specified by the author in the `EventSource` constructor (possibly including a `lastEventId` HTTP header, etc).
7. The browser allows the mobile device to go to sleep.
8. The server sends another message.
9. The "push proxy" service uses a technology such as OMA push to convey the event to the mobile device, which wakes only enough to process the event and then returns to sleep.

This can reduce the total data usage, and can therefore result in considerable power savings.

As well as implementing the existing API and `text/event-stream` wire format as defined by this specification and in more distributed ways as described above, formats of event framing defined by [other applicable specifications](#) may be supported. This specification does not define how they are to be parsed or processed.

9.2.8 Garbage collection

While an `EventSource` object's `readyState` is `CONNECTING`, and the object has one or more event listeners registered for `open`, `message` or `error` events, there must be a strong reference from the `Window` or `WorkerGlobalScope` object that the `EventSource` object's constructor was invoked from to the `EventSource` object itself.

While an `EventSource` object's `readyState` is `OPEN`, and the object has one or more event listeners registered for `message` or `error` events, there must be a strong reference from the `Window` or `WorkerGlobalScope` object that the `EventSource` object's constructor was invoked from to the `EventSource` object itself.

While there is a task queued by an `EventSource` object on the `remote event task source`, there must be a strong reference from the `Window` or `WorkerGlobalScope` object that the `EventSource` object's constructor was invoked from to that `EventSource` object.

If a user agent is to *forcibly close* an `EventSource` object (this happens when a `Document` object goes away permanently), the user agent must abort any instances of the `fctch` algorithm started for this `EventSource` object, and must set the `readyState` attribute to `CLOSED`.

If an `EventSource` object is garbage collected while its connection is still open, the user agent must abort any instance of the `fctch` algorithm opened by this `EventSource`.

9.2.9 Implementation advice

This section is non-normative.

User agents are strongly urged to provide detailed diagnostic information about `EventSource` objects and their related network connections in their development consoles, to aid authors in debugging code using this API.

For example, a user agent could have a panel displaying all the `EventSource` objects a page has created, each listing the constructor's arguments, whether there was a network error, what the CORS status of the connection is and what headers were sent by the client and received from the server to lead to that status, the messages that were received and how they were parsed, and so forth.

Implementations are especially encouraged to report detailed information to their development consoles whenever an `error` event is fired, since little to no information can be made available in the events themselves.

9.3 Web sockets

Support: websocketsChrome for Android 81+Chrome 16+iOS Safari 6.0+Safari 7+Firefox 11+Samsung Internet 4+Edge 12+UC Browser for Android 12.12+IE 10+Opera 12.1+Opera Mini NoneFirefox for Android 68+

Source: caniuse.com

9.3.1 Introduction

This section is non-normative.

To enable Web applications to maintain bidirectional communications with server-side processes, this specification introduces the `WebSocket` interface.

Note

This interface does not allow for raw access to the underlying network. For example, this interface could not be used to implement an IRC client without proxying messages through a custom server.

9.3.2 The `WebSocket` interface

WebSocket

Support in all current engines.

Firefox 11+Safari 5+Chrome 4+

Opera 12.1+Edge 79+

Edge (Legacy) 12+Internet Explorer 10+

Firefox, Android 4+Safari iOS 4.2+Chrome Android 8+WebView Android 37+Samsung Internet 1.0+Opera Android 12.1+

```
IDLAttribute BinaryType { "blob", "arraybuffer" };
[Exposed=(Window, Worker)]
interface WebSocket : EventTarget {
  [Constructable] (URIBlobString url, optional (DOMString or sequence<DOMString>) protocols = {});
  readonly attribute USVString url;
  // ready state
  const unsigned short CONNECTING = 0;
  const unsigned short OPEN = 1;
  const unsigned short CLOSING = 2;
  const unsigned short CLOSED = 3;
  readonly attribute unsigned short readyState;
  readonly attribute unsigned long long bufferedAmount;
  // networking
  attribute EventHandler onopen;
  attribute EventHandler onclose;
  attribute EventHandler onerror;
  readonly attribute USVString extensions;
```

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

```
// messaging
attribute <event Handler> message;
attribute <event Handler> error;
void send(Blob data);
void send(ArrayBuffer data);
void send(ArrayBufferView data);
}
```

Each `WebSocket` object has an associated `url` (a [URL record](#)).

For web developers (non-normative)

```
socket = new WebSocket(url [, protocols ])
```

Creates a new `WebSocket` object, immediately establishing the associated WebSocket connection.

`url` is a string giving the [URL](#) over which the connection is established. Only “`ws`” or “`ws*`” schemes are allowed; others will cause a “[SyntaxError](#)” `DOMException`. URLs with `fragments` will also cause such an exception.

`protocols` is either a string or an array of strings. If it is a string, it is equivalent to an array consisting of just that string; if it is omitted, it is equivalent to the empty array. Each string in the array is a subprotocol name. The connection will only be established if the server reports that it has selected one of these subprotocols. The subprotocol names have to match the requirements for elements that comprise the value of `sec-WebSocket-Protocol` fields as defined by *The WebSocket protocol* [WSP].

```
socket . send( data )
```

Transmits `data` using the WebSocket connection. `data` can be a string, a `Blob`, an `ArrayBuffer`, or an `ArrayBufferView`.

```
socket . close( [ code ] [, reason ] )
```

Closes the WebSocket connection, optionally using `code` as the [the WebSocket connection close code](#) and `reason` as the [the WebSocket connection close reason](#).

```
socket . readyState
```

Returns the [URL that was used](#) to establish the WebSocket connection.

```
socket . readystate
```

Returns the state of the `WebSocket` object's connection. It can have the values described below.

```
socket . bufferedAmount
```

Returns the number of bytes of application data (UTF-8 text and binary data) that have been queued using `send()` but not yet been transmitted to the network.

If the WebSocket connection is closed, this attribute's value will only increase with each call to the `send()` method. (The number does not reset to zero once the connection closes.)

```
socket . extensions
```

Returns the extensions selected by the server, if any.

```
socket . protocol
```

Returns the subprotocol selected by the server, if any. It can be used in conjunction with the array form of the constructor's second argument to perform subprotocol negotiation.

```
socket . binaryType [= value ]
```

Returns a string that indicates how binary data from the `WebSocket` object is exposed to scripts:

`"blob"`

Binary data is returned in `Blob` form.

`"arraybuffer"`

Binary data is returned in `ArrayBuffer` form.

Can be set, to change how binary data is returned. The default is “`blob`”.

Firefox Android7+Safari iOS7Chrome AndroidYesWebView AndroidYesSamsung InternetYesOpera Android?

The `WebSocket(url, protocols)` constructor, when invoked, must run these steps:

1. Let `urlRecord` be the result of applying the [URL_parse](#) to `url`.
2. If `urlRecord` is failure, then throw a “[SyntaxError](#)” `DOMException`.
3. If `urlRecord`'s `scheme` is not “`ws`” or “`ws*`”, then throw a “[SyntaxError](#)” `DOMException`.
4. If `urlRecord`'s `fragment` is non-null, then throw a “[SyntaxError](#)” `DOMException`.
5. If `protocols` is a string, set `protocols` to a sequence consisting of just that string.
6. If any of the values in `protocols` occur more than once or otherwise fail to match the requirements for elements that comprise the value of `sec-WebSocket-Protocol` fields as defined by *The WebSocket protocol*, then throw a “[SyntaxError](#)” `DOMException`. [WSP]
7. Run this step [in parallel](#):

1. Establish a WebSocket connection given `urlRecord`, `protocols`, and the `entry settings object`. [FETCH]

Note
If the establish a WebSocket connection algorithm fails, it triggers the [fail the WebSocket connection](#) algorithm, which then invokes the [close the WebSocket connection](#) algorithm, which then establishes that [the WebSocket connection is closed](#), which fires the [close event](#) as described below.

8. Return a new `WebSocket` object whose `url` is `urlRecord`.

MDN

WebSocketUrl

Support in all current engines.

FirefoxYesSafariYesChromeYes

WebSocket.close

Support in all current engines.

Firefox3+Safari5+Chrome4+

Opera12.1+Edge79+

Edge (Legacy)12+Internet Explorer10+

Firefox, Android8+Safari iOS4.2+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android12.1+

The `close(code, reason)` method, when invoked, must run these steps:

1. If `code` is present, but is neither an integer equal to 1000 nor an integer in the range 3000 to 4999, inclusive, throw an `"invalidAccessError"` `DOMException`.
2. If `reason` is present, then run these substeps:

1. Let `reasonBytes` be the result of `encoding` `reason`.

2. If `reasonBytes` is longer than 123 bytes, then throw a `"byteLengthError"` `DOMException`.

3. Run the first matching steps from the following list:

If the `readyState` attribute is in the `CLOSING` (2) or `CLOSED` (3) state

Do nothing.

Note

The connection is already closing or is already closed. If it has not already, a `close` event will eventually fire as described below.

If the WebSocket connection is not yet `established` [WSP]

Fail the WebSocket connection and set the `readyState` attribute's value to `CLOSING` (2) [WSP]

Note

The *Fail the WebSocket connection* algorithm invokes the `close the WebSocket connection` algorithm, which then establishes that `the WebSocket connection is closed`, which fires the `close` event as described below.

If the WebSocket closing handshake has not yet been `started` [WSP]

Start the WebSocket closing handshake and set the `readyState` attribute's value to `CLOSING` (2) [WSP]

If neither `code` nor `reason` is present, the WebSocket Close message must not have a body.

Note

WebSocket Protocol erroneously states that the status code is required for the *start the WebSocket closing handshake* algorithm.

If `code` is present, then the status code to use in the WebSocket Close message must be the integer given by `close`. [WSP]

If `reason` is also present, then `reasonBytes` must be provided in the Close message after the status code. [WSP]

Note

The *start the WebSocket closing handshake* algorithm eventually invokes the `close the WebSocket connection` algorithm, which then establishes that `the WebSocket connection is closed`, which fires the `close` event as described below.

Otherwise

Set the `readyState` attribute's value to `CLOSED` (2).

Note

The WebSocket closing handshake is started, and will eventually invoke the `close the WebSocket connection` algorithm, which will establish that `the WebSocket connection is closed`, and thus the `close` event will fire, as described below.

Note

The close() method does not discard previously sent messages before starting the WebSocket closing handshake — even if, in practice, the user agent is still busy sending those messages, the handshake will only start after the messages are sent.

MDN

WebSocket.bufferedAmount

Support in all current engines.

FirefoxYesSafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet Explorer?

Firefox, AndroidYesSafari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

The `bufferedAmount` attribute must return the number of bytes of application data (UTF-8 text and binary data) that have been queued using `send()` but that, as of the last time the `event loop` reached `step 1`, had not yet been transmitted to the network. (This thus includes any text sent during the execution of the current task, regardless of whether the user agent is able to transmit text in the background `in parallel` with script execution.) This does not include framing overhead incurred by the protocol, or buffering done by the operating system or network hardware.

Example

```
In this simple example, the bufferedAmount attribute is used to ensure that updates are sent either at the rate of one update every 50ms, if the network can handle that rate, or at whatever rate the network can handle, if that is too fast.

var socket = new WebSocket("ws://game.example.com:12010/updates");
socket.open();
socket.onopen = function() {
  setInterval(function() {
    if (socket.bufferedAmount == 0)
      socket.send(getUpdateData());
  }, 50);
}

The bufferedAmount attribute can also be used to saturate the network without sending the data at a higher rate than the network can handle, though this requires more careful monitoring of the value of the attribute over time.
```

MDN

WebSocket.binaryType

Support in all current engines.

FirefoxYesSafariYesChromeYes

OperaYesEdgeYes

Edge (Legacy)12+Internet Explorer?

Firefox AndroidYesSafari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera AndroidYes

When a `WebSocket` object is created, its `binaryType` IDL attribute must be set to the string `"blob"`. On getting, it must return the last value it was set to. On setting, the user agent must set the IDL attribute to the new value.

Note

User agents can use the `binaryType` attribute as a hint for how to handle incoming binary data: if the attribute is set to `"blob"`, it is safe to spool it to disk, and if it is set to `"arraybuffer"`, it is likely more efficient to keep the data in memory. Naturally, user agents are encouraged to use more subtle heuristics to decide whether to keep incoming data in memory or not, e.g. based on how big the data is or how common it is for a script to change the attribute at the last minute. This latter aspect is important in particular because it is quite possible for the attribute to be changed after the user agent has received the data but before the user agent has fired the event for it.

MDN

WebSocket.send

Support in all current engines.

Firefox18+Safari5+Chrome4+

Opera12.1+Edge79+

Edge (Legacy)12+Internet Explorer10+

Firefox, Android18+Safari iOS4.2+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android12.1+

The `send(data)` method transmits data using the connection. If the `readyState` attribute is `CONNECTING`, it must throw an `"invalidStateError"` `DOMException`. Otherwise, the user agent must run the appropriate set of steps from the following list:

If the argument is a string

If `the WebSocket connection is established` and `the WebSocket closing handshake has not yet started`, then the user agent must `send a WebSocket Message` comprised of `data` argument using a text frame opcode; if the data cannot be sent, e.g. because it would need to be buffered but the buffer is full, the user agent must `flag the WebSocket as full` and then `close the WebSocket connection`. Any invocation of this method with a string argument that does not throw an exception must increase the `bufferedAmount` attribute by the number of bytes needed to express the argument as UTF-8. [UNICODE] [ENCODING] [WSP]

If the argument is a `blob` object

If `the WebSocket connection is established` and `the WebSocket closing handshake has not yet started`, then the user agent must `send a WebSocket Message` comprised of `data` using a binary frame opcode; if the data cannot be sent, e.g. because it would need to be buffered but the buffer is full, the user agent must `flag the WebSocket as full` and then `close the WebSocket connection`. The data to be sent is the raw data represented by the `blob` object. Any invocation of this method with a `blob` argument that does not throw an exception must increase the `bufferedAmount` attribute by the number of bytes needed to express the argument as a blob. [FILEAPI] [WSP]

If the argument is an `arraybuffer` object

If `the WebSocket connection is established` and `the WebSocket closing handshake has not yet started`, then the user agent must `send a WebSocket Message` comprised of `data` using a binary frame opcode; if the data cannot be sent, e.g. because it would need to be buffered but the buffer is full, the user agent must `flag the WebSocket as full` and then `close the WebSocket connection`. The data to be sent is the data stored in the buffer described by the `arraybuffer` object. Any invocation of this method with an `arraybuffer` argument that does not throw an exception must increase the `bufferedAmount` attribute by the length of the `arraybuffer` in bytes. [WSP]

If the argument is an object that matches the `arraybuffer` type definition

If `the WebSocket connection is established` and `the WebSocket closing handshake has not yet started`, then the user agent must `send a WebSocket Message` comprised of `data` using a binary frame opcode; if the data cannot be sent, e.g. because it would need to be buffered but the buffer is full, the user agent must `flag the WebSocket as full` and then `close the WebSocket connection`. The data to be sent is the data stored in the object that `arraybuffer` refers to. Any invocation of this method with this kind of argument that does not throw an exception must increase the `bufferedAmount` attribute by the length of `data`'s buffer in bytes. [WSP]

The following are the `event handlers` (and their corresponding `event handler event types`) that must be supported, as `event handler IDL attributes`, by all objects implementing the `WebSocket` interface:

9.3.3 Feedback from the protocol

When [the WebSocket connection is established](#), the user agent must [queue a task](#) to run these steps:

1. Change the `readyState` attribute's value to [OPEN](#) (1).
2. Change the `extensions` attribute's value to the [extensions in use](#), if it is not the null value. [WSP]
3. Change the `protocol` attribute's value to the [subprotocol in use](#), if it is not the null value. [WSP]
4. [Fire an event](#) named `open` at the `WebSocket` object.

Note

Since the algorithm above is [queued as a task](#), there is no race condition between [the WebSocket connection being established](#) and the script setting up an event listener for the `open` event.

When [a WebSocket message has been received](#) with type `type` and data `data`, the user agent must [queue a task](#) to follow these steps: [WSP]

1. If the `readyState` attribute's value is not [OPEN](#) (1), then return.
2. Let `dataForEvent` be determined by switching on `type` and `binaryType`:
 - `type` indicates that the data is Text
a new [DOMString](#) containing `data`
 - `type` indicates that `data` is Binary and `binaryType` is "arraybuffer"
a new [ArrayBuffer](#) object, created in the [relevant Realm](#) of the `MessageEvent` object, that represents `data` as its raw data [FILE API]
 - `type` indicates that the data is Binary and `binaryType` is "arrayofbuffers"
a new [ArrayBuffer](#) object, created in the [relevant Realm](#) of the `WebSocket` object, whose contents are `data`
3. [Fire an event](#) named `message` at the `WebSocket` object, using `MessageEvent`, with the `origin` attribute initialized to the [serialization](#) of the `WebSocket` object's `url`'s `origin`, and the `data` attribute initialized to `dataForEvent`.

Note

User agents are encouraged to check if they perform the above steps efficiently before they run the task, picking tasks from other `task queues` while they prepare the buffers if not. For example, if the `binaryType` attribute was set to "[blob](#)" when the data arrived, and the user agent spooled all the data to disk, but just before running the above `task` for this particular message the script switched `binaryType` to "[arraybuffer](#)", the user agent would want to page the data back to RAM before running this `task` so as to avoid stalling the main thread while it created the `ArrayBuffer` object.

Example

Here is an example of how to define a handler for the `message` event in the case of text frames:

```
websocket.onmessage = function (event) {
  if (event.data == 'on') {
    timestampOn();
  } else if (event.data == 'off') {
    timestampOff();
  }
};
```

The protocol here is a trivial one, with the server just sending "on" or "off" messages.

When [the WebSocket closing handshake is started](#), the user agent must [queue a task](#) to change the `readyState` attribute's value to [CLOSING](#) (2). (If the `close()` method was called, the `readyState` attribute's value will already be set to [CLOSING](#) (2) when this task runs.) [WSP]

When [the WebSocket connection is closed](#), possibly cleanly, the user agent must [queue a task](#) to run the following substeps:

1. Change the `readyState` attribute's value to [CLOSED](#) (3).
2. If the user agent was required to [fail the WebSocket connection](#), or if the [the WebSocket connection was closed](#) after being flagged as full, [fire an event](#) named `error` at the `WebSocket` object. [WSP]
3. [Fire an event](#) named `close` at the `WebSocket` object, using `CloseEvent`, with the `wasClean` attribute initialized to true if the connection closed [cleanly](#) and false otherwise, the `code` attribute initialized to [the WebSocket connection close code](#), and the `reason` attribute initialized to the result of applying [UTF-8 decode without BOM](#) to [the WebSocket connection close reason](#). [WSP]

⚠ Warning!

User agents must not convey any failure information to scripts in a way that would allow a script to distinguish the following situations:

- A server whose host name could not be resolved.
- A server to which packets could not successfully be routed.
- A server that refused the connection on the specified port.
- A server that failed to correctly perform a TLS handshake (e.g., the server certificate can't be verified).
- A server that did not complete the opening handshake (e.g., because it was not a WebSocket server).
- A WebSocket server that sent a correct opening handshake, but that specified options that caused the client to drop the connection (e.g., the server specified a subprotocol that the client did not offer).
- A WebSocket server that abruptly closed the connection after successfully completing the opening handshake.

In all of these cases, the [the WebSocket connection close code](#) would be 1006, as required by [WebSocket Protocol](#). [WSP]

Allowing a script to distinguish these cases would allow a script to probe the user's local network in preparation for an attack.

Note

In particular, this means the code 1015 is not used by the user agent (unless the server erroneously uses it in its close frame, of course).

The `task source` for all `tasks queued` in this section is the [WebSocket task source](#).

9.3.4 Ping and Pong frames

The [WebSocket protocol](#) defines Ping and Pong frames that can be used for keep-alive, heart-beats, network status probing, latency instrumentation, and so forth. These are not currently exposed in the API.

User agents may send ping and unsolicited pong frames as desired, for example in an attempt to maintain local network NAT mappings, to detect failed connections, or to display latency metrics to the user. User agents must not use pings or unsolicited pongs to aid the server; it is assumed that servers will solicit pongs whenever appropriate for the server's needs.

9.3.5 The `CloseEvent` interface

MDN

`CloseEvent`

Support in all current engines.

Firefox 8+ Safari 6+ Chrome 13+

Opera 12.1+ Edge 79+

Edge (Legacy) 12+ Internet Explorer 10+

Firefox Android 8+ Safari iOS 6+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 12.1+

`WebSocket` objects use the `closeEvent` interface for their `close` events:

MDN

`CloseEvent`/`CloseEvent`

Support in one engine only.

Firefox 8+ Safari? Chrome?

Opera? Edge?

Edge (Legacy)? Internet Explorer?

Firefox Android 8+ Safari iOS? Chrome? Android? WebView? Android? Samsung Internet? Opera? Android?

```
IDBExposed<(Window, Worker)>
interface CloseEvent : Event {
  constructor(DOMString type, optional CloseEventInit eventInitDict = ());
  readonly attribute boolean wasClean;
  readonly attribute unsigned short code;
  readonly attribute DOMString reason;
};
```

```
boolean wasClean = false;
unsigned short code = 0;
USVString reason = "";
};
```

For web developers (non-normative)`event.wasClean`

Returns true if the connection closed cleanly; false otherwise.

`event.code`

Returns the WebSocket connection close code provided by the server.

`event.reason`

Returns the WebSocket connection close reason provided by the server.

The `wasClean` attribute must return the value it was initialized to. It represents whether the connection closed cleanly or not.

The `code` attribute must return the value it was initialized to. It represents the WebSocket connection close code provided by the server.

The `reason` attribute must return the value it was initialized to. It represents the WebSocket connection close reason provided by the server.

9.3.6 Garbage collection

A `WebSocket` object whose `readyState` attribute's value was set to `CONNECTING` (0) as of the last time the `event loop` reached `step 1` must not be garbage collected if there are any event listeners registered for `open` events, `message` events, `error` events, or `close` events.

A `WebSocket` object whose `readyState` attribute's value was set to `OPEN` (1) as of the last time the `event loop` reached `step 1` must not be garbage collected if there are any event listeners registered for `message` events, `error`, or `close` events.

A `WebSocket` object whose `readyState` attribute's value was set to `CLOSING` (2) as of the last time the `event loop` reached `step 1` must not be garbage collected if there are any event listeners registered for `error` or `close` events.

A `WebSocket` object with `an established connection` that has data queued to be transmitted to the network must not be garbage collected. [WSP]

If a `WebSocket` object is garbage collected while its connection is still open, the user agent must `start the WebSocket closing handshake`, with no status code for the Close message. [WSP]

If a user agent is to *make disappear* a `WebSocket` object (this happens when a `Document` object goes away), the user agent must follow the first appropriate set of steps from the following list:

If the WebSocket connection is not yet `established` [WSP]

Fail the WebSocket connection. [WSP]

If the WebSocket closing handshake has not yet been `started` [WSP]

Start the WebSocket closing handshake, with the status code to use in the WebSocket Close message being 1001. [WSP]

Otherwise

Do nothing.

[OMN]

`Window.postMessage`

9.4 Cross-document messaging

[...]

Support: x-doc-messagingChrome for Android 81+Chrome 4+iOS Safari 3.2+Safari 4+Firefox 3+Samsung Internet 4+Edge 12+UC Browser for Android 12.12+IE (limited) 8+Opera 9.5+Opera Mini all+Firefox for Android 68+

Source: caniuse.com

Web browsers, for security and privacy reasons, prevent documents in different domains from affecting each other; that is, cross-site scripting is disallowed.

While this is an important security feature, it prevents pages from different domains from communicating even when those pages are not hostile. This section introduces a messaging system that allows documents to communicate with each other regardless of their source domain, in a way designed to not enable cross-site scripting attacks.

Note

The `postMessage()` API can be used as a `tracking vector`.

9.4.1 Introduction

This section is non-normative.

Example

For example, if document A contains an `iframe` element that contains document B, and script in document A calls `postMessage()` on the `Window` object of document B, then a message event will be fired on that object, marked as originating from the `Window` of document A. The script in document A might look like:

```
var o = document.getElementById('myIframe')[0];
o.contentWindow.postMessage('Hello world', 'https://b.example.org/');

To register an event handler for incoming events, the script would use addEventListener() (or similar mechanisms). For example, the script in document B might look like:
window.addEventListener('message', receiver, false);
function receiver(e) {
  if (e.origin == 'https://a.example.com') {
    if (e.data == 'Hello world') {
      e.source.postMessage('Hello', e.origin);
    } else {
      alert(e.data);
    }
  }
}

This script first checks the domain is the expected domain, and then looks at the message, which it either displays to the user, or responds to by sending a message back to the document which sent the message in the first place.
```

9.4.2 Security**9.4.2.1 Authors**

⚠️ Warning!

Use of this API requires extra care to protect users from hostile entities abusing a site for their own purposes.

Authors should check the `origin` attribute to ensure that messages are only accepted from domains that they expect to receive messages from. Otherwise, bugs in the author's message handling code could be exploited by hostile sites.

Furthermore, even after checking the `origin` attribute, authors should also check that the data in question is of the expected format. Otherwise, if the source of the event has been attacked using a cross-site scripting flaw, further unchecked processing of information sent using the `postMessage()` method could result in the attack being propagated into the receiver.

Authors should not use the wildcard keyword (*) in the `targetOrigin` argument in messages that contain any confidential information, as otherwise there is no way to guarantee that the message is only delivered to the recipient to which it was intended.

Authors who accept messages from any origin are encouraged to consider the risks of a denial-of-service attack. An attacker could send a high volume of messages; if the receiving page performs expensive computation or causes network traffic to be sent for each such message, the attacker's message could be multiplied into a denial-of-service attack. Authors are encouraged to employ rate limiting (only accepting a certain number of messages per minute) to make such attacks impractical.

9.4.2.2 User agents

The integrity of this API is based on the inability for scripts of one `origin` to post arbitrary events (using `dispatchEvent()` or otherwise) to objects in other origins (those that are not the `same`).

Note
Implementors are urged to take extra care in the implementation of this feature. It allows authors to transmit information from one domain to another domain, which is normally disallowed for security reasons. It also requires that UAs be careful to allow access to certain properties but not others.

User agents are also encouraged to consider rate-limiting message traffic between different `origins`, to protect naive sites from denial-of-service attacks.

9.4.3 Posting messages**For web developers (non-normative)**

`window.postMessage(message [, options])`

Posts a message to the given window. Messages can be structured objects, e.g. nested objects and arrays, can contain JavaScript values (strings, numbers, `date` objects, etc), and can contain certain data objects such as `File Blob`, `FileList`, and `ArrayBuffer` objects.

Objects listed in the `transfer` member of `options` are transferred, not just cloned, meaning that they are no longer usable on the sending side.

A target origin can be specified using the `targetOrigin` member of `options`. If not provided, it defaults to "*". This default restricts the message to same-origin targets only.

If the origin of the target window doesn't match the given target origin, the message is discarded, to avoid information leakage. To send the message to the target regardless of origin, set the target origin to "*".

Throws a `DataCloneError` DOMException if `transfer` array contains duplicate objects or if `message` could not be cloned.

`window.postMessage(message, targetOrigin [, transfer])`

This is an alternate version of `postMessage()` where the target origin is specified as a parameter. Calling `window.postMessage(message, target, transfer)` is equivalent to `window.postMessage(message, [targetOrigin, transfer])`.

Note

When posting a message to a `Window` of a `browsing context` that has just been navigated to a new `Document`, it is likely to result in the message not receiving its intended recipient: the scripts in the target `browsing context` have to have had time to set up listeners for the messages. Thus, for instance, in situations where a message is to be sent to the `Window` of newly created child `iframe`, authors are advised to have the child `document` post a message to their parent announcing their readiness to receive messages, and for the parent to wait for this message before beginning posting messages.

The `window.postMessage` steps, given a `targetWindow`, `message`, and `options`, are as follows:

1. Let `targetRealm` be `targetWindow's Realm`.

2. Let `incumbentSettings` be the `incumbent settings object`.

3. Let `targetOrigin` be `options['targetOrigin']`.

4. If `targetOrigin` is a single U+002F SOLIDUS character (/), then set `targetOrigin` to `incumbentSettings's origin`.

5. Otherwise, if `targetOrigin` is not a single U+002A ASTERISK character (*), then:

1. Let `parsedURL` be the result of running the `URL.parse` on `targetOrigin`.

3. Set `targetOrigin` to `parsedURL's origin`.
 6. Let `transfer` be `options["transfer"]`.
 7. Let `serializeWithTransferResult` be `StructuredSerializeWithTransfer(message, transfer)`. Rethrow any exceptions.
 8. Queue a task on the posted message task source of `targetWindow`'s relevant agent's event loop to run the following steps:
 1. If the `targetOrigin` argument is not a single literal U+002A ASTERISK character (*) and `targetWindow`'s associated document's `origin` is not same origin with `targetOrigin`, then return.
 2. Let `origin` be the serialization of `incumbentSetting's global object` (a `Window` object).
 3. Let `windowFromSource` be the `Window` object corresponding to `incumbentSetting's global object` (a `Window` object).
 4. Let `deserializeRecord` be `StructuredDeserializeWithTransfer(serializeWithTransferResult, targetRealm)`.
 If this throws an exception, catch it, fire an event named `messageerror` at `targetWindow`, using `MessageEvent`, with the `origin` attribute initialized to `origin` and the `source` attribute initialized to `source`, and then return.
 5. Let `messageClone` be `deserializeRecord[[Deserialized]]`.
 6. Let `newPorts` be a new `frozen array` consisting of all `MessagePort` objects in `deserializeRecord[[TransferredValues]]`, if any, maintaining their relative order.
 7. Fire an event named `message` at `targetWindow`, using `MessageEvent`, with the `origin` attribute initialized to `origin`, the `source` attribute initialized to `source`, the `data` attribute initialized to `messageClone`, and the `ports` attribute initialized to `newPorts`.
 The `postMessage(message, options)` method, when invoked on a `Window` object, must run the following steps:
 1. Let `targetWindow` be this `Window` object.
 2. Run the `window.postMessage steps` providing `targetWindow`, `message`, and `options`.

Edge (Legacy)12+Internet Explorer10+

Firefox Android41+Safari iOS5.1+Chrome Android18+WebView Android4.4+Samsung Internet1.0+Opera Android11+

9.5.1 Introduction*This section is non-normative.*To enable independent pieces of code (e.g. running in different `browsing contexts`) to communicate directly, authors can use `channel messaging`.

Communication channels in this mechanism are implemented as two-way pipes, with a port at each end. Messages sent in one port are delivered at the other port, and vice-versa. Messages are delivered as DOM events, without interrupting or blocking running tasks.

To create a connection (two "entangled" ports), the `MessageChannel()` constructor is called:

```
var channel = new MessageChannel();  
  
One of the ports is kept as the local port, and the other port is sent to the remote code, e.g. using postMessage():  
  
otherWindow.postMessage("hello", "https://example.com", [channel.port2]);  
  
To send messages, the postMessage() method on the port is used:  
  
channel.port1.postMessage("hello");  
  
To receive messages, one listens to message events:  
  
channel.port1.onmessage = handleMessage;  
function handleMessage(event) {  
  // message is in event.data  
}  
  
Data sent on a port can be structured data; for example here an array of strings is passed on a MessagePort:  
  
port1.postMessage(["hello", "world"]);
```

9.5.1.1 Examples*This section is non-normative.***Example**In this example, two JavaScript libraries are connected to each other using `MessagePorts`. This allows the libraries to later be hosted in different frames, or in `worker` objects, without any change to the APIs.

```
<script src="contacts.js"></script> <!-- exposes a contacts object -->  
<script src="compose-mail.js"></script> <!-- exposes a composer object -->  
var channel = new MessageChannel();  
composer.addContactProvider(channel.port1);  
contacts.registerConsumer(channel.port2);  
</script>
```

Here's what the `"addContactsProvider()"` function's implementation could look like:

```
function addContactsProvider(port) {  
  port.addEventListener("message", event => {  
    if (event.data.messageType === "search-result")  
      handleSearchResult(event.data.results);  
    else if (event.data.messageType === "search-done")  
      handleSearchDone();  
    else if (event.data.messageType === "search-error")  
      handleSearchError(event.data.message);  
  });  
}
```

Alternatively, it could be implemented as follows:

```
function addContactsProvider(port) {  
  port.addEventListener("message", event => {  
    if (event.data.messageType === "search-result")  
      handleSearchResult(event.data.results);  
    else if (event.data.messageType === "search-done")  
      handleSearchDone();  
    else if (event.data.messageType === "search-error")  
      handleSearchError(event.data.message);  
  });  
}  
  
port.start();
```

The key difference is that when using `addEventListener()`, the `start()` method must also be invoked. When using `onmessage`, the call to `start()` is implied.The `start()` method, whether called explicitly or implicitly (by setting `onmessage`) starts the flow of messages: messages posted on message ports are initially paused, so that they don't get dropped on the floor before the script has had a chance to set up its handlers.**9.5.1.2 Ports as the basis of an object-capability model on the Web***This section is non-normative.*

Ports can be viewed as a way to expose limited capabilities (in the object-capability model sense) to other actors in the system. This can either be a weak capability system, where the ports are merely used as a convenient model within a particular origin, or as a strong capability model, where they are provided by one origin provider as the only mechanism by which another origin consumer can effect change in or obtain information from provider.

For example, consider a situation in which a social Web site embeds in one `iframe` the user's e-mail contacts provider (an address book site, from a second origin), and in a second `iframe` a game (from a third origin). The outer social site and the game in the second `iframe` cannot access anything inside the first `iframe`; together they can only:

- Navigate the `iframe` to a new URL such as the same URL but with a different fragment, causing the `Window` in the `iframe` to receive a `hashchange` event.

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

• Send a `message` event to the `Window` in the `iframe` using the `window.postMessage()` API.

The contacts provider can use these methods, most particularly the third one, to provide an API that can be accessed by other origins to manipulate the user's address book. For example, it could respond to a message "`add-contact Guillaume Tell <tell@poème.example.net>`" by adding the given person and e-mail address to the user's address book.

To avoid any site on the Web being able to manipulate the user's contacts, the contacts provider might only allow certain trusted sites, such as the social site, to do this.

Now suppose the game wanted to add a contact to the user's address book, and that the social site was willing to allow it to do so on its behalf, essentially "sharing" the trust that the contacts provider had with the social site. There are several ways it could do this; most simply, it could just proxy messages between the game site and the contacts site. However, this solution has a number of difficulties: it requires the social site to either completely trust the game site not to abuse the privilege, or it requires that the social site verify each request to make sure it's not a request that it doesn't want to allow (such as adding multiple contacts, reading the contacts, or deleting them); it also requires some additional complexity if there's the possibility of multiple games simultaneously trying to interact with the contacts provider.

Using message channels and `MessagePort` objects, however, all of these problems can go away. When the game tells the social site that it wants to add a contact, the social site can ask the contacts provider not for it to add a contact, but for the capability to add a single contact. The contacts provider then creates a pair of `MessagePort` objects, and sends one of them back to the social site, who forwards it on to the game. The game and the contacts provider then have a direct connection, and the contacts provider knows to only honor a single "add contact" request, nothing else. In other words, the game has been granted the capability to add a single contact.

9.5.1.3 Ports as the basis of abstracting out service implementations

This section is non-normative.

Continuing the example from the previous section, consider the contacts provider in particular. While an initial implementation might have simply used `XMLHttpRequest` objects in the service's `iframe`, an evolution of the service might instead want to use a `shared worker` with a single `WebSocket` connection.

If the initial design used `MessagePort` objects to grant capabilities, or even just to allow multiple simultaneous independent sessions, the service implementation can switch from the `XMLHttpRequests-in-each-iframe` model to the shared-`WebSocket` model without changing the API at all: the ports on the service provider side can all be forwarded to the shared worker without it affecting the users of the API in the slightest.

9.5.2 Message channels

 MDN

`MessageChannel`

Support in all current engines.

Firefox41+Safari5+Chrome4+

Opera10.6+Edge79+

Edge (Legacy)12+Internet Explorer10+

Firefox Android41+Safari iOS5.1+Chrome Android18+WebView Android4.4+Samsung Internet1.0+Opera Android11+

```
IID([Constructable], Exposed<Window, Worker>)
interface MessageChannel {
  readonly attribute MessagePort port1;
  readonly attribute MessagePort port2;
};
```

For web developers (non-normative)

`channel = new MessageChannel();`

Returns a new `MessageChannel` object with two new `MessagePort` objects.

`channel.port1`

Returns the first `MessagePort` object.

`channel.port2`

Returns the second `MessagePort` object.

 MDN

`MessageChannel.MessageChannel`

Support in all current engines.

Firefox41+Safari5+Chrome4+

Opera10.6+Edge79+

Edge (Legacy)12+Internet Explorer10+

Firefox Android41+Safari iOS5.1+Chrome Android18+WebView Android4.4+Samsung Internet1.0+Opera Android11+

When the `MessageChannel()` constructor is called, it must run the following algorithm:

1. Create a new `MessagePort` object whose `owner` is the `incumbent settings object`, and let `port1` be that object.
2. Create a new `MessagePort` object whose `owner` is the `incumbent settings object`, and let `port2` be that object.
3. **Entangle** the `port1` and `port2` objects.
4. Instantiate a new `MessageChannel` object, and let `channel` be that object.
5. Let the `port1` attribute of the `channel` object be `port1`.
6. Let the `port2` attribute of the `channel` object be `port2`.
7. Return `channel`.

 MDN

`MessageChannel.port1`

Support in all current engines.

Opera10.6+Edge79+

Edge (Legacy)12+Internet Explorer10+

Firefox AndroidYesSafari iOS5.1+Chrome Android18+WebView AndroidYesSamsung Internet1.0+Opera Android11+

Each channel has two message ports. Data sent through one port is received by the other port, and vice versa.

```
IID([Exposed<Window, Worker>, Autoworkerlet], Transferable)
interface MessagePort : EventTarget {
  void postMessage(any message, sequence<Object> transfer);
  void postMessage(any message, optional PostMessageOptions options = ());
  void close();
  void start();
};

// event handlers
attribute EventHandler onmessage;
attribute EventHandler onmessageerror;
};

dictionary PostMessageOptions {
  sequence<Object> transfer = [];
};

For web developers (non-normative)
port.postMessage(message [, transfer])
port.postMessage(message [, { transfer }])
```

Posts a message through the channel. Objects listed in `transfer` are transferred, not just cloned, meaning that they are no longer usable on the sending side.

Throws a `DataCloneError` `DOMException` if `transfer` contains duplicate objects or `port`, or if `message` could not be cloned.

`port.start()`

Begins dispatching messages received on the port.

`port.close()`

Disconnects the port, so that it is no longer active.

Each `MessagePort` object can be entangled with another (a symmetric relationship). Each `MessagePort` object also has a `task source` called the `port message queue`, initially empty. A `port message queue` can be enabled or disabled, and is initially disabled. Once enabled, a port can never be disabled again (though messages in the queue can get moved to another queue or removed altogether, which has much the same effect). A `MessagePort` also has a `has been shipped` flag, which must initially be false, and an `owner`, which is a `settings object` set when the object is created, as described below.

When a port's `port message queue` is enabled, the `event loop` must use it as one of its `task sources`. When a port's `owner's responsible event loop` is a `window event loop`, all `tasks queued` on its `port message queue` must be associated with the port's `owner's responsible document`.

Note
If the port's `owner's responsible document` is `fully active`, but the event listeners all have scripts whose `settings object`s specify `responsible documents` that are `not fully active`, then the messages will be lost.

Each event loop has a `task source` called the `unshipped port message queue`. This is a virtual `task source`: it must act as if it contained the `tasks` of each `port message queue` of each `MessagePort` whose `has been shipped` flag is false, whose `port message queue` is enabled, and whose `owner's responsible event loop` is that `event loop`, in the order in which they were

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

When a `MessagePort`'s `has been shipped` flag is false, its `port message queue` must be ignored for the purposes of the `event loop`. (The `unshipped port message queue` is used instead.)

Note
`The has been shipped` flag is set to true when a port, its twin, or the object it was cloned from, is or has been transferred. When a `MessagePort`'s `has been shipped` flag is true, its `port message queue` acts as a first-class `task source`, unaffected by any `unshipped port message queue`.

When the user agent is to *create a new MessagePort object* with a particular `environment settings object` as its `owner`, it must instantiate a new `MessagePort` object, and let its `owner` be `owner`.

When the user agent is to *entangle two MessagePort objects*, it must run the following steps:

1. If one of the ports is already entangled, then disentangle it and the port that it was entangled with.

Note
`If those two previously entangled ports were the two ports of a MessageChannel object, then that MessageChannel object no longer represents an actual channel: the two ports in that object are no longer entangled.`

2. Associate the two ports to be entangled, so that they form the two parts of a new channel. (There is no `MessageChannel` object that represents this channel.)

Two ports *A* and *B* that have gone through this step are now said to be entangled; one is entangled to the other, and vice versa.

Note
`While this specification describes this process as instantaneous, implementations are more likely to implement it via message passing. As with all algorithms, the key is "merely" that the end result be indistinguishable, in a black-box sense, from the specification.`

`MessagePort` objects are `transferrable objects`. Their `transfer steps`, given `value` and `dataHolder`, are:

1. Set `value`'s `has been shipped` flag to true.

2. Set `dataHolder.[[PortMessageQueue]]` to `value`'s `port message queue`.

3. If `value` is entangled with another port `remotePort`, then:
 1. Set `remotePort`'s `has been shipped` flag to true.
 2. Set `dataHolder.[[RemotePort]]` to `remotePort`.

4. Otherwise, set `dataHolder.[[RemotePort]]` to null.

Their `transfer-receiving steps`, given `dataHolder` and `value`, are:

1. Set `value`'s `has been shipped` flag to true.

2. Set `value`'s `owner` to `value`'s `relevant settings object`.

3. Move all the `tasks` that are to fire `message` events in `dataHolder.[[PortMessageQueue]]` to the `port message queue` of `value`, if any, leaving `value`'s `port message queue` in its initial disabled state, and, if `value`'s `owner`'s `responsible event loop` is a `window event loop`, associating the moved `tasks` with `value`'s `owner`'s `responsible document`.

4. If `dataHolder.[[RemotePort]]` is not null, then `change dataHolder.[[RemotePort]]` and `value`. (This will disentangle `dataHolder.[[RemotePort]]` from the original port that was transferred.)

The message port `post message steps`, given a `targetPort`, `message` and `options` are as follows:

1. Let `transfer` be `options["transfer"]`.

2. If `transfer` `contains` the `messagePort`, then throw a `"dataCloneError"` `DOMException`.

3. Let `doomed` be false.

4. If `targetPort` is not null and `transfer` `contains` `targetPort`, then set `doomed` to true and optionally report to a developer console that the target port was posted to itself, causing the communication channel to be lost.

5. Let `serializeWithTransferResult` be `StructuredSerializeWithTransfer`(`message`, `transfer`). Rethrow any exceptions.

6. If `targetPort` is null, or if `doomed` is true, then return.

7. Add a `task` that runs the following steps to the `port message queue` of `targetPort`:

1. Let `finalTargetPort` be the `MessagePort` in whose `port message queue` the task now finds itself.

Note
`This can be different from targetPort, if targetPort itself was transferred and thus all its tasks moved along with it.`

2. Let `targetRealm` be `finalTargetPort's relevant Realm`.

3. Let `deserialzeRecord` be `StructuredDeserializeWithTransfer`(`serializeWithTransferResult`, `targetRealm`).

If this throws an exception, catch it, `fire an event` named `messageerror` at `finalTargetPort`, using `MessageEvent`, and then return.

4. Let `messageClone` be `deserialzeRecord.[[Deserialized]]`.

5. Let `newPorts` be a new `frozen array` consisting of all `MessagePort` objects in `deserialzeRecord.[[TransferredValues]]`, if any, maintaining their relative order.

6. `Fire an event` named `message` at `finalTargetPort`, using `MessageEvent`, with the `data` attribute initialized to `messageClone` and the `ports` attribute initialized to `newPorts`.

The `posttheMessage(message, options)` method, when invoked on a `MessagePort` object must run the following steps:

1. Let `targetPort` be the port with which this `MessagePort` is entangled, if any; otherwise let it be null.

2. Run the `message port post message steps` providing `targetPort`, `message` and `options`.

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

The first time a `MessagePort` object's `onmessage` IDL attribute is set, the port's `port.message_queue` must be enabled, as if the `start()` method had been called.

9.5.4 Broadcasting to many ports

This section is non-normative.

Broadcasting to many ports is in principle relatively simple: keep an array of `MessagePort` objects to send messages to, and iterate through the array to send a message. However, this has one rather unfortunate effect: it prevents the ports from being garbage collected, even if the other side has gone away. To avoid this problem, implement a simple protocol whereby the other side acknowledges it still exists. If it doesn't do so after a certain amount of time, assume it's gone, close the `MessagePort` object, and let it be garbage collected.

9.5.5 Ports and garbage collection

When a `MessagePort` object is entangled, user agents must either act as if `o`'s entangled `MessagePort` object has a strong reference to `o`, or as if the `globalObject` specified by `o`'s `open()` has a strong reference to `o`.

Note

Thus, a message port can be received, given an event listener, and then forgotten, and so long as that event listener could receive a message, the channel will be maintained.

Of course, if this was to occur on both sides of the channel, then both ports could be garbage collected, since they would not be reachable from live code, despite having a strong reference to each other.

Furthermore, a `MessagePort` object must not be garbage collected while there exists an event referenced by a `task` in a `task queue` that is to be dispatched on that `MessagePort` object, or while the `MessagePort` object's `port.message_queue` is enabled and not empty.

Note

Authors are strongly encouraged to explicitly close `MessagePort` objects to disentangle them, so that their resources can be recycled. Creating many `MessagePort` objects and discarding them without closing them can lead to high transient memory usage since garbage collection is not necessarily performed promptly, especially for `MessagePorts` where garbage collection can involve cross-process coordination.

9.6 Broadcasting to other browsing contexts

Firefox/Android/Safari/IOS/Chrome/Android54+WebView/Android54+Samsung Internet6.0+Opera/Android41+

Pages on a single `origin` opened by the same user in the same user agent but in different unrelated `browsing contexts` sometimes need to send notifications to each other, for example "hey, the user logged in over here, check your credentials again".

For elaborate cases, e.g. to manage locking of shared state, to manage synchronization of resources between a server and multiple local clients, to share a `Websocket` connection with a remote host, and so forth, `shared workers` are the most appropriate solution.

For simple cases, though, where a shared worker would be an unreasonable overhead, authors can use the simple channel-based broadcast mechanism described in this section.

[BroadcastChannel](#)

Firefox38+SafariNonChrome54+

Opera41+Edge79+

Edge (Legacy)NonInternet ExplorerNo

Firefox/Android/Safari/IOS/Chrome/Android54+WebView/Android54+Samsung Internet6.0+Opera/Android41+

```
IDL [Exposed (Window, Worker)]
interface BroadcastChannel : EventTarget {
    constructor(DOMString name);
    readonly attribute DOMString name;
    void postMessage(any message);
    void close();
    attribute EventHandle onmessage;
    attribute EventHandle onmessageerror;
};
```

For web developers (non-normative)

`broadcastChannel = new BroadcastChannel(name)`

Returns a new `BroadcastChannel` object via which messages for the given channel name can be sent and received.

`broadcastChannel.name`

Returns the channel name (as passed to the constructor).

`broadcastChannel.postMessage(message)`

Sends the given message to other `BroadcastChannel` objects set up for this channel. Messages can be structured objects, e.g. nested objects and arrays.

`broadcastChannel.close()`

Closes the `BroadcastChannel` object, opening it up to garbage collection.

A `BroadcastChannel` object has a `channel name`, a `BroadcastChannel settings object`, and a `closed flag`.

[BroadcastChannel/BroadcastChannel](#)

Edge (Legacy)NonInternet ExplorerNo

Firefox/Android/Safari/IOS/Chrome/Android54+WebView/Android54+Samsung Internet6.0+Opera/Android41+

The `postMessage(message)` method, when invoked on a `BroadcastChannel` object, must run the following steps:

1. Let `source` be this `BroadcastChannel`.
 2. Let `sourceSettings` be `source`'s `BroadcastChannel settings object`.
 3. If `source`'s `closed flag` is true, then throw an `"InvalidStateError"` `DOMException`.
 4. Let `sourceChannel` be `source`'s `channel name`.
 5. Let `targetRealm` be a user-agent defined Realm.
 6. Let `serialized` be `StructuredSerialize(message)`. Rethrow any exceptions.
 7. Let `destinations` be a list of `BroadcastChannel` objects that match the following criteria:
 - Their `BroadcastChannel settings object` specifies either:
 - a `global object` that is a `Window` object whose `associated document` is `fully active`, or
 - a `global object` that is a `WorkerGlobalScope` object whose `closing` flag is false and whose `worker` is not a `suspendable worker`.
 - Their `BroadcastChannel settings object`'s `origin` is `same origin` with `sourceSettings`'s `origin`.
 - Their `channel name` is a `case-sensitive` match for `sourceChannel`.
 - Their `closed flag` is false.
 - 8. Remove `source` from `destinations`.
 - 9. Sort `destinations` such that all `BroadcastChannel` objects whose `BroadcastChannel settings object` specify the same `responsible event loop` are sorted in creation order, oldest first. (This does not define a complete ordering. Within this constraint, user agents may sort the list in any user-agent defined manner.)
 - 10. For each `BroadcastChannel` object `destination` in `destinations`, `queue a task` on the `DOM manipulation task source` of `destination`'s `relevant agent`'s `event loop` that runs the following steps. If that event loop is a `window event loop`, then the `task's document` must be set to `destination`'s `BroadcastChannel settings object`'s `responsible document`.
 1. Let `targetRealm` be `destination`'s `relevant Realm`.
 2. Let `data` be `StructuredDeserialize(serialized, targetRealm)`.
- If this throws an exception, catch it, `fire an event` named `messageerror` at `destination`, using `MessageEvent`, with the `detail` attribute initialized to the `serialization` of `sourceSettings`'s `origin`, and then return.

While a `broadcastChannel` object whose `closed` flag is false has an event listener registered for `message` events, there must be a strong reference from `globalObject` specified by the `broadcastChannel` object's `broadcastChannelSettingsObject` to the `broadcastChannel` object itself.

[MDN](#)

`broadcastChannel.close`

Firefox 38+; Safari iOS/Chrome 54+

[Web_Workers_API/using_web_workers](#)

10.1 Introduction

10.1.1 Scope

This section is non-normative.

This specification defines an API for running scripts in the background independently of any user interface scripts.

This allows for long-running scripts that are not interrupted by scripts that respond to clicks or other user interactions, and allows long tasks to be executed without yielding to keep the page responsive.

Workers (as these background scripts are called herein) are relatively heavy-weight, and are not intended to be used in large numbers. For example, it would be inappropriate to launch one worker for each pixel of a four megapixel image. The examples below show some appropriate uses of workers.

Generally, workers are expected to be long-lived, have a high start-up performance cost, and a high per-instance memory cost.

10.1.2 Examples

This section is non-normative.

There are a variety of uses that workers can be put to. The following subsections show various examples of this use.

10.1.2.1 A background number-crunching worker

This section is non-normative.

The simplest use of workers is for performing a computationally expensive task without interrupting the user interface.

In this example, the main document spawns a worker to (natively) compute prime numbers, and progressively displays the most recently found prime number.

The main page is as follows:

```
<!DOCTYPE HTML>
<html>
  <head>
    <meta charset="utf-8">
    <title>Worker example: One-core computation</title>
  </head>
  <body>
    <p>The highest prime number discovered so far is: <output id="result"></output></p>
    <script>
      var worker = new Worker('worker.js');
      worker.onmessage = function (event) {
        document.getElementById('result').textContent = event.data;
      }
    </script>
  </body>
</html>
```

The `Worker()` constructor call creates a worker and returns a `Worker` object representing that worker, which is used to communicate with the worker. That object's `onmessage` event handler allows the code to receive messages from the worker.

The worker itself is as follows:

```
var n = 1;
search: while (true) {
  n += 1;
  for (var i = 2; i <= Math.sqrt(n); i += 1)
    if (n % i == 0)
      continue search;
    // Found a prime!
    postMessage(n);
}

The bulk of this code is simply an unoptimized search for a prime number. The postMessage() method is used to send a message back to the page when a prime is found.
```

10.1.2.2 Using a JavaScript module as a worker

This section is non-normative.

All of our examples so far show workers that run `classic scripts`. Workers can instead be instantiated using `module scripts`, which have the usual benefits: the ability to use the `JavaScript import` statement to import other modules; strict mode by default; and top-level declarations not polluting the worker's global scope.

Note that such module-based workers follow different restrictions regarding cross-origin content, compared to classic workers. Unlike classic workers, module workers can be instantiated using a cross-origin script, as long as that script is exposed using the `CORS protocol`. Additionally, the `importScripts()` method will automatically fail inside module workers; the `JavaScript import` statement is generally a better choice.

In this example, the main document uses a worker to do off-main-thread image manipulation. It imports the filters used from another module.

```
The main page is as follows:
<!DOCTYPE html>
<meta charset="utf-8">
<title>Worker example: image decoding</title>
<script>
  window>
    Type an image URL to decode
</script>
```

```

<option value="https://html.spec.whatwg.org/images/drawImage.png">
<option value="https://html.spec.whatwg.org/images/robots.jpg">
<option value="https://html.spec.whatwg.org/images/arcTo2.png">
</datalist>
</label>
</p>
<p><label>
  Choose a filter to apply
  <select id="filter">
    <option value="none">none</option>
    <option value="grayscale">grayscale</option>
    <option value="brighten">brighten by 20%</option>
  </select>
</label>
</p>
<div>
  <img id="output">
</div>
<script type="module">
  const worker = new Worker("worker.js", { type: "module" });
  worker.onmessage = receiveFromWorker;

  const url = document.querySelector("#image-url");
  const filter = document.querySelector("#filter");
  const output = document.querySelector("#output");

  url.oninput = updateImage;
  filter.oninput = sendToWorker;
  let imageData, context;
  function updateImage() {
    const img = document.createElement("img");
    img.src = url.value;
    img.onload = () => {
      output.innerHTML = "";
      const canvas = document.createElement("canvas");
      canvas.width = img.width;
      canvas.height = img.height;
      context = canvas.getContext("2d");
      context.drawImage(img, 0, 0);
      imageData = context.getImageData(0, 0, canvas.width, canvas.height);

      sendToWorker();
      output.appendChild(canvas);
    }
  }

  function sendToWorker() {
    worker.postMessage({ imageData, filter: filter.value });
  }

  function receiveFromWorker(e) {
    context.putImageData(e.data, 0, 0);
  }
</script>

```

The worker file is then:

```

import * as filters from "./filters.js";

self.onmessage = e => {
  const { imageData, filter } = e.data;
  filters[filter](imageData);
  self.postMessage([imageData, [imageData.data.buffer]]);
};

Which imports the file filters.js:

```

```

export function none() {}

export function grayscale([ data: d ]) {
  for (let i = 0; i < d.length; i += 4) {
    const [ r, g, b, a ] = [ d[i], d[i + 1], d[i + 2] ];
    // CRT luminance formula
    // The human eye is bad at seeing red and blue, so we de-emphasize them.
    d[i] = d[i + 1] = d[i + 2] = 0.2126 * r + 0.7152 * g + 0.0722 * b;
  }
}

export function brighten([ data: d ]) {
  for (let i = 0; i < d.length; i += 4) {
    d[i] *= 1.2;
  }
}

```

SharedWorker

Firefox29+Safari5-6.1Chrome4+

Open10.6+Edge79+

Edge (Legacy)\Internet ExplorerNo

FirefoxAndroid33+Safari iOS5.1-7Chrome AndroidNoWebView AndroidNoSamsung Internet4.0-5.0Opera Android11-14

This section is non-normative.

This section introduces shared workers using a Hello World example. Shared workers use slightly different APIs, since each worker can have multiple connections.

This first example shows how you connect to a worker and how a worker can send a message back to the page when it connects to it. Received messages are displayed in a log.

Here is the HTML page:

```

<!DOCTYPE HTML>
<meta charset="utf-8">
<title>Shared workers: demo 1</title>
<pre id="log">Log:</pre>
<script>
  var worker = new SharedWorker("test.js");
  var log = document.getElementById("log");
  worker.onmessage = function(e) {
    log.textContent += "\n" + e.data;
  };
</script>

```

Here is the JavaScript worker:

```

onconnect = function(e) {
  var port = e.ports[0];
  port.postMessage("Hello World!");
}

```

[View this example online.](#)

This second example extends the first one by changing two things: first, messages are received using `addEventListener()` instead of an `event handler IDL attribute`, and second, a message is sent to the worker, causing the worker to send another message in return. Received messages are again displayed in a log.

Here is the HTML page:

```

<!DOCTYPE HTML>
<meta charset="utf-8">
<title>Shared workers: demo 2</title>
<pre id="log">Log:</pre>
<script>
  var worker = new SharedWorker("test.js");
  var log = document.getElementById("log");
  worker.addEventListener("message", function(e) {
    log.textContent += "\n" + e.data;
  }, false);
  worker.start(); // note: need this when using addEventListener
  worker.port.postMessage("ping");
</script>

```

Here is the JavaScript worker:

```

onconnect = function(e) {
  var port = e.ports[0];
  port.postMessage("Hello World!");
  port.postMessage("pong"); // not e.ports[0].postMessage!
  // e.target.postMessage("pong"); would work also
}

```

[View this example online.](#)

Finally, the example is extended to show how two pages can connect to the same worker; in this case, the second page is merely in an `iframe` on the first page, but the same principle would apply to an entirely separate page in a separate `top-level browsing context`.

Here is the outer HTML page:

```

<!DOCTYPE HTML>
<meta charset="utf-8">
<title>Shared workers: demo 3</title>
<pre id="log">Log:</pre>
<script>
  var worker = new SharedWorker("test.js");
  var log = document.getElementById("log");
  worker.addEventListener("message", function(e) {
    log.textContent += "\n" + e.data;
  }, false);
  worker.start();
  worker.port.postMessage("ping");
</script>
<iframe src="inner.html"></iframe>

```

Here is the inner HTML page:

```

<!DOCTYPE HTML>
<meta charset="utf-8">
<title>Shared workers: demo 3</title>
<pre id="log">Log:</pre>
<script>
  worker.port.addEventListener("message", function(e) {
    log.textContent += "\n" + e.data;
  }, false);
</script>

```

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

```

<pre id=log>Inner log:</pre>
<script>
var worker = new SharedWorker('test.js');
worker.port.onmessage = function(e) {
  log.textContent += '\n' + e.data;
}
</script>

Here is the JavaScript worker.

var count = 0;
onmessage = function(e) {
  count += 1;
  var port = e.ports[0];
  port.postMessage('World! You are connection #' + count);
  port.onmessage = function(e) {
    port.postMessage('pong');
  }
}

```

[View this example online.](#)

10.2.2.4 Shared state using a shared worker

This section is non-normative.

In this example, multiple windows (viewers) can be opened that are all viewing the same map. All the windows share the same map information, with a single worker coordinating all the viewers. Each viewer can move around independently, but if they set any data on the map, all the viewers are updated.

The main page isn't interesting, it merely provides a way to open the viewers:

```

<!DOCTYPE HTML>
<html>
<head>
<meta charset="utf-8">
<title>Workers example: Multiviewer</title>
<script>
  function openViewer() {
    window.open('viewer.html');
  }
</script>
</head>
<body>
<p><button type="button" onclick="openViewer()">Open a new viewer</button></p>
<p>This viewer opens in a new window. You can have as many viewers as you like, they all view the same data.</p>
</body>

```

The viewer is more involved:

```

<!DOCTYPE HTML>
<html>
<head>
<meta charset="utf-8">
<title>Workers example: Multiviewer viewer</title>
<var worker = new SharedWorker('worker.js', 'core');

// CONFIGURATION
function configure(event) {
  if (event.data.substring(0, 4) != 'cfg') return;
  var name = event.data.substring(4).split(',')[0];
  // update display to mention our name is name
  document.getElementById('name').innerHTML[0].textContent += ' ' + name;
  document.removeEventListener('message', configure, false);
  worker.port.removeEventListener('message', configure, false);
}

// MAP
function paintMap(event) {
  if (event.data.substring(0, 4) != 'map') return;
  var data = event.data.substring(4).split(',');
  // display tiles data[0] .. data[8]
  var canvas = document.getElementById('map');
  var context = canvas.getContext('2d');
  for (var y = 0; y < 3; y += 1)
    for (var x = 0; x < 3; x += 1) {
      var tile = data[y * 3 + x];
      if (tile == '0')
        context.fillStyle = 'green';
      else
        context.fillStyle = 'brown';
      context.fillRect(x * 50, y * 50, 50, 50);
    }
}
worker.port.addEventListener('message', paintMap, false);

// PUBLIC CHAT
function updatePublicChat(event) {
  if (event.data.substring(0, 4) != 'ext') return;
  var data = event.data.substring(4).split(',')[0];
  var message = event.data.substring(4 + name.length + 1);
  var public = document.getElementById('public');
  var p = document.createElement('p');
  p.textContent = message;
  public.appendChild(p);
  public.scrollTop = public.scrollHeight;
}
worker.port.addEventListener('message', updatePublicChat, false);

// PRIVATE CHAT
function startPrivateChat(event) {
  if (event.data.substring(0, 4) != 'msg') return;
  var data = event.data.substring(4).split(',')[0];
  var port = event.ports[0];
  // display a private chat UI
  var li = document.createElement('li');
  var h3 = document.createElement('h3');
  h3.textContent = 'private';
  li.appendChild(h3);
  var form = document.createElement('form');
  var t = document.createElement('textArea');
  t.value = '';
  t.name = name;
  li.appendChild(t);
  var p = document.createElement('p');
  p.appendChild(n);
  n.textContent = '<input type="button" value="Post"/>';
  p.appendChild(t);
  t.appendChild(n);
  p.appendChild(t);
  div.appendChild(p);
}

port.onmessage = function (event) {
  if (event.data.substring(0, 4) != 'addMessage') return;
  var data = event.data.substring(4).split(',');
  var name = data[0];
  var message = data[1];
  var p = document.createElement('p');
  var t = document.createElement('textArea');
  t.value = message;
  t.name = name;
  p.appendChild(t);
  startPrivateChat();
}

port.start();
</script>
</head>
<body>
<h1>Workers</h1>
<h2>Map</h2>
<p><canvas id="map" height=150 width=150></canvas></p>
<button type="button" onclick="worker.port.postMessage('map up')">Up</button>
<button type="button" onclick="worker.port.postMessage('map down')">Down</button>
<button type="button" onclick="worker.port.postMessage('map right')">Right</button>
<button type="button" onclick="worker.port.postMessage('map left')">Left</button>
<button type="button" onclick="worker.port.postMessage('set 1')">Set 1</button>
<button type="button" onclick="worker.port.postMessage('set 1')">Set 1</button>
</p>
<h2>Public Chat</h2>
<div id="public"></div>
<form onsubmit="worker.port.postMessage('txt ' + message.value); message.value = ''> return false;</form>
<input type="text" name="message" size="50">
<button type="button" value="Post"/>
</form>
<h2>Private Chat</h2>
<ul id="private"></ul>
</body>

```

There are several key things worth noting about the way the viewer is written.

Multiple listeners. Instead of a single message processing function, the code here attaches multiple event listeners, each one performing a quick check to see if it is relevant for the message. In this example it doesn't make much difference, but if multiple authors wanted to collaborate using a single port to communicate with a worker, it would allow for independent code instead of changes having to all be made to a single event handling function.

Registering event listeners in this way also allows you to unregister specific listeners when you are done with them, as is done with the `configure()` method in this example.

Finally, the worker:

```

var neatnames = 0;
function getNeatName() {
  // this could use more friendly names
  // but for now just return a number
  return neatname++;
}

var map = [
  [0, 0, 0, 0, 0, 0],
  [0, 1, 0, 1, 0, 1],
  [0, 1, 0, 1, 0, 1],
];

```

```
[0, 0, 0, 1, 0, 0, 0],
[1, 0, 0, 1, 1, 0, 1];
[1, 1, 0, 1, 1, 0, 1];

function wrap(x) {
  if (x < 0) return wrap(x + map[0].length);
  if (x >= map[0].length) return wrap(x - map[0].length);
  return x;
}

function wrap(y) {
  if (y < 0) return wrap(y + map.length);
  if (y >= map[0].length) return wrap(y - map.length);
  return y;
}

function wrap(val, min, max) {
  if (val < min)
    return val + (max-min)+1;
  if (val > max)
    return val - (max-min)-1;
  return val;
}

function sendMapData(viewer) {
  var data = '';
  for (var y = viewer.y-1; y <= viewer.y+1; y += 1) {
    for (var x = viewer.x-1; x <= viewer.x+1; x += 1) {
      if (data != ',')
        data += ',';
      data += map[wrap(y, 0, map[0].length-1)][wrap(x, 0, map.length-1)];
    }
  }
  viewer.port.postMessage('map' + data);
}

var viewers = [];
connect = function (event) {
  var name = event.data.name();
  var port = event.data.port;
  event.data.name = name;
  event.data.port = port;
  viewers[name] = event;
  sendMapData(event);
  sendMapData(event);
};

function getMessage(event) {
  switch (event.data.substring(0, 4)) {
    case 'mov':
      var direction = event.data.substring(4);
      var dx = 0;
      var dy = 0;
      switch (direction) {
        case 'up': dy -= 1; break;
        case 'down': dy += 1; break;
        case 'left': dx -= 1; break;
        case 'right': dx += 1; break;
      }
      event.target._data = wrap(event.target._data.x + dx);
      event.target._data = wrap(event.target._data.y + dy);
      sendMapData(event.target._data);
      break;
    case 'set':
      var value = event.data.substring(4);
      map[event.target._data.x][event.target._data.y] = value;
      for (var viewer in viewers)
        sendMapData(viewer);
      break;
    case 'txt':
      var name = event.target._data.name;
      var message = event.data.substring(4);
      for (var viewer in viewers)
        viewers[viewer].port.postMessage('txt ' + name + ' ' + message);
      break;
    case 'msg':
      var target = event.target._data;
      var party2 = viewers[event.data.substring(4).split(' ', 1)[0]];
      if (party2) {
        var channel = new MessageChannel();
        party1.port.postMessage('msg ' + party2.name, [channel.port1]);
        party2.port.postMessage('msg ' + party1.name, [channel.port2]);
      }
      break;
  }
}

```

Connecting to multiple pages. The script uses the `connect` event listener to listen for multiple connections.

Direct channels. When the worker receives a "msg" message from one viewer naming another viewer, it sets up a direct connection between the two, so that the two viewers can communicate directly without the worker having to proxy all the messages.

[View this example online.](#)

10.2.25 Delegation

This section is non-normative.

With multicore CPUs becoming prevalent, one way to obtain better performance is to split computationally expensive tasks amongst multiple workers. In this example, a computationally expensive task that is to be performed for every number from 1 to 10,000,000 is farmed out to ten subworkers.

The main page is as follows, it just reports the result:

```
<!DOCTYPE HTML>
<html>
<head>
  <meta charset="utf-8">
  <title>Worker example: Multicore computation</title>
</head>
<body>
<pre>Result: <output id="result"></output></pre>
<script>
  var worker = new Worker('worker.js');
  worker.onmessage = function (event) {
    document.getElementById('result').textContent = event.data;
  }
</script>
</body>
</html>
```

The worker itself is as follows:

```
// settings
var num_workers = 10;
var items_per_worker = 1000000;
// start the workers
var start;
var pending_workers = num_workers;
for (var i = 0; i < num_workers; i++) {
  var worker = new Worker('worker.js');
  worker.postMessage('start');
  worker.onmessage = storeResult;
}
// handle the results
function storeResult(event) {
  pending_workers -= 1;
  if (pending_workers < 0)
    postMessage(result); // finished!
}
```

It consists of a loop to start the subworkers, and then a handler that waits for all the subworkers to respond.

The subworkers are implemented as follows:

```
var start;
onmessage = getStart;
function getStart(event) {
  start = 1*event.data;
  onmessage = getEnd;
}

var end;
function getEnd(event) {
  end = 1*event.data;
  onmessage = null;
  work();
}

function work() {
  var result = 0;
  for (var i = start; i < end; i += 1) {
    // do some complex calculation here
    result += i;
  }
  postMessage(result);
  close();
}
```

They receive two numbers in two events, perform the computation for the range of numbers thus specified, and then report the result back to the parent.

[View this example online.](#)

10.2.26 Providing libraries

This section is non-normative.

Suppose that a cryptography library is made available that provides three tasks:

Generate a public/private key pair

Takes a port, on which it will send two messages, first the public key and then the private key.

Given a port, and a public key, return the corresponding ciphertext

Takes a port, to which the number of messages can be sent, the first giving the plaintext, each of which is encrypted and then sent on that same channel as the ciphertext. The user can close the port when it is done encrypting content.

Given a ciphertext, and a private key, return the corresponding plaintext

Takes a port, to which any number of messages can be sent, the first giving the private key, and the remainder giving the ciphertext, each of which is decrypted and then sent on that same channel as the plaintext. The user can close the port when it is done decrypting content.

The library itself is as follows:

```
function handleMessage(a) {
  if (a.data == "genkeys") {
    genkeys();
  } else if (a.data == "encrpyt") {
    encrypt(a.port[0]);
  } else if (a.data == "decryp") {
    decrypt(a.port[0]);
}

function genkeys(p) {
  var keys = _generateKeyPair();
  p.postMessage(keys);
}

function encrypt(p) {
  var data = p.data;
  p.postMessage(data);
}

function decrypt(p) {
  var data = p.data;
  p.postMessage(data);
}
```

```

}

function encrypt(p) {
  var key, state = 0;
  p.onmessage = function (e) {
    if (state === 0) {
      key = e.data;
      state = 1;
    } else {
      p.postMessage(_encrypt(key, e.data));
    }
  };
}

function decrypt(p) {
  var key, state = 0;
  p.onmessage = function (e) {
    if (state === 0) {
      key = e.data;
      state = 1;
    } else {
      p.postMessage(_decrypt(key, e.data));
    }
  };
}

// support being used as a shared worker as well as a dedicated worker
if ('onmessage' in this) // dedicated worker
  onmessage = handleMessage;
else // shared worker
  onconnect = function (e) { e.port.onmessage = handleMessage; }

// the "crypto" functions:
function generateKeyPair() {
  return [Math.random(), Math.random()];
}

function _encrypt(k, s) {
  return "encrpted" + k + " " + s;
}

function _decrypt(k, s) {
  return s.substr(s.indexOf(" ") + 1);
}

Note that the crypto functions here are just stubs and don't do real cryptography.
This library could be used as follows:

<!DOCTYPE HTML>
<html>
<head>
<meta charset="UTF-8">
<title>Worker example: Crypto library</title>
<script>
const cryptoLib = new Worker('libcrypto-v1.js'); // or could use 'libcrypto-v2.js'
function startConversation(source, messageChannel) {
  const messageChannel = new MessageChannel();
  source.postMessage(message, [messageChannel.port2]);
  return messageChannel.port1;
}
function getKeys() {
  let state = 0;
  startConversation(cryptoLib, "genkeys").onmessage = function (e) {
    if (state === 0) {
      document.getElementById("public").value = e.data;
    } else if (state === 1) {
      document.getElementById("private").value = e.data;
    }
    state += 1;
  };
}
function enc() {
  const port = startConversation(cryptoLib, "encrypt");
  port.postMessage(document.getElementById("public").value);
  port.postMessage(document.getElementById("input").value);
  port.onmessage = function (e) {
    document.getElementById("input").value = e.data;
    port.close();
  };
}
function dec() {
  const port = startConversation(cryptoLib, "decrypt");
  port.postMessage(document.getElementById("private").value);
  port.postMessage(document.getElementById("input").value);
  port.onmessage = function (e) {
    document.getElementById("input").value = e.data;
    port.close();
  };
}
</script>
<style>
  textarea { display: block; }
</style>
<head>
<body onload="getKeys()">
<legend>Keys</legend>
<p><label>Public Key: <textarea id="public"></textarea></label></p>
<p><label>Private Key: <textarea id="private"></textarea></label></p>
<fieldset>
<p><label>Input: <textarea id="input"></textarea></label></p>
<button onclick="enc()">Encrypt</button> <button onclick="dec()">Decrypt</button>
</body>
</html>

```

A later version of the API, though, might want to offload all the crypto work onto subworkers. This could be done as follows:

```

function handleMessage(e) {
  if (e.data === "genkeys") {
    genkeys(e.ports[0]);
  } else if (e.data === "encrypt") {
    encrypt(e.ports[0]);
  } else if (e.data === "decrypt") {
    decrypt(e.ports[0]);
  }
}

function genkeys(p) {
  var generator = new Worker('libcrypto-v2-generator.js');
  generator.postMessage("", [p]);
}

function encrypt(p) {
  p.onmessage = function (e) {
    var key = e.data;
    var encryptor = new Worker('libcrypto-v2-encryptor.js');
    encryptor.postMessage(key, [p]);
  };
}

function decrypt(p) {
  p.onmessage = function (e) {
    var key = e.data;
    var decryptor = new Worker('libcrypto-v2-decryptor.js');
    decryptor.postMessage(key, [p]);
  };
}

// support being used as a shared worker as well as a dedicated worker
if ('onmessage' in this) // dedicated worker
  onmessage = handleMessage;
else // shared worker
  onconnect = function (e) { e.ports[0].onmessage = handleMessage; }

The little subworkers would then be as follows.

```

For generating key pairs:

```

onmessage = function (e) {
  e.ports[0].postMessage(k[0]);
  e.ports[0].postMessage(k[1]);
  close();
}

function generateKeyPair() {
  return [Math.random(), Math.random()];
}

```

For encrypting:

```

onmessage = function (e) {
  var key = e.data;
  e.ports[0].onmessage = function (e) {
    var s = e.data;
    postMessage(_encrypt(key, s));
  };
}

function encrypt(k, s) {
  return "encrypted" + k + " " + s;
}

```

For decrypting:

```

onmessage = function (e) {
  var key = e.data;
  e.ports[0].onmessage = function (e) {
    var s = e.data;
    postMessage(_decrypt(key, s));
  };
}

function _decrypt(k, s) {
  return s.substr(s.indexOf(" ") + 1);
}

```

Note how the users of the API don't have to even know that this is happening — the API hasn't changed; the library can delegate to subworkers without changing its API, even though it is accepting data using message channels.

[View this example online.](#)

10.1.3 Tutorials

10.1.3.1 Creating a dedicated worker

This section is non-normative.

Creating a worker requires a URL to a JavaScript file. The `Worker()` constructor is invoked with the URL to that file as its only argument; a worker is then created and returned:

```
var worker = new Worker('helper.js');
```

If you want your worker script to be interpreted as a `module script` instead of the default `classic script`, you need to use a slightly different signature:

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

10.1.3.2 Communicating with a dedicated worker

This section is non-normative.

Dedicated workers use `MessagePort` objects behind the scenes, and thus support all the same features, such as sending structured data, transferring binary data, and transferring other ports.

To receive messages from a dedicated worker, use the `onmessage` event handler IDL attribute on the `Worker` object:

```
worker.onmessage = function (event) { ... }
```

You can also use the `addPostListener()` method.

Note
The implicit `MessagePort` used by dedicated workers has its `port message queue` implicitly enabled when it is created, so there is no equivalent to the `MessagePort` interface's `start()` method on the `Worker` interface.

To send data to a worker, use the `postMessage()` method. Structured data can be sent over this communication channel. To send `ArrayBuffer` objects efficiently (by transferring them rather than cloning them), list them in an array in the second argument.

```
worker.postMessage(
  operation: "find-eedges",
  input: buffer, // an ArrayBuffer object
  threshold: 0.6,
  [buffers])
```

To receive a message inside the worker, the `onmessage` event handler IDL attribute is used.

```
onmessage = function (event) { ... }
```

You can again also use the `addPostListener()` method.

In either case, the data is provided in the event object's `data` attribute.

To send messages back, you again use `postMessage()`. It supports the structured data in the same manner.

```
postMessage(event.data.input, [event.data.input]) // transfer the buffer back
```

10.1.3.3 Shared workers

MDN

SharedWorker

Firefox29+Safari5–6.1Chrome4+

Opera10.6+Edge79+

Edge (Legacy)NoInternet ExplorerNo

Firefox Android33+Safari iOS5.1–7Chrome AndroidNoWebView AndroidNoSamsung Internet4.0–5.0Opera Android11–14

This section is non-normative.

Shared workers are identified by the URL of the script used to create it, optionally with an explicit name. The name allows multiple instances of a particular shared worker to be started.

Shared workers are scoped by `origin`. Two different sites using the same names will not collide. However, if a page tries to use the same shared worker name as another page on the same site, but with a different script URL, it will fail.

Creating shared workers is done using the `SharedWorker()` constructor. This constructor takes the URL to the script to use for its first argument, and the name of the worker, if any, as the second argument.

```
var worker = new SharedWorker("service.js");
```

Communicating with shared workers is done with explicit `MessagePort` objects. The object returned by the `SharedWorker()` constructor holds a reference to the port on its `port` attribute.

```
worker.port.onmessage = function (event) { ... };
worker.port.postMessage("some message");
worker.port.postMessage({foo: "structured", bar: ["data", "also", "possible"]});
```

Inside the shared worker, new clients of the worker are announced using the `connect` event. The port for the new client is given by the event object's `source` attribute.

```
onconnect = function (event) {
  var newPort = event.source;
  // set up a listener
  newPort.addEventListener("message", function (event) {
    // sends a message back to the port
    newPort.postMessage("ready!");
    // can also send structured data, of course
  });
}
```

10.2 Infrastructure

There are two kinds of workers: dedicated workers, and shared workers. Dedicated workers, once created, are linked to their creator; but message ports can be used to communicate from a dedicated worker to multiple other browsing contexts or workers. Shared workers, on the other hand, are named, and once created any script running in the same `origin` can obtain a reference to that worker and communicate with it.

10.2.1 The global scope

The global scope is the “inside” of a worker.

10.2.1.1 The `WorkerGlobalScope` common interface

MDN

WorkerGlobalScope

Support in all current engines.

Firefox3.5+Safari4+Chrome4+

Opera10.6+Edge79+

Edge (Legacy)12+Internet Explorer10+

Firefox Android4+Safari iOS3.2+Chrome AndroidYesWebView AndroidYesSamsung InternetYesOpera Android11+

```
IDL[Exposed=Worker]
interface WorkerGlobalScope : EventTarget {
  readonly attribute WorkerGlobalScope owner;
  readonly attribute WorkerGlobalScope parent;
  readonly attribute WorkerGlobalScope navigator;
  void importScripts(UAString,... urls);

  attribute WorkerGlobalScope message;
  attribute WorkerGlobalScope messageHandler;
  attribute EventHandler onmessage;
  attribute EventHandler onmessageerror;
  attribute EventHandler onmessagehandled;
  attribute EventHandler onmessageunhandled;
}
```

`WorkerGlobalScope` serves as the base class for specific types of worker global scope objects, including `DedicatedWorkerGlobalScope`, `SharedWorkerGlobalScope`, and `ServiceWorkerGlobalScope`.

A `WorkerGlobalScope` object has an associated `owner` set (a set of `Document` and `WorkerGlobalScope` objects). It is initially empty and populated when the worker is created or obtained.

Note
It is a `Set`, instead of a single `owner`, to accommodate `SharedWorkerGlobalScope` objects.

A `WorkerGlobalScope` object has an associated `worker set` (a set of `WorkerGlobalScope` objects). It is initially empty and populated when the worker creates or obtains further workers.

A `WorkerGlobalScope` object has an associated `type` (“classic” or “module”). It is set during creation.

A `WorkerGlobalScope` object has an associated `url` (null or a `URL`). It is initially null.

A `WorkerGlobalScope` object has an associated `name` (a string). It is set during creation.

Note
The `name` can have different semantics for each subclass of `WorkerGlobalScope`. For `DedicatedWorkerGlobalScope` instances, it is simply a developer-supplied name, useful mostly for debugging purposes. For `SharedWorkerGlobalScope` instances, it allows obtaining a reference to a common shared worker via the `share()` constructor. For `ServiceWorkerGlobalScope` objects, it doesn't make sense (and as such isn't exposed through the JavaScript API at all).

A `WorkerGlobalScope` object has an associated `HTTPS state` (an `HTTPS` value). It is initially “none”.

A `WorkerGlobalScope` object has an associated `referrer policy` (a `referrerPolicy`). It is initially the empty string.

A `WorkerGlobalScope` object has an associated `CSP list`, which is a `CSPList` containing all of the `Content Security Policy` objects active for the worker. It is initially an empty list.

A `WorkerGlobalScope` object has an associated `module map`. It is a `ModuleMap`, initially empty.

For web developers (non-normative)

```
workerGlobal.self
  Returns workerGlobal's self object.
workerGlobal.parent
  Returns workerGlobal's parent object.
workerGlobal.navigator
  Returns workerGlobal's navigator object.
workerGlobal.importScript(url...)
  Fetches each URL in url, executes them one-by-one in the order they are passed, and then returns (or throws if something went amiss).
```

MDN

WorkerGlobalScope.self

Support in all current engines.

Firefox3.5+Safari4+Chrome4+

Opera11.5+Edge79+

Edge (Legacy)12+Internet ExplorerYes

Firefox Android34+Safari iOS5.1+Chrome Android40+WebView Android37+Samsung Internet4.0+Opera AndroidYes

The `self` attribute must return the `WorkerGlobalScope` object itself.

MDN

WorkerGlobalScope.location

Support in all current engines.

Firefox3.5+Safari4+Chrome4+

For the purposes of the [application cache](#) networking model, a dedicated worker is an extension of the `cache host` from which it was created.

10.2.1.3 Shared workers and the `SharedWorkerGlobalScope` interface

MDN

`SharedWorkerGlobalScope`

Support in all current engines

Firefox 29+ Safari 5+ Chrome 4+

Opera 10.6+ Edge 79+

Edge (Legacy) No Internet Explorer No

Firefox Android 4+ Safari iOS 7+ Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android 11+

Android 4.1+ (Note: `SharedWorkerGlobalScope` is a shared class across all workers)

Interface `SharedWorkerGlobalScope` `WorkerGlobalScope`

(Replaceable) readonly attribute DOMString `name`

void `close()`

attribute `Event Handler` `onconnect`

;

A `SharedWorkerGlobalScope` object has an associated `constructor origin`, and `constructor url`. They are initialized when the `SharedWorkerGlobalScope` object is created, in the [run a worker](#) algorithm.

Shared workers receive message posts through `connect` events on their `SharedWorkerGlobalScope` object for each connection.

For web developers (non-normative)

`SharedWorkerGlobalScope.name`
Returns `SharedWorkerGlobalScope`'s `name`, i.e. the value given to the `SharedWorker` constructor. Multiple `SharedWorker` objects can correspond to the same shared worker (and `SharedWorkerGlobalScope`), by reusing the same name.
`SharedWorkerGlobalScope.close()`
Aborts `SharedWorkerGlobal`.

MDN

`SharedWorkerGlobalScope.name`

Firefox 55+ Safari No Chrome Yes

Opera 10.6+ Edge Yes

Edge (Legacy) No Internet Explorer No

Firefox Android 55+ Safari iOS No Chrome Android 4.0+ WebView Android Yes Samsung Internet 4.0+ Opera Android Yes

The `name` attribute must return the `SharedWorkerGlobalScope` object's `name`. Its value represents the name that can be used to obtain a reference to the worker using the `sharedWorker` constructor.

MDN

`SharedWorkerGlobalScope.close`

Support in one engine only.

Firefox 54+ Safari? Chrome No

Opera No Edge No

Edge (Legacy) No Internet Explorer No

onconnect MDN	
SharedWorkerGlobalScope.onconnect	

Firefox 29+ Safari No Chrome 4+
Opera 10.6+ Edge 79+

Edge (Legacy) No Internet Explorer No

Firefox Android 29+ Safari iOS? Chrome Android 18+ WebView Android Yes Samsung Internet 1.0+ Opera Android Yes

10.2.2 The event loop

A `worker` event loop's `task queue` only have events, callbacks, and networking activity as `tasks`. These `worker` event loops are created by the [run a worker](#) algorithm.

Each `WorkerGlobalScope` object has a `closing` flag, which must be initially false, but which can get set to true by the algorithms in the processing model section below.

Once the `WorkerGlobalScope`'s `closing` flag is set to true, the `event loop's task queue` must discard any further `tasks` that would be added to them (tasks already on the queue are unaffected except where otherwise specified). Effectively, once the `closing` flag is true, timers stop firing, notifications for all pending background operations are dropped, etc.

10.2.3 The worker's lifetime

Workers communicate with other workers and with `browsing contexts` through `message channels` and their `MessagePort` objects.

Each `WorkerGlobalScope` object `worker global scope` has a list of the `worker's ports`, which consists of all the `MessagePort` objects that are entangled with another port and that have one (but only one) port owned by `worker global scope`. This list includes the implicit `MessagePort` in the case of [dedicated workers](#).

Given an `environment settings object` `o` when creating or obtaining a worker, the relevant owner to add depends on the type of `global object` specified by `o`. If `o` specifies a `global object` that is a `WorkerGlobalScope` object (i.e., if we are creating a nested worker), then the relevant owner is that global object. Otherwise, `o` specifies a `global object` that is a `Window` object, and the relevant owner is the `responsible object` specified by `o`.

A worker is said to be a [permissible worker](#) if its `WorkerGlobalScope.owner` is not `empty` or:

- its `owner` has been `empty` for no more than a short user-agent-defined timeout value,
- its `owner` object is a `SharedWorkerGlobalScope` object (i.e., the worker is a shared worker), and
- the user agent has a `browsing context` whose `MessagePort` object is not `completely loaded`.

Note

The second part of this definition allows a shared worker to survive for a short time while a page is loading, in case that page is going to contact the shared worker again. This can be used by user agents as a way to avoid the cost of restarting a shared worker used by a site when the user is navigating from page to page within that site.

A worker is said to be an [active needed worker](#) if any its `workers` are either `Document` objects that are `fully active` or [active needed workers](#).

A worker is said to be a [protected worker](#) if it is an [active needed worker](#) and either it has outstanding timers, database transactions, or network connections, or its list of the `worker's ports` is not empty, or its `WorkerGlobalScope` is actually a `SharedWorkerGlobalScope` object (i.e. the worker is a shared worker).

A worker is said to be a [suspendable worker](#) if it is not an [active needed worker](#) but it is a [permissible worker](#).

10.2.4 Processing model

When a user agent is to `run a worker` for a script with `Worker` or `SharedWorker` object `worker`, `URL url`, `environment settings object` `outside settings`, `MessagePort outside port`, and a `workerOptions` dictionary `options`, it must run the following steps.

1. Create a separate parallel execution environment (i.e. a separate thread or process or equivalent construct), and run the rest of these steps in that context.

For the purposes of timing APIs, this is the [official moment of creation](#) of the worker.

2. Let `is shared` be true if `worker` is a `SharedWorker` object, and false otherwise.

3. Let `owner` be the `relevant owner to add` given `outside settings`.

4. Let `parent worker global scope` be null.

5. If `owner` is a `WorkerGlobalScope` object (i.e., we are creating a nested worker), then set `parent worker global scope` to `owner`.

6. Let `realm execution context` be the result of [creating a new JavaScript realm](#) with the following customizations:

- For the global object, if `is shared` is true, create a new `SharedWorkerGlobalScope` object. Otherwise, create a new `DedicatedWorkerGlobalScope` object.

7. Let `worker global scope` be the `global object` of `realm execution context's Realm component`.

Note
This is the `DedicatedWorkerGlobalScope` or `SharedWorkerGlobalScope` object created in the previous step.

8. Set up a `worker environment settings object` with `realm execution context` and `outside settings`, and let `inside settings` be the result.

9. Set `worker global scope's name` to the value of `options.name` member.

10. If `is shared` is true, then:

2. Set worker global scope's `constructor url` to `url`.
11. Let `destination` be "sharedworker" if `is shared` is true, and "worker" otherwise.
12. Obtain `script` by switching on the value of `options`'s `type` member:
 - "classic" Fetch a classic worker script given `url`, `outside settings`, `destination`, and `inside settings`.
 - "module" Fetch a module worker script graph given `url`, `outside settings`, `destination`, the value of the `credentials` member of `options`, and `inside settings`.

In both cases, to `perform the fetch` given `request`, perform the following steps if the `is top-level` flag is set:

1. Set `request`'s `reserved client` to `inside settings`.
2. `Fetch request`, and asynchronously wait to run the remaining steps as part of fetch's `process response` for the `response response`.
3. Set worker global scope's `url` to `response`'s `url`.
4. Set worker global scope's `HTTPPS state` to `response`'s `HTTPPS state`.
5. Set worker global scope's `referrer policy` to the result of `parsing the "Referrer-Policy" header of response`.
6. Execute the `Initialize a global object's CSP list` algorithm on worker global scope and `response`. [CSP]
7. Asynchronously complete the `perform the fetch` steps with `response`.

If the algorithm asynchronously completes with null, then:

1. Queue a task to fire an event named `error` at `worker`.
2. Run the `environment discarding steps` for `inside settings`.
3. Return.

Otherwise, continue the rest of these steps after the algorithm's asynchronous completion, with `script` being the asynchronous completion value.

13. Associate `worker` with worker global scope.
14. Create a new `MessagePort` object whose `owner` is `inside settings`. Let `inside port` be this new object.
15. Associate `inside port` with worker global scope.
16. Entangle `outside port` and `inside port`.
17. Append `owner` to worker global scope's `owner set`.
18. If parent worker global scope is not null, then append worker global scope to parent worker global scope's `worker set`.
19. Set worker global scope's `type` to the value of the `type` member of `options`.
20. Create a new `WorkerLocation` object and associate it with worker global scope.
21. **Closing orphan workers**: Start monitoring the worker such that no sooner than it stops being a `protected worker`, and no later than it stops being a `permissible worker`, worker global scope's `closing` flag is set to true.
22. **Suspending workers**: Start monitoring the worker, such that whenever worker global scope's `closing` flag is false and the worker is a `suspendable worker`, the user agent suspends execution of script in that worker until such time as either the `closing` flag switches to true or the worker stops being a `suspendable worker`.
23. Set `inside settings`'s `execution ready flag`.
24. If script is a `classic script`, then `run the classic script script`. Otherwise, it is a `module script`: `run the module script script`.

Note

In addition to the usual possibilities of returning a value or failing due to an exception, this could be `prematurely aborted` by the `terminate a worker` algorithm defined below.

25. Enable `outside port`'s `port message queue`.
26. If `is shared` is false, enable the `port message queue` of the worker's implicit port.
27. If `is shared` is true, then queue a task, using the `DOM manipulation task source`, to fire an event named `connect` at worker global scope, using `MessageEvent`, with the `data` attribute initialized to the empty string, the `ports` attribute initialized to a new `frozen array` containing `inside port`, and the `source` attribute initialized to `inside port`.
28. Enable the `client message queue` of the `ServiceWorkerContainer` object whose associated `service worker client` is worker global scope's `relevant settings object`.
29. **Event loop**: Run the `responsible event loop` specified by `inside settings` until it is destroyed.

Note

The handling of events or the execution of callbacks by `tasks` run by the `event loop` might get `prematurely aborted` by the `terminate a worker` algorithm defined below.

Note

The worker processing model remains on this step until the event loop is destroyed, which happens after the `closing` flag is set to true, as described in the `event loop` processing model.

30. Empty the worker global scope's `list of active timers`.
31. Disentangle all the ports in the list of `the worker's ports`.
32. Empty worker global scope's `owner set`.

When a user agent is to `terminate a worker` it must run the following steps `in parallel` with the worker's main loop (the "`run a worker`" processing model defined above):

1. Set the worker's `WorkerGlobalScope` object's `closing` flag to true.
2. If there are any `tasks` queued in the `WorkerGlobalScope` object's `event loop's task queue`, discard them without processing them.
3. **Abort the script** currently running in the worker.
4. If the worker's `WorkerGlobalScope` object is actually a `DedicatedWorkerLocalScope` object (i.e. the worker is a dedicated worker), then empty the `port message queue` of the port that the worker's implicit port is entangled with.

User agents may invoke the `terminate a worker` algorithm when a worker stops being an `active needed worker` and the worker continues executing even after its `closing` flag was set to true.

The `task source` for the tasks mentioned above is the `DOM manipulation task source`.

10.2.5 Runtime script errors

Whenever an uncaught runtime script error occurs in any of the worker's scripts, if the error did not occur while handling a previous script error, the user agent must `report the error` for that `script`, with the position (line number and column number) where the error occurred, using the `WorkerGlobalScope` object as the target.

For shared workers, if the error is still `not handled` afterwards, the error may be reported to a developer console.

For dedicated workers, if the error is still `not handled` afterwards, the user agent must `queue a task` to run these steps:

1. Let `not handled` be the result of `fire an event` named `error` at the `Worker` object associated with the worker, using `ErrorEvent`, with the `cancelable` attribute initialized to true, the `message`, `filename`, `lineno`, and `colno` attributes initialized appropriately, and the `error` attribute initialized to null.
2. If `not handled` is true, then the user agent must act as if the uncaught runtime script error had occurred in the global scope that the `Worker` object is in, thus repeating the entire runtime script error reporting process one level up.

If the implicit port connecting the worker to its `Worker` object has been disentangled (i.e. if the parent worker has been terminated), then the user agent must act as if the `Worker` object had no `error` event handler and as if that worker's `onerror` attribute was null, but must otherwise act as described above.

Note

This error reports propagate up to the chain of dedicated workers up to the original `document`, even if some of the workers along this chain have been terminated and garbage collected.

The `task source` for the task mentioned above is the `DOM manipulation task source`.

10.2.6 Creating workers

6. Let `settings object` be a new `environment settings object` whose algorithms are defined as follows:

The `realm execution context`
Return `execution context`.
The `module map`
Return worker global scope's `module map`.
The `responsible browsing context`
Return `inherited responsible browsing context`.
The `responsible event loop`
Return worker event loop.
The `responsible document`
Not applicable (the `responsible event loop` is not a `window event loop`).
The `API URL character encoding`
Return `UTF-8`.
The `API base URL`
Return worker global scope's `url`.
The `origin`
Return a unique `opaque origin` if worker global scope's `url`'s `scheme` is `"data"`, and `inherited origin` otherwise.

The `HTTPS state`
Return worker global scope's `HTTPS state`.
The `referrer policy`
Return worker global scope's `referrer policy`.
7. Set `settings object's id` to a new unique opaque string, `settings object's creation URL`, to worker global scope's `url`, `settings object's target browsing context` to null, and `settings object's active service worker` to null.
8. Set `realm's [[HostDefined]]` field to `settings object`.
9. Return `settings object`.

10.2.6.3 Dedicated workers and the `Worker` interface

MDN

`Worker`

Support in all current engines.

Firefox3.5+Safari4+Chrome4+

Opera10.6+Edge79+

Edge (Legacy)12+Internet Explorer10+

Firefox Android4+Safari iOS5.1+Chrome Android18+WebView Android4+Samsung Internet1.0+Opera Android11+

```
IDL([Exposed=(Window, Worker)])
interface [NoInterfaceObject] Worker {
  constructor(USVString scriptURL, optional WorkerOptions options = ());
  void terminate();
  void postMessage(any message, sequence<object> transfer);
  void postMessage(any message, optional PostMessageOptions options = ());
  attribute EventTarget onmessage;
  attribute EventHandler onmessageerror;
};

dictionary WorkerOptions {
  WorkerType type = "classic";
  CredentialMode credentials = "same-origin"; // credentials is only used if type is "module"
  String name = "";
};

enum WorkerType { "classic", "module" };
Worker includes AbstractWorker;
```

For web developers (non-normative)

```
worker = new Worker(scriptURL[, options])
  Returns a new Worker object. scriptURL will be fetched and executed in the background, creating a new global environment for which worker represents the communication channel. options can be used to define the name of that global environment via the name option, primarily for debugging purposes. It can also ensure this new global environment supports JavaScript modules (specify type: "module"), and if that is specified, can also be used to specify how scriptURL is fetched through the credentials option.
worker.terminate()
  Aborts worker's associated global environment.
worker.postMessage(message [, transfer])
worker.postMessage(message [, {transfer} ])
  Clones message and transmits it to worker's global environment. transfer can be passed as a list of objects that are to be transferred rather than cloned.
```

MDN

`Worker/terminate`

Support in all current engines.

Firefox3.5+Safari4+Chrome4+

Opera10.6+Edge79+

Edge (Legacy)12+Internet Explorer10+

Firefox Android4+Safari iOS5.1+Chrome Android18+WebView Android4+Samsung Internet1.0+Opera Android11+

The `terminate()` method, when invoked, must cause the `terminate a worker` algorithm to be run on the worker with which the object is associated.

`Worker` objects act as if they had an implicit `MessagePort` associated with them. This port is part of a channel that is set up when the worker is created, but it is not exposed. This object must never be garbage collected before the `Worker` object.

All messages received by that port must immediately be retargeted at the `Worker` object.

MDN

`Worker/postMessage`

Support in all current engines.

Firefox Yes/Safari Yes/Chrome Yes

Opera47+Edge Yes

Edge (Legacy)12+Internet Explorer10+

Firefox Android Yes/Safari iOS Yes/Chrome Android Yes/WebView Android Yes/Samsung Internet Yes/Opera Android44+

The `postMessage(message, transfer)` and `postMessage(message, options)` methods on `Worker` objects act as if, when invoked, they immediately invoked the respective `postMessage(message, transfer)` and `postMessage(message, options)` on the port, with the same arguments, and returned the same return value.

Example

The `postMessage()` method's first argument can be structured data:

```
worker.postMessage({opcode: "activate", device: 1938, parameters: [23, 102]});
```

The following are the `event handlers` (and their corresponding `event handler event types`) that must be supported, as `event handler IDL attributes`, by objects implementing the `Worker` interface:

`Worker/Worker`

▶ THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Edge (Legacy)12+Internet Explorer10+

Firefox44+Safari iOSS.1+Chrome Android18+WebView Android4+Samsung Internet1.0+Opera Android11+

When the `Worker(scriptURL, options)` constructor is invoked, the user agent must run the following steps:

1. The user agent may throw a `"SecurityError"` `DOMException` if the request violates a policy decision (e.g. if the user agent is configured to not allow the page to start dedicated workers).
2. Let `outsideSettings` be the `currentSettingsObject`.
3. Parse the `scriptURL` argument relative to `outsideSettings`.
4. If this fails, throw a `"SyntaxError"` `DOMException`.
5. Let `workerURL` be the `resultingURLRecord`.

NoteAny `same-origin` URL (including `blob:` URLs) can be used. `data:` URLs can also be used, but they create a worker with an `opaque origin`.

6. Let `worker` be a new `SharedWorker` object.

7. Create a new `MessagePort` object whose `owner` is `outsideSettings`. Let this be the `outsidePort`.

8. Associate the `outsidePort` with `worker`.

9. Run this step `in parallel`:

1. Run `Run worker` given `worker`, `workerURL`, `outsideSettings`, `outsidePort`, and `options`.

10. Return `worker`.

10.2.6 Shared workers and the `SharedWorker` interface**MDN****SharedWorker**

Firefox29+Safari5-6.1Chrome4+

Opera10.6+Edge79+

Edge (Legacy)NoInternet ExplorerNo

Firefox Android33+Safari iOS5.1-7Chrome AndroidNoWebView AndroidNoSamsung Internet4.0-5.0Opera Android11-14

```
IDL([Exposed=(Window, Worker)])
interface SharedWorker {
  constructor(USVString scriptURL, optional (DOMString or WorkerOptions) options = {});
  readonly attribute MessagePort port;
}; SharedWorker includes AbstractWorker;
```

For web developers (non-normative)

```
SharedWorker = new SharedWorker(scriptURL, name)
  Returns a new SharedWorker object. scriptURL will be fetched and executed in the background, creating a new global environment for which sharedWorker represents the communication channel. name can be used to define the name of that global environment.
sharedWorker = new SharedWorker(scriptURL, options)
  Returns a new SharedWorker object. scriptURL will be fetched and executed in the background, creating a new global environment for which sharedWorker represents the communication channel. options can be used to define the name of that global environment via the name option. It can also ensure this new global environment supports JavaScript modules (specify type="module"), and if that is specified, can also be used to specify how scriptURL is fetched through the credentials option.
sharedWorker.port
  Returns sharedWorker's MessagePort object which can be used to communicate with the global environment.
```

MDN**SharedWorker.port**

Firefox29+Safari5-6.1Chrome4+

Opera10.6+Edge79+

Edge (Legacy)NoInternet ExplorerNo

Firefox Android33+Safari iOS5.1-7Chrome AndroidNoWebView AndroidNoSamsung Internet4.0-5.0Opera Android11-14

The `port` attribute must return the value it was assigned by the object's constructor. It represents the `MessagePort` for communicating with the shared worker.A user agent has an associated `shared worker manager` which is the result of `starting a new parallel queue`.**Note**Each user agent has a single `shared worker manager` for simplicity. Implementations could use one per `origin`; that would not be observably different and enables more concurrency.**MDN****SharedWorker/SharedWorker**

Firefox29+Safari5-6.1Chrome4+

Opera10.6+Edge79+

Edge (Legacy)NoInternet ExplorerNo

Firefox Android33+Safari iOS5.1-7Chrome AndroidNoWebView AndroidNoSamsung Internet4.0-5.0Opera Android11-14

When the `SharedWorker(scriptURL, options)` constructor is invoked:

1. Optionally, throw a `"SecurityError"` `DOMException` if the request violates a policy decision (e.g. if the user agent is configured to not allow the page to start shared workers).
2. If `options` is a `DOMString`, set `options` to a new `WorkerOptions` dictionary whose `name` member is set to the value of `options` and whose other members are set to their default values.
3. Let `outsideSettings` be the `currentSettingsObject`.
4. Parse `scriptURL` relative to `outsideSettings`.
5. If this fails, throw a `"SyntaxError"` `DOMException`.
6. Otherwise, let `urlRecord` be the `resultingURLRecord`.

NoteAny `same-origin` URL (including `blob:` URLs) can be used. `data:` URLs can also be used, but they create a worker with an `opaque origin`.

7. Let `worker` be a new `SharedWorker` object.

8. Create a new `MessagePort` object whose `owner` is `outsideSettings`. Let this be the `outsidePort`.

9. Assign `outsidePort` to the `port` attribute of `worker`.

10. Let `callerIsSecureContext` be the result of executing `Is environment settings object a secure context?` on `outsideSettings`.

11. Execute the following steps to the `shared worker manager`:

1. Let `workerGlobalScope` be null.

2. If there exists a `SharedWorkerGlobalScope` object whose `closing` flag is false, `constructor.origin` is `sameOrigin` with `outsideSettings`'s `origin`, `constructor.url.equals(urlRecord)`, and `name` equals the value of `options`'s `name` member, then set `workerGlobalScope` to that `SharedWorkerGlobalScope` object.

Note
`data:` URLs create a worker with an `opaque origin`. Both the `constructor.origin` and `constructor.url` are compared so the same `data:` URL can be used within an `origin` to get to the same `SharedWorkerGlobalScope` object, but cannot be used to bypass the `sameOrigin` restriction.

3. If `workerGlobalScope` is not null, but the user agent has been configured to disallow communication between the worker represented by the `workerGlobalScope` and the `scripts` whose `settingsObject` is `outsideSettings`, then set `workerGlobalScope` to null.

Note
For example, a user agent could have a development mode that isolates a particular `top-level browsing context` from all other pages, and scripts in that development mode could be blocked from connecting to shared workers running in the normal browser mode.

4. If `workerGlobalScope` is not null, then run these substeps:

1. Let `settingsObject` be the `relevantSettingsObject` for `workerGlobalScope`.

2. Let `workersSecureContext` be the result of executing `Is environment settings object a secure context?` on `settingsObject`.

3. If `workersSecureContext` is not `callerIsSecureContext`, then `queue a task to fire an event named "error"` at `worker` and abort these substeps. **[SECURE-CONTEXTS]**

4. Associate `worker` with `workerGlobalScope`.

5. Create a new `MessagePort` object whose `owner` is `settingsObject`. Let this be the `insidePort`.

6. `Extract outsidePort and insidePort`.

7. Queue a task, using the `DOMManipulationTaskSource`, to `fire an event named "connect"` at `workerGlobalScope`, using `MessageEvent`, with the `data` attribute initialized to the empty string, the `ports` attribute initialized to a new `frozenArray` containing only `insidePort`, and the `source` attribute initialized to `insidePort`.

8. `Append the relevant owner to add` given `outsideSettings` to `workerGlobalScope`'s `ownerSet`.

9. If `outsideSettings`'s `globalObject` is a `WorkerGlobalScope` object, then `append workerGlobalScope to outsideSettings's globalObject's workerSet`.

5. Otherwise, `in parallel, run a worker` given `worker`, `urlRecord`, `outsideSettings`, `outsidePort`, and `options`.

12. Return `worker`.

10.2.7 Concurrent hardware capabilities**MDN****NavigatorConcurrentHardware**

Firefox48+Safari?Chrome37+

Opera24+Edg79+

Edge (Legacy)18+Internet Explorer?

```
IDLInterface mixin NavigatorConcurrentHardware {
  readonly attribute unsigned long long hardwareConcurrency;
};
```

For web developers (non-normative)
`self, navigator, hardwareConcurrency`

Returns the number of logical processors potentially available to the user agent.

MDN

[NavigatorConcurrentHardware.hardwareConcurrency](#)

Firefox48+ Safari/Chrome37+

Opera24+ Edge79+

Edge (Legacy)15+ Internet Explorer?

Firefox Android48+ Safari iOS7 Chrome Android37+ WebView Android37+ Samsung Internet3.0+ Opera Android24+

The `navigator.hardwareConcurrency` attribute's getter must return a number between 1 and the number of logical processors potentially available to the user agent. If this cannot be determined, the getter must return 1.

User agents should err toward exposing the number of logical processors available, using lower values only in cases where there are user-agent specific limits in place (such as a limitation on the number of `workers` that can be created) or when the user agent desires to limit fingerprinting possibilities.

10.3 APIs available to workers

10.3.1 Importing scripts and libraries

MDN

[WorkerGlobalScope/importScripts](#)

Support in all current engines.

Firefox4+ Safari4+ Chrome4+

Opera10.6+ Edge79+

Edge (Legacy)12+ Internet Explorer10+

Firefox Android44+ Safari iOS3.2+ Chrome Android18+ WebView Android37+ Samsung Internet1.0+ Opera Android11+

When a script invokes the `importScripts(urls)` method on a `WorkerGlobalScope` object, the user agent must `import scripts into worker global scope` given this `WorkerGlobalScope` object and `urls`.

To `import scripts into worker global scope`, given a `WorkerGlobalScope` object `worker global scope` and a sequence`<DOMString>` `urls`, run these steps. The algorithm may optionally be customized by supplying custom `perform the fetch` hooks, which if provided will be used when invoking `fetch a classic worker-imported script`.

1. If `worker global scope's page` is "module", throw a `TypeError` exception.

2. Let `settings object` be the `current settings object`.

3. If `urls` is empty, return.

4. Parse each value in `urls` relative to `settings object`. If any fail, throw a `"SyntaxError" DOMException`.

5. For each `url` in the `routing URL records`, run these substeps:

1. Fetch a classic worker-imported script given `url` and `settings object`, passing along any custom `perform the fetch` steps provided. If this succeeds, let `script` be the result. Otherwise, rethrow the exception.

2. Run the classic `script`, with the `rethrow errors` argument set to true.

Note
`script` will run until it either returns, fails to parse, fails to catch an exception, or gets `prematurely aborted` by the `terminate a worker` algorithm defined above.

If an exception was thrown or if the script was `prematurely aborted`, then abort all these steps, letting the exception or aborting continue to be processed by the calling `script`.

Note

`Service Workers` is an example of a specification that runs this algorithm with its own options for the `perform the fetch` hook. [SW]

10.3.2 The `WorkerNavigator` interface

MDN

[WorkerGlobalScope/navigator](#)

Support in all current engines.

Firefox3.5+ Safari4+ Chrome4+

Opera11.5+ Edge79+

Edge (Legacy)11+ Internet ExplorerYes

Firefox Android4+ Safari iOS5.1+ Chrome Android10+ WebView Android37+ Samsung Internet4.0+ Opera AndroidYes

The `navigator` attribute of the `WorkerGlobalScope` interface must return an instance of the `WorkerNavigator` interface, which represents the identity and state of the user agent (the client).

MDN

[WorkerNavigator](#)

Firefox3.5+ Safari7+ Chrome1+

OperaYes Edge79+

Edge (Legacy)No Internet Explorer?

Firefox Android4+ Safari iOS7 Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidYes

```
IDL([Exposed=Worker])
interface WorkerNavigator {
  string readonly attribute USVString href;
  string readonly attribute USVString origin;
  string readonly attribute USVString host;
  string readonly attribute USVString port;
  string readonly attribute USVString pathname;
  string readonly attribute USVString search;
  string readonly attribute USVString hash;
};
```

10.3.3 The `WorkerLocation` interface

MDN

[WorkerLocation](#)

Firefox3.5+ Safari7+ Chrome1+

OperaYes Edge79+

Edge (Legacy)No Internet Explorer?

Firefox Android4+ Safari iOS7 Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidYes

```
IDL([Exposed=Worker])
interface WorkerLocation {
  string readonly attribute USVString href;
  string readonly attribute USVString origin;
  string readonly attribute USVString host;
  string readonly attribute USVString port;
  string readonly attribute USVString pathname;
  string readonly attribute USVString search;
  string readonly attribute USVString hash;
};
```

A `WorkerLocation` object has an associated `WorkerGlobalScope` object (a `WorkerGlobalScope` object).

The `href` attribute's getter must return the associated `WorkerGlobalScope` object's `url.serialized`.

The `origin` attribute's getter must return the `serialization` of the associated `WorkerGlobalScope` object's `url.origin`.

The `protocol` attribute's getter must return the associated `WorkerGlobalScope` object's `url.scheme`, followed by ":".

The `host` attribute's getter must run these steps:

1. Let `url` be the associated `WorkerGlobalScope` object's `url`.

2. If `url's host` is null, return the empty string.

3. If `url's port` is null, return `url's host.serialized`.

4. Return `url's host.serialized`, followed by ":" and `url's port.serialized`.

The `hostname` attribute's getter must run these steps:

1. Let `host` be the associated `WorkerGlobalScope` object's `url.host`.

2. If `host` is null, return the empty string.

3. Return `host.serialized`.

The `port` attribute's getter must run these steps:

1. Let `port` be the associated `WorkerGlobalScope` object's `url.port`.

2. If `port` is null, return the empty string.

3. Return `port.serialized`.

The `pathname` attribute's getter must run these steps:

1. Let `url` be the associated `WorkerGlobalScope` object's `url`.

2. If `url's cannot-be-a-base-URL` flag is set, return the first string in `url's path`.

The `search` attribute's getter must run these steps:

1. Let `query` be the associated `WorkerGlobalScope` object's `url`'s `query`.
2. If `query` is either null or the empty string, return the empty string.
3. Return `"+"`, followed by `query`.

The `hash` attribute's getter must run these steps:

1. Let `fragment` be the associated `WorkerGlobalScope` object's `url`'s `fragment`.
2. If `fragment` is either null or the empty string, return the empty string.
3. Return `"+"`, followed by `fragment`.

[Web Storage API/Using the Web Storage API](#)

11.1 Introduction

This section is non-normative.

This specification introduces two related mechanisms, similar to HTTP session cookies, for storing name-value pairs on the client side: [COOKIES](#)

The first is designed for scenarios where the user is carrying out a single transaction, but could be carrying out multiple transactions in different windows at the same time.

Cookies don't really handle this case well. For example, a user could be buying plane tickets in two different windows, using the same site. If the site used cookies to keep track of which ticket the user was buying, then as the user clicked from page to page in both windows, the ticket currently being purchased would "leak" from one window to the other, potentially causing the user to buy two tickets for the same flight without really noticing.

To address this, this specification introduces the `sessionStorage` IDL attribute. Sites can add data to the session storage, and it will be accessible to any page from the same site opened in that window.

Example

For example, a page could have a checkbox that the user ticks to indicate that they want insurance:

```
<label><input type="checkbox" onchange="sessionStorage.insurance = checked ? 'true' : ''">
  I want insurance on this trip.
</label>
```

A later page could then check, from script, whether the user had checked the checkbox or not:

```
if (sessionStorage.insurance) { ... }
```

If the user had multiple windows opened on the site, each one would have its own individual copy of the session storage object.

The second storage mechanism is designed for storage that spans multiple windows, and lasts beyond the current session. In particular, Web applications might wish to store megabytes of user data, such as entire user-authored documents or a user's mailbox, on the client side for performance reasons.

Again, cookies do not handle this case well, because they are transmitted with every request.

The `localStorage` IDL attribute is used to access a page's local storage area.

Example

The site at example.com can display a count of how many times the user has loaded its page by putting the following at the bottom of its page:

```
<p> You have viewed this page
<span id="count">an untold number of</span>
</p>

<script>
  if (!localStorage.pageLoadCount)
    localStorage.pageLoadCount = 0;
  localStorage.pageLoadCount = parseInt(localStorage.pageLoadCount) + 1;
  document.getElementById("count").textContent = localStorage.pageLoadCount;
</script>
```

Each site has its own separate storage area.

11.2 The API

Support: namevalue-storageChrome for Android 81+Chrome 4+iOS Safari 3.2+Safari 4+Firefox 3.5+Samsung Internet 4+Edge 12+UC Browser for Android 12.12+IE 8+Opera 10.5+Opera Mini NoneFirefox for Android 68+

Source: [caniuse.com](#)

11.2.1 The `storage` interface

MDN

[Storage](#)

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 4+

Opera 10.5+ Edge 79+

Edge (Legacy) 12+ Internet Explorer 8+

Firefox Android+ Safari iOS 3.2+ Chrome Android 18+ WebView Android 37+ Samsung Internet 1.0+ Opera Android 11+

```
IDL([Exposed=Window])
interface Storage {
  long getLength();
  DOMString? getItem(unsigned long index);
  getter DOMString? getsetItem(DOMString key);
  void removeItem(DOMString key, DOMString value);
  deleter void removeItem(DOMString key);
  void clear();
}
```

Each `storage` object provides access to a list of key/value pairs, which are sometimes called items. Keys are strings. Any string (including the empty string) is a valid key. Values are similarly strings.

Each `storage` object is associated with a list of key/value pairs when it is created, as defined in the sections on the `sessionStorage` and `localStorage` attributes. Multiple separate objects implementing the `storage` interface can all be associated with the same list of key/value pairs simultaneously.

For web developers (non-normative)

`storage.length`

Returns the number of key/value pairs currently present in the list associated with the object.

`storage.key(n)`

Returns the name of the `n`th key in the list, or null if `n` is greater than or equal to the number of key/value pairs in the object.

`value = storage.getItem(key)`

`value = storage[key]`

Returns the current value associated with the given `key`, or null if the given `key` does not exist in the list associated with the object.

`storage.setItem(key, value)`

`storage[key] = value`

Sets the value of the pair identified by `key` to `value`, creating a new key/value pair if none existed for `key` previously.

Throws a `"QuotaExceededError"` `DOMException` exception if the new value couldn't be set. (Setting could fail if, e.g., the user has disabled storage for the site, or if the quota has been exceeded.)

`storage.removeItem(key)`

`delete storage[key]`

Removes the key/value pair with the given `key` from the list associated with the object, if a key/value pair with the given `key` exists.

`storage.clear()`

Empties the list associated with the object of all key/value pairs, if there are any.

MDN

[Storage.length](#)

Support in all current engines.

Firefox 3.5+ Safari 4+ Chrome 4+

Opera 10.5+ Edge 79+

Edge (Legacy) 12+ Internet Explorer 8+

Firefox Android+ Safari iOS 3.2+ Chrome Android 18+ WebView Android Yes Samsung Internet 1.0+ Opera Android 11+

The `length` attribute must return the number of key/value pairs currently present in the list associated with the object.

MDN

[Storage\[key\]](#)

Firefox3.5+Safari4+Chrome4+

Opera10.5+Edge79+

Edge (Legacy)12+Internet Explorer8+

Firefox Android6+Safari iOS3.2+Chrome Android18+WebView AndroidYesSamsung Internet1.0+Opera Android1.0+

The `key(n)` method must return the name of the *n*th key in the list. The order of keys is user-agent defined, but must be consistent within an object so long as the number of keys doesn't change. (Thus, [adding](#) or [removing](#) a key may change the order of the keys, but merely changing the value of an existing key must not.) If *n* is greater than or equal to the number of key/value pairs in the object, then this method must return null.

The [supported property names](#) on a `storage` object are the keys of each key/value pair currently present in the list associated with the object, in the order that the keys were last added to the storage area.

MDN

[Storage/getItem](#)

Support in all current engines.

Firefox3.5+Safari4+Chrome4+

Opera10.5+Edge79+

Edge (Legacy)12+Internet Explorer8+

Firefox Android6+Safari iOS3.2+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android1.1+

The `getItem(key)` method must return the current value associated with the given `key`. If the given `key` does not exist in the list associated with the object then this method must return null.

MDN

[Storage/setItem](#)

Support in all current engines.

Firefox3.5+Safari4+Chrome4+

Opera10.5+Edge79+

Edge (Legacy)12+Internet Explorer8+

Firefox Android6+Safari iOS3.2+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android1.1+

The `setItem(key, value)` method must first check if a key/value pair with the given `key` already exists in the list associated with the object.

If it does not, then a new key/value pair must be added to the list, with the given `key` and with its value set to `value`.

If the given `key` does exist in the list, and its value is not equal to `value`, then it must have its value updated to `value`. If its previous value is equal to `value`, then the method must do nothing.

If it couldn't set the new value, the method must throw a ["SyntaxError" DOMException](#).

MDN

[Storage/removeItem](#)

Support in all current engines.

Firefox3.5+Safari4+Chrome4+

Opera10.5+Edge79+

Edge (Legacy)12+Internet Explorer8+

Firefox Android6+Safari iOS3.2+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android1.1+

The `removeItem(key)` method must cause the key/value pair with the given `key` to be removed from the list associated with the object, if it exists. If no item with that `key` exists, the method must do nothing.

The `setItem()` and `removeItem()` methods must be atomic with respect to failure. In the case of failure, the method does nothing. That is, changes to the data storage area must either be successful, or the data storage area must not be changed at all.

MDN

[Storage/clear](#)

Support in all current engines.

Firefox3.5+Safari4+Chrome4+

Opera10.5+Edge79+

Edge (Legacy)12+Internet Explorer8+

Firefox Android6+Safari iOS3.2+Chrome Android18+WebView AndroidYesSamsung Internet1.0+Opera Android1.1+

The `clear()` method must atomically cause the list associated with the object to be emptied of all key/value pairs, if there are any. If there are none, then the method must do nothing.

Note
When the `setItem()`, `removeItem()`, and `clear()` methods are invoked, events are fired on the [relevant global objects](#) of other `Document` objects that can access the newly stored or removed data, as defined in the sections on the `sessionStorage` and `localStorage` attributes.

Note
This specification does not require that the above methods wait until the data has been physically written to disk. Only consistency in what different scripts accessing the same underlying list of key/value pairs see is required.

11.2.2 The `sessionStorage` attribute

```
IDLInterface mixin WindowSessionStorage {
  readonly attribute Storage sessionStorage;
};  
Window includes WindowSessionStorage;
```

MDN

[Window/sessionStorage](#)

Support in all current engines.

Firefox2+Safari4+Chrome6+

Opera10.5+Edge79+

Edge (Legacy)12+Internet Explorer8+

Firefox Android4+Safari iOS3.2+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android1.1+

The `sessionStorage` attribute represents the set of storage areas specific to the current [top-level browsing context](#).

For web developers (non-normative)`window.sessionStorage`

Returns the `Storage` object associated with that origin's session storage area.

Each [top-level browsing context](#) has a unique set of session storage areas, one for each [origin](#).

User agents should not expire data from a browsing context's session storage areas, but may do so when the user requests that such data be deleted, or when the UA detects that it has limited storage space, or for security reasons. User agents should always avoid deleting data while a script that could access that data is running. When a top-level browsing context is destroyed (and therefore permanently inaccessible to the user) the data stored in its session storage areas can be discarded with it, as the API described in this specification provides no way for that data to ever be subsequently retrieved.

Note

The lifetime of a browsing context can be unrelated to the lifetime of the actual user agent process itself, as the user agent can support resuming sessions after a restart.

When a new `Document` is created in a [browsing context](#) which has a [top-level browsing context](#), the user agent must check to see if that [top-level browsing context](#) has a session storage area for that document's [origin](#). If it does, then that is the `Document`'s assigned session storage area. If it does not, a new storage area for that document's [origin](#) must be created, and then that is the `Document`'s assigned session storage area. A `Document`'s assigned storage area does not change during the lifetime of a `Document`.

Note

In the case of an `iframe` being moved to another `Document`, its nested browsing context is destroyed and a new one created.

The `sessionStorage` attribute must return a `Storage` object associated with the `Document`'s assigned session storage area. Each `Document` object must have a separate object for its [relevant global object's](#) `sessionStorage` attribute.

While [creating a new auxiliary browsing context](#), the session storage area is [copied](#) over.

When the `setItem()`, `removeItem()`, and `clear()` methods are called on a `Storage` object *x* that is associated with a session storage area, if the methods did not throw an exception or "do nothing" as defined above, then for every `Document` object whose [relevant global object's](#) `sessionStorage` attribute's `Storage` object is associated with the same storage area, other than *x*, [send a storage notification](#).

11.2.3 The `localStorage` attribute

```
IDLInterface mixin WindowLocalStorage {
  readonly attribute Storage localStorage;
};  
Window includes WindowLocalStorage;
```

MDN

[Window/localStorage](#)

Support in all current engines.

Firefox3.5+Safari4+Chrome4+

Opera10.5+Edge79+

Edge (Legacy)12+Internet Explorer8+

Firefox Android4+Safari iOS3.2+Chrome Android18+WebView Android37+Samsung Internet1.0+Opera Android1.1+

The `localStorage` object provides a `Storage` object for an [origin](#).

For web developers (non-normative)`window.localStorage`

Returns the `Storage` object associated with that origin's local storage area.

Throws a ["SecurityError" DOMException](#) if the `Document`'s [origin](#) is an [opaque origin](#) or if the request violates a policy decision (e.g. if the user agent is configured to not allow the page to persist data).

User agents should expire data from the local storage areas only for security reasons or when requested to do so by the user. User agents should always avoid deleting data while a script that could access that data is running.

When the `localStorage` attribute is accessed, the user agent must run the following steps, which are known as the `storage object initialization steps`:

1. If the request violates a policy decision (e.g. if the user agent is configured to not allow the page to persist data), the user agent may throw a `"security@error" DOMException` instead of returning a `Storage` object
2. If the `document's origin` is an `opaque origin`, then throw a `"SecurityError" DOMException`.
3. Check to see if the user agent has allocated a local storage area for the `origin` of the `Window` object on which the attribute was accessed. If it has not, create a new storage area for that `origin`.
4. Return the `Storage` object associated with that origin's local storage area. Each `Document` object must have a separate object for its `relevant global object's localStorage` attribute.

When the `setItem()`, `removeItem()`, and `clear()` methods are called on a `Storage` object `x` that is associated with a local storage area, if the methods did not throw an exception or "do nothing" as defined above, then for every `Document` object whose `relevant global object's localStorage` object is associated with the same storage area, other than `x`, send a `storage notification`.

⚠️ Warning!
The `localStorage` attribute provides access to shared state. This specification does not define the interaction with other browsing contexts in a multiprocess user agent, and authors are encouraged to assume that there is no locking mechanism. A site could, for instance, try to read the value of a key, increment its value, then write it back out, using the new value as a unique identifier for the session; if the site does this twice in two different browser windows at the same time, it might end up using the same "unique" identifier for both sessions, with potentially disastrous effects.

11.2.4 The `storage` event

The `storage` event is fired on a `Document` object's `relevant global object` when a storage area changes, as described in the previous two sections (for `session storage`, for `local storage`).

When a user agent is to send a `storage notification` for a `Document`, the user agent must queue a task to fire an event named `storage` at the `Document` object's `relevant global object`, using `StorageEvent`.

Note

Such a `Document` object is not necessarily `fully active`, but events fired on such objects are ignored by the `event loop` until the `Document` becomes `fully active` again.

The `task source` for these tasks is the `DOM manipulation task source`.

If the event is being fired due to an invocation of the `setItem()` or `removeItem()` methods, the event must have its `key` attribute initialized to the name of the key in question, its `oldValue` attribute initialized to the old value of the key in question, or null if the key is newly added, and its `newValue` attribute initialized to the new value of the key in question, or null if the key was removed.

Otherwise, if the event is being fired due to an invocation of the `clear()` method, the event must have its `key`, `oldValue`, and `newValue` attributes initialized to null.

In addition, the event must have its `url` attribute initialized to the `URL` of the document whose `Storage` object was affected; and its `storageArea` attribute initialized to the `Storage` object from the `relevant global object` of the target `Document` that represents the same kind of `Storage` area as was affected (i.e. session or local).

11.2.4.1 The `StorageEvent` interface

MDN

`StorageEvent`

Support in all current engines.

Firefox Yes Safari Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

```
IDBRequestStorage;
Constructor(DOMString type, optional StorageEventInit eventInitDict = {});
interface StorageEvent : Event {
  DOMString? key;
  DOMString? oldValue;
  DOMString? newValue;
  DOMString? url;
  Storage? storageArea;
};

void initStorageEvent(DOMString type, optional boolean bubbles = false, optional boolean cancelable = false, optional DOMString? key = null, optional DOMString? oldValue = null, optional DOMString? newValue = null, optional USVString url = "", optional Storage? storageArea = null);
};

dictionary StorageEventInit : EventInit {
  DOMString? key = null;
  DOMString? oldValue = null;
  DOMString? newValue = null;
  USVString url = "";
  Storage? storageArea = null;
};
```

For web developers (non-normative)

event `key`

Returns the key of the storage item being changed.

event `oldValue`

Returns the old value of the key of the storage item whose value is being changed.

event `newValue`

Returns the new value of the key of the storage item whose value is being changed.

event `url`

Returns the `URL` of the document whose storage item changed.

event `storageArea`

Returns the `Storage` object that was affected.

The `key`, `oldValue`, `newValue`, `url`, and `storageArea` attributes must return the values they were initialized to.

The `initStorageEvent()` method must initialize the event in a manner analogous to the similarly-named `initEvent()` method. [DOM]

11.3 Disk space

User agents should limit the total amount of space allowed for storage areas, because hostile authors could otherwise use this feature to exhaust the user's available disk space.

User agents should guard against sites storing data under their origin's other affiliated sites, e.g. storing up to the limit in a1.example.com, a2.example.com, a3.example.com, etc, circumventing the main example.com storage limit.

User agents may prompt the user when quotas are reached, allowing the user to grant a site more space. This enables sites to store many user-created documents on the user's computer, for instance.

User agents should allow users to see how much space each domain is using.

A mostly arbitrary limit of five megabytes per `origin` is suggested. Implementation feedback is welcome and will be used to update this suggestion in the future.

For predictability, quotas should be based on the uncompressed size of data stored.

11.4 Privacy

11.4.1 User tracking

A third-party advertiser (or any entity capable of getting content distributed to multiple sites) could use a unique identifier stored in its local storage area to track a user across multiple sessions, building a profile of the user's interests to allow for highly targeted advertising. In conjunction with a site that is aware of the user's real identity (for example an e-commerce site that requires authenticated credentials), this could allow oppressive groups to target individuals with greater accuracy than in a world with purely anonymous Web usage.

There are a number of techniques that can be used to mitigate the risk of user tracking:

Blocking third-party storage

User agents may restrict access to the `localStorage` objects to scripts originating at the domain of the `active-document` of the `top-level browsing context`, for instance denying access to the API for pages from other domains running in `iframes`.

Expiring stored data

User agents may, possibly in a manner configured by the user, automatically delete stored data after a period of time.

For example, a user agent could be configured to treat third-party local storage areas as session-only storage, deleting the data once the user had closed all the `browsing contexts` that could access it.

This can restrict the ability of a site to track a user, as the site would then only be able to track the user across multiple sessions when they authenticate with the site itself (e.g. by making a purchase or logging in to a service).

However, this also reduces the usefulness of the API as a long-term storage mechanism. It can also put the user's data at risk, if the user does not fully understand the implications of data expiration.

Treating persistent storage as cookies

User agents may allow sites to access session storage areas in an unrestricted manner, but require the user to authorize access to local storage areas.

Origin-tracking of stored data

User agents may record the `origin` of sites that contained content from third-party origins that caused data to be stored.

If this information is then used to present the view of data currently in persistent storage, it would allow the user to make informed decisions about which parts of the persistent storage to prune. Combined with a blocklist ("delete this data and prevent this domain from ever storing data again"), the user can restrict the use of persistent storage to sites that they trust.

Shared blocklists

User agents may allow users to share their persistent storage domain blocklists.

This would allow communities to act together to protect their privacy.

While these suggestions prevent trivial use of this API for user tracking, they do not block it altogether. Within a single domain, a site can continue to track the user during a session, and can then pass all this information to the third party along with any identifying information (names, credit card numbers, addresses) obtained by the site. If a third party cooperates with multiple sites to obtain such information, a profile can still be created.

However, user tracking is to some extent possible even with no cooperation from the user agent whatsoever, for instance by using session identifiers in URLs, a technique already commonly used for innocuous purposes but easily repurposed for user tracking (even retroactively). This information can then be shared with other sites, using visitors' IP addresses and other user-specific data (e.g. user-agent headers and configuration settings) to combine separate sessions into coherent user profiles.

11.4.2 Sensitivity of data

User agents should treat persistently stored data as potentially sensitive; it's quite possible for e-mails, calendar appointments, health records, or other confidential documents to be stored in this mechanism.

To this end, user agents should ensure that when deleting data, it is promptly deleted from the underlying storage.

11.5 Security

11.5.1 DNS spoofing attacks

11.5.2 Cross-directory attacks

Different authors sharing one host name, for example users hosting content on the now defunct [geocities.com](#), all share one local storage object. There is no feature to restrict the access by pathname. Authors on shared hosts are therefore urged to avoid using these features, as it would be trivial for other authors to read the data and overwrite it.

Note

Even if a path-restriction feature was made available, the usual DOM scripting security model would make it trivial to bypass this protection and access the data from any path.

11.5.3 Implementation risks

The two primary risks when implementing these persistent storage features are letting hostile sites read information from other domains, and letting hostile sites write information that is then read from other domains.

Letting third-party sites read data that is not supposed to be read from their domain causes *information leakage*. For example, a user's shopping wishlist on one domain could be used by another domain for targeted advertising; or a user's work-in-progress confidential documents stored by a word-processing site could be examined by the site of a competing company.

Letting third-party sites write data to the persistent storage of other domains can result in *information spoofing*, which is equally dangerous. For example, a hostile site could add items to a user's wishlist; or a hostile site could set a user's session identifier to a known ID that the hostile site can then use to track the user's actions on the victim site.

Thus, strictly following the [script](#) model described in this specification is important for user security.

12 The HTML syntax

Note

This section only describes the rules for resources labeled with an [HTML MIME type](#). Rules for XML resources are discussed in the section below entitled "[The XML syntax](#)".

12.1 Writing HTML documents

This section only applies to documents, authoring tools, and markup generators. In particular, it does not apply to conformance checkers; conformance checkers must use the requirements given in the next section ("parsing HTML documents").

Documents must consist of the following parts, in the given order:

1. Optionally, a single U+FEFF BYTE ORDER MARK (BOM) character.
2. One or more [comments](#) and [ASCII whitespace](#).
3. A DOCTYPE.
4. Any number of [comments](#) and [ASCII whitespace](#).
5. The document element, in the form of an [html element](#).
6. Any number of [comments](#) and [ASCII whitespace](#).

The various types of content mentioned above are described in the next few sections.

In addition, there are some restrictions on how [character encoding declarations](#) are to be serialized, as discussed in the section on that topic.

Note

[ASCII whitespace](#) before the [html](#) element, at the start of the [html](#) element and before the [head](#) element, will be dropped when the document is parsed; [ASCII whitespace](#) after the [html](#) element will be parsed as if it were at the end of the [body](#) element. Thus, [ASCII whitespace](#) around the [document element](#) does not round-trip.

It is suggested that newlines be inserted after the DOCTYPE, after any comments that are before the document element, after the [html](#) element's start tag (if it is not [omitted](#)), and after any comments that are inside the [html](#) element but before the [head](#) element.

Many strings in the HTML syntax (e.g. the names of elements and their attributes) are case-insensitive, but only for [ASCII upper alphas](#) and [ASCII lower alphas](#). For convenience, in this section this is just referred to as "case-insensitive".

12.1.1 The DOCTYPE

A DOCTYPE is a required preamble.

Note

DOCTYPEs are required for legacy reasons. When omitted, browsers tend to use a different rendering mode that is incompatible with some specifications. Including the DOCTYPE in a document ensures that the browser makes a best-effort attempt at following the relevant specifications.

A DOCTYPE must consist of the following components, in this order:

1. A string that is an [ASCII case-insensitive](#) match for the string "`<!DOCTYPE`".
2. One or more [ASCII whitespace](#).
3. A string that is an [ASCII case-insensitive](#) match for the string "`html`".
4. Optionally, a DOCTYPE legacy string.
5. Zero or more [ASCII whitespace](#).
6. A U+003E GREATER-THAN SIGN character (>).

Note

In other words, `<!DOCTYPE html>`, case-insensitively

For the purposes of HTML generators that cannot output HTML markup with the short DOCTYPE "`<!DOCTYPE html>`", a DOCTYPE legacy string may be inserted into the DOCTYPE (in the position defined above). This string must consist of:

1. One or more [ASCII whitespace](#).
2. A string that is an [ASCII case-insensitive](#) match for the string "`SYSTEM`".
3. One or more [ASCII whitespace](#).
4. A U+0022 QUOTATION MARK or U+0027 APOSTROPHE character (the *quote mark*).
5. The literal string "`<!-->`".
6. A matching U+0022 QUOTATION MARK or U+0027 APOSTROPHE character (i.e. the same character as in the earlier step labeled *quote mark*).

Note

In other words, `<!DOCTYPE html SYSTEM "<!-->">` or `<!DOCTYPE html SYSTEM "<!-->-->">`, case-insensitively except for the part in single or double quotes.

The DOCTYPE legacy string should not be used unless the document is generated from a system that cannot output the shorter string.

12.1.2 Elements

There are six different kinds of elements: [void elements](#), the [template element](#), [raw text elements](#), [escapable raw text elements](#), [foreign elements](#), and [normal elements](#).

[Void elements](#)

`<a>

<input>
<link>
<meta>
<param>
<source>
<track>
`

[The template element](#)

`<template>`

[Raw text elements](#)

`<text><pre>`

[Escapable raw text elements](#)

`<script><title>`

[Foreign elements](#)

Elements from the [MathML namespace](#) and the [SVG namespace](#).

[Normal elements](#)

All other allowed [HTML elements](#) are normal elements.

Tags are used to define the start and end of elements in the markup. [Raw text](#), [escapable raw text](#), and [normal](#) elements have a [start tag](#) to indicate where they begin, and an [end tag](#) to indicate where they end. The start and end tags of certain [normal elements](#) can be [omitted](#), as described below in the section on [optional tags](#). Those that cannot be omitted must not be omitted. [Void elements](#) only have a start tag; end tags must not be specified for [void elements](#). [Foreign elements](#) must either have a start tag and an end tag, or a start tag that is marked as self-closing, in which case they must not have an end tag.

The [contents](#) of the element must be placed between just after the start tag (which [might be implied in certain cases](#)) and just before the end tag (which again, [might be implied in certain cases](#)). The exact allowed contents of each individual element depend on the [content model](#) of that element, as described earlier in this specification. Elements must not contain content that their content model disallows. In addition to the restrictions placed on the contents by those content models, however, the five types of elements have additional [syntactic requirements](#).

[Void elements](#) can't have any contents (since there's no end tag, no content can be put between the start tag and the end tag).

The [template element](#) can have [contents](#), but such children are not children of the [template element](#) itself. Instead, they are stored in a [DocumentFragment](#), associated with a different [Document](#) — without a [browsing context](#) — so as to avoid the [template](#) contents interfering with the main [Document](#). The markup for the [template contents](#) of a [template element](#) is placed just after the [template element](#)'s start tag and just before [template element](#)'s end tag (as with other elements), and may consist of any [text](#), [character references](#), [elements](#), and [comments](#), but the text must not contain the character U+003C LESS-THAN SIGN (<) or an [ambiguous ampersand](#).

[Raw text elements](#) can have [text](#), though it has [restrictions](#) described below.

[Escapable raw text elements](#) can have [text](#) and [character references](#), but the text must not contain an [ambiguous ampersand](#). There are also [further restrictions](#) described below.

[Foreign elements](#) whose start tag is marked as self-closing can't have any contents (since, again, as there's no end tag, no content can be put between the start tag and the end tag). [Foreign elements](#) whose start tag is [not](#) marked as self-closing can have [text](#), [character references](#), [CDATA sections](#), [other elements](#), and [comments](#), but the text must not contain the character U+003C LESS-THAN SIGN (<) or an [ambiguous ampersand](#).

Note

The HTML syntax does not support namespace declarations, even in [foreign elements](#).

For instance, consider the following HTML fragment:

```
<p>
<svg>
<!-- this is invalid -->
<drilllicense xmlns:dril="https://www.example.com/cdr/metadata" name="M11">
</drilllicense>
</svg>
</p>
```

The innermost element, `drilllicense`, is actually in the SVG namespace, as the `xmlns:dril` attribute has no effect (unlike in XML). In fact, as the comment in the fragment above says, the fragment is actually non-conforming. This is because SVG 2 does not define any elements called "`drilllicense`" in the SVG namespace.

[Normal elements](#) can have [text](#), [character references](#), [other elements](#), and [comments](#), but the text must not contain the character U+003C LESS-THAN SIGN (<) or an [ambiguous ampersand](#). Some [normal elements](#) also have [various restrictions](#) on what content they are allowed to hold, beyond the restrictions imposed by the content model and those described in this paragraph. Those restrictions are described below.

Tags contain a [tag name](#), giving the element's name. HTML elements all have names that only use [ASCII alphanumeric](#)s. In the HTML syntax, tag names, even those for [foreign elements](#), may be written with any mix of lower- and uppercase letters that, when converted to all-lowercase, matches the element's tag name; tag names are case-insensitive.

12.1.2.1 Start tags

Start tags must have the following format:

1. The first character of a start tag must be a U+00C0 LESS-THAN SIGN character (<).
2. The second character of a start tag must be the element's [tag name](#).
3. If there are to be any attributes in the next step, there must first be one or more [ASCII whitespace](#).
4. Then, the start tag may have a number of attributes, the [syntax for which](#) is described below. Attributes must be separated from each other by one or more [ASCII whitespace](#).
5. After the attributes, or after the [tag name](#) if there are no attributes, there may be one or more [ASCII whitespace](#). (Some attributes are required to be followed by a space. See the [attributes section](#) below.)
6. Then, if the element is one of the [void elements](#), or if the element is a [foreign element](#), there may be a single U+002F SOLIDUS character (/). This character has no effect on [void elements](#), but on [foreign elements](#) it marks the start tag as self-closing.
7. Finally, start tags must be closed by a U+003E GREATER-THAN SIGN character (>).

12.1.2.2 End tags

End tags must have the following format:

1. The first character of an end tag must be a U+003C LESS-THAN SIGN character (<).
2. The second character of an end tag must be a U+002F SOLIDUS character (/).
3. The next few characters of an end tag must be the element's [tag name](#).
4. After the tag name, there may be one or more [ASCII whitespace](#).
5. Finally, end tags must be closed by a U+003E GREATER-THAN SIGN character (>).

12.1.2.3 Attributes

[Attributes](#) for an element are expressed inside the element's start tag.

Attributes have a name and a value. [Attribute names](#) must consist of one or more characters other than [controls](#), U+0020 SPACE, U+0022 ("), U+0027 ('), U+003E (>), U+002F (/), U+003D (=), and [noncharacters](#). In the HTML syntax, attribute names, even those for [foreign elements](#), may be written with any mix of [ASCII lower](#) and [ASCII upper alphas](#).

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Attributes can be specified in four different ways:

Empty attribute syntax

Just the `attribute name`. The value is implicitly the empty string.

Example

In the following example, the `disabled` attribute is given with the empty attribute syntax:

```
<input disabled>
```

If an attribute using the empty attribute syntax is to be followed by another attribute, then there must be [ASCII whitespace](#) separating the two.

Unquoted attribute value syntax

The `attribute name`, followed by zero or more [ASCII whitespace](#), followed by a single U+003D EQUALS SIGN character, followed by zero or more [ASCII whitespace](#), followed by the `attribute value`, which, in addition to the requirements given above for attribute values, must not contain any literal [ASCII whitespace](#), any U+0022 QUOTATION MARK characters ("), U+0027 APOSTROPHE characters ('), U+003D EQUALS SIGN characters (=), U+003C LESS-THAN SIGN characters (<), U+003E GREATER-THAN SIGN characters (>), or U+0060 GRAVE ACCENT characters (`), and must not be the empty string.

Example

In the following example, the `value` attribute is given with the unquoted attribute value syntax:

```
<input value=yes>
```

If an attribute using the unquoted attribute syntax is to be followed by another attribute or by the optional U+002F SOLIDUS character (/) allowed in step 6 of the `start tag` syntax above, then there must be [ASCII whitespace](#) separating the two.

Single-quoted attribute value syntax

The `attribute name`, followed by zero or more [ASCII whitespace](#), followed by a single U+003D EQUALS SIGN character, followed by zero or more [ASCII whitespace](#), followed by a single U+0027 APOSTROPHE character ('), followed by the `attribute value`, which, in addition to the requirements given above for attribute values, must not contain any literal U+0027 APOSTROPHE characters ('), and finally followed by a second single U+0027 APOSTROPHE character (').

Example

In the following example, the `type` attribute is given with the single-quoted attribute value syntax:

```
<input type='checkbox'>
```

If an attribute using the single-quoted attribute syntax is to be followed by another attribute, then there must be [ASCII whitespace](#) separating the two.

Double-quoted attribute value syntax

The `attribute name`, followed by zero or more [ASCII whitespace](#), followed by a single U+003D EQUALS SIGN character, followed by zero or more [ASCII whitespace](#), followed by a single U+0022 QUOTATION MARK character ("), followed by the `attribute value`, which, in addition to the requirements given above for attribute values, must not contain any literal U+0022 QUOTATION MARK characters ("), and finally followed by a second single U+0022 QUOTATION MARK character (").

Example

In the following example, the `name` attribute is given with the double-quoted attribute value syntax:

```
<input name="the evil">
```

If an attribute using the double-quoted attribute syntax is to be followed by another attribute, then there must be [ASCII whitespace](#) separating the two.

There must never be two or more attributes on the same start tag whose names are an [ASCII case-insensitive](#) match for each other.

When a `forgien element` has one of the namespaced attributes given by the local name and namespace of the first and second cells of a row from the following table, it must be written using the name given by the third cell from the same row.

Local name	Namespace	Attribute name
actuate	XLink namespace	xlink:actuate
arcrole	XLink namespace	xlink:arcrole
href	XLink namespace	xlink:href
role	XLink namespace	xlink:role
show	XLink namespace	xlink:show
title	XLink namespace	xlink:title
type	XLink namespace	xlink:type
lang	XML namespace	xml:lang
space	XML namespace	xml:space
xmlns	XMLNS namespace	xmlns
xlink	XMLNS namespace	xmlns:xlink

No other namespaced attribute can be expressed in [the HTML syntax](#).

Note
Whether the attributes in the table above are conforming or not is defined by other specifications (e.g. *SVG 2* and *MathML*); this section only describes the syntax rules if the attributes are serialized using the HTML syntax.

12.1.2.4 Optional tags

Certain tags can be *omitted*.

Note
Omitting an element's `start tag` in the situations described below does not mean the element is not present; it is implied, but it is still there. For example, an HTML document always has a root `html` element, even if the string `<html>` doesn't appear anywhere in the markup.

An `html` element's `start tag` may be omitted if the first thing inside the `html` element is not a [comment](#).

Example

For example, in the following case it's ok to remove the "`<html>`" tag:

```
<!DOCTYPE HTML>
<html>
  <head>
    <title>Hello</title>
  </head>
  <body>
    <p>Welcome to this example.</p>
  </body>
</html>
```

Doing so would make the document look like this:

```
<!DOCTYPE HTML>
<head>
  <title>Hello</title>
</head>
<body>
  <p>Welcome to this example.</p>
</body>
</html>
```

This has the exact same DOM. In particular, note that whitespace around the `document element` is ignored by the parser. The following example would also have the exact same DOM:

```
<!DOCTYPE HTML>
<head>
  <!-- where is this comment in the DOM? -->
  <title>Hello</title>
</head>
<body>
  <p>Welcome to this example.</p>
</body>
</html>
```

However, in the following example, removing the start tag moves the comment to before the `html` element:

```
<!DOCTYPE HTML>
<html>
  <!-- where is this comment in the DOM? -->
  <head>
    <title>Hello</title>
  </head>
  <body>
    <p>Welcome to this example.</p>
  </body>
</html>
```

With the tag removed, the document actually turns into the same as this:

```
<!DOCTYPE HTML>
<!-- where is this comment in the DOM? -->
<head>
  <title>Hello</title>
</head>
<body>
  <p>Welcome to this example.</p>
</body>
</html>
```

This is why the tag can only be removed if it is not followed by a comment: removing the tag when there is a comment there changes the document's resulting parse tree. Of course, if the position of the comment does not matter, then the tag can be omitted, as if the comment had been moved to before the start tag in the first place.

An `html` element's `end tag` may be omitted if the `html` element is not immediately followed by a [comment](#).

A `head` element's `start tag` may be omitted if the element is empty, or if the first thing inside the `head` element is an element.

A `head` element's `end tag` may be omitted if the `head` element is not immediately followed by [ASCII whitespace](#) or a [comment](#).

A `body` element's `start tag` may be omitted if the element is empty, or if the first thing inside the `body` element is not [ASCII whitespace](#) or a [comment](#), except if the first thing inside the `body` element is a `meta`, `link`, `script`, `style`, or `template` element.

A `body` element's `end tag` may be omitted if the `body` element is not immediately followed by a [comment](#).

Example

Note that in the example above, the `head` element start and end tags, and the `body` element start tag, can't be omitted, because they are surrounded by whitespace:

```
<!DOCTYPE HTML>
<html>
  <head>
    <title>Hello</title>
  </head>
  <body>
    <p>Welcome to this example.</p>
  </body>
</html>
```

(The `body` and `html` element end tags could be omitted without trouble; any spaces after those get parsed into the `body` element anyway.)

Usually, however, whitespace isn't an issue. If we first remove the whitespace we don't care about:

```
<!DOCTYPE HTML><html><head><title>Hello</title></head><body><p>Welcome to this example.</p></body></html>
```

EXPAND

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

Then we can omit a number of tags without affecting the DOM:

```
<!DOCTYPE HTML><title>Hello</title><p>Welcome to this example.</p>
At that point, we can also add some whitespace back:
<!DOCTYPE HTML>
<title>Hello</title>
<p>Welcome to this example.</p>
```

This would be equivalent to this document, with the omitted tags shown in their parser-implied positions; the only whitespace text node that results from this is the newline at the end of the `head` element:

```
<!DOCTYPE HTML>
<head><title>Hello</title>
</head><body><p>Welcome to this example.</p></body></html>
```

An `u` element's `end tag` may be omitted if the `u` element is immediately followed by another `u` element or if there is no more content in the parent element.

A `u` element's `end tag` may be omitted if the `u` element is immediately followed by another `u` element or a `u` element.

A `u` element's `end tag` may be omitted if the `u` element is immediately followed by another `u` element or a `u` element, or if there is no more content in the parent element.

A `u` element's `end tag` may be omitted if the `u` element is immediately followed by an `address`, `article`, `aside`, `blockquote`, `details`, `div`, `dl`, `fieldset`, `figcaption`, `figure`, `footer`, `form`, `h1`, `h2`, `h3`, `h4`, `h5`, `h6`, `header`, `hgroup`, `hr`, `main`, `menu`, `nav`, `ol`, `p`, `pre`, `section`, `table`, or `ul` element, or if there is no more content in the parent element and the parent element is an `HTML` element that is not an `a`, `audio`, `del`, `img`, `map`, `script`, or `video` element, or an `autonomous custom element`.

Example

We can thus simplify the earlier example further:

```
<!DOCTYPE HTML><title>Hello</title><p>Welcome to this example.
```

An `u` element's `end tag` may be omitted if the `u` element is immediately followed by an `u` or `u` element, or if there is no more content in the parent element.

An `u` element's `end tag` may be omitted if the `u` element is immediately followed by another `u` element, or if there is no more content in the parent element.

An `option` element's `end tag` may be omitted if the `option` element is immediately followed by another `option` element, or if it is immediately followed by an `optgroup` element, or if there is no more content in the parent element.

A `caption` element's `start tag` may be omitted if the first thing inside the `caption` element is a `u` element, and if the element is not immediately preceded by another `caption` element whose `end tag` has been omitted. (It can't be omitted if the element is empty.)

A `caption` element's `end tag` may be omitted if the `caption` element is not immediately followed by `ASCII whitespace` or a `comment`.

A `caption` element's `end tag` may be omitted if the `caption` element is not immediately followed by a `thead` or `tfoot` element.

A `tbody` element's `start tag` may be omitted if the first thing inside the `tbody` element is a `u` element, and if the element is not immediately preceded by a `tbody`, `thead`, or `tfoot` element whose `end tag` has been omitted. (It can't be omitted if the element is empty.)

A `tbody` element's `end tag` may be omitted if the `tbody` element is immediately followed by a `thead` or `tfoot` element, or if there is no more content in the parent element.

A `tfoot` element's `end tag` may be omitted if there is no more content in the parent element.

A `tr` element's `end tag` may be omitted if the `tr` element is immediately followed by another `tr` element, or if there is no more content in the parent element.

A `td` element's `end tag` may be omitted if the `td` element is immediately followed by a `td` or `th` element, or if there is no more content in the parent element.

A `th` element's `end tag` may be omitted if the `th` element is immediately followed by a `td` or `th` element, or if there is no more content in the parent element.

Example

The ability to omit all these table-related tags makes table markup much terser.

Take this example:

```
<table>
<caption>37547 TEE Electric Powered Rail Car Train Functions (Abbreviated)</caption>
<colgroup><col><col><col></colgroup>
<thead>
<tr>
<td>Function</td>
<td>Control Unit</td>
<td>Central Station</td>
</tr>
</thead>
<tbody>
<tr>
<td>Headlights</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Interior Lights</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Electric locomotive operating sounds</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Engineer's cab lighting</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Station Announcements - Swiss</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>
```

The exact same table, modulo some whitespace differences, could be marked up as follows:

```
<table>
<caption>37547 TEE Electric Powered Rail Car Train Functions (Abbreviated)</caption>
<colgroup><col><col><col></colgroup>
<thead>
<tr>
<td>Function</td>
<td>Control Unit</td>
<td>Central Station</td>
</tr>
</thead>
<tbody>
<tr>
<td>Headlights</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Interior Lights</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Electric locomotive operating sounds</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Engineer's cab lighting</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Station Announcements - Swiss</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>
```

Since the cells take up much less room this way, this can be made even terser by having each row on one line:

```
<table>
<caption>37547 TEE Electric Powered Rail Car Train Functions (Abbreviated)</caption>
<colgroup><col><col><col></colgroup>
<thead>
<tr>
<td>Function</td> <td>Control Unit</td> <td>Central Station</td>
</tr>
</thead>
<tbody>
<tr> <td>Headlights</td> <td>✓</td> <td>✓</td>
<tr> <td>Interior Lights</td> <td>✓</td> <td>✓</td>
<tr> <td>Electric locomotive operating sounds</td> <td>✓</td> <td>✓</td>
<tr> <td>Engineer's cab lighting</td> <td>✓</td> <td>✓</td>
<tr> <td>Station Announcements - Swiss</td> <td>✓</td> <td>✓</td>
</tbody>
</table>
```

The only differences between these tables, at the DOM level, is with the precise position of the (in any case semantically-neutral) whitespace.

However, a `start tag` must never be omitted if it has any attributes.

Example

Returning to the earlier example with all the whitespace removed and then all the optional tags removed:

```
<!DOCTYPE HTML><title>Hello</title><p>Welcome to this example.
```

If the `body` element in this example had to have a `class` attribute and the `html` element had to have a `lang` attribute, the markup would have to become:

```
<!DOCTYPE HTML><html lang="en"><title>Hello</title><body class="demo"><p>Welcome to this example.
```

Note

This section assumes that the document is conforming, in particular, that there are no `content model` violations. Omitting tags in the fashion described in this section in a document that does not conform to the `content models` described in this specification is likely to result in unexpected DOM differences (this is, in part, what the content models are designed to avoid).

12.1.2.5 Restrictions on content models

For historical reasons, certain elements have extra restrictions beyond even the restrictions given by their content model.

A `table` element must not contain `u` elements, even though these elements are technically allowed inside `table` elements according to the content models described in this specification. (If a `u` element is put inside a `table` in the markup, it will in fact imply a `tbody` start tag before it.)

A single `newline` may be placed immediately after the `start tag` of `pre` and `textarea` elements. This does not affect the processing of the element. The otherwise optional `newline` must be included if the element's contents themselves start with a `newline` (because otherwise the leading newline in the contents would be treated like the optional newline, and ignored).

Example

The following two `pre` blocks are equivalent:

Code	Description
<code>absence-of-digits-in-numeric-character-reference</code>	This error occurs if the parser encounters a numeric character reference that doesn't contain any digits (e.g., <code>&#qux;</code>). In this case the parser doesn't resolve the character reference.
<code>cdata-in-html-content</code>	This error occurs if the parser encounters a CDATA section outside of foreign content (SVG or MathML). The parser treats such CDATA sections (including leading " <code>[CDATA(</code> " and trailing " <code>)</code> " strings) as comments.
<code>character-reference-outside-unicode-range</code>	This error occurs if the parser encounters a numeric character reference that references a code point that is greater than the valid Unicode range. The parser resolves such a character reference to a U+FFFD REPLACEMENT CHARACTER.
<code>control-character-in-input-stream</code>	This error occurs if the input stream contains a control code point that is not ASCII whitespace or <code>U+0000 NULL</code> . Such code points are parsed as-is and usually, where parsing rules don't apply any additional restrictions, make their way into the DOM.
<code>control-character-reference</code>	This error occurs if the parser encounters a numeric character reference that references a control code point that is not ASCII whitespace , a <code>U+000D CARRIAGE RETURN</code> , or <code>U+0000 NULL</code> . The parser resolves such character references as-is except C1 control references that are replaced according to the numeric character reference end state .
<code>end-tag-with-attributes</code>	This error occurs if the parser encounters an end tag with attributes . Attributes in end tags are completely ignored and do not make their way into the DOM.
<code>duplicate-attribute</code>	This error occurs if the parser encounters an attribute in a tag that already has an attribute with the same name. The parser ignores all such duplicate occurrences of the attribute.
<code>end-tag-with-trailing-solidus</code>	This error occurs if the parser encounters an end tag that has a <code>U+002F (/)</code> code point right before the closing <code>U+003E (>)</code> code point (e.g., <code></div/></code>). Such a tag is treated as a regular end tag.
<code>eof-before-tag-name</code>	This error occurs if the parser encounters the end of the input stream where a tag name is expected. In this case the parser treats the beginning of a start tag (i.e., <code><</code>) or an end tag (i.e., <code></</code>) as text content.
<code>eof-in-cdata</code>	This error occurs if the parser encounters the end of the input stream in a CDATA section . The parser treats such CDATA sections as if they are closed immediately before the end of the input stream.
<code>eof-in-comment</code>	This error occurs if the parser encounters the end of the input stream in a comment . The parser treats such comments as if they are closed immediately before the end of the input stream.
<code>eof-in-doctype</code>	This error occurs if the parser encounters the end of the input stream in a DOCTYPE . In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the document to quirks mode .
<code>eof-in-script-html-comment-like-text</code>	This error occurs if the parser encounters the end of the input stream in text that resembles an HTML comment inside script element content (e.g., <code><script><!-- foo</code>).
Note	
Syntactic structures that resemble HTML comments in script elements are parsed as text content. They can be a part of a scripting language specific syntactic structure or be treated as an HTML-like comment, if the scripting language supports them (e.g., parsing rules for HTML-like comments can be found in Annex B of the JavaScript specification). The common reason for this error is a violation of the restrictions for contents of script elements (JavaScript) .	
<code>eof-in-tag</code>	This error occurs if the parser encounters the end of the input stream in a start tag or an end tag (e.g., <code><div id=</code>). Such a tag is completely ignored.
<code>incorrectly-closed-comment</code>	This error occurs if the parser encounters a comment that is closed by the " <code>--></code> code point sequence. The parser treats such comments as if they are correctly closed by the " <code>--></code> code point sequence.
<code>incorrectly-opened-comment</code>	This error occurs if the parser encounters the " <code><!--</code> code point sequence that is not immediately followed by two <code>U+002D (-)</code> code points and that is not the start of a DOCTYPE or a CDATA section . All content that follows the " <code><!--</code> code point sequence up to a <code>U+003E (>)</code> code point (if present) or to the end of the input stream is treated as a comment.
Note	
One possible cause of this error is using an XML markup declaration (e.g., <code><ELEMENT br EMPTY></code>) in HTML.	
<code>invalid-character-sequence-after-doctype-name</code>	This error occurs if the parser encounters any code point sequence other than " <code>PUBLIC</code> " and " <code>SYSTEM</code> " keywords after a DOCTYPE name. In such a case, the parser ignores any following public or system identifiers, and if the DOCTYPE is correctly placed as a document preamble, sets the document to quirks mode .
Note	
This error occurs if the parser encounters a code point that is not an ASCII alpha where first code point of a start tag name or an end tag name is expected. If a start tag was expected such code point and a preceding <code>U+003C (<)</code> is treated as text content, and all content that follows is treated as markup. Whereas, if an end tag was expected, such code point and all content that follows up to a <code>U+003E (>)</code> code point (if present) or to the end of the input stream is treated as a comment.	
Example	
For example, consider the following markup:	
<code><div><42></code>	
This will be parsed into:	
<ul style="list-style-type: none"> • <code>html</code> <ul style="list-style-type: none"> ◦ <code>head</code> ◦ <code>body</code> <ul style="list-style-type: none"> ▪ <code>start:42</code> ▪ <code>end:42</code> 	
Note	
While the first code point of a tag name is limited to an ASCII alpha , a wide range of code points (including ASCII digits) is allowed in subsequent positions.	
<code>missing-attribute-value</code>	This error occurs if the parser encounters a <code>U+003E (>)</code> code point where an attribute value is expected (e.g., <code><div id=</code>). The parser treats the attribute as having an empty value.
<code>missing-doctype-name</code>	This error occurs if the parser encounters a DOCTYPE that is missing a name (e.g., <code><!DOCTYPE</code>). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the document to quirks mode .
<code>missing-doctype-public-identifier</code>	This error occurs if the parser encounters a <code>U+003E (>)</code> code point where start of the DOCTYPE public identifier is expected (e.g., <code><!DOCTYPE html PUBLIC</code> <code>></code>). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the document to quirks mode .
<code>missing-doctype-system-identifier</code>	This error occurs if the parser encounters a <code>U+003E (>)</code> code point where start of the DOCTYPE system identifier is expected (e.g., <code><!DOCTYPE html SYSTEM</code> <code>></code>). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the document to quirks mode .
<code>missing-end-tag-name</code>	This error occurs if the parser encounters a <code>U+003E (>)</code> code point where an end tag name is expected, i.e., <code></></code> . The parser completely ignores whole " <code></></code> code point sequence.
<code>missing-quote-before-doctype-public-identifier</code>	This error occurs if the parser encounters the DOCTYPE public identifier that is not preceded by a quote (e.g., <code><!DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01//EN"</code>). In such a case, the parser ignores the public identifier, and if the DOCTYPE is correctly placed as a document preamble, sets the document to quirks mode .
<code>missing-quote-before-doctype-system-identifier</code>	This error occurs if the parser encounters the DOCTYPE system identifier that is not preceded by a quote (e.g., <code><!DOCTYPE html SYSTEM http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd"></code>). In such a case, the parser ignores the system identifier, and if the DOCTYPE is correctly placed as a document preamble, sets the document to quirks mode .
<code>missing-semicolon-after-character-reference</code>	This error occurs if the parser encounters a character reference that is not terminated by a <code>U+003B (;)</code> code point . Usually the parser behaves as if character reference is terminated by the <code>U+003B (;)</code> code point; however, there are some ambiguous cases in which the parser includes subsequent code points in the character reference.
Example	
For example, <code>snotin</code> will be parsed as " <code>=in</code> " whereas <code>snotin</code> will be parsed as " <code>=e</code> ".	
Note	
This error occurs if the parser encounters a DOCTYPE whose " <code>PUBLIC</code> " keyword and public identifier are not separated by ASCII whitespace . In this case the parser behaves as if ASCII whitespace is present.	
Note	
This error occurs if the parser encounters a DOCTYPE whose " <code>SYSTEM</code> " keyword and system identifier are not separated by ASCII whitespace . In this case the parser behaves as if ASCII whitespace is present.	
Note	
This error occurs if the parser encounters a DOCTYPE whose " <code>PUBLIC</code> " keyword and name are not separated by ASCII whitespace . In this case the parser behaves as if ASCII whitespace is present.	
Note	
This error occurs if the parser encounters attributes that are not separated by ASCII whitespace (e.g., <code><div id="foo class="bar"></code>). In this case the parser behaves as if ASCII whitespace is present.	
Note	
This error occurs if the parser encounters a DOCTYPE whose public and system identifiers are not separated by ASCII whitespace . In this case the parser behaves as if ASCII whitespace is present.	
Note	
This error occurs if the parser encounters a nested comment (e.g., <code><!-- <!-- nested --> --></code>). Such a comment will be closed by the first occurring " <code>--></code> code point sequence and everything that follows will be treated as markup.	
Note	
This error occurs if the parser encounters a numeric character reference that references a noncharacter . The parser resolves such character references as-is.	
Note	
This error occurs if the input stream contains a noncharacter . Such code points are parsed as-is and usually, where parsing rules don't apply any additional restrictions, make their way into the DOM.	
Note	
This error occurs if the parser encounters a start tag for an element that is not in the list of void elements or is not a part of foreign content (i.e., not an SVG or MathML element) that has a <code>U+002F (/)</code> code point right before the closing <code>U+003E (>)</code> code point. The parser behaves as if the <code>U+002F (/)</code> is not present.	
Example	
For example, consider the following markup:	
<code><div></div></code>	
This will be parsed into:	
<ul style="list-style-type: none"> • <code>html</code> <ul style="list-style-type: none"> ◦ <code>head</code> ◦ <code>body</code> <ul style="list-style-type: none"> ▪ <code>start:42</code> ▪ <code>span</code> ▪ <code>span</code> 	
Note	
The trailing <code>U+002F (/)</code> in a start tag name can be used only in foreign content to specify self-closing tags. (Self-closing tags don't exist in HTML.) It is also allowed for void elements, but doesn't have any effect in this case.	
<code>null-character-reference</code>	This error occurs if the parser encounters a numeric character reference that references a <code>U+0000 NULL</code> code point . The parser resolves such character references to a U+FFFD REPLACEMENT CHARACTER.
<code>surrogate-character-reference</code>	This error occurs if the parser encounters a numeric character reference that references a surrogate . The parser resolves such character references to a U+FFFD REPLACEMENT CHARACTER.
<code>surrogate-in-input-stream</code>	This error occurs if the input stream contains a surrogate . Such code points are parsed as-is and usually, where parsing rules don't apply any additional restrictions, make their way into the DOM.
<code>unexpected-character-after-doctype-system-identifier</code>	This error occurs if the parser encounters any code points other than ASCII whitespace or closing <code>U+003E (>)</code> after the DOCTYPE system identifier. The parser ignores these code points.
Note	
This error occurs if the parser encounters a <code>U+0022 ("")</code> , <code>U+0027 ('')</code> , or <code>U+003C (<)</code> code point in an attribute name . The parser includes such code points in the attribute name.	
Note	
Code points that trigger this error are usually a part of another syntactic construct and can be a sign of a typo around the attribute name.	
Example	
For example, consider the following markup:	
<code><div foo><div></code>	
Due to a forgotten <code>U+003D (=)</code> code point after <code>foo</code> the parser treats this markup as a single <code>div</code> element with a " <code>foo<div</code> " attribute.	
As another example of this error, consider the following markup:	
<code><div id="bar"></code>	
Due to a forgotten <code>U+003D (=)</code> code point between an attribute name and value the parser treats this markup as a <code>div</code> element with the attribute " <code>id="bar"</code> " that has an empty value.	
Note	
This error occurs if the parser encounters a <code>U+0022 ("")</code> , <code>U+0027 ('')</code> , <code>U+003C (<)</code> , <code>U+003D (=)</code> , or <code>U+0060 (`)</code> code point in an unquoted attribute value . The parser includes such code points in the attribute value.	
Note	
Code points that trigger this error are usually a part of another syntactic construct and can be a sign of a typo around the attribute value.	
<code>unexpected-character-in-unquoted-attribute-value</code>	<code>U+0060 (`)</code> is in the list of code points that trigger this error because certain legacy user agents treat it as a quote.
Example	

Code	Description																																																																						
<pre><div foo=b>az></pre>	<p>Due to a misplaced U+0027 (?) code point the parser sets the value of the "foo" attribute to "b'az".</p> <p>This error occurs if the parser encounters a U+003D (=) code point before an attribute name. In this case the parser treats U+003D (=) as the first code point of the attribute name.</p>																																																																						
Note The common reason for this error is a forgotten attribute name.																																																																							
unexpected-equals-sign-before-attribute-name Example For example, consider the following markup: <pre><div foo="bar" =ba></pre>	<p>Due to a forgotten attribute name the parser treats this markup as a dug element with two attributes: a "foo" attribute with a "bar" value and a "=ba" attribute with an empty value.</p>																																																																						
unexpected-null-character Example For example, consider the following markup: <pre><xm><stylesheet type="text/css" href="style.css"></pre>	<p>This will be parsed into:</p> <ul style="list-style-type: none"> • comment: xm<stylesheet type="text/css" href="style.css" • html • head • body 																																																																						
unexpected-question-mark-instead-of-tag-name Note The common reason for this error is an XML processing instruction (e.g., <xm!<stylesheet type="text/css" href="style.css"?>) or an XML declaration (e.g., <xm! version="1.0" encoding="UTF-8"?>) being used in HTML.	<p>This error occurs if the parser encounters a U+0000 NULL code point in the input stream in certain positions. In general, such code points are either completely ignored or, for security reasons, replaced with a U+FFFD REPLACEMENT CHARACTER.</p> <p>This error occurs if the parser encounters a U+003F (?) code point where first code point of a start tag name is expected. The U+003F (?) and all content that follows up to a U+003E (=) code point (if present) or to the end of the input stream is treated as a comment.</p>																																																																						
unexpected-solidus-in-tag unknown-named-character-reference 12.2.3 The input byte stream	<p>This error occurs if the parser encounters a U+002F (/) code point that is not a part of a quoted attribute value and not immediately followed by a U+003E (=) code point in a tag (e.g., <div / id="foo">). In this case the parser behaves as if it encountered ASCII whitespace.</p> <p>This error occurs if the parser encounters an ambiguous ampersand. In this case the parser doesn't resolve the character reference.</p> <p>The stream of code points that comprises the input to the tokenization stage will be initially seen by the user agent as a stream of bytes (typically coming over the network or from the local file system). The bytes encode the actual characters according to a particular <i>character encoding</i>, which the user agent uses to decode the bytes into characters.</p> <p>Note For XML documents, the algorithm user agents are required to use to determine the character encoding is given by <i>XMT</i>. This section does not apply to XML documents. (XML)</p> <p>Usually, the encoding sniffing algorithm defined below is used to determine the character encoding.</p> <p>Given a character encoding, the bytes in the input byte stream must be converted to characters for the tokenizer's input stream, by passing the input byte stream and character encoding to decode.</p> <p>Note A leading Byte Order Mark (BOM) causes the character encoding argument to be ignored and will itself be skipped.</p> <p>Note Bytes or sequences of bytes in the original byte stream that did not conform to the Encoding standard (e.g. invalid UTF-8 byte sequences in a UTF-8 input byte stream) are errors that conformance checkers are expected to report. (ENCODING)</p> <p>⚠️ Warning! The decoder algorithms describe how to handle invalid input; for security reasons, it is imperative that those rules be followed precisely. Differences in how invalid byte sequences are handled can result in, amongst other problems, script injection vulnerabilities ("XSS").</p> <p>When the HTML parser is decoding an input byte stream, it uses a character encoding and a <i>confidence</i>. The confidence is either <i>tentative</i>, <i>certain</i>, or <i>irrelevant</i>. The encoding used, and whether the confidence in that encoding is <i>tentative</i> or <i>certain</i>, is used during the parsing to determine whether to change the encoding. If no encoding is necessary, e.g. because the parser is operating on a Unicode stream and doesn't have to use a character encoding at all, then the <i>confidence</i> is <i>irrelevant</i>.</p> <p>Note Some algorithms feed the parser by directly adding characters to the input stream rather than adding bytes to the input byte stream.</p> <p>12.2.3.1 Parsing with a known character encoding When the HTML parser is to operate on an input byte stream that has a <i>known definite encoding</i>, then the character encoding is that encoding and the confidence is <i>certain</i>.</p> <p>12.2.3 Determining the character encoding In some cases, it might be impractical to unambiguously determine the encoding before parsing the document. Because of this, this specification provides for a two-pass mechanism with an optional pre-scan. Implementations are allowed, as described below, to apply a simplified parsing algorithm to whatever bytes they have available before beginning to parse the document. Then, the real parser is started, using a tentative encoding derived from this pre-scan and other out-of-band metadata. If, while the document is being loaded, the user agent discovers a character encoding declaration that conflicts with this information, then the parser can get reinvoked to perform a parse of the document with the real encoding.</p> <p>User agents must use the following algorithm, called the encoding sniffing algorithm, to determine the character encoding to use when decoding a document in the first pass. This algorithm takes as input any out-of-band metadata available to the user agent (e.g. the Content-Type metadata of the document) and all the bytes available so far, and returns a character encoding and a confidence that is either <i>tentative</i> or <i>certain</i>.</p> <ol style="list-style-type: none"> If the user has explicitly instructed the user agent to override the document's character encoding with a specific encoding, optionally return that encoding with the confidence <i>certain</i>. <p>Note Typically, user agents remember such user requests across sessions, and in some cases apply them to documents in streams as well.</p> The user agent may wait for more bytes of the resource to be available, either in this step or at any later step in this algorithm. For instance, a user agent might wait 500ms or 1024 bytes, whichever came first. In general preparing the source to find the encoding improves performance, as it reduces the need to throw away the data structures used when parsing upon finding the encoding information. However, if the user agent delays too long to obtain data to determine the encoding, then the cost of the delay could outweigh any performance improvements from the preparse. If the transport layer specifies a character encoding, and it is supported, return that encoding with the confidence <i>certain</i>. Optionally prescan the byte stream to determine its encoding. The <i>end condition</i> is that the user agent decides that scanning further bytes would not be efficient. User agents are encouraged to only prescan the first 1024 bytes. User agents may decide that scanning <i>any</i> bytes is not efficient, in which case these substeps are entirely skipped. The aforementioned algorithm either succeeds or returns a character encoding. If it returns a character encoding, then return the same encoding, with confidence <i>tentative</i>. If the HTML_parser for which this algorithm is being run is associated with a Document <i>d</i> whose browsing context is non-null and a child browsing context, then: <ol style="list-style-type: none"> Let parentDocument be <i>d</i>'s browsing context's container document. If parentDocument's origin is same origin with <i>d</i>'s origin and parentDocument's character encoding is an ASCII-compatible encoding, then return parentDocument's character encoding, with the confidence <i>tentative</i>. Otherwise, if the user agent has information on the likely encoding for this page, e.g. based on the encoding of the page when it was last visited, then return that encoding, with the confidence <i>tentative</i>. The user agent may attempt to autodetect the character encoding from applying frequency analysis or other algorithms to the data stream. Such algorithms may use information about the resource other than the resource's contents, including the address of the resource. If autodetection succeeds in determining a character encoding, and that encoding is a supported encoding, then return that encoding, with the confidence <i>tentative</i>. (UNIVCHARDET) <p>Note User agents are generally discouraged from attempting to autodetect encodings for resources obtained over the network, since doing so involves inherently non-interoperable heuristics. Attempting to detect encodings based on an HTML document's preamble is especially tricky since HTML markup typically uses only ASCII characters, and HTML documents tend to begin with a lot of markup rather than with text content.</p> <p>Note The UTF-8 encoding has a highly detectable bit pattern. Files from the local file system that contain bytes with values greater than 0x7F which match the UTF-8 pattern are very likely to be UTF-8, while documents with byte sequences that do not match it are very likely not. When a user agent can examine the whole file, rather than just the preamble, detecting for UTF-8 specifically can be especially effective. (PPUTF8) (UTF8DET)</p> <p>8. Otherwise, return an implementation-defined or user-specified default character encoding, with the confidence <i>tentative</i>.</p> <p>In controlled environments or in environments where the encoding of documents can be prescribed (for example, for user agents intended for dedicated use in new networks), the comprehensive UTF-8 encoding is suggested.</p> <p>In other environments, the default encoding is typically dependent on the user's locale (an approximation of the languages, and thus often encodings, of the pages that the user is likely to frequent). The following table gives suggested defaults based on the user's locale, for compatibility with legacy content. Locales are identified by BCP 47 language tags. (BCP47) (ENCODING)</p> <table border="1"> <thead> <tr> <th>Locale language</th> <th>Suggested default encoding</th> </tr> </thead> <tbody> <tr> <td>ar Arabic</td> <td>windows-1256</td> </tr> <tr> <td>ba Bashkir</td> <td>windows-1251</td> </tr> <tr> <td>be Belarusian</td> <td>windows-1251</td> </tr> <tr> <td>bg Bulgarian</td> <td>windows-1251</td> </tr> <tr> <td>cs Czech</td> <td>windows-1250</td> </tr> <tr> <td>el Greek</td> <td>ISO-8859-7</td> </tr> <tr> <td>et Estonian</td> <td>windows-1257</td> </tr> <tr> <td>fa Persian</td> <td>windows-1256</td> </tr> <tr> <td>he Hebrew</td> <td>windows-1255</td> </tr> <tr> <td>hr Croatian</td> <td>windows-1250</td> </tr> <tr> <td>hu Hungarian</td> <td>ISO-8859-2</td> </tr> <tr> <td>ja Japanese</td> <td>Shift_JIS</td> </tr> <tr> <td>kk Kazakh</td> <td>windows-1251</td> </tr> <tr> <td>ko Korean</td> <td>EUC-KR</td> </tr> <tr> <td>ku Kurdish</td> <td>windows-1254</td> </tr> <tr> <td>ky Kyrgyz</td> <td>windows-1251</td> </tr> <tr> <td>lt Lithuanian</td> <td>windows-1257</td> </tr> <tr> <td>lv Latvian</td> <td>windows-1257</td> </tr> <tr> <td>mk Macedonian</td> <td>windows-1251</td> </tr> <tr> <td>pl Polish</td> <td>ISO-8859-2</td> </tr> <tr> <td>ru Russian</td> <td>windows-1251</td> </tr> <tr> <td>sah Yakut</td> <td>windows-1251</td> </tr> <tr> <td>sk Slovak</td> <td>windows-1250</td> </tr> <tr> <td>sl Slovenian</td> <td>ISO-8859-2</td> </tr> <tr> <td>sr Serbian</td> <td>windows-1251</td> </tr> <tr> <td>tg Tajik</td> <td>windows-1251</td> </tr> <tr> <td>th Thai</td> <td>windows-874</td> </tr> <tr> <td>tr Turkish</td> <td>windows-1254</td> </tr> <tr> <td>tt Tatar</td> <td>windows-1251</td> </tr> <tr> <td>uk Ukrainian</td> <td>windows-1251</td> </tr> <tr> <td>vi Vietnamese</td> <td>windows-1258</td> </tr> <tr> <td>zh-CN Chinese (People's Republic of China)</td> <td>gb18030</td> </tr> <tr> <td>zh-TW Chinese (Taiwan)</td> <td>Big5</td> </tr> <tr> <td>All other locales</td> <td>windows-1252</td> </tr> </tbody> </table>	Locale language	Suggested default encoding	ar Arabic	windows-1256	ba Bashkir	windows-1251	be Belarusian	windows-1251	bg Bulgarian	windows-1251	cs Czech	windows-1250	el Greek	ISO-8859-7	et Estonian	windows-1257	fa Persian	windows-1256	he Hebrew	windows-1255	hr Croatian	windows-1250	hu Hungarian	ISO-8859-2	ja Japanese	Shift_JIS	kk Kazakh	windows-1251	ko Korean	EUC-KR	ku Kurdish	windows-1254	ky Kyrgyz	windows-1251	lt Lithuanian	windows-1257	lv Latvian	windows-1257	mk Macedonian	windows-1251	pl Polish	ISO-8859-2	ru Russian	windows-1251	sah Yakut	windows-1251	sk Slovak	windows-1250	sl Slovenian	ISO-8859-2	sr Serbian	windows-1251	tg Tajik	windows-1251	th Thai	windows-874	tr Turkish	windows-1254	tt Tatar	windows-1251	uk Ukrainian	windows-1251	vi Vietnamese	windows-1258	zh-CN Chinese (People's Republic of China)	gb18030	zh-TW Chinese (Taiwan)	Big5	All other locales	windows-1252

The [document's character encoding](#) must immediately be set to the value returned from this algorithm, at the same time as the user agent uses the returned value to select the decoder to use for the input byte stream.

When an algorithm requires a user agent to *prescan a byte stream to determine its encoding*, given some defined *end condition*, then it must run the following steps. These steps either abort unsuccessfully or return a character encoding. If at any point during these steps (including during instances of the [get an attribute](#) algorithm invoked by this one) the user agent either runs out of bytes (meaning the *position* pointer created in the first step below goes beyond the end of the byte stream obtained so far) or reaches its *end condition*, then abort the [prescan a byte stream to determine its encoding](#) algorithm unsuccessfully.

1. Let *position* be a pointer to a byte in the input byte stream, initially pointing at the first byte.

2. Loop: If *position* points to:

A sequence of bytes starting with: 0x3C 0x21 0x2D 0x2D ('<!--')

Advance the *position* pointer so that it points at the first 0x3E byte which is preceded by two 0x2D bytes (i.e. at the end of an ASCII '<-->' sequence) and comes after the 0x3C byte that was found. (The two 0x2D bytes can be the same as those in the '<!-->' sequence.)

A sequence of bytes starting with: 0x3C, 0x4D or 0x6D, 0x45 or 0x65, 0x54 or 0x74, 0x41 or 0x61, and one of 0x09, 0x0A, 0x0C, 0x0D, 0x20, or 0x2F byte (the one in sequence of characters matched above).

1. Advance the *position* pointer so that it points at the next 0x09, 0x0A, 0x0C, 0x0D, 0x20, or 0x2F byte (the one in sequence of characters matched above).

2. Let *attribute list* be an empty list of strings.

3. Let *got pragma* be false.

4. Let *need pragma* be null.

5. Let *charset* be the null value (which, for the purposes of this algorithm, is distinct from an unrecognized encoding or the empty string).

6. Attributes: [Get an attribute](#) and its value. If no attribute was sniffed, then jump to the *processing* step below.

7. If the attribute's name is already in *attribute list*, then return to the step labeled *attributes*.

8. Add the attribute's name to *attribute list*.

9. Run the appropriate step from the following list, if one applies:

If the attribute's name is "[http-equiv](#)"

If the attribute's value is "content-type", then set *got pragma* to true.

If the attribute's name is "content"

Apply the [algorithm for extracting a character encoding from a meta element](#), giving the attribute's value as the string to parse. If a character encoding is returned, and if *charset* is still set to null, let *charset* be the encoding returned, and set *need pragma* to true.

If the attribute's name is "charset"

Let *charset* be the result of [getting an encoding](#) from the attribute's value, and set *need pragma* to false.

10. Return to the step labeled *attributes*.

11. Processing: If *need pragma* is null, then jump to the step below labeled *next byte*.

12. If *need pragma* is true but *got pragma* is false, then jump to the step below labeled *next byte*.

13. If *charset* is failure, then jump to the step below labeled *next byte*.

14. If *charset* is a [UTF-16 encoding](#), then set *charset* to [UTF-8](#).

15. If *charset* is [x-user-defined](#), then set *charset* to [windows-1252](#).

16. Abort the [prescan a byte stream to determine its encoding](#) algorithm, returning the encoding given by *charset*.

A sequence of bytes starting with a 0x3C byte (<), optionally a 0x2F byte (/), and finally a byte in the range 0x41-0x5A or 0x61-0x7A (A-Z or a-z)

1. Advance the *position* pointer so that it points at the next 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), 0x20 (SP), or 0x3E (>) byte.

2. Repeatedly [get an attribute](#) until no further attributes can be found, then jump to the step below labeled *next byte*.

A sequence of bytes starting with: 0x3C 0x21 (<`')

A sequence of bytes starting with: 0x3C 0x2F (<`')

A sequence of bytes starting with: 0x3C 0x3F (<`')

Advance the *position* pointer so that it points at the first 0x3E byte (>) that comes after the 0x3C byte that was found.

Any other byte

Do nothing with that byte.

3. Next byte: Move *position* so it points at the next byte in the input byte stream, and return to the step above labeled *loop*.

When the [prescan a byte stream to determine its encoding](#) algorithm says to [get an attribute](#), it means doing this:

1. If the byte at *position* is one of 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), or 0x20 (SP) then advance *position* to the next byte and redo this step.

2. If the byte at *position* is 0x3E (>,) then abort the [get an attribute](#) algorithm. There isn't one.

3. Otherwise, the byte at *position* is the start of the attribute name. Let *attribute name* and *attribute value* be the empty string.

4. Process the byte at *position* as follows:

If it is 0x3D (=), and the *attribute name* is longer than the empty string

 Advance *position* to the next byte and jump to the step below labeled *value*.

If it is 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), or 0x20 (SP)

 Jump to the step below labeled *values*.

If it is 0x2F (/) or 0x3E (>)

 Abort the [get an attribute](#) algorithm. The attribute's name is the value of *attribute name*, its value is the empty string.

If it is in the range 0x41 (A) to 0x5A (Z)

 Append the code point b+0x20 to *attribute value* (where b is the value of the byte at *position*). (This converts the input to lowercase.)

Anything else

 Append the code point with the same value as the byte at *position* to *attribute name*. (It doesn't actually matter how bytes outside the ASCII range are handled here, since only ASCII bytes can contribute to the detection of a character encoding.)

5. Advance *position* to the next byte and return to the previous step.

6. Spaces: If the byte at *position* is one of 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), or 0x20 (SP) then advance *position* to the next byte, then, repeat this step.

7. If the byte at *position* is not 0x3D (=), about the [get an attribute](#) algorithm. The attribute's name is the value of *attribute name*, its value is the empty string.

8. Advance *position* past the 0x3D (=) byte.

9. False: If the byte at *position* is one of 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), or 0x20 (SP) then advance *position* to the next byte, then, repeat this step.

10. Process the byte at *position* as follows:

If it is 0x22 (" ") or 0x27 ('')

 Let b be the value of the byte at *position*.

 2. Quote loop: Advance *position* to the next byte.

 3. If the value of the byte at *position* is the value of b, then advance *position* to the next byte and abort the "get an attribute" algorithm. The attribute's name is the value of *attribute name*, and its value is the value of *attribute value*.

 4. Otherwise, if the value of the byte at *position* is in the range 0x41 (A) to 0x5A (Z), then append a code point to *attribute value* whose value is 0x20 more than the value of the byte at *position*.

 5. Otherwise, append a code point to *attribute value* whose value is the same as the value of the byte at *position*.

 6. Return to the step above labeled quote loop.

If it is 0x23 (#)

 Abort the [get an attribute](#) algorithm. The attribute's name is the value of *attribute name*, its value is the empty string.

If it is in the range 0x41 (A) to 0x5A (Z)

 Append a code point b+0x20 to *attribute value* (where b is the value of the byte at *position*). Advance *position* to the next byte.

Anything else

 Append a code point with the same value as the byte at *position* to *attribute value*. Advance *position* to the next byte.

11. Process the byte at *position* as follows:

If it is 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), or 0x20 (SP) or 0x3E (>)

 Abort the [get an attribute](#) algorithm. The attribute's name is the value of *attribute name* and its value is the value of *attribute value*.

If it is in the range 0x41 (A) to 0x5A (Z)

 Append a code point b+0x20 to *attribute value* (where b is the value of the byte at *position*).

Anything else

 Append a code point with the same value as the byte at *position* to *attribute value*.

12. Advance *position* to the next byte and return to the previous step.

For the sake of interoperability, user agents should not use a pre-scan algorithm that returns different results than the one described above. (But, if you do, please at least let us know, so that we can improve this algorithm and benefit everyone...)

12.2.3.3 Character encoding

User agents must support the encodings defined in *Encoding*, including, but not limited to, [UTF-8](#), [ISO-8859-2](#), [ISO-8859-7](#), [ISO-8859-8](#), [windows-874](#), [windows-1250](#), [windows-1251](#), [windows-1252](#), [windows-1254](#), [windows-1255](#), [windows-1256](#), [windows-1257](#), [windows-1258](#), [gb18030](#), [Big5](#), [ISO-2022-JP](#), [Shift_JIS](#), [EUC-KR](#), [UTF-16BE](#), [UTF-16LE](#), and [x-user-defined](#). User agents must not support other encodings.

Note
The above prohibits supporting, for example, CESU-8, UTF-7, BOCU-1, SCSU, EBCDIC, and UTF-32. This specification does not make any attempt to support prohibited encodings in its algorithms: support and use of prohibited encodings would thus lead to unexpected behavior. [CESU8](#) | [UTF7](#) | [BOCU1](#) | [SCSU](#)

12.2.3.4 Changing the encoding while parsing

When the parser requires the user agent to *change the encoding*, it must run the following steps. This might happen if the [encoding sniffing algorithm](#) described above failed to find a character encoding, or if it found a character encoding that was not the actual encoding of the file.

1. If the encoding that is already being used to interpret the input stream is a [UTF-16 encoding](#), then set the [confidence](#) to *certain* and return. The new encoding is ignored; if it was anything but the same encoding, then it would be clearly incorrect.

2. If the new encoding is a [UTF-16 encoding](#), then change it to [UTF-8](#).

3. If the new encoding is [x-user-defined](#), then change it to [windows-1252](#).

4. If the new encoding is identical or equivalent to the encoding that is already being used to interpret the input stream, then set the [confidence](#) to *certain* and return. This happens when the encoding information found in the file matches what the [encoding sniffing algorithm](#) determined to be the encoding, and in the second pass through the parser if the first pass found that the encoding sniffing algorithm described in the earlier section failed to find the right encoding.

5. If all the bytes up to the last byte converted by the current decoder have the same Unicode interpretations in both the current encoding and the new encoding, and if the user agent supports changing the converter on the fly, then the user agent may change to the new converter for the encoding on the fly. Set the [document's character encoding](#) and the encoding used to convert the input stream to the new encoding, set the [confidence](#) to *certain*, and return.

6. Otherwise, *navigate* to the document again, with [replacement enabled](#), and using the same [source browsing context](#), but this time skip the [encoding sniffing algorithm](#) and instead just set the encoding to the new encoding and the [confidence](#) to *certain*. Whenever possible, this should be done without actually contacting the network layer (the bytes should be re-parsed from memory), even if, e.g., the document is marked as not being cacheable. If this is not possible and contacting the network layer would involve repeating a request that uses a method other than `get`, then instead set the [confidence](#) to *certain* and ignore the new encoding. The resource will be misinterpreted. User agents may notify the user of the situation, to allow an application development.

Note

This algorithm is only invoked when a new encoding is found declared on a [meta](#) element.

12.2.3.5 Preprocessing the input stream

The [input stream](#) consists of the characters pushed into it as the [input byte stream](#) is decoded or from the various APIs that directly manipulate the input stream.

When the user agent processes the [input stream](#), it must run the following steps. These steps are intended to be run before the document's character encoding is set.

EXPAND

The [stack of open elements](#) is said to have a particular element in *select scope* when it has that element in the specific scope consisting of all element types except the following:

- [optgroup in the HTML namespace](#)
- [option in the HTML namespace](#)

Nothing happens if at any time any of the elements in the [stack of open elements](#) are moved to a new location in, or removed from, the [Document tree](#). In particular, the stack is not changed in this situation. This can cause, amongst other strange effects, content to be appended to nodes that are no longer in the DOM.

Note

In some cases (namely, when [closing misnested formatting elements](#)), the stack is manipulated in a random-access fashion.

12.2.4.3 The list of active formatting elements

Initially, the *list of active formatting elements* is empty. It is used to handle mis-nested [formatting element tags](#).

The list contains elements in the [formatting category](#), and [markers](#). The markers are inserted when entering [span](#), [object](#), [marque](#), [template](#), [td](#), [th](#), and [caption](#) elements, and are used to prevent formatting from "leaking" into [span](#), [object](#), [marque](#), [template](#), [td](#), [th](#), and [caption](#) elements.

In addition, each element in the *list of active formatting elements* is associated with the token for which it was created, so that further elements can be created for that token if necessary.

When the steps below require UA to *push onto* the *list of active formatting elements* an element, the UA must perform the following steps:

1. If there are already three elements in the *list of active formatting elements* after the last [marker](#), if any, or anywhere in the list if there are no [markers](#), that have the same tag name, namespace, and attributes as *element*, then remove the earliest such element from the *list of active formatting elements*. For these purposes, the attributes must be compared as they were when the elements were created by the parser; two elements have the same attributes if all their parsed attributes can be paired such that the two attributes in each pair have identical names, namespaces, and values (the order of the attributes does not matter).

Note
This is the Noah's Ark clause. But with three per family instead of two.

2. Add *element* to the *list of active formatting elements*.

When the steps below require UA to *reconstruct the active formatting elements*, the UA must perform the following steps:

1. If there are no entries in the *list of active formatting elements*, then there is nothing to reconstruct; stop this algorithm.
2. If the last (most recently added) entry in the *list of active formatting elements* is a [marker](#), or if it is an element that is in the [stack of open elements](#), then there is nothing to reconstruct; stop this algorithm.
3. Let *entry* be the last (most recently added) element in the *list of active formatting elements*.
4. *Rewind*: If there are no entries before entry in the *list of active formatting elements*, then jump to the step labeled *create*.
5. Let *entry* be the entry one earlier than entry in the *list of active formatting elements*.
6. If *entry* is neither a [marker](#) nor an element that is also in the [stack of open elements](#), go to the step labeled *rewind*.
7. *Advance*: Let *entry* be the element one later than *entry* in the *list of active formatting elements*.
8. *Create*: [Insert an HTML element](#) for the token for which the element *entry* was created, to obtain *new element*.
9. Replace the entry for *entry* in the list with an entry for *new element*.
10. If the entry for *new element* in the *list of active formatting elements* is not the last entry in the list, return to the step labeled *advance*.

This has the effect of reopening all the formating elements that were opened in the current body, cell, or caption (whichever is youngest) that haven't been explicitly closed.

Note
The way this specification is written, the *list of active formatting elements* always consists of elements in chronological order with the least recently added element first and the most recently added element last (except for while steps 7 to 10 of the above algorithm are being executed, of course).

When the steps below require the UA to clear the *list of active formatting elements up to the last marker*, the UA must perform the following steps:

1. Let *entry* be the last (most recently added) entry in the *list of active formatting elements*.
2. Remove entry from the *list of active formatting elements*.
3. If *entry* was a [marker](#), then stop the algorithm at this point. The list has been cleared up to the last [marker](#).
4. Go to step 1.

12.2.4.4 The element pointers

Initially, the [head element pointer](#) and the [form element pointer](#) are both null.

Once a [head](#) element has been parsed (whether implicitly or explicitly) the [head element pointer](#) gets set to point to this node.

The [form element pointer](#) points to the last [form](#) element that was opened and whose end tag has not yet been seen. It is used to make form controls associate with forms in the face of dramatically bad markup, for historical reasons. It is ignored inside [template](#) elements.

12.2.4.5 Other parsing state flags

The [scripting flag](#) is set to "enabled" if [scripting was enabled](#) for the [document](#) with which the parser is associated when the parser was created, and "disabled" otherwise.

Note
The [scripting flag](#) can be enabled even when the parser was created as part of the [HTML fragment parsing algorithm](#), even though [script](#) elements don't execute in that case.

The [frameset-ok flag](#) is set to "ok" when the parser is created. It is set to "not ok" after certain tokens are seen.

12.2.5 Tokenization

Implementations must act as if they used the following state machine to tokenize HTML. The state machine must start in the [data state](#). Most states consume a single character, which may have various side-effects, and either switches the state machine to a new state to [reconsume the current input character](#), or switches it to a new state to consume the [next character](#), or stays in the same state to consume the next character. Some states have more complicated behavior and can consume several characters before switching to another state. In some cases, the tokenizer state is also changed by the tree construction stage.

When a state says to [reconsume](#) a matched character in a specified state, that means to switch to that state, but when it attempts to consume the [next input character](#), provide it with the [current input character](#) instead.

The exact behavior of certain states depends on the [insertion mode](#) and the [stack of open elements](#). Certain states also use a [temporary buffer](#) to track progress, and the [character reference state](#) uses a [return state](#) to return to the state it was invoked from.

The output of the tokenization step is a series of zero or more of the following tokens: DOCTYPE, start tag, end tag, comment, character, end-of-file. DOCTYPE tokens have a name, a public identifier, a system identifier, and a [force-quirks flag](#). When a DOCTYPE token is created, its name, public identifier, and system identifier must be marked as missing (which is a distinct state from the empty string), and the [force-quirks flag](#) must be set to off (its other state is on). Start and end tag tokens have a tag name, a [self-closing flag](#), and a list of attributes, each of which has a name and a value. When a start or end tag token is created, its [self-closing flag](#) must be unset (its other state is that it be set), and its attributes list must be empty. Comment and character tokens have data.

When a token is emitted, it must immediately be handled by the [tree construction](#) stage. The tree construction stage can affect the state of the tokenization stage, and can insert additional characters into the stream. (For example, the [script](#) element can result in scripts executing and using the [dynamic markup insertion](#) APIs to insert characters into the stream being tokenized.)

Note

Creating a token and emitting it are distinct actions. It is possible for a token to be created but implicitly abandoned (never emitted), e.g. if the file ends unexpectedly while processing the characters that are being parsed into a start tag token.

When a start tag token is emitted with its [self-closing flag](#) set, if the flag is not acknowledged when it is processed by the tree construction stage, that is a [non-void-html-element-start-tag-with-trailing-solidus parse error](#).

When an end tag is emitted with attributes, that is an [end-tag-with-attributes parse error](#).

When an end tag token is emitted with its [self-closing flag](#) set, that is an [end-tag-with-trailing-solidus parse error](#).

An appropriate end tag token is an end tag token whose tag name matches the tag name of the last start tag to have been emitted from this tokenizer, if any. If no start tag has been emitted from this tokenizer, then no end tag token is appropriate.

A [character reference](#) is said to be consumed as part of an attribute if the [return state](#) is either [attribute value \(double-quoted\) state](#), [attribute value \(single-quoted\) state](#) or [attribute value \(unquoted\) state](#).

When a state says to flush code points consumed as a character reference, it means that for each [code point](#) in the [temporary buffer](#) (in the order they were added to the buffer) user agent must append the code point from the buffer to the current attribute's value if the character reference was consumed as part of an attribute, or emit the code point as a character token otherwise.

Before each step of the tokenizer, the user agent must first check the [parser pause flag](#). If it is true, then the tokenizer must abort the processing of any nested invocations of the tokenizer, yielding control back to the caller.

The tokenizer state machine consists of the states defined in the following subsections.

12.2.5.1 Data state

Consume the [next input character](#).

U+0026 AMPERSAND (&)

 Set the [return state](#) to the [data state](#). Switch to the [character reference state](#).

U+003C LESS-THAN SIGN (<)

 Switch to the [tag open state](#).

U+0000 NULL

 This is an [unexpected-null-character parse error](#). Emit the [current input character](#) as a character token.

EOF

 Emit an end-of-file token.

Anything else

 Emit the [current input character](#) as a character token.

12.2.5.2 RCDATA state

Consume the [next input character](#).

U+0026 AMPERSAND (&)

 Consume the character to the [RCDATA state](#). Switch to the [character reference state](#).

U+003C LESS-THAN SIGN (<)

 Switch to the [RCDATA less-than sign state](#).

U+0000 NULL

 This is an [unexpected-null-character parse error](#). Emit a U+FFFFD REPLACEMENT CHARACTER character token.

EOF

 Emit an end-of-file token.

Anything else

 Emit the [current input character](#) as a character token.

12.2.5.3 RAWTEXT state

Consume the [next input character](#).

U+003C LESS-THAN SIGN (<)

 Switch to the [RAWTEXT less-than sign state](#).

U+0000 NULL

 This is an [unexpected-null-character parse error](#). Emit a U+FFFFD REPLACEMENT CHARACTER character token.

EOF

 Emit an end-of-file token.

Anything else

 Emit the [current input character](#) as a character token.

12.2.5.4 Script data state

Consume the [next input character](#).

U+003C LESS-THAN SIGN (<)

 Switch to the [script data less-than sign state](#).

U+0000 NULL

 This is an [unexpected-null-character parse error](#). Emit a U+FFFFD REPLACEMENT CHARACTER character token.

EOF

 Emit an end-of-file token.

Anything else

 Emit the [current input character](#) as a character token.

Anything else
 Emit the [current input character](#) as a character token.

12.2.5.5 PLAINTEXT state

Consume the [next input character](#).

U+0000 NULL
 This is an [unexpected-null-character parse error](#). Emit a U+FFFFD REPLACEMENT CHARACTER character token.

EOF
 Emit an end-of-file token.

Anything else
 Emit the [current input character](#) as a character token.

12.2.5.6 Tag open state

Consume the [next input character](#).

U+0021 EXCLAMATION MARK (!)
 Switch to the [markup declaration open state](#).

U+002F SOLIDUS (/)
 Switch to the [end tag open state](#).

ASCII alpha

Create a new start tag token, set its tag name to the empty string. [Reconsume](#) in the [tag name state](#).

U+002F QUESTION MARK (?)
 This is an [unexpected-question-mark-instead-of-tag-name parse error](#). Create a comment token whose data is the empty string. [Reconsume](#) in the [comment state](#).

EOF
 This is an [eof-before-tag-name parse error](#). Emit a U+003C LESS-THAN SIGN character token and an end-of-file token.

Anything else
 This is an [invalid-first-character-of-tag-name parse error](#). Emit a U+003C LESS-THAN SIGN character token. [Reconsume](#) in the [data state](#).

12.2.5.7 End tag open state

Consume the [next input character](#).

ASCII alpha

Create a new end tag token, set its tag name to the empty string. [Reconsume](#) in the [tag name state](#).

U+003E GREATER-THAN SIGN (>)
 This is a [missing-end-tag-name parse error](#). Switch to the [data state](#).

EOF
 This is an [eof-before-tag-name parse error](#). Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token and an end-of-file token.

Anything else
 This is an [invalid-first-character-of-tag-name parse error](#). Create a comment token whose data is the empty string. [Reconsume](#) in the [comment state](#).

12.2.5.8 Tag name state

Consume the [next input character](#).

U+0009 CHARACTER TABULATION (tab)

U+000A LINE FEED (LF)

U+000C FORM FEED (FF)

U+0020 SPACE

 Switch to the [before attribute name state](#).

U+002F SOLIDUS (/)

 Switch to the [self-closing start tag state](#).

U+003E GREATER-THAN SIGN (>)
 Switch to the [data state](#). Emit the current tag token.

ASCII alpha

Append the lowercase version of the [current input character](#) (add 0x0020 to the character's code point) to the current tag token's tag name.

U+0000 NULL

 This is an [unexpected-null-character parse error](#). Append a U+FFFFD REPLACEMENT CHARACTER character to the current tag token's tag name.

EOF
 This is an [eof-in-tag parse error](#). Emit an end-of-file token.

Anything else
 Append the [current input character](#) to the current tag token's tag name.

12.2.5.9 RCDATA less-than sign state

Consume the [next input character](#).

U+002F SOLIDUS (/)

 Set the [temporary buffer](#) to the empty string. Switch to the [RCDATA end tag open state](#).

Anything else
 Emit a U+003C LESS-THAN SIGN character token. [Reconsume](#) in the [RCDATA state](#).

12.2.5.10 RCDATA end tag open state

Consume the [next input character](#).

ASCII alpha

Create a new end tag token, set its tag name to the empty string. [Reconsume](#) in the [RCDATA end tag name state](#).

Anything else
 Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. [Reconsume](#) in the [RCDATA state](#).

12.2.5.11 RCDATA end tag name state

Consume the [next input character](#).

U+0009 CHARACTER TABULATION (tab)

U+000A LINE FEED (LF)

U+000C FORM FEED (FF)

U+0020 SPACE

 If the current and tag token is an [appropriate end tag token](#), then switch to the [before attribute name state](#). Otherwise, treat it as per the "anything else" entry below.

U+002F SOLIDUS (/)

 If the current and tag token is an [appropriate end tag token](#), then switch to the [self-closing start tag state](#). Otherwise, treat it as per the "anything else" entry below.

U+003E GREATER-THAN SIGN (>)
 If the current and tag token is an [appropriate end tag token](#), then switch to the [data state](#) and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.

ASCII alpha

Append the lowercase version of the [current input character](#) (add 0x0020 to the character's code point) to the current tag token's tag name. Append the [current input character](#) to the [temporary buffer](#).

ASCII lower alpha

 Append the [current input character](#) to the current tag token's tag name. Append the [current input character](#) to the [temporary buffer](#).

Anything else
 Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token, and a character token for each of the characters in the [temporary buffer](#) (in the order they were added to the buffer). [Reconsume](#) in the [RCDATA state](#).

12.2.5.12 RAWTEXT less-than sign state

Consume the [next input character](#).

U+002F SOLIDUS (/)

 Set the [temporary buffer](#) to the empty string. Switch to the [RAWTEXT end tag open state](#).

Anything else
 Emit a U+003C LESS-THAN SIGN character token. [Reconsume](#) in the [RAWTEXT state](#).

12.2.5.13 RAWTEXT end tag open state

Consume the [next input character](#).

ASCII alpha

Create a new end tag token, set its tag name to the empty string. [Reconsume](#) in the [RAWTEXT end tag name state](#).

Anything else
 Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. [Reconsume](#) in the [RAWTEXT state](#).

12.2.5.14 RAWTEXT end tag name state

Consume the [next input character](#).

U+0009 CHARACTER TABULATION (tab)

U+000A LINE FEED (LF)

U+000C FORM FEED (FF)

U+0020 SPACE

 If the current and tag token is an [appropriate end tag token](#), then switch to the [before attribute name state](#). Otherwise, treat it as per the "anything else" entry below.

U+002F SOLIDUS (/)

 If the current and tag token is an [appropriate end tag token](#), then switch to the [self-closing start tag state](#). Otherwise, treat it as per the "anything else" entry below.

U+003E GREATER-THAN SIGN (>)
 If the current and tag token is an [appropriate end tag token](#), then switch to the [data state](#) and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.

ASCII alpha

Append the lowercase version of the [current input character](#) (add 0x0020 to the character's code point) to the current tag token's tag name. Append the [current input character](#) to the [temporary buffer](#).

ASCII lower alpha

 Append the [current input character](#) to the current tag token's tag name. Append the [current input character](#) to the [temporary buffer](#).

Anything else
 Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token, and a character token for each of the characters in the [temporary buffer](#) (in the order they were added to the buffer). [Reconsume](#) in the [RAWTEXT state](#).

12.2.5.15 Script data less-than sign state

Consume the [next input character](#).

U+002F SOLIDUS (/)

 Set the [temporary buffer](#) to the empty string. Switch to the [script data end tag open state](#).

U+0021 EXCLAMATION MARK (!)
 Switch to the [script data escape start state](#). Emit a U+003C LESS-THAN SIGN character token and a U+0021 EXCLAMATION MARK character token.

Anything else
 Emit a U+003C LESS-THAN SIGN character token. [Reconsume](#) in the [script data state](#).

12.2.5.16 Script data end tag open state

Consume the [next input character](#).

ASCII alpha

Create a new end tag token, set its tag name to the empty string. [Reconsume](#) in the [script data end tag name state](#).

Anything else
 Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. [Reconsume](#) in the [script data state](#).

12.2.5.17 Script data end tag name state

Consume the [next input character](#).

ASCII alpha

Create a new end tag token, set its tag name to the empty string. [Reconsume](#) in the [script data end tag name state](#).

Anything else
 Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. [Reconsume](#) in the [script data state](#).

U+0009 CHARACTER TABULATION (tab)
U+000A LINE FEED (LF)
U+000C FORM FEED (FF)
U+0020 SPACE
If the current end tag token is an [appropriate end tag token](#), then switch to the [before attribute name state](#). Otherwise, treat it as per the "anything else" entry below.
U+0027 SOLIDUS (/)
If the current end tag token is an [appropriate end tag token](#), then switch to the [self-closing start tag state](#). Otherwise, treat it as per the "anything else" entry below.
U+003E GREATER-THAN SIGN (>)
If the current end tag token is an [appropriate end tag token](#), then switch to the [data state](#) and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.
ASCII upper alpha
Append the lowercase version of the [current input character](#) (add 0x0020 to the character's code point) to the current tag token's tag name. Append the [current input character](#) to the [temporary buffer](#).
ASCII lower alpha
Append the [current input character](#) to the current tag token's tag name. Append the [current input character](#) to the [temporary buffer](#).
Anything else
Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token, and a character token for each of the characters in the [temporary buffer](#) (in the order they were added to the buffer). [Reconsume](#) in the [script data state](#).

12.2.5.18 Script data escape start state
Consume the [next input character](#).
U+002D HYPHEN-MINUS (-)
Switch to the [script data escape start dash state](#). Emit a U+002D HYPHEN-MINUS character token.
Anything else
[Reconsume](#) in the [script data state](#).

12.2.5.19 Script data escape start dash state
Consume the [next input character](#).
U+002D HYPHEN-MINUS (-)
Switch to the [script data escaped dash dash state](#). Emit a U+002D HYPHEN-MINUS character token.
Anything else
[Reconsume](#) in the [script data state](#).

12.2.5.20 Script data escaped state
Consume the [next input character](#).
U+002D HYPHEN-MINUS (-)
Switch to the [script data escaped dash state](#). Emit a U+002D HYPHEN-MINUS character token.
U+003C LESS-THAN SIGN (<)
Switch to the [script data escaped less-than sign state](#).
U+0000 NULL
This is an [unexpected-null-character parse error](#). Emit a U+FFFFD REPLACEMENT CHARACTER character token.
EOF
This is an [eof-in-script-html-comment-like-text parse error](#). Emit an end-of-file token.
Anything else
Emit the [current input character](#) as a character token.

12.2.5.21 Script data escaped dash state
Consume the [next input character](#).
U+002D HYPHEN-MINUS (-)
Switch to the [script data escaped dash dash state](#). Emit a U+002D HYPHEN-MINUS character token.
U+003C LESS-THAN SIGN (<)
Switch to the [script data escaped less-than sign state](#).
U+0000 NULL
This is an [unexpected-null-character parse error](#). Switch to the [script data escaped state](#). Emit a U+FFFFD REPLACEMENT CHARACTER character token.
EOF
This is an [eof-in-script-html-comment-like-text parse error](#). Emit an end-of-file token.
Anything else
Switch to the [script data escaped state](#). Emit the [current input character](#) as a character token.

12.2.5.22 Script data escaped dash dash state
Consume the [next input character](#).
U+002D HYPHEN-MINUS (-)
Emit a U+002D HYPHEN-MINUS character token.
U+003C LESS-THAN SIGN (<)
Switch to the [script data escaped less-than sign state](#).
U+003E GREATER-THAN SIGN (>)
Switch to the [script data state](#). Emit a U+003E GREATER-THAN SIGN character token.
U+0000 NULL
This is an [unexpected-null-character parse error](#). Switch to the [script data escaped state](#). Emit a U+FFFFD REPLACEMENT CHARACTER character token.
EOF
This is an [eof-in-script-html-comment-like-text parse error](#). Emit an end-of-file token.
Anything else
Switch to the [script data escaped state](#). Emit the [current input character](#) as a character token.

12.2.5.23 Script data escaped less-than sign state
Consume the [next input character](#).
U+002F SOLIDUS (/)
Set the [temporary buffer](#) to the empty string. Switch to the [script data escaped end tag open state](#).
ASCII alpha
Set the [temporary buffer](#) to the empty string. Emit a U+003C LESS-THAN SIGN character token. [Reconsume](#) in the [script data double escape start state](#).
Anything else
Emit a U+003C LESS-THAN SIGN character token. [Reconsume](#) in the [script data escaped state](#).

12.2.5.24 Script data escaped end tag open state
Consume the [next input character](#).
ASCII alpha
Create a new end tag token, set its tag name to the empty string. [Reconsume](#) in the [script data escaped end tag name state](#).
Anything else
Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. [Reconsume](#) in the [script data escaped state](#).

12.2.5.25 Script data escaped end tag name state
Consume the [next input character](#).

Anything else:

Append the [current input character](#) to the current attribute's name.

When the user agent leaves the attribute name state (and before emitting the tag token, if appropriate), the complete attribute's name must be compared to the other attributes on the same token; if there is already an attribute on the token with the exact same name, then this is a [duplicate-attribute parse error](#) and the new attribute must be removed from the token.

Note
If an attribute is so removed from a token, it, and the value that gets associated with it, if any, are never subsequently used by the parser, and are therefore effectively discarded. Removing the attribute in this way does not change its status as the "current attribute" for the purposes of the tokenizer, however.

 Switch to the [CDATA section bracket state](#).

EOF
 This is an [eof-in-cdata parse error](#). Emit an end-of-file token.

Anything else
 Emit the [current input character](#) as a character token.

Note
 U+0000 NULL characters are handled in the tree construction stage, as part of the [in foreign content](#) insertion mode, which is the only place where CDATA sections can appear.

Consume the [next input character](#):

U+005D RIGHT SQUARE BRACKET ()
Switch to the [CDATA section end state](#).
Anything else:
 Emit a U+005D RIGHT SQUARE BRACKET character token. [Reconsume](#) in the [CDATA section state](#).

12.2.5.71 CDATA section end state

Consume the [next input character](#):

U+005D RIGHT SQUARE BRACKET ()
 Emit a U+005D RIGHT SQUARE BRACKET character token.
U+00FE GREATER-THAN SIGN character
 Switch to the [data state](#).
Anything else:
 Emit two U+005D RIGHT SQUARE BRACKET character tokens. [Reconsume](#) in the [CDATA section state](#).

12.2.5.72 Character reference state

Set the [temporary buffer](#) to the empty string. Append a U+0026 AMPERSAND (&) character to the [temporary buffer](#). Consume the [next input character](#):

ASCII alphanumeric:
 [Reconsume](#) in the [named character reference state](#).
U+0023 NUMBER SIGN (#)
 Append the [current input character](#) to the [temporary buffer](#). Switch to the [numeric character reference state](#).

Anything else:
 [Flush code points consumed as a character reference](#). [Reconsume](#) in the [return state](#).

12.2.5.73 Named character reference state

Consume the maximum number of characters possible, with the consumed characters matching one of the identifiers in the first column of the [named character references](#) table (in a [case-sensitive](#) manner). Append each character to the [temporary buffer](#) when it's consumed.

If there is a match:

If the character reference was [consumed as part of an attribute](#), and the last character matched is not a U+003B SEMICOLON character (;), and the [next input character](#) is either a U+003D EQUALS SIGN character (=) or an **ASCII alphanumeric**, then, for historical reasons, [flush code points consumed as a character reference](#) and switch to the [return state](#).

Otherwise:

1. If the last character matched is not a U+003B SEMICOLON character (;), then this is a [missing-semicolon-after-character-reference parse error](#).
2. Set the [temporary buffer](#) to the empty string. Append one or two characters corresponding to the character reference name (as given by the second column of the [named character references](#) table) to the [temporary buffer](#).
3. [Flush code points consumed as a character reference](#). Switch to the [return state](#).

Otherwise:

[Flush code points consumed as a character reference](#). Switch to the [ambiguous ampersand state](#).

Example
If the markup contains (not in an attribute) the string I'm ∉ I tell you, the character reference is parsed as "not", as in, I'm -it; I tell you (and this is a parse error). But if the markup was I'm ∉ I tell you, the character reference would be parsed as "notin;", resulting in I'm & I tell you (and no parse error). However, if the markup contains the string I'm ∉ I tell you in an attribute, no character reference is parsed and string remains intact (and there is no parse error).

12.2.5.74 Ambiguous ampersand state

Consume the [next input character](#):

ASCII alphanumeric:
 If the character reference was [consumed as part of an attribute](#), then append the [current input character](#) to the current attribute's value. Otherwise, emit the [current input character](#) as a character token.
U+003B SEMICOLON (;)
 This is an [unknown-named-character-reference parse error](#). [Reconsume](#) in the [return state](#).

Anything else:
 [Reconsume](#) in the [return state](#).

12.2.5.75 Numeric character reference state

Set the [character reference code](#) to zero (0).

Consume the [next input character](#):

U+0078 LATIN SMALL LETTER X
U+0058 LATIN CAPITAL LETTER X
 Append the [current input character](#) to the [temporary buffer](#). Switch to the [hexadecimal character reference start state](#).
Anything else:
 [Reconsume](#) in the [decimal character reference start state](#).

12.2.5.76 Hexadecimal character reference start state

Consume the [next input character](#):

ASCII hex digit:
 [Reconsume](#) in the [hexadecimal character reference state](#).
Anything else:
 This is an [absence-of-digits-in-numeric-character-reference parse error](#). [Flush code points consumed as a character reference](#). [Reconsume](#) in the [return state](#).

12.2.5.77 Decimal character reference start state

Consume the [next input character](#):

ASCII digit:
 [Reconsume](#) in the [decimal character reference state](#).
Anything else:
 This is an [absence-of-digits-in-numeric-character-reference parse error](#). [Flush code points consumed as a character reference](#). [Reconsume](#) in the [return state](#).

12.2.5.78 Hexadecimal character reference state

Consume the [next input character](#):

ASCII digit:
 Multiply the [character reference code](#) by 16. Add a numeric version of the [current input character](#) (subtract 0x0030 from the character's code point) to the [character reference code](#).
ASCII upper hex digit:
 Multiply the [character reference code](#) by 16. Add a numeric version of the [current input character](#) as a hexadecimal digit (subtract 0x0037 from the character's code point) to the [character reference code](#).
ASCII lower hex digit:
 Multiply the [character reference code](#) by 16. Add a numeric version of the [current input character](#) as a hexadecimal digit (subtract 0x0057 from the character's code point) to the [character reference code](#).
U+003B SEMICOLON (;)
 Switch to the [numeric character reference end state](#).
Anything else:
 This is a [missing-semicolon-after-character-reference parse error](#). [Reconsume](#) in the [numeric character reference end state](#).

12.2.5.79 Decimal character reference state

Consume the [next input character](#):

ASCII digit:
 Multiply the [character reference code](#) by 10. Add a numeric version of the [current input character](#) (subtract 0x0030 from the character's code point) to the [character reference code](#).
U+003B SEMICOLON (;)
 Switch to the [numeric character reference end state](#).
Anything else:
 This is a [missing-semicolon-after-character-reference parse error](#). [Reconsume](#) in the [numeric character reference end state](#).

12.2.5.80 Numeric character reference end state

Check the [character reference code](#):

- If the number is 0x00, then this is a [null-character-reference parse error](#). Set the [character reference code](#) to 0xFFFFD.
- If the number is greater than 0x10FFFF, then this is a [character-reference-outside-unicode-range parse error](#). Set the [character reference code](#) to 0xFFFFD.
- If the number is a [surrogate](#), then this is a [surrogate-character-reference parse error](#). Set the [character reference code](#) to 0xFFFFD.
- If the number is a [noncharacter](#), then this is a [noncharacter-character-reference parse error](#).
- If the number is 0x0D, or a [control](#) that's not [ASCII whitespace](#), then this is a [control-character-reference parse error](#). If the number is one of the numbers in the first column of the following table, then find the row with that number in the first column, and set the [character reference code](#) to the number in the second column of that row.

Number	Code Point
0x80	0x20AC EURO SIGN (€)

 0xF 0x0178 LATIN CAPITAL LETTER Y WITH DIACRESIS (Ŷ)

Set the `temporary buffer` to the empty string. Append a code point equal to the `character reference code` to the `temporary buffer`. Flush code points consumed as a character reference. Switch to the `return state`.

12.2.6 Tree construction

The input to the tree construction stage is a sequence of tokens from the `tokenization` stage. The tree construction stage is associated with a DOM `Document` object when a parser is created. The "output" of this stage consists of dynamically modifying or extending that document's DOM tree.

This specification does not define when an interactive user agent has to render the `documents` so that it is available to the user, or when it has to begin accepting user input.

As each token is emitted from the tokenizer, the user agent must follow the appropriate steps from the following list, known as the `tree construction dispatcher`:

If the `stack of open elements` is empty:
 If the `adjusted current node` is an element in the `HTML namespace`
 If the `adjusted current node` is a `MathML text integration point` and the token is a start tag whose tag name is neither "mglyph" nor "malignmark"
 If the `adjusted current node` is a `MathML text integration point` and the token is a character token
 If the `adjusted current node` is a `HTML integration point` and the token is a start tag "svg"
 If the `adjusted current node` is a `HTML integration point` and the token is a start tag "img"
 If the `adjusted current node` is an `HTML integration point` and the token is a character token
 If the token is an end-of-file token

Process the token according to the rules given in the section corresponding to the current `insertion mode` in HTML content.

Otherwise:

Process the token according to the rules given in the section for parsing tokens `in foreign content`.

The `next token` is the token that is about to be processed by the `tree construction dispatcher` (even if the token is subsequently just ignored).

A node is a `MathML text integration point` if it is one of the following elements:

- A `MathML_m` element
- A `MathML_mi` element
- A `MathML_mn` element
- A `MathML_mo` element
- A `MathML_ms` element
- A `MathML_mtext` element

A node is an `HTML integration point` if it is one of the following elements:

- A `MathML_annotation-xml` element whose start tag token had an attribute with the name "encoding" whose value was an `ASCII case-insensitive` match for the string "text/html"
- A `MathML_annotation-xml` element whose start tag token had an attribute with the name "encoding" whose value was an `ASCII case-insensitive` match for the string "application/xhtml+xml"
- An `SVGforeignObject` element
- An `SVG_desc` element
- An `SVG_title` element

Note

If the node in question is the `context` element passed to the `HTML fragment parsing algorithm`, then the start tag token for that element is the "fake" token created during that `HTML fragment parsing algorithm`.

Note

Not all of the tag names mentioned below are conformant tag names in this specification; many are included to handle legacy content. They still form part of the algorithm that implementations are required to implement to claim conformance.

Note

The algorithm described below places no limit on the depth of the DOM tree generated, or on the length of tag names, attribute names, attribute values, `text` nodes, etc. While implementers are encouraged to avoid arbitrary limits, it is recognized that `practical concerns` will likely force user agents to impose nesting depth constraints.

12.2.6.1 Creating and inserting nodes

While the parser is processing a token, it can enable or disable *foster parenting*. This affects the following algorithm.

The *appropriate place for inserting a node*, optionally using a particular *override target*, is the position in an element returned by running the following steps:

1. If there was an *override target* specified, then let *target* be the *override target*.

Otherwise, let *target* be the `current node`.

2. Determine the *adjusted insertion location* using the first matching steps from the following list:

If `foster parenting` is enabled and *target* is a `table`, `tbody`, `tfoot`, `thead` or `tr` element

Note
 Foster parenting happens when content is misnested in tables.

Run these substeps:

1. Let *last template* be the last `template` element in the `stack of open elements`, if any.
2. Let *last table* be the last `table` element in the `stack of open elements`, if any.
3. If there is a *last template* and either there is one, but *last template* is lower (more recently added) than *last table* in the `stack of open elements`, then: let *adjusted insertion location* be inside *last template*'s `template contents`, after its last child (if any), and abort these substeps.
4. If there is no *last table*, then let *adjusted insertion location* be inside the first element in the `stack of open elements` (the `html` element), after its last child (if any), and abort these substeps. (`fragment case`)
5. If *last table* has a parent node, then let *adjusted insertion location* be inside *last table*'s parent node, immediately before *last table*, and abort these substeps.
6. Let *previous element* be the element immediately above *last table* in the `stack of open elements`.
7. Let *adjusted insertion location* be inside *previous element*, after its last child (if any).

Note
 These steps are involved in part because it's possible for elements, the `table` element in this case in particular, to have been moved by a script around in the DOM, or indeed removed from the DOM entirely, after the element was inserted by the parser.

Otherwise

Let *adjusted insertion location* be inside *target*, after its last child (if any).

3. If the *adjusted insertion location* is inside a `template` element, let it instead be inside the `template` element's `template contents`, after its last child (if any).

4. Return the *adjusted insertion location*.

When the steps below require the UA to *create an element for a token* in a particular given `namespace` and with a particular *intended parent*, the UA must run the following steps:

1. Let *document* be *intended parent*'s `node document`.
2. Let *local name* be the tag name of the token.
3. Let *is* be the value of the "`is`" attribute in the given token, if such an attribute exists, or null otherwise.
4. Let *definition* be the result of *looking up a custom element definition* given *document*, *given namespace*, *local name*, and *is*.
5. If *definition* is non-null and the parser was not created as part of the `HTML fragment parsing algorithm`, then let *will execute script* be true. Otherwise, let it be false.
6. If *will execute script* is true, then:
 1. Increment *document*'s `throw-on-dynamic-markup-insertion counter`.
 2. If the `JavaScript execution context stack` is empty, then *perform a microtask checkpoint*.
 3. Push a new `element queue` onto *document*'s `relevant agent's custom element reactions stack`.
7. Let *element* be the result of *creating an element* given *document*, *localName*, *given namespace*, *null*, and *is*. If *will execute script* is true, set the `synchronous custom elements flag`; otherwise, leave it unset.

Note
 This will cause `custom element constructor` to run, if *will execute script* is true. However, since we incremented the `throw-on-dynamic-markup-insertion counter`, this cannot cause `new characters` to be inserted into the tokenizer, or the document to be blown away.

8. *Append* each attribute in the given token to *element*.

Note
 This can enqueue a custom element callback reaction for the `attributeChangedCallback`, which might run immediately (in the next step).

Note
 Even though the `is` attribute governs the creation of a customized built-in element, it is not present during the execution of the relevant `custom element constructor`; it is appended in this step, along with all other attributes.

9. If *will execute script* is true, then:
 1. Let *queue* be the result of popping from *document*'s `relevant agent's custom element reactions stack`. (This will be the same `element queue` as was pushed above.)
 2. *Invoke custom element reactions* in *queue*.
 3. Decrement *document*'s `throw-on-dynamic-markup-insertion counter`.

10. If *element* has an `xmlns` attribute in the `XMLS namespace` whose value is not exactly the same as the element's namespace, that is a `parse error`. Similarly, if *element* has an `xmns:xlink` attribute in the `XMLS namespace` whose value is not the `XLink Namespace`, that is a `parse error`.

11. If *element* is a `resactable element`, invoke its `reset algorithm`. (This initializes the element's `value` and `checkboxes` based on the element's attributes.)

12. If *element* is a `form-associated element` and not a `form-associated custom element`, the `form element pointer` is not null, there is no `placeholder` element on the `stack of open elements`, *element* is either not `listed` or doesn't have a `form` attribute, and the *intended parent* is in the same `tree` as the element pointed to by the `form element pointer` and set *element's parser inserted flag*.

13. Return *element*.

When the steps below require the user agent to *insert a foreign element* for a token in a given namespace, the user agent must run these steps:

1. Let the *adjusted insertion location* be the *appropriate place for inserting a node*.

2. Let *element* be the result of *creating an element for the token* in the given namespace, with the intended parent being the element in which the *adjusted insertion location* finds itself.

3. If it is possible to insert *element* at the *adjusted insertion location*, then:
 1. If the parser was not created as part of the `HTML fragment parsing algorithm`, then push a new `element queue` onto *element*'s `relevant agent's custom element reactions stack`.
 2. Insert *element* at the *adjusted insertion location*.
 3. If the parser was not created as part of the `HTML fragment parsing algorithm`, then pop the `element queue` from *element*'s `relevant agent's custom element reactions stack`, and *invoke custom element reactions* in that queue.

Note
 If the *adjusted insertion location* cannot accept more elements, e.g. because it's a `document`, that already has an element child, then *element* is dropped on the floor.

4. Push *element* onto the `stack of open elements` so that it is the new `current node`.

5. Return *element*.

When the steps below require the user agent to *adjust MathML attributes* for a token, then, if the token has an attribute named `definitionuri`, change its name to `definitionURL` (note the case difference).

When the steps below require the user agent to *adjust SVG attributes* for a token, then, for each attribute on the token whose attribute name is one of the ones in the first column of the following table, change the attribute's name to the name given in the corresponding cell in the second column. (This fixes the case of SVG attributes that are not all lowercase.)

Attribute name on token	Attribute name on element

<code>(none)</code>	XMLNS	xmlns	XMLNS namespace
<code>xmlns:xlink</code>	XMLNS	xlink	XMLNS namespace

When the steps below require the user agent to *insert a character* while processing a token, the user agent must run the following steps:

1. Let `data` be the characters passed to the algorithm, or, if no characters were explicitly specified, the character of the character token being processed.
2. Let the *adjusted insertion location* be the [appropriate place for inserting a node](#).
3. If the *adjusted insertion location* is in a `Document` node, then return.

Note
The DOM will not let `Document` nodes have `Text` node children, so they are dropped on the floor.

4. If there is a `Text` node immediately before the *adjusted insertion location*, then append `data` to that `Text` node's data.
- Otherwise, create a new `Text` node whose data is `data` and whose `nodeDocument` is the same as that of the element in which the *adjusted insertion location* finds itself, and insert the newly created node at the *adjusted insertion location*.

Example

Here are some sample inputs to the parser and the corresponding number of `Text` nodes that they result in, assuming a user agent that executes scripts.

Input	Number of <code>Text</code> nodes
<pre><script> var script = document.getElementsByName("script")[0]; document.body.removeChild(script); </script></pre>	One <code>Text</code> node in the document, containing "AB".
<pre><script> var text = document.createTextNode("B"); document.body.appendChild(text); </script></pre>	Three <code>Text</code> nodes; "A" before the script, the script's contents, and "BC" after the script (the parser appends to the <code>Text</code> node created by the script).
<pre><script> var text = document.getElementsByTagName("script")[0].firstChild; text.data = "B"; document.body.appendChild(text); </script></pre>	Two adjacent <code>Text</code> nodes in the document, containing "A" and "BC".
<pre><table><tr><td>A</td><td>B</td><td>C</td></tr></table></pre>	One <code>Text</code> node before the table, containing "ABCD". (This is caused by foster parenting .)
<pre><table><tr><td>A </td><td>B </td><td>C</td></tr></table></pre>	One <code>Text</code> node before the table, containing " A B C" (A-space-B-space-C). (This is caused by foster parenting .)
<pre><table><tr><td>A </td><td>B </td></tr></table></pre>	One <code>Text</code> node before the table, containing " A B" (A-space-B, and one <code>Text</code> node inside the table (as a child of a <code>td</code>) with a single space character. (Space characters separated from non-space characters by non-character tokens are not affected by foster parenting , even if those other tokens then get ignored.)

When the steps below require the user agent to *insert a comment* while processing a comment token, optionally with an explicitly insertion position `position`, the user agent must run the following steps:

1. Let `data` be the data given in the comment token being processed.
2. If `position` was specified, then let the *adjusted insertion location* be `position`. Otherwise, let *adjusted insertion location* be the [appropriate place for inserting a node](#).
3. Create a `Comment` node whose `data` attribute is set to `data` and whose `nodeDocument` is the same as that of the node in which the *adjusted insertion location* finds itself.
4. Insert the newly created node at the *adjusted insertion location*.

DOM mutation events must not fire for changes caused by the UA parsing the document. This includes the parsing of any content inserted using `document.write()` and `document.writeln()` calls. ([UIEVENTS](#))

However, `mutationObserver` do fire, as required by [DOM](#).

12.2.6.2 Parsing elements that contain only text

The generic raw text element parsing algorithm and the generic RCDATA element parsing algorithm consist of the following steps. These algorithms are always invoked in response to a start tag token.

1. Insert an HTML element for the token.
2. If the algorithm that was invoked is the [generic raw text element parsing algorithm](#), switch the tokenizer to the `RAWTEXT state`; otherwise the algorithm invoked was the [generic RCDATA element parsing algorithm](#), switch the tokenizer to the `RCDATA state`.
3. Let the `original insertion mode` be the current [insertion mode](#).
4. Then, switch the [insertion mode](#) to "`text`".

12.2.6.3 Closing elements that have implied end tags

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

[Insert a comment](#)

A DOCTYPE token

[Parse error](#). Ignore the token.

A start tag whose tag name is "html"

Process the token [using the rules for the "in body" insertion mode](#).

A start tag whose tag name is "head"

[Insert an HTML element](#) for the token.

Set the [head element pointer](#) to the newly created [head](#) element.

Switch the [insertion mode](#) to "[in head](#)".

An end tag whose tag name is one of: "head", "body", "html", "br"

Act as described in the "anything else" entry below.

Any other end tag

[Parse error](#). Ignore the token.

Anything else

[Insert an HTML element](#) for a "head" start tag token with no attributes.

Set the [head element pointer](#) to the newly created [head](#) element.

Switch the [insertion mode](#) to "[in head](#)".

Reprocess the current token.

12.2.4.4 The "in head" insertion mode

When the user agent is to apply the rules for the "[in head](#)" [insertion mode](#), the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

[Insert the character](#).

A comment token

[Insert a comment](#)

A DOCTYPE token

[Parse error](#). Ignore the token.

A start tag whose tag name is "html"

Process the token [using the rules for the "in body" insertion mode](#).

A start tag whose tag name is one of: "base", "basefont", "bgsound", "link"

[Insert an HTML element](#) for the token. Immediately pop the [current node](#) off the [stack of open elements](#).

[Acknowledge the token's self-closing flag](#), if it is set.

A start tag whose tag name is "meta"

[Insert an HTML element](#) for the token. Immediately pop the [current node](#) off the [stack of open elements](#).

[Acknowledge the token's self-closing flag](#), if it is set.

If the element has a [charset](#) attribute, and [getting an encoding](#) from its value results in an [encoding](#), and the [confidence](#) is currently [tentative](#), then [change the encoding](#) to the resulting encoding.

Otherwise, if the element has an [http-equiv](#) attribute whose value is an [ASCII case-insensitive](#) match for the string "Content-Type", and the element has a [content](#) attribute, and applying the [algorithm for extracting a character encoding from a meta element](#) to that attribute's value returns an [encoding](#), and the [confidence](#) is currently [tentative](#), then [change the encoding](#) to the extracted encoding.

A start tag whose tag name is "title"

Follow the [generic RCDATA element parsing algorithm](#).

A start tag whose tag name is "noscript", if the [scripting flag](#) is enabled

A start tag whose tag name is one of: "noframes", "style"

Follow the [generic raw text element parsing algorithm](#).

A start tag whose tag name is "noscript", if the [scripting flag](#) is disabled

[Insert an HTML element](#) for the token.

Switch the [insertion mode](#) to "[in head noscript](#)".

A start tag whose tag name is "script"

Run these steps:

1. Let the [adjusted insertion location](#) be the [appropriate place for inserting a node](#).

2. [Create an element for the token in the HTML namespace](#), with the intended parent being the element in which the [adjusted insertion location](#) finds itself.

3. Set the element's [parser-document](#) to the [document](#), and unset the element's [non-blocking](#) flag.

Note
This ensures that, if the script is external, any [document.write\(\)](#) calls in the script will execute in-line, instead of blowing the document away, as would happen in most other cases. It also prevents the script from executing until the end tag is seen.

4. If the parser was created as part of the [HTML fragment parsing algorithm](#), then mark the [script](#) element as "[already started](#)" ([fragment case](#))

5. If the parser was invoked via the [document.write\(\)](#) or [document.writeInLine\(\)](#) methods, then optionally mark the [script](#) element as "[already started](#)". (For example, the user agent might use this clause to prevent execution of [cross-origin](#) scripts inserted via [document.write\(\)](#) under slow network conditions, or when the page has already taken a long time to load.)

6. Insert the newly created element at the [adjusted insertion location](#).

7. Push the element onto the [stack of open elements](#) so that it is the new [current node](#).

8. Switch the tokenizer to the [script data state](#).

9. Let the [original insertion mode](#) be the current [insertion mode](#).

10. Switch the [insertion mode](#) to "[text](#)".

An end tag whose tag name is "head"

Pop the [current node](#) (which will be the [head](#) element) off the [stack of open elements](#).

Switch the [insertion mode](#) to "[after head](#)".

An end tag whose tag name is one of: "body", "html", "br"

Act as described in the "anything else" entry below.

A start tag whose tag name is "template"

[Insert an HTML element](#) for the token.

Insert a [marker](#) at the end of the [list of active formatting elements](#).

Set the [frameset-ok flag](#) to "not ok".

Switch the [insertion mode](#) to "[in template](#)".

Push "[in template](#)" onto the [stack of template insertion modes](#) so that it is the new [current template insertion mode](#).

An end tag whose tag name is "template"

If there is no [template](#) element on the [stack of open elements](#), then this is a [parse error](#); ignore the token.

Otherwise, run these steps:

1. [Generate all implied end tags thoroughly](#).

2. If the [current node](#) is not a [template](#) element, then this is a [parse error](#).

3. Pop elements from the [stack of open elements](#) until a [template](#) element has been popped from the stack.

4. [Clear the list of active formatting elements up to the last marker](#).

5. Pop the [current template insertion mode](#) off the [stack of template insertion modes](#).

6. [Reset the insertion mode appropriately](#).

A start tag whose tag name is "head"

Any other end tag

[Parse error](#). Ignore the token.

Anything else

Pop the [current node](#) (which will be the [head](#) element) off the [stack of open elements](#).

Switch the [insertion mode](#) to "[after head](#)".

Reprocess the token.

12.2.4.5 The "in head noscript" insertion mode

When the user agent is to apply the rules for the "[in head noscript](#)" [insertion mode](#), the user agent must handle the token as follows:

A DOCTYPE token

A start tag whose tag name is "html"

Process the token [using the rules for the "in body" insertion mode](#).

An end tag whose tag name is "nosecrt"

Pop the [current node](#) (which will be a [nosecrt](#) element) from the [stack of open elements](#); the new [current node](#) will be a [head](#) element.

Switch the [insertion mode](#) to "[in head](#)".

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

A comment token

A start tag whose tag name is one of: "basefont", "bgsound", "link", "meta", "noframes", "style"

Process the token [using the rules for the "in head" insertion mode](#).

An end tag whose tag name is "br"

Act as described in the "anything else" entry below.

A start tag whose tag name is one of: "head", "nosecrt"

Any other end tag

[Parse error](#): Ignore the token.

Anything else

[Parse error](#):

Pop the [current node](#) (which will be a [nosecrt](#) element) from the [stack of open elements](#); the new [current node](#) will be a [head](#) element.

Switch the [insertion mode](#) to "[in head](#)".

Reprocess the token.

12.2.6.4.4 The "after head" insertion mode

When the user agent is to apply the rules for the "[after head](#)" [insertion mode](#), the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

[Insert the character](#)

A comment token

[Insert a comment](#)

A DOCTYPE token

[Parse error](#): Ignore the token.

A start tag whose tag name is "html"

Process the token [using the rules for the "in body" insertion mode](#).

A start tag whose tag name is "body"

[Insert an HTML element](#) for the token.

Set the [frameset-ok flag](#) to "not ok".

Switch the [insertion mode](#) to "[in body](#)".

A start tag whose tag name is "frameset"

[Insert an HTML element](#) for the token.

Switch the [insertion mode](#) to "[in frameset](#)".

A start tag whose tag name is one of: "base", "basefont", "bgsound", "link", "meta", "noframes", "script", "style", "template", "title"

[Parse error](#):

Push the node pointed to by the [head element pointer](#) onto the [stack of open elements](#).

Process the token [using the rules for the "in head" insertion mode](#).

Remove the node pointed to by the [head element pointer](#) from the [stack of open elements](#). (It might not be the [current node](#) at this point.)

Note

The [head element pointer](#) cannot be null at this point.

An end tag whose tag name is "template"

Process the token [using the rules for the "in head" insertion mode](#).

An end tag whose tag name is one of: "body", "html", "br"

Act as described in the "anything else" entry below.

A start tag whose tag name is "head"

Any other end tag

[Parse error](#): Ignore the token.

Anything else

[Insert an HTML element](#) for a "body" start tag token with no attributes.

Switch the [insertion mode](#) to "[in body](#)".

Reprocess the current token.

12.2.6.4.5 The "in body" insertion mode

When the user agent is to apply the rules for the "[in body](#)" [insertion mode](#), the user agent must handle the token as follows:

A character token that is U+0000 NULL

[Parse error](#): Ignore the token.

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

[Reconstruct the active formatting elements](#), if any.

[Insert the token's character](#).

Any other character token

[Reconstruct the active formatting elements](#), if any.

[Insert the token's character](#).

Set the [frameset-ok flag](#) to "not ok".

A comment token

[Insert a comment](#)

A DOCTYPE token

[Parse error](#): Ignore the token.

A start tag whose tag name is "html"

[Parse error](#):

If there is a [template](#) element on the [stack of open elements](#), then ignore the token.

Otherwise, for each attribute on the token, check to see if the attribute is already present on the top element of the [stack of open elements](#). If it is not, add the attribute and its corresponding value to that element.

A start tag whose tag name is one of: "base", "basefont", "bgsound", "link", "meta", "noframes", "script", "style", "template", "title"

An end tag whose tag name is "template"

Process the token [using the rules for the "in head" insertion mode](#).

A start tag whose tag name is "body"

[Parse error](#):

If the second element on the [stack of open elements](#) is not a [body](#) element, if the [stack of open elements](#) has only one node on it, or if there is a [template](#) element on the [stack of open elements](#), then ignore the token. ([fragment case](#))

Otherwise, set the [frameset-ok flag](#) to "not ok"; then, for each attribute on the token, check to see if the attribute is already present on the [body](#) element (the second element) on the [stack of open elements](#), and if it is not, add the attribute and its corresponding value to that element.

A start tag whose tag name is "frameset"

[Parse error](#):

If the [stack of open elements](#) has only one node on it, or if the second element on the [stack of open elements](#) is not a [body](#) element, then ignore the token. ([fragment case](#))

If the [frameset-ok flag](#) is set to "not ok", ignore the token.

Otherwise, run the following steps:

1. Remove the second element on the [stack of open elements](#) from its parent node, if it has one.

2. Pop all the nodes from the bottom of the [stack of open elements](#) from the [current node](#) up, but not including, the root [real](#) element.

3. [Insert an HTML element](#) for the token.

4. Switch the [insertion mode](#) to "[in frameset](#)".

An end-of-file token

If the [stack of template insertion modes](#) is not empty, then process the token [using the rules for the "in template" insertion mode](#).

If there is a node in the [stack of open elements](#) that is not either a [dd](#) element, a [dt](#) element, an [li](#) element, an [optgroup](#) element, an [option](#) element, a [p](#) element, an [hr](#) element, an [hr](#) element, an [tbody](#) element, a [td](#) element, a [tfoot](#) element, a [th](#) element, a [thead](#) element, a [tr](#) element, the [body](#) element, or the [html](#) element, then this is a [parse_error](#).

2 Stop parsing

An end tag whose tag name is "body"

If the [stack of open elements](#) does not [have a body element in scope](#), this is a [parse_error](#); ignore the token.

Otherwise, if there is a node in the [stack of open elements](#) that is not either a [dd](#) element, a [dt](#) element, an [li](#) element, an [optgroup](#) element, an [option](#) element, a [p](#) element, an [hr](#) element, an [hr](#) element, an [tbody](#) element, a [td](#) element, a [tfoot](#) element, a [th](#) element, a [thead](#) element, a [tr](#) element, the [body](#) element, or the [html](#) element, then this is a [parse_error](#).

Switch the [insertion mode](#) to "after body".

An end tag whose tag name is "html"

If the [stack of open elements](#) does not [have a html element in scope](#), this is a [parse_error](#); ignore the token.

Otherwise, if there is a node in the [stack of open elements](#) that is not either a [dd](#) element, a [dt](#) element, an [li](#) element, an [optgroup](#) element, an [option](#) element, a [p](#) element, an [hr](#) element, an [hr](#) element, an [tbody](#) element, a [td](#) element, a [tfoot](#) element, a [th](#) element, a [thead](#) element, a [tr](#) element, the [body](#) element, or the [html](#) element, then this is a [parse_error](#).

Switch the [insertion mode](#) to "after body".

Reprocess the token.

A start tag whose tag name is one of: "address", "article", "aside", "blockquote", "center", "details", "dialog", "div", "div", "fieldset", "figcaption", "figure", "footer", "header", "hgroup", "main", "menu", "nav", "ol", "p", "section", "summary", "ul"

If the [stack of open elements](#) has a [v](#) element in button scope, then [close a v element](#).

[Insert an HTML element](#) for the token.

A start tag whose tag name is one of: "h1", "h2", "h3", "h4", "h5", "h6"

If the [stack of open elements](#) has a [v](#) element in button scope, then [close a v element](#).

If the [current node](#) is an [HTML element](#) whose tag name is one of "h1", "h2", "h3", "h4", "h5", or "h6", then this is a [parse_error](#); pop the [current node](#) off the [stack of open elements](#).

[Insert an HTML element](#) for the token.

A start tag whose tag name is one of: "pre", "listing"

If the [stack of open elements](#) has a [v](#) element in button scope, then [close a v element](#).

[Insert an HTML element](#) for the token.

If the [next token](#) is a U+000A LINE FEED (LF) character token, then ignore that token and move on to the next one. (Newlines at the start of [pre](#) blocks are ignored as an authoring convenience.)

Set the [frameset-ok flag](#) to "not ok".

A start tag whose tag name is "form"

If the [form element pointer](#) is not null, and there is no [template](#) element on the [stack of open elements](#), then this is a [parse_error](#); ignore the token.

Otherwise:

If the [stack of open elements](#) has a [v](#) element in button scope, then [close a v element](#).

[Insert an HTML element](#) for the token, and, if there is no [template](#) element on the [stack of open elements](#), set the [form element pointer](#) to point to the element created.

A start tag whose tag name is "li"

Run these steps:

1. Set the [frameset-ok flag](#) to "not ok".

2. Initialize [node](#) to be the [current node](#) (the bottommost node of the stack).

3. Loop: If [node](#) is an [li](#) element, then run these substeps:

1. [Generate implied end tags](#), except for [li](#) elements.

2. If the [current node](#) is not an [li](#) element, then this is a [parse_error](#).

3. Pop elements from the [stack of open elements](#) until an [li](#) element has been popped from the stack.

4. Jump to the step labeled [done](#) below.

4. If [node](#) is in the [special](#) category, but is not an [address](#), [div](#), or [p](#) element, then jump to the step labeled [done](#) below.

5. Otherwise, set [node](#) to the previous entry in the [stack of open elements](#) and return to the step labeled [loop](#).

6. Done: If the [stack of open elements](#) has a [v](#) element in button scope, then [close a v element](#).

7. Finally, [insert an HTML element](#) for the token.

A start tag whose tag name is one of: "dd", "dt"

Run these steps:

1. Set the [frameset-ok flag](#) to "not ok".

2. Initialize [node](#) to be the [current node](#) (the bottommost node of the stack).

3. Loop: If [node](#) is a [dd](#) element, then run these substeps:

1. [Generate implied end tags](#), except for [dd](#) elements.

2. If the [current node](#) is not a [dd](#) element, then this is a [parse_error](#).

3. Pop elements from the [stack of open elements](#) until a [dd](#) element has been popped from the stack.

4. Jump to the step labeled [done](#) below.

4. If [node](#) is a [dt](#) element, then run these substeps:

1. [Generate implied end tags](#), except for [dt](#) elements.

2. If the [current node](#) is not a [dt](#) element, then this is a [parse_error](#).

3. Pop elements from the [stack of open elements](#) until a [dt](#) element has been popped from the stack.

4. Jump to the step labeled [done](#) below.

5. If [node](#) is in the [special](#) category, but is not an [address](#), [div](#), or [p](#) element, then jump to the step labeled [done](#) below.

6. Otherwise, set [node](#) to the previous entry in the [stack of open elements](#) and return to the step labeled [loop](#).

7. Done: If the [stack of open elements](#) has a [v](#) element in button scope, then [close a v element](#).

8. Finally, [insert an HTML element](#) for the token.

A start tag whose tag name is "plaintext"

If the [stack of open elements](#) has a [v](#) element in button scope, then [close a v element](#).

[Insert an HTML element](#) for the token.

Switch the tokenizer to the [PLAINTEXT state](#).

Note
Once a start tag with the tag name "plaintext" has been seen, that will be the last token ever seen other than character tokens (and the end-of-file token), because there is no way to switch out of the [PLAINTEXT state](#).

A start tag whose tag name is "button"

If the [stack of open elements](#) has a [button](#) element in scope, then run these substeps:

1. [Parse error](#).

2. [Generate implied end tags](#).

3. Pop elements from the [stack of open elements](#) until a [button](#) element has been popped from the stack.

2. [Reconstruct the active formatting elements](#), if any.

3. [Insert an HTML element](#) for the token.

4. Set the [frameset-ok flag](#) to "not ok".

A end tag whose tag name is one of: "address", "article", "aside", "blockquote", "button", "center", "details", "dialog", "div", "div", "fieldset", "figcaption", "figure", "footer", "header", "hgroup", "listing", "main", "menu", "nav", "ol", "pre", "section", "summary", "ul"

If the [stack of open elements](#) does not [have an element in scope](#) that is an [HTML element](#) with the same tag name as that of the token, then this is a [parse_error](#); ignore the token.

Otherwise, run these steps:

1. [Generate implied end tags](#).

2. If the [current node](#) is not an [HTML element](#) with the same tag name as that of the token, then this is a [parse_error](#).

3. Pop elements from the [stack of open elements](#) until an [HTML element](#) with the same tag name as that of the token has been popped from the stack.

A end tag whose tag name is "form"

If there is no [template](#) element on the [stack of open elements](#), then run these substeps:

1. Let [node](#) be the element that the [form element pointer](#) is set to, or null if it is not set to an element.

2. Set the [form element pointer](#) to null.

3. If [node](#) is null or if the [stack of open elements](#) does not [have node in scope](#), then this is a [parse_error](#); return and ignore the token.

4. [Generate implied end tags](#).

5. If the [current node](#) is not [node](#), then this is a [parse_error](#).

6. Remove [node](#) from the [stack of open elements](#).

If there is a [template](#) element on the [stack of open elements](#), then run these substeps instead:

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

1. If the stack of open elements does not have a `form` element in scope, then this is a parse error; return and ignore the token.

2. Generate implied end tags.

3. If the current node is not a `form` element, then this is a parse error.

4. Pop elements from the stack of open elements until a `form` element has been popped from the stack.

An end tag whose tag name is "p"

If the stack of open elements does not have a `v` element in button scope, then this is a parse error; insert an HTML element for a "p" start tag token with no attributes.

Close a `v` element

An end tag whose tag name is "i"

If the stack of open elements does not have an `li` element in list item scope, then this is a parse error; ignore the token.

Otherwise, run these steps:

1. Generate implied end tags, except for `li` elements.

2. If the current node is not an `li` element, then this is a parse error.

3. Pop elements from the stack of open elements until an `li` element has been popped from the stack.

An end tag whose tag name is one of: "df", "dt"

If the stack of open elements does not have an element in scope that is an HTML element with the same tag name as that of the token, then this is a parse error; ignore the token.

Otherwise, run these steps:

1. Generate implied end tags, except for HTML elements with the same tag name as the token.

2. If the current node is not an HTML element with the same tag name as that of the token, then this is a parse error.

3. Pop elements from the stack of open elements until an HTML element with the same tag name as the token has been popped from the stack.

An end tag whose tag name is one of: "h1", "h2", "h3", "h4", "h5", "h6"

If the stack of open elements does not have an element in scope that is an HTML element and whose tag name is one of "h1", "h2", "h3", "h4", "h5", or "h6", then this is a parse error; ignore the token.

Otherwise, run these steps:

1. Generate implied end tags.

2. If the current node is not an HTML element with the same tag name as that of the token, then this is a parse error.

3. Pop elements from the stack of open elements until an HTML element whose tag name is one of "h1", "h2", "h3", "h4", "h5", or "h6" has been popped from the stack.

An end tag whose tag name is "sarcasm"

Take a deep breath, then act as described in the "any other end tag" entry below.

A start tag whose tag name is "a"

If the list of active formatting elements contains an a element between the end of the list and the last marker on the list (or the start of the list if there is no marker on the list), then this is a parse error; run the adoption agency algorithm for the token, then remove that element from the list of active formatting elements and the stack of open elements if the adoption agency algorithm didn't already remove it (it might not have if the element is not in table scope).

Example

In the non-conforming stream = `<hr><a><table><tr><td></td></tr></table>`, the first a element would be closed upon seeing the second one, and the "a" character would be inside a link to "b", not to "a". This is despite the fact that the outer a element is not in table scope (meaning that a regular end tag at the start of the table wouldn't close the outer a element). The result is that the two a elements are indirectly nested inside each other — non-conforming markup will often result in non-conforming DOMs when parsed.

Reconstruct the active formatting elements, if any.

Insert an HTML element for the token. Push onto the list of active formatting elements that element.

A start tag whose tag name is one of: "b", "big", "code", "em", "font", "i", "s", "small", "strike", "strong", "tt", "u"

Reconstruct the active formatting elements, if any.

If the stack of open elements has a code element in scope, then this is a parse error; run the adoption agency algorithm for the token, then once again reconstruct the active formatting elements, if any.

Insert an HTML element for the token. Push onto the list of active formatting elements that element.

A start tag whose tag name is "nobr"

Reconstruct the active formatting elements, if any.

If the stack of open elements has a nobr element in scope, then this is a parse error; run the adoption agency algorithm for the token.

Insert an HTML element for the token. Push onto the list of active formatting elements that element.

An end tag whose tag name is one of: "a", "b", "big", "code", "em", "font", "i", "nobr", "s", "small", "strike", "strong", "tt", "u"

Run the adoption agency algorithm for the token.

A start tag whose tag name is one of: "applet", "marquee", "object"

Reconstruct the active formatting elements, if any.

Insert an HTML element for the token.

Insert a marker at the end of the list of active formatting elements.

Set the frameset-ok flag to "not ok".

An end tag taken whose tag name is one of: "applet", "marquee", "object"

If the stack of open elements does not have an element in scope that is an HTML element with the same tag name as that of the token, then this is a parse error; ignore the token.

Otherwise, run these steps:

1. Generate implied end tags.

2. If the current node is not an HTML element with the same tag name as that of the token, then this is a parse error.

3. Pop elements from the stack of open elements until an HTML element with the same tag name as the token has been popped from the stack.

4. Clear the list of active formatting elements up to the last marker.

A start tag whose tag name is "table"

If the document is not set to quirks mode, and the stack of open elements has a v element in button scope, then close a `v` element.

Insert an HTML element for the token.

Set the frameset-ok flag to "not ok".

Switch the insertion mode to "in table".

An end tag whose tag name is "br"

Parse error. Drop the attributes from the token, and act as described in the next entry; i.e. act as if this was a "br" start tag token with no attributes, rather than the end tag token that it actually is.

A start tag whose tag name is one of: "area", "br", "embed", "img", "keygen", "wbr"

Reconstruct the active formatting elements, if any.

Insert an HTML element for the token. Immediately pop the current node off the stack of open elements.

Acknowledge the token's self-closing flag, if it is set.

Set the frameset-ok flag to "not ok".

A start tag whose tag name is "input"

Reconstruct the active formatting elements, if any.

Insert an HTML element for the token. Immediately pop the current node off the stack of open elements.

Acknowledge the token's self-closing flag, if it is set.

If the token does not have an attribute with the name "type", or if it does, but that attribute's value is not an ASCII case-insensitive match for the string "hidden", then: set the frameset-ok flag to "not ok".

A start tag whose tag name is one of: "param", "source", "track"

Insert an HTML element for the token. Immediately pop the current node off the stack of open elements.

Acknowledge the token's self-closing flag, if it is set.

A start tag whose tag name is "hr"

If the stack of open elements has a v element in button scope, then close a `v` element.

Insert an HTML element for the token. Immediately pop the current node off the stack of open elements.

Acknowledge the token's self-closing flag, if it is set.

Set the frameset-ok flag to "not ok".

A start tag whose tag name is "image"

Parse error. Change the token's tag name to "img" and reprocess it. (Don't ask.)

A start tag whose tag name is "textarea"

Run these steps:

1. Insert an HTML element for the token.

2. If the next token is a U+000A LINE FEED (LF) character token, then ignore that token and move on to the next one. (Newlines at the start of textarea elements are ignored as an authoring convenience.)

3. Switch the tokenizer to the CDATA state.

4. Let the original insertion mode be the current insertion mode.

5. Set the frameset-ok flag to "not ok".

6. Switch the insertion mode to "text".

A start tag whose tag name is "xmp"

If the [stack of open elements](#) has a [element](#) in button scope, then [close a `<u>` element](#).

[Reconstruct the active formatting elements](#), if any.

Set the [frameset-ok flag](#) to "not ok".

Follow the [generic raw text element parsing algorithm](#).

A start tag whose tag name is "iframe"

Set the [frameset-ok flag](#) to "not ok".

Follow the [generic raw text element parsing algorithm](#).

A start tag whose tag name is "noembed"

A start tag whose tag name is "noscript", if the [scripting flag](#) is enabled

Follow the [generic raw text element parsing algorithm](#).

A start tag whose tag name is "select"

[Reconstruct the active formatting elements](#), if any.

[Insert an HTML element](#) for the token.

Set the [frameset-ok flag](#) to "not ok".

If the [insertion mode](#) is one of "[in table](#)", "[in caption](#)", "[in table body](#)", "[in row](#)", or "[in cell](#)", then switch the [insertion mode](#) to "[in select in table](#)". Otherwise, switch the [insertion mode](#) to "[in select](#)".

A start tag whose tag name is one of: "optgroup", "option"

If the [current node](#) is an [option](#) element, then pop the [current node](#) off the [stack of open elements](#).

[Reconstruct the active formatting elements](#), if any.

[Insert an HTML element](#) for the token.

A start tag whose tag name is one of: "rb", "rt"

If the [stack of open elements](#) has a [rb](#) element in scope, then [generate implied end tags](#). If the [current node](#) is not now a [rb](#) element, this is a [parse error](#).

[Insert an HTML element](#) for the token.

[Insert an HTML element](#) for the token.

A start tag whose tag name is "math"

[Reconstruct the active formatting elements](#), if any.

[Adjust MathML attributes](#) for the token. (This fixes the case of MathML attributes that are not all lowercase.)

[Adjust foreign attributes](#) for the token. (This fixes the use of namespace attributes, in particular XLink.)

[Insert a foreign element](#) for the token, in the [MathML namespace](#).

If the token has its [self-closing flag](#) set, pop the [current node](#) off the [stack of open elements](#) and [acknowledge the token's self-closing flag](#).

A start tag whose tag name is "svg"

[Reconstruct the active formatting elements](#), if any.

[Adjust SVG attributes](#) for the token. (This fixes the case of SVG attributes that are not all lowercase.)

[Adjust foreign attributes](#) for the token. (This fixes the use of namespace attributes, in particular XLink in SVG.)

[Insert a foreign element](#) for the token, in the [SVG namespace](#).

If the token has its [self-closing flag](#) set, pop the [current node](#) off the [stack of open elements](#) and [acknowledge the token's self-closing flag](#).

A start tag whose tag name is one of: "caption", "col", "colgroup", "frame", "head", "body", "td", "tfoot", "th", "thead", "tr"

[Parse error](#). Ignore the token.

Any other start tag

[Reconstruct the active formatting elements](#), if any.

[Insert an HTML element](#) for the token.

Note

This element will be an [ordinary](#) element.

Any other end tag

Run these steps:

1. Initialize [node](#) to be the [current node](#) (the bottommost node of the stack).

2. *Loop*: If [node](#) is an [HTML element](#) with the same tag name as the token, then:

 1. [Generate implied end tags](#), except for [HTML elements](#) with the same tag name as the token.

 2. If [node](#) is not the [current node](#), then this is a [parse error](#).

 3. Pop all the nodes from the [current node](#) up to [node](#), including [node](#), then stop these steps.

 3. Otherwise, if [node](#) is in the [special](#) category, then this is a [parse error](#); ignore the token, and return.

 4. Set [node](#) to the previous entry in the [stack of open elements](#).

 5. Return to the step labeled *loop*.

When the steps above say the user agent is to [close a `<p>` element](#), it means that the user agent must run the following steps:

1. [Generate implied end tags](#), except for [p](#) elements.

2. If the [current node](#) is not a [p](#) element, then this is a [parse error](#).

3. Pop elements from the [stack of open elements](#) until a [p](#) element has been popped from the stack.

The [adoption agency algorithm](#), which takes as its only argument a token [token](#) for which the algorithm is being run, consists of the following steps:

1. Let [subject](#) be [token's](#) tag name.

2. If the [current node](#) is an [HTML element](#) whose tag name is [subject](#), and the [current node](#) is not in the [list of active formatting elements](#), then pop the [current node](#) off the [stack of open elements](#), and return.

3. Let [outer loop counter](#) be zero.

4. *Outer loop*: If [outer loop counter](#) is greater than or equal to eight, then return.

5. Increment [outer loop counter](#) by one.

6. Let [formatting element](#) be the last element in the [list of active formatting elements](#) that:

 • is between the end of the list and the [marker](#) in the list, if any, or the start of the list otherwise, and

 • has the tag name [subject](#).

If there is no such element, then return and instead act as described in the "any other end tag" entry above.

7. If [formatting element](#) is not in the [stack of open elements](#), then this is a [parse error](#); remove the element from the list, and return.

8. If [formatting element](#) is in the [stack of open elements](#), but the element is not [in scope](#), then this is a [parse error](#); return.

9. If [formatting element](#) is not the [current node](#), this is a [parse error](#). (But do not return.)

10. Let [furthest block](#) be the topmost node in the [stack of open elements](#) that is lower in the stack than [formatting element](#), and is an element in the [special](#) category. There might not be one.

11. If there is no [furthest block](#), then the UA must first pop all the nodes from the bottom of the [stack of open elements](#), from the [current node](#) up to and including [formatting element](#), then remove [formatting element](#) from the [list of active formatting elements](#), and finally return.

12. Let [common ancestor](#) be the element immediately above [formatting element](#) in the [stack of open elements](#).

13. Let a bookmark note the position of [formatting element](#) in the [list of active formatting elements](#) relative to the elements on either side of it in the list.

14. Let [node](#) and [last node](#) be [furthest block](#). Follow these steps:

1. Let [inner loop counter](#) be zero.

2. *Inner loop*: Increment [inner loop counter](#) by one.

3. Let [node](#) be the element immediately above [node](#) in the [stack of open elements](#), or if [node](#) is no longer in the [stack of open elements](#) (e.g. because it got removed by this algorithm), the element that was immediately above [node](#) in the [stack of open elements](#) before [node](#) was removed.

4. If [node](#) is [formatting element](#), then go to the next step in the overall algorithm.

5. If [inner loop counter](#) is greater than three and [node](#) is in the [list of active formatting elements](#), then remove [node](#) from the [list of active formatting elements](#).

6. If [node](#) is not in the [list of active formatting elements](#), then remove [node](#) from the [stack of open elements](#) and then go back to the step labeled *inner loop*.

7. Create an element for the token for which [formatting element](#) was created, in the [HTML namespace](#), with [common ancestor](#) as the intended parent; replace the entry for [node](#) in the [list of active formatting elements](#) with an entry for the new element, replace the entry for [node](#) in the [stack of open elements](#) with an entry for the new element, and let [node](#) be the new element.

8. If [last node](#) is [furthest block](#), then move the aforementioned bookmark to be immediately after the new [node](#) in the [list of active formatting elements](#).

9. Insert [last node](#) into [node](#), first removing it from its previous parent node if any.

10. Let [last node](#) be [node](#).

11. Return to the step labeled *inner loop*.

15. Insert whatever [last node](#) ended up being in the previous step at the [appropriate place for inserting a node](#), but using [common ancestor](#) as the [override target](#).

16. Create an element for the token for which [formatting element](#) was created, in the [HTML namespace](#), with [furthest block](#) as the intended parent.

17. Take all of the child nodes of *furthest block* and append them to the element created in the last step.
18. Append new element to *furthest block*.
19. Remove *formatting element* from the [list of active formatting elements](#), and insert the new element into the [list of active formatting elements](#) at the position of the aforementioned bookmark.
20. Remove *formatting element* from the [stack of open elements](#), and insert the new element into the [stack of open elements](#) immediately below the position of *furthest block* in that stack.
21. Jump back to the step labeled *outer loop*.

Note

This algorithm's name, the "adoption agency algorithm", comes from the way it causes elements to change parents, and is in contrast with [other possible algorithms](#) for dealing with misnested content.

12.2.6.4.8 The "text" insertion mode

When the user agent is to apply the rules for the ["text" insertion mode](#), the user agent must handle the token as follows:

A character token

[Insert the token's character](#)

Note

This can never be a U+0000 NULL character; the tokenizer converts those to U+FFFFD REPLACEMENT CHARACTER characters.

An end-of-file token

[Parse error](#)

If the *current node* is a [script](#) element, mark the [script](#) element as ["already started"](#).

Pop the *current node* off the [stack of open elements](#).

Switch the [insertion mode](#) to the [original insertion mode](#) and reprocess the token.

An end tag whose tag name is "script"

If the [JavaScript execution context stack](#) is empty, [perform a microtask checkpoint](#).

Let *script* be the *current node* (which will be a [script](#) element).

Pop the *current node* off the [stack of open elements](#).

Switch the [insertion mode](#) to the [original insertion mode](#).

Let the *old insertion point* have the same value as the current [insertion point](#). Let the *insertion point* be just before the [next input character](#).

Increment the parser's [script nesting level](#) by one.

[Prepare the script](#). This might cause some script to execute, which might cause [new characters to be inserted into the tokenizer](#), and might cause the tokenizer to output more tokens, resulting in a [reentrant invocation of the parser](#).

Decrement the parser's [script nesting level](#) by one. If the parser's [script nesting level](#) is zero, then set the [parser pause flag](#) to false.

Let the *insertion point* have the value of the *old insertion point*. (In other words, restore the *insertion point* to its previous value. This value might be the "undefined" value.)

At this stage, if there is a [pending parsing-blocking script](#), then:

If the [script nesting level](#) is not zero:

Set the [parser pause flag](#) to true, and abort the processing of any nested invocations of the tokenizer, yielding control back to the caller. (Tokenization will resume when the caller returns to the "outer" tree construction stage.)

Note

The tree construction stage of this particular parser is [being called reentrantly](#), say from a call to [document.write\(\)](#).

Otherwise:

Run these steps:

1. Let the *script* be the [pending parsing-blocking script](#). There is no longer a [pending parsing-blocking script](#).
2. Block the [tokenizer](#) for this instance of the [HTML parser](#), such that the [event loop](#) will not run tasks that invoke the [tokenizer](#).
3. If the parser's [document has a style sheet that is blocking scripts](#) or the *script*'s ["ready to be parser-executed"](#) flag is not set: [spin the event loop](#) until the parser's [document has no style sheet that is blocking scripts](#) and the *script*'s ["ready to be parser-executed"](#) flag is set.
4. If this [parser has been aborted](#) in the meantime, return.

Note

This could happen if, e.g., while the [spin the event loop](#) algorithm is running, the [browsing context](#) gets closed, or the [document.open\(\)](#) method gets invoked on the [Document](#).

5. Unblock the [tokenizer](#) for this instance of the [HTML parser](#), such that tasks that invoke the [tokenizer](#) can again be run.
6. Let the [insertion point](#) be just before the [next input character](#).
7. Increment the parser's [script nesting level](#) by one (it should be zero before this step, so this sets it to one).
8. [Execute the script](#).
9. Decrement the parser's [script nesting level](#) by one. If the parser's [script nesting level](#) is zero (which it always should be at this point), then set the [parser pause flag](#) to false.
10. Let the [insertion point](#) be undefined again.
11. If there is once again a [pending parsing-blocking script](#), then repeat these steps from step 1.

Any other end tag

Pop the *current node* off the [stack of open elements](#).

Switch the [insertion mode](#) to the [original insertion mode](#).

12.2.6.4.9 The "in table" insertion mode

When the user agent is to apply the rules for the ["in table" insertion mode](#), the user agent must handle the token as follows:

A character token, if the *current node* is [table](#), [tbody](#), [tfoot](#), [thead](#), or [tr](#) element

Let the *pending table character tokens* be an empty list of tokens.

Let the [original insertion mode](#) be the current [insertion mode](#).

Switch the [insertion mode](#) to ["in table text"](#) and reprocess the token.

A comment token

[Insert a comment](#)

A DOCTYPE token

[Parse error](#). Ignore the token.

A start tag whose tag name is "caption"

[Clear the stack back to a table context](#). (See below.)

Insert a [marker](#) at the end of the [list of active formatting elements](#).

[Insert an HTML element](#) for the token, then switch the [insertion mode](#) to ["in caption"](#).

A start tag whose tag name is "colgroup"

[Clear the stack back to a table context](#). (See below.)

[Insert an HTML element](#) for the token, then switch the [insertion mode](#) to ["in column group"](#).

A start tag whose tag name is "col"

[Clear the stack back to a table context](#). (See below.)

[Insert an HTML element](#) for a "colgroup" start tag token with no attributes, then switch the [insertion mode](#) to ["in column group"](#).

Reprocess the current token.

A start tag whose tag name is one of: "body", "tfoot", "thead"

[Clear the stack back to a table context](#). (See below.)

[Insert an HTML element](#) for the token, then switch the [insertion mode](#) to ["in table body"](#).

A start tag whose tag name is one of: "td", "th", "tr"

[Clear the stack back to a table context](#). (See below.)

[Insert an HTML element](#) for a "body" start tag token with no attributes, then switch the [insertion mode](#) to ["in table body"](#).

Reprocess the current token.

A start tag whose tag name is "table"

[Parse error](#)

If the *stack of open elements* does not [have a table element in table scope](#), ignore the token.

Otherwise:

Pop elements from this stack until a [table](#) element has been popped from the stack.

[Reset the insertion mode appropriately](#).

Reprocess the token.

An end tag whose tag name is "table"

If the *stack of open elements* does not [have a table element in table scope](#), this is a [parse error](#); ignore the token.

Otherwise:

Pop elements from this stack until a [table](#) element has been popped from the stack.

An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html", "tbody", "td", "tfoot", "th", "thead", "tr"

[Parse error](#). Ignore the token.

A start tag whose tag name is one of: "style", "script", "template"

Process the token [using the rules for the "in head" insertion mode](#).

A start tag whose tag name is "input"

If the token does not have an attribute with the name "type", or if it does, but that attribute's value is not an [ASCII case-insensitive](#) match for the string "hidden", then: act as described in the "anything else" entry below.

Otherwise:

[Parse error](#).

[Insert an HTML element](#) for the token.

Pop that [input](#) element off the [stack of open elements](#).

[Acknowledge the token's self-closing flag](#), if it is set.

A start tag whose tag name is "form"

[Parse error](#).

If there is a [template](#) element on the [stack of open elements](#), or if the [form element pointer](#) is not null, ignore the token.

Otherwise:

[Insert an HTML element](#) for the token, and set the [form element pointer](#) to point to the element created.

Pop that [form](#) element off the [stack of open elements](#).

An end-of-file token

Process the token [using the rules for the "in body" insertion mode](#).

Anything else

[Parse error](#). Enable [foster parenting](#), process the token [using the rules for the "in body" insertion mode](#), and then disable [foster parenting](#).

When the steps above require the UA to clear the stack back to a table context, it means that the UA must, while the [current node](#) is not a [table](#), [template](#), or [tr](#) element, pop elements from the [stack of open elements](#).

Note

This is the same list of elements as used in the [has an element in table scope](#) steps.

Note

The [current node](#) being an [tr](#) element after this process is a [fragment case](#).

12.2.6.4.10 The "in table cell" insertion mode

When the user agent is to apply the rules for the ["in table cell"](#) insertion mode, the user agent must handle the token as follows:

A character token that is U+0000 NULL

[Parse error](#). Ignore the token.

Any other character token

Append the character token to the [pending table character tokens](#) list.

Anything else

If any of the tokens in the [pending table character tokens](#) list are character tokens that are not [ASCII whitespace](#), then this is a [parse error](#); reprocess the character tokens in the [pending table character tokens](#) list using the rules given in the "anything else" entry in the ["in table"](#) insertion mode.

Otherwise, [insert the characters](#) given by the [pending table character tokens](#) list.

Switch the [insertion mode](#) to the [original insertion mode](#) and reprocess the token.

12.2.6.4.11 The "in caption" insertion mode

When the user agent is to apply the rules for the ["in caption"](#) insertion mode, the user agent must handle the token as follows:

An end tag whose tag name is "caption"

If the [stack of open elements](#) does not [have a caption element in table scope](#), this is a [parse error](#); ignore the token. ([fragment case](#))

Otherwise:

[Generate implied end tags](#).

Now, if the [current node](#) is not a [caption](#) element, then this is a [parse error](#).

Pop elements from this stack until a [caption](#) element has been popped from the stack.

[Clear the list of active formatting elements up to the last marker](#)

Switch the [insertion mode](#) to "[in table](#)".

A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "td", "tfoot", "th", "thead", "tr"

An end tag whose tag name is "table"

If the [stack of open elements](#) does not [have a caption element in table scope](#), this is a [parse error](#); ignore the token. ([fragment case](#))

Otherwise:

[Generate implied end tags](#).

Now, if the [current node](#) is not a [caption](#) element, then this is a [parse error](#).

Pop elements from this stack until a [caption](#) element has been popped from the stack.

[Clear the list of active formatting elements up to the last marker](#)

Switch the [insertion mode](#) to "[in table](#)".

Reprocess the token.

An end tag whose tag name is one of: "body", "col", "colgroup", "html", "tbody", "td", "tfoot", "th", "thead", "tr"

[Parse error](#). Ignore the token.

Anything else

Process the token [using the rules for the "in body" insertion mode](#).

12.2.6.4.12 The "in column group" insertion mode

When the user agent is to apply the rules for the ["in column group"](#) insertion mode, the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

[Insert the character](#).

A comment token

[Insert a comment](#).

A DOCTYPE token

[Parse error](#). Ignore the token.

A start tag whose tag name is "html"

Process the token [using the rules for the "in body" insertion mode](#).

A start tag whose tag name is "col"

[Insert an HTML element](#) for the token. Immediately pop the [current node](#) off the [stack of open elements](#).

[Acknowledge the token's self-closing flag](#), if it is set.

An end tag whose tag name is "colgroup"

If the [current node](#) is not a [colgroup](#) element, then this is a [parse error](#); ignore the token.

Otherwise, pop the [current node](#) from the [stack of open elements](#). Switch the [insertion mode](#) to "[in table](#)".

An end tag whose tag name is "col"

[Parse error](#). Ignore the token.

A start tag whose tag name is "template"

An end tag whose tag name is "template"

Process the token [using the rules for the "in head" insertion mode](#).

An end-of-file token

Process the token [using the rules for the "in body" insertion mode](#).

Anything else

If the [current node](#) is not a [colgroup](#) element, then this is a [parse error](#); ignore the token.

Otherwise, pop the [current node](#) from the [stack of open elements](#).

Switch the [insertion mode](#) to "[in table](#)".

Reprocess the token.

12.2.6.4.13 The "in table body" insertion mode

When the user agent is to apply the rules for the ["in table body"](#) insertion mode, the user agent must handle the token as follows:

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

A start tag whose tag name is "u"
[Clear the stack back to a table body context](#) (See below.)
[Insert an HTML element for the token, then switch the insertion mode to "in row".](#)
A start tag whose tag name is one of: "th", "td"
[Parse error.](#)
[Clear the stack back to a table body context](#) (See below.)
[Insert an HTML element for a "tr" start tag token with no attributes, then switch the insertion mode to "in row".](#)
Reprocess the current token.
An end tag whose tag name is one of: "tbody", "tfoot", "thead"
If the [stack of open elements](#) does not [have an element in table scope](#) that is an [HTML element](#) with the same tag name as the token, this is a [parse error](#); ignore the token.
Otherwise:
[Clear the stack back to a table body context](#) (See below.)
Pop the [current node](#) from the [stack of open elements](#). Switch the [insertion mode](#) to "in table".
A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "tfoot", "thead"
An end tag whose tag name is "table"
If the [stack of open elements](#) does not [have a tbody, tthead, or tfoot element in table scope](#), this is a [parse error](#); ignore the token.
Otherwise:
[Clear the stack back to a table body context](#) (See below.)
Pop the [current node](#) from the [stack of open elements](#). Switch the [insertion mode](#) to "in table".
Reprocess the token.
An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html", "td", "th", "tr"
[Parse error](#). Ignore the token.
Anything else
Process the token [using the rules for the "in table" insertion mode](#).

When the steps above require the UA to *clear the stack back to a table body context*, it means that the UA must, while the [current node](#) is not a [tbody](#), [tfoot](#), [tthead](#), [pagemap](#), or [html](#) element, pop elements from the [stack of open elements](#).

Note
The [current node](#) being an [tr](#) element after this process is a [fragment case](#).

12.2.6.4.14 The "in row" insertion mode
When the user agent is to apply the rules for the "[in row](#)" [insertion mode](#), the user agent must handle the token as follows:
A start tag whose tag name is one of: "th", "td"
[Clear the stack back to a table row context](#) (See below.)
[Insert an HTML element for the token, then switch the insertion mode to "in cell".](#)
Insert a [marker](#) at the end of the [list of active formatting elements](#).
An end tag whose tag name is "tr"
If the [stack of open elements](#) does not [have a tr element in table scope](#), this is a [parse error](#); ignore the token.
Otherwise:
[Clear the stack back to a table row context](#) (See below.)
Pop the [current node](#) (which will be a [tr](#) element) from the [stack of open elements](#). Switch the [insertion mode](#) to "in table body".
A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "tfoot", "thead", "tr"
An end tag whose tag name is "table"
If the [stack of open elements](#) does not [have a tr element in table scope](#), this is a [parse error](#); ignore the token.
Otherwise:
[Clear the stack back to a table row context](#) (See below.)
Pop the [current node](#) (which will be a [tr](#) element) from the [stack of open elements](#). Switch the [insertion mode](#) to "in table body".
Reprocess the token.
An end tag whose tag name is one of: "tbody", "tfoot", "thead"
If the [stack of open elements](#) does not [have an element in table scope](#) that is an [HTML element](#) with the same tag name as the token, this is a [parse error](#); ignore the token.
If the [stack of open elements](#) does not [have a tr element in table scope](#), ignore the token.
Otherwise:
[Clear the stack back to a table row context](#) (See below.)
Pop the [current node](#) (which will be a [tr](#) element) from the [stack of open elements](#). Switch the [insertion mode](#) to "in table body".
Reprocess the token.
An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html", "td", "th"
[Parse error](#). Ignore the token.
Anything else
Process the token [using the rules for the "in table" insertion mode](#).

When the steps above require the UA to *clear the stack back to a table row context*, it means that the UA must, while the [current node](#) is not a [tr](#), [template](#), or [html](#) element, pop elements from the [stack of open elements](#).

Note
The [current node](#) being an [tr](#) element after this process is a [fragment case](#).

12.2.6.4.15 The "in cell" insertion mode

When the user agent is to apply the rules for the "[in cell](#)" [insertion mode](#), the user agent must handle the token as follows:

An end tag whose tag name is one of: "td", "th"
If the [stack of open elements](#) does not [have an element in table scope](#) that is an [HTML element](#) with the same tag name as that of the token, then this is a [parse error](#); ignore the token.
Otherwise:
[Generate implied end tags](#).
Now, if the [current node](#) is not an [HTML element](#) with the same tag name as the token, then this is a [parse error](#).
Pop elements from the [stack of open elements](#) stack until an [HTML element](#) with the same tag name as the token has been popped from the stack.
[Clear the list of active formatting elements up to the last marker](#).

Switch the [insertion mode](#) to "in rows".
A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "td", "tfoot", "th", "thead", "tr"
If the [stack of open elements](#) does not [have a td or th element in table scope](#), then this is a [parse error](#); ignore the token. ([fragment case](#))
Otherwise, [close the cell](#) (see below) and reprocess the token.

An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html"
[Parse error](#). Ignore the token.
An end tag whose tag name is one of: "table", "tbody", "tfoot", "thead", "tr"
If the [stack of open elements](#) does not [have an element in table scope](#) that is an [HTML element](#) with the same tag name as that of the token, then this is a [parse error](#); ignore the token.
Otherwise, [close the cell](#) (see below) and reprocess the token.

Anything else
Process the token [using the rules for the "in body" insertion mode](#).

Where the steps above say to *close the cell*, they mean to run the following algorithm:

1. [Generate implied end tags](#).
2. If the [current node](#) is not now a [td](#) element or a [th](#) element, then this is a [parse error](#).
3. Pop elements from the [stack of open elements](#) stack until a [td](#) element or a [th](#) element has been popped from the stack.
4. [Clear the list of active formatting elements up to the last marker](#).
5. Switch the [insertion mode](#) to "in row".

Note
The [stack of open elements](#) cannot have both a [td](#) and a [th](#) element [in table scope](#) at the same time, nor can it have neither when the [close the cell](#) algorithm is invoked.

12.2.6.4.16 The "in select" insertion mode

When the user agent is to apply the rules for the "[in select](#)" [insertion mode](#), the user agent must handle the token as follows:

A character token that is U+0000 NULL

Any other character token

[Insert the token's character.](#)

A comment token

[Insert a comment.](#)

A DOCTYPE token

[Parse_error](#). Ignore the token.

A start tag whose tag name is "html"

Process the token [using the rules for the "in body" insertion mode](#).

A start tag whose tag name is "option"

If the [current_node](#) is an [option](#) element, pop that node from the [stack of open elements](#).

[Insert an HTML element](#) for the token.

A start tag whose tag name is "optgroup"

If the [current_node](#) is an [option](#) element, pop that node from the [stack of open elements](#).

If the [current_node](#) is an [optgroup](#) element, pop that node from the [stack of open elements](#).

[Insert an HTML element](#) for the token.

An end tag whose tag name is "optgroup"

First, if the [current_node](#) is an [option](#) element, and the node immediately before it in the [stack of open elements](#) is an [optgroup](#) element, then pop the [current_node](#) from the [stack of open elements](#).

If the [current_node](#) is an [optgroup](#) element, then pop that node from the [stack of open elements](#). Otherwise, this is a [parse_error](#); ignore the token.

An end tag whose tag name is "option"

If the [current_node](#) is an [option](#) element, then pop that node from the [stack of open elements](#). Otherwise, this is a [parse_error](#); ignore the token.

An end tag whose tag name is "select"

If the [stack of open elements](#) does not [have a select element in select scope](#), this is a [parse_error](#); ignore the token. ([fragment case](#))

Otherwise:

Pop elements from the [stack of open elements](#) until a [select](#) element has been popped from the stack.

[Reset the insertion mode appropriately.](#)

A start tag whose tag name is "select"

[Parse_error](#).

If the [stack of open elements](#) does not [have a select element in select scope](#), ignore the token. ([fragment case](#))

Otherwise:

Pop elements from the [stack of open elements](#) until a [select](#) element has been popped from the stack.

[Reset the insertion mode appropriately.](#)

A start tag whose tag name is one of: "input", "keygen", "textarea"

[Parse_error](#).

If the [stack of open elements](#) does not [have a select element in select scope](#), ignore the token. ([fragment case](#))

Otherwise:

Pop elements from the [stack of open elements](#) until a [select](#) element has been popped from the stack.

[Reset the insertion mode appropriately.](#)

Reprocess the token.

A start tag whose tag name is one of: "script", "template"

An end tag whose tag name is "template"

Process the token [using the rules for the "in head" insertion mode](#).

An end-of-file token

Process the token [using the rules for the "in body" insertion mode](#).

Anything else

[Parse_error](#). Ignore the token.

12.2.6.4.17 The "in select in table" insertion mode

When the user agent is to apply the rules for the "[in select in table](#)" insertion mode, the user agent must handle the token as follows:

A start tag whose tag name is one of: "caption", "table", "tbody", "tfoot", "thead", "tr", "td", "th"

[Parse_error](#).

Pop elements from the [stack of open elements](#) until a [select](#) element has been popped from the stack.

[Reset the insertion mode appropriately.](#)

Reprocess the token.

An end tag whose tag name is one of: "caption", "table", "tbody", "tfoot", "thead", "tr", "td", "th"

[Parse_error](#).

If the [stack of open elements](#) does not [have an element in table scope](#) that is an [HTML_element](#) with the same tag name as that of the token, then ignore the token.

Otherwise:

Pop elements from the [stack of open elements](#) until a [select](#) element has been popped from the stack.

[Reset the insertion mode appropriately.](#)

Reprocess the token.

Anything else

Process the token [using the rules for the "in select" insertion mode](#).

12.2.6.4.18 The "in template" insertion mode

When the user agent is to apply the rules for the "[in template](#)" insertion mode, the user agent must handle the token as follows:

A character token

A comment token

A DOCTYPE token

Process the token [using the rules for the "in body" insertion mode](#).

A start tag whose tag name is one of: "base", "basefont", "bgsound", "link", "meta", "noframes", "script", "style", "template", "title"

An end tag whose tag name is "template"

Process the token [using the rules for the "in head" insertion mode](#).

A start tag whose tag name is one of: "caption", "colgroup", "tbody", "tfoot", "thead"

Pop the [current template insertion mode](#) off the [stack of template insertion modes](#).

Push "[in table](#)" onto the [stack of template insertion modes](#) so that it is the new [current template insertion mode](#).

Switch the [insertion mode](#) to "[in table](#)", and reprocess the token.

A start tag whose tag name is "col"

Pop the [current template insertion mode](#) off the [stack of template insertion modes](#).

Push "[in column group](#)" onto the [stack of template insertion modes](#) so that it is the new [current template insertion mode](#).

Switch the [insertion mode](#) to "[in column group](#)", and reprocess the token.

A start tag whose tag name is "tr"

Pop the [current template insertion mode](#) off the [stack of template insertion modes](#).

Push "[in table body](#)" onto the [stack of template insertion modes](#) so that it is the new [current template insertion mode](#).

Switch the [insertion mode](#) to "[in table body](#)", and reprocess the token.

A start tag whose tag name is one of: "td", "th"

Pop the [current template insertion mode](#) off the [stack of template insertion modes](#).

Push "[in row](#)" onto the [stack of template insertion modes](#) so that it is the new [current template insertion mode](#).

Switch the [insertion mode](#) to "[in row](#)", and reprocess the token.

Any other start tag

Pop the [current template insertion mode](#) off the [stack of template insertion modes](#).

Switch the [insertion mode](#) to "[in_body](#)", and reprocess the token.

Any other end tag

[Parse_error](#): Ignore the token.

An end-of-file token

If there is no [template](#) element on the [stack of open elements](#), then [stop_parsing](#). ([fragment case](#))

Otherwise, this is a [parse_error](#).

Pop elements from the [stack of open elements](#) until a [template](#) element has been popped from the stack.

[Clear the list of active formatting elements up to the last marker](#)

Pop the [current template insertion mode](#) off the [stack of template insertion modes](#).

[Reset the insertion mode appropriately](#).

Reprocess the token.

12.2.6.4.1 The "[after_body](#)" insertion mode

When the user agent is to apply the rules for the "[after_body](#)" [insertion mode](#), the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

[Process the token using the rules for the "in_body" insertion mode](#).

A comment token

[Insert a comment](#) as the last child of the first element in the [stack of open elements](#) (the [html](#) element).

A DOCTYPE token

[Parse_error](#): Ignore the token.

A start tag whose tag name is "html"

[Process the token using the rules for the "in_body" insertion mode](#).

An end tag whose tag name is "html"

If the parser was created as part of the [HTML fragment parsing algorithm](#), this is a [parse_error](#); ignore the token. ([fragment case](#))

Otherwise, switch the [insertion mode](#) to "[after_after_body](#)".

An end-of-file token

[Stop_parsing](#).

Anything else

[Parse_error](#): Switch the [insertion mode](#) to "[in_body](#)" and reprocess the token.

12.2.6.4.20 The "[in_frameset](#)" insertion mode

When the user agent is to apply the rules for the "[in_frameset](#)" [insertion mode](#), the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

[Insert the character](#).

A comment token

[Insert a comment](#).

A DOCTYPE token

[Parse_error](#): Ignore the token.

A start tag whose tag name is "html"

[Process the token using the rules for the "in_body" insertion mode](#).

A start tag whose tag name is "frameset"

If the [current_node](#) is the root [html](#) element, then this is a [parse_error](#); ignore the token. ([fragment case](#))

Otherwise, pop the [current_node](#) from the [stack of open elements](#).

If the parser was not created as part of the [HTML fragment parsing algorithm \(fragment case\)](#), and the [current_node](#) is no longer a [frameset](#) element, then switch the [insertion mode](#) to "[after_frameset](#)".

A start tag whose tag name is "frame"

[Insert an HTML element](#) for the token. Immediately pop the [current_node](#) off the [stack of open elements](#).

[Acknowledge the token's self-closing flag](#), if it is set.

A start tag whose tag name is "noframes"

[Process the token using the rules for the "in_head" insertion mode](#).

An end-of-file token

If the [current_node](#) is not the root [html](#) element, then this is a [parse_error](#).

Note
The [current_node](#) can only be the root [html](#) element in the [fragment case](#).

[Stop_parsing](#).

Anything else

[Parse_error](#): Ignore the token.

12.2.6.4.21 The "[after_frameset](#)" insertion mode

When the user agent is to apply the rules for the "[after_frameset](#)" [insertion mode](#), the user agent must handle the token as follows:

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

[Insert the character](#).

A comment token

[Insert a comment](#).

A DOCTYPE token

[Parse_error](#): Ignore the token.

A start tag whose tag name is "html"

[Process the token using the rules for the "in_body" insertion mode](#).

An end tag whose tag name is "html"

[Switch the insertion mode to "after_after_frameset](#).

A start tag whose tag name is "noframes"

[Process the token using the rules for the "in_head" insertion mode](#).

An end-of-file token

[Stop_parsing](#).

Anything else

[Parse_error](#): Ignore the token.

12.2.6.4.22 The "[after_after_body](#)" insertion mode

When the user agent is to apply the rules for the "[after_after_body](#)" [insertion mode](#), the user agent must handle the token as follows:

A comment token

[Insert a comment](#) as the last child of the [Document](#) object.

A DOCTYPE token

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

An end tag whose tag name is "html"

[Process the token using the rules for the "in_body" insertion mode](#).

An end-of-file token

[Stop_parsing](#).

Anything else

[Parse_error](#): Switch the [insertion mode](#) to "[in_body](#)" and reprocess the token.

12.2.6.4.23 The "[after_after_frameset](#)" insertion mode

When the user agent is to apply the rules for the "[after_after_frameset](#)" [insertion mode](#), the user agent must handle the token as follows:

A comment token

[Insert a comment](#) as the last child of the [Document](#) object.

A DOCTYPE token

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

An end tag whose tag name is "html"

[Process the token using the rules for the "in_body" insertion mode](#).

An end-of-file token

[Stop_parsing](#).

Anything else

[Parse_error](#): Switch the [insertion mode](#) to "[in_body](#)" and reprocess the token.

[Insert a comment](#) as the last child of the `Document` object.

A DOCTYPE token

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

A start tag whose tag name is "html"

Process the token [using the rules for the "in body" insertion mode](#).

An end-of-file token

[Stop parsing](#).

A start tag whose tag name is "noframes"

Process the token [using the rules for the "in head" insertion mode](#).

Anything else

[Parse error](#). Ignore the token.

12.2.6.5 The rules for parsing tokens in foreign content

When the user agent is to apply the rules for parsing tokens in foreign content, the user agent must handle the token as follows:

A character token that is U+0000 NULL

[Parse error](#). Insert a U+FFFD REPLACEMENT CHARACTER character.

A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

[Insert the token's character](#).

Any other character token

[Insert the token's character](#).

Set the `frameset-ok` flag to "not ok".

A comment token

[Insert a comment](#).

A DOCTYPE token

[Parse error](#). Ignore the token.

A start tag whose tag name is one of: "b", "big", "blockquote", "body", "br", "center", "code", "dd", "div", "dt", "em", "embed", "h1", "h2", "h3", "h4", "h5", "h6", "head", "hr", "i", "img", "li", "listing", "menu", "meta", "nobr", "ol", "p", "pre", "ruby", "s", "small", "span", "strong", "strike", "sub", "sup", "table", "tt", "u", "ul", "var". A start tag whose tag name is "font", if the token has any attributes named "color", "face", or "size".

[Parse error](#).

If the parser was created as part of the [HTML fragment parsing algorithm](#), then act as described in the "any other start tag" entry below. ([fragment case](#))

Otherwise:

Pop an element from the [stack of open elements](#), and then keep popping more elements from the [stack of open elements](#) until the `current node` is a [MathML text integration point](#), an [HTML integration point](#), or an element in the [HTML namespace](#).

Then, reprocess the token.

Any other start tag

If the [adjusted current node](#) is an element in the [MathML namespace](#), [adjust MathML attributes](#) for the token. (This fixes the case of MathML attributes that are not all lowercase.)

If the [adjusted current node](#) is an element in the [SVG namespace](#), and the token's tag name is one of the ones in the first column of the following table, change the tag name to the name given in the corresponding cell in the second column. (This fixes the case of SVG elements that are not all lowercase.)

Tag name	Element name
<code>altglyph</code>	<code>altGlyph</code>
<code>altglyphdef</code>	<code>altGlyphDef</code>
<code>altglyphitem</code>	<code>altGlyphItem</code>
<code>animatecolor</code>	<code>animateColor</code>
<code>animatemotion</code>	<code>animateMotion</code>
<code>animatetransform</code>	<code>animateTransform</code>
<code>clippath</code>	<code>clipPath</code>
<code>fblen2d</code>	<code>fBBlend</code>
<code>fecolormatrix</code>	<code>fECColorMatrix</code>
<code>fecomponenttransfer</code>	<code>fECComponentTransfer</code>
<code>fecomposite</code>	<code>fECComposite</code>
<code>fconvolvematrix</code>	<code>fECConvolveMatrix</code>
<code>fediffuselighting</code>	<code>fEDiffuseLighting</code>
<code>fedisplacementmap</code>	<code>fEDisplacementMap</code>
<code>feditistantlight</code>	<code>fEDistantLight</code>
<code>fedropshadow</code>	<code>fEDropShadow</code>
<code>fedlood</code>	<code>fELlood</code>
<code>fefunc</code>	<code>fEFuncA</code>
<code>fefuncb</code>	<code>fEFuncB</code>
<code>fefuncg</code>	<code>fEFuncG</code>
<code>fefuncr</code>	<code>fEFuncR</code>
<code>fegaussianblur</code>	<code>fEGaussianBlur</code>
<code>felimage</code>	<code>fELImage</code>
<code>femerge</code>	<code>fEMerge</code>
<code>femergenode</code>	<code>fEMergeNode</code>
<code>femorphology</code>	<code>fEMorphology</code>
<code>feoffset</code>	<code>fEOffset</code>
<code>fepointlight</code>	<code>fEPointLight</code>
<code>fespecularlighting</code>	<code>fESpecularLighting</code>
<code>fespotlight</code>	<code>fEPotLight</code>
<code>fetile</code>	<code>fETile</code>
<code>fterbulence</code>	<code>fETurbulence</code>
<code>foreignobject</code>	<code>fOREignObject</code>
<code>glyphref</code>	<code>glyphRef</code>
<code>lineargradient</code>	<code>linearGradient</code>
<code>radialgradient</code>	<code>radialGradient</code>
<code>textpath</code>	<code>textPath</code>

If the [adjusted current node](#) is an element in the [SVG namespace](#), [adjust SVG attributes](#) for the token. (This fixes the case of SVG attributes that are not all lowercase.)

[Adjust foreign attributes](#) for the token. (This fixes the use of namespaced attributes, in particular XLink in SVG.)

[Insert a foreign element](#) for the token, in the same namespace as the [adjusted current node](#).

If the token has its `self-closing` flag set, then run the appropriate steps from the following list:

If the token's tag name is "script", and the new `current node` is in the [SVG namespace](#)

[Acknowledge the token's self-closing flag](#), and then act as described in the steps for a "script" end tag below.

Otherwise

Pop the `current node` off the [stack of open elements](#) and [acknowledge the token's self-closing flag](#).

An end tag whose tag name is "script", if the `current node` is an [SVG script](#) element

Pop the `current node` off the [stack of open elements](#).

Let the `old insertion point` have the same value as the `current insertion point`. Let the `insertion point` be just before the `next input character`.

Increment the parser's `script nesting level` by one. Set the `parser reuse flag` to true.

[Process the SVG script element](#) according to the SVG rules, if the user agent supports SVG. ([SVG](#))

Note

Even if this causes `new characters to be inserted into the tokenizer`, the parser will not be executed reentrantly, since the `parser pause flag` is true.

Decrement the parser's `script nesting level` by one. If the parser's `script nesting level` is zero, then set the `parser reuse flag` to false.

Let the `insertion point` have the value of the `old insertion point`. (In other words, restore the `insertion point` to its previous value. This value might be the "undefined" value.)

Any other end tag

Run these steps:

1. Initialize `node` to be the `current node` (the bottommost node of the stack).
2. If `node`'s tag name, [converted to ASCII lowercase](#), is not the same as the tag name of the token, then this is a [parse error](#).
3. *Loop*: If `node` is the topmost element in the [stack of open elements](#), then return. ([fragment case](#))
4. If `node`'s tag name, [converted to ASCII lowercase](#), is the same as the tag name of the token, pop elements from the [stack of open elements](#) until `node` has been popped from the stack, and then return.
5. Set `node` to the previous entry in the [stack of open elements](#).
6. If `node` is not an element in the [HTML namespace](#), return to the step labeled *loop*.
7. Otherwise, process the token according to the rules given in the section corresponding to the [current insertion mode](#) in HTML content.

12.2.7 The end

1. Set the [current_document.readiness](#) to "interactive" and the [insertion_point](#) to undefined.

2. Pop all the nodes off the stack of open elements.

3. If the [list of scripts that will execute when the document has finished parsing](#) is not empty, run these substeps:1. Spin the event loop until the first [script](#) in the [list of scripts that will execute when the document has finished parsing](#) has its "ready to be parser-executed" flag set and the parser's [Document](#) has no style sheet that is blocking scripts.2. Execute the first [script](#) in the [list of scripts that will execute when the document has finished parsing](#).3. Remove the first [script](#) element from the [list of scripts that will execute when the document has finished parsing](#) (i.e. shift out the first entry in the list).4. If the [list of scripts that will execute when the document has finished parsing](#) is still not empty, repeat these substeps again from substep 1.4. [Queue a task](#) to run the following substeps:1. [Fire an event](#) named [DOMContentLoaded](#) at the [document](#) object, with its [bubbles](#) attribute initialized to true.2. Enable the [client message queue](#) of the [ServiceWorkerContainer](#) object whose associated [service_worker_client](#) is the [Document](#) object's [relevant settings object](#).5. [Spin the event loop](#) until the [set of scripts that will execute as soon as possible](#) and the [list of scripts that will execute in order as soon as possible](#) are empty.6. [Spin the event loop](#) until there is nothing that [delays the load event](#) in the [document](#).7. [Queue a task](#) to run the following substeps:1. Set the [current_document.readiness](#) to "complete".2. [Load event](#): If the [document](#) object's [browsing_context](#) is non-null, then [fire an event](#) named [load](#) at the [document](#) object's [relevant global object](#), with [legacy target override flag](#) set.8. If the [document](#) object's [browsing_context](#) is non-null, then [queue a task](#) to run these steps:1. If the [document](#)'s [page_showing](#) flag is true, then return (i.e. don't fire the event below).2. Set the [document](#)'s [page_showing](#) flag to true.3. [Fire an event](#) named [pageShow](#) at the [document](#) object's [relevant global object](#), using [PageTransitionEvent](#), with the [persisted](#) attribute initialized to false, and [legacy target override flag](#) set.9. If the [document](#) has any pending application cache download process tasks, then [queue](#) each such [task](#) in the order they were added to the list of [pending application cache download process tasks](#), and then empty the list of [pending application cache download process tasks](#). The [task source](#) for these [tasks](#) is the [networking task source](#).10. If the [document](#)'s [print when loaded](#) flag is set, then run the [printing steps](#).11. The [document](#) is now ready for post-load tasks.12. [Queue a task](#) to mark the [document](#) as completely loaded.When the user agent is to *abort a parser*, it must run the following steps:1. Throw away any pending content in the [input stream](#), and discard any future content that would have been added to it.2. Set the [current_document.readiness](#) to "interactive".

3. Pop all the nodes off the stack of open elements.

4. Set the [current_document.readiness](#) to "complete".Except where otherwise specified, the [task source](#) for the [tasks](#) mentioned in this section is the [DOM manipulation task source](#).

12.2.8 Coercing an HTML DOM into an infoset

When an application uses an [HTML_parser](#) in conjunction with an XML pipeline, it is possible that the constructed DOM is not compatible with the XML tool chain in certain subtle ways. For example, an XML toolchain might not be able to represent attributes with the name `xmnia`, since they conflict with the Namespaces in XML syntax. There is also some data that the [HTML_parser](#) generates that isn't included in the DOM itself. This section specifies some rules for handling these issues.

If the XML API being used doesn't support DOCTYPES, the tool may drop DOCTYPES altogether.

If the XML API doesn't support attributes in no namespace that are named "`xmnia`", attributes whose names start with "`xmnia`", or attributes in the [XMLNS namespace](#), then the tool may drop such attributes.

The tool may annotate the output with any namespace declarations required for proper operation.

If the XML API being used restricts the allowable characters in the local names of elements and attributes, then the tool may map all element and attribute local names that the API wouldn't support to a set of names that *are* allowed, by replacing any character that isn't supported with the uppercase letter U and the six digits of the character's code point when expressed in hexadecimal, using digits 0-9 and capital letters A-F as the symbols, in increasing numeric order.

Example

For example, the element name `for:bar`, which can be output by the [HTML_parser](#), though it is neither a legal HTML element name nor a well-formed XML element name, would be converted into `for000003bar`, which is a well-formed XML element name (though it's still not legal in HTML by any means).

Example

As another example, consider the attribute `xlink:href`. Used on a MathML element, it becomes, after being [adjusted](#), an attribute with a prefix "`xlink`" and a local name "`href`". However, used on an HTML element, it becomes an attribute with no prefix and the local name "`xlink:href`", which is not a valid NCName, and thus might not be accepted by an XML API. It could thus get converted, becoming "`xlink00003ahref`".

Note

The resulting names from this conversion conveniently can't clash with any attribute generated by the [HTML_parser](#), since those are all either lowercase or those listed in the [adjust foreign attributes](#) algorithm's table.

If the XML API restricts comments from having two consecutive U+002D HYPHEN-MINUS characters (-), the tool may insert a single U+0020 SPACE character between any such offending characters.

If the XML API restricts comments from ending in a U+002D HYPHEN-MINUS character (-), the tool may insert a single U+0020 SPACE character at the end of such comments.

If the XML API restricts allowed characters in character data, attribute values, or comments, the tool may replace any U+000C FORM FEED (FF) character with a U+0020 SPACE character, and any other literal non-XML character with a U+FFFF REPLACEMENT CHARACTER.

If the tool has no way to convey out-of-band information, then the tool may drop the following information:

- Whether the document is set to [no-quirks mode](#), [limited-quirks mode](#), or [quirks mode](#)
- The association between form controls and forms that aren't their nearest [form](#) element ancestor (use of the [form element pointer](#) in the parser)
- The [template contents](#) of any [template](#) elements.

Note

The mutations allowed by this section apply *after* the [HTML_parser](#)'s rules have been applied. For example, a `<:a>` start tag will be closed by a `</:a>` end tag, and never by a `</a00003AU00003A>` end tag, even if the user agent is using the rules above to then generate an actual element in the DOM with the name `a00003AU00003A` for that start tag.

12.2.9 An introduction to error handling and strange cases in the parser

This section is non-normative.

This section examines some erroneous markup and discusses how the [HTML_parser](#) handles these cases.

12.2.9.1 Ministed tags: <i><h></></i></h>

This section is non-normative.

The most-often discussed example of erroneous markup is as follows:

`<p>1
2<i>3</i><h>4</h><h>5</p>`

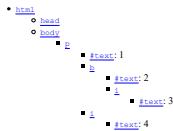

The parsing of this markup is straightforward up to the "3". At this point, the DOM looks like this:

Here, the [stack of open elements](#) has five elements on it: `html`, `body`, `b`, `i`, and `h`. The [list of active formatting elements](#) just has two: `b` and `i`. The [insertion mode](#) is "[in body](#)".

Upon receiving the end tag token with the tag name "`b`", the "[adoption agency algorithm](#)" is invoked. This is a simple case, in that the [formatting element](#) is the `i` element, and there is no [furthest block](#). Thus, the [stack of open elements](#) ends up with just three elements: `html`, `body`, and `i`, while the [list of active formatting elements](#) has just one: `i`. The DOM tree is modified at this point.

The next token is a character ("4"), triggers the [reconstruction of the active formatting elements](#), in this case just the `i` element. A new `i` element is thus created for the "`4`" [text](#) node. After the end tag token for the "`i`" is also received, and the "`5`" [text](#) node is inserted, the DOM looks as follows:

12.2.9.2 Ministed tags: <p></p>

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

This section is non-normative.

A case similar to the previous one is the following:

```
<hp><cp><cp>2</cp><cp>3</cp>
```

Up to the "2" the parsing here is straightforward:

The interesting part is when the end tag token with the tag name "b" is parsed.

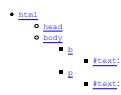

Before that token is seen, the stack of open elements has four elements on it: html, body, b, and b. The list of active formatting elements just has the one: b. The insertion mode is "in body".

Upon receiving the end tag token with the tag name "b", the "adoption agency algorithm" is invoked, as in the previous example. However, in this case, there is a *farthest block*, namely the b element. Thus, this time the adoption agency algorithm isn't skipped over.

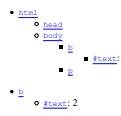

The common ancestor is the b element. A conceptual "bookmark" marks the position of the b in the list of active formatting elements, but since that list has only one element in it, the bookmark won't have much effect.

As the algorithm progresses, node ends up set to the formatting element (b), and last node ends up set to the *farthest block* (b).

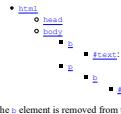

The last node gets appended (moved) to the common ancestor, so that the DOM looks like:

A new b element is created, and the children of the b element are moved to it:

Finally, the new b element is appended to the u element, so that the DOM looks like:

The b element is removed from the list of active formatting elements and the stack of open elements, so that when the "3" is parsed, it is appended to the b element:

12.2.9.3 Unexpected markup in tables

This section is non-normative.

Error handling in tables is, for historical reasons, especially strange. For example, consider the following markup:

```
<table><tr><td>aaa</td></tr><tr>bbb</tr></table><cc>
```

The highlighted u element start tag is not allowed directly inside a table like that, and the parser handles this case by placing the element *before* the table. (This is called foster parenting.) This can be seen by examining the DOM tree as it stands just after the table element's start tag has been seen:

...and then immediately after the b element start tag has been seen:

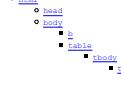

At this point, the stack of open elements has on it the elements html, body, table, and b (in that order, despite the resulting DOM tree); the list of active formatting elements just has the b element in it; and the insertion mode is "in table".

The tr start tag causes the b element to be popped off the stack and a tbody start tag to be implied; the tbody and tr elements are then handled in a rather straight-forward manner, taking the parser through the "in table body" and "in row" insertion modes, after which the DOM looks as follows:

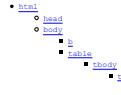

Here, the stack of open elements has on it the elements html, body, table, tbody, and tr; the list of active formatting elements still has the b element in it; and the insertion mode is "in row".

The tr element start tag, after putting a td element on the tree, puts a marker on the list of active formatting elements (it also switches to the "in cell" insertion mode).

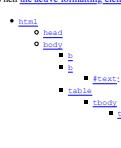

The marker means that when the "aaa" character tokens are seen, no b element is created to hold the resulting Text node:

The end tags are handled in a straight-forward manner; after handling them, the stack of open elements has on it the elements html, body, table, and tbody; the list of active formatting elements still has the b element in it (the marker having been removed by the "td" end tag token); and the insertion mode is "in table body".

Thus it is that the "bbb" character tokens are found. These trigger the "in table text" insertion mode to be used (with the original insertion mode set to "in table body"). The character tokens are collected, and when the next token (the tbody element end tag) is seen, they are processed as a group. Since they are not all spaces, they are handled as per the "anything else" rules in the "in table" insertion mode, which defer to the "in body" insertion mode but with foster parenting.

When the active formatting elements are reconstructed, a b element is created and foster parented, and then the "bbb" Text node is appended to it:

The stack of open elements has on it the elements html, body, table, tbody, and the new b (again, note that this doesn't match the resulting tree!); the list of active formatting elements has the new b element in it; and the insertion mode is still "in table body".

Had the character tokens been only ASCII whitespace instead of "bbb", then that ASCII whitespace would just be appended to the tbody element.

Finally, the tbody is closed by a "tbody" end tag. This pops all the nodes from the stack of open elements up to and including the tbody element, but it doesn't affect the list of active formatting elements, so the "ccc" character tokens after the table result in yet another b element being created, this time after the table:

`iframe`
`embed`
`noframes`
Switch the tokenizer to the [RAWTEXT state](#).

`script`
Switch the tokenizer to the [script data state](#).

`noscript`
If the [scripting flag](#) is enabled, switch the tokenizer to the [RAWTEXT state](#). Otherwise, leave the tokenizer in the [data state](#).

`plaintext`
Switch the tokenizer to the [PLAINTEXT state](#).

Any other element
Leave the tokenizer in the [data state](#).

Note
For performance reasons, an implementation that does not report errors and that uses the actual state machine described in this specification directly could use the [PLAINTEXT state](#) instead of the [RAWTEXT state](#) and script data states where those are mentioned in the list above. Except for rules regarding parse errors, they are equivalent, since there is no [inappropriate end tag token](#) in the fragment case, yet they involve far fewer state transitions.

5. Let `root` be a new [html](#) element with no attributes.
6. Append the element `root` to the [document](#) node created above.
7. Set up the parser's [stack of open elements](#) so that it contains just the single element `root`.
8. If the [context](#) element is a [template](#) element, push "in template" onto the [stack of template insertion modes](#) so that it is the new [current template insertion mode](#).
9. Create a start tag token whose name is the local name of [context](#) and whose attributes are the attributes of [context](#).

Let this start tag token be the start tag tokens of the [context](#) node, e.g. for the purposes of determining if it is an [HTML integration point](#).

10. [Reset the parser's insertion mode appropriately](#).

Note
The parser will reference the [context](#) element as part of that algorithm.

11. Set the parser's [current element pointer](#) to the nearest node to the [context](#) element that is a [parsing element](#) (going straight up the ancestor chain, and including the element itself, if it is a [parsing element](#), if any. (If there is no such [parsing element](#), the [current element pointer](#) keeps its initial value, null.)

12. Place the [input](#) into the [input stream](#) for the [HTML parser](#) just created. The encoding [confidence](#) is [irrelevant](#).

13. Start the parser and let it run until it has consumed all the characters just inserted into the input stream.

14. Return the child nodes of `root`, in [tree order](#).

12.5 Named character references

This table lists the character reference names that are supported by HTML, and the code points to which they refer. It is referenced by the previous sections.

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION

EXPAND

This data is also available [as a JSON file](#).

The glyphs displayed above are non-normative. Refer to Unicode for formal definitions of the characters listed above.

Note

The character reference names originate from *XML Entity Definitions for Characters*, though only the above is considered normative. [\[XML ENTITY\]](#)

Note

This section only describes the rules for XML resources. Rules for `text/html` resources are discussed in the section above entitled ["The HTML syntax"](#).

13.1 Writing documents in the XML syntax

Note

The XML syntax for HTML was formerly referred to as "XHTML", but this specification does not use that term (among other reasons, because no such term is used for the HTML syntaxes of MathML and SVG).

The syntax for XML is defined in *XML and Namespaces in XML*. [\[XML\] \[XMLNS\]](#)

This specification does not define any syntax-level requirements beyond those defined for XML proper.

XML documents may contain a `DOCTYPE` if desired, but this is not required to conform to this specification. This specification does not define a public or system identifier, nor provide a formal DTD.

Note

According to *XML*, XML processors are not guaranteed to process the external DTD subset referenced in the DOCTYPE. This means, for example, that using `entity references` for characters in XML documents is unsafe if they are defined in an external file (except for `<lt;`, `<gt;`, `<amp;`, `<quot;` and `<apos;`).

13.2 Parsing XML documents

This section describes the relationship between XML and the DOM, with a particular emphasis on how this interacts with HTML.

An `XML parser`, for the purposes of this specification, is a construct that follows the rules given in *XML* to map a string of bytes or characters into a `Document` object.

Note

At the time of writing, no such rules actually exist.

An `XML parser` is either associated with a `Document` object when it is created, or creates one implicitly.

This `Document` must then be populated with DOM nodes that represent the tree structure of the input passed to the parser, as defined by *XML*, *Namespaces in XML*, and *DOM*. When creating DOM nodes representing elements, the `create an element for a token` algorithm or some equivalent that operates on appropriate XML datastructures must be used, to ensure the proper `element interfaces` are created and that `custom elements` are set up correctly.

DOM mutation events must fire for the operations that the `Document` performs on the `Document`'s tree, but the user agent must act as if elements and attributes were individually appended and set respectively so as to trigger rules in this specification regarding what happens when an element is inserted into a document or has its attributes set, and *DOM*'s requirements regarding `mutation observers` mean that mutation observers are fired (unlike mutation events). [\[XML\] \[XMLNS\] \[DOM\] \[UIEVENTS\]](#)

Between the time an element's start tag is parsed and the time either the element's end tag is parsed or the parser detects a well-formedness error, the user agent must act as if the element was in a `stack of open elements`.

Note

This is used, e.g. by the `object` element to avoid instantiating plugins before the `script` element children have been parsed.

This specification provides the following additional information that user agents should use when retrieving an external entity: the public identifiers given in the following list all correspond to [the URL given by this link](#). (This URL is a DTD containing the `entity declarations` for the names listed in the [named character references](#) section.) [\[XML\]](#)

- [//W3C//DTD XHTML 1.0 Transitional//EN](#)
- [//W3C//DTD XHTML 1.0 Strict//EN](#)
- [//W3C//DTD XHTML 1.0 Frameset//EN](#)
- [//W3C//DTD XHTML Basic 1.0//EN](#)
- [//W3C//DTD XHTML 1.1 plus MathML 2.0//EN](#)
- [//W3C//DTD XHTML 1.1 plus MathML 2.0 plus SVG 1.1//EN](#)
- [//W3C//DTD MathML 2.0//EN](#)
- [//W3C//DTD XHTML Mobile 1.0//EN](#)

Furthermore, user agents should attempt to retrieve the above external entity's content when one of the above public identifiers is used, and should not attempt to retrieve any other external entity's content.

Note

This is not strictly a *violation of XML*, but it does contradict the spirit of *XML*'s requirements. This is motivated by a desire for user agents to all handle entities in an interoperable fashion without requiring any network access for handling external subsets. [\[XML\]](#)

XML parsers can be invoked with `XML scripting support enabled` or `XML scripting support disabled`. Except where otherwise specified, XML parsers are invoked with `XML scripting support enabled`.

When an `XML parser` with `XML scripting support enabled` creates a `script` element, it must have its `parser_document` set and its `"non-blocking"` flag must be unset. If the parser was created as part of the *XML fragment parsing algorithm*, then the element must be marked as `"already_starting"` also. When the element's end tag is subsequently parsed, the user agent must perform a `microtask` checkpoint, and then `parse` the `script` element. If this causes there to be a `pending parsing-blocking script`, then the user agent must run the following steps:

1. Block this instance of the `XML parser`, such that the `event loop` will not run `tasks` that invoke it.
2. *Span the event loop* until the parser's `document` has no style sheet that is blocking scripts and the `pending parsing-blocking script`'s `"ready to be parser-executed"` flag is set.
3. Unblock this instance of the `XML parser`, such that `tasks` that invoke it can again be run.
4. *Execute the pending parsing-blocking script*.
5. There is no longer a `pending parsing-blocking script`.

Note

Since the `document.write()` API is not available for `XML documents`, much of the complexity in the *HTML parser* is not needed in the *XML parser*.

Note

When the `XML parser` has `XML scripting support disabled`, none of this happens.

When an `XML parser` would append a node to a `template` element, it must instead append it to the `template` element's `template_contents` (a `DocumentFragment` node).

Note

This is a *willful violation of XML*; unfortunately, XML is not formally extensible in the manner that is needed for `template` processing. [\[XML\]](#)

When an `XML parser` creates a `node` object, its `node_document` must be set to the `node_document` of the node into which the newly created node is to be inserted.

Certain algorithms in this specification *spoon-feed the parser* characters one string at a time. In such cases, the `XML parser` must act as it would have if faced with a single string consisting of the concatenation of all those characters.

When an `XML parser` reaches the end of its input, it must `stop parsing`, following the same rules as the `HTML parser`. An `XML parser` can also be `aborted`, which must again be done in the same way as for an `HTML parser`.

For the purposes of conformance checkers, if a resource is determined to be in the `XML syntax`, then it is an `XML document`.

13.3 Serializing XML fragments

The *XML fragment serialization algorithm* for a `Document` or `Element` node either returns a fragment of XML that represents that node or throws an exception.

For `Document`s, the algorithm must return a string in the form of a `document entity`, if none of the error cases below apply.

For `Element`s, the algorithm must return a string in the form of an `internal general parsed entity`, if none of the error cases below apply.

In both cases, the string returned must be XML namespace-well-formed and must be an isomorphic serialization of all of that node's `relevant child nodes`, in `tree order`. User agents may adjust prefixes and namespace declarations in the serialization (and indeed might be forced to do so in some cases to obtain namespace-well-formed XML). User agents may use a combination of regular text and character references to represent `text` nodes in the DOM.

A node's `relevant child nodes` are those that apply given the following rules:

For `template` elements

The `relevant child nodes` are the child nodes of the `template` element's `template_contents`, if any.

For all other nodes

The `relevant child nodes` are the child nodes of node itself, if any.

For `Element`s, if any of the elements in the serialization are in no namespace, the default namespace in scope for those elements must be explicitly declared as the empty string. (This doesn't apply in the `Document` case.) [\[XML\] \[XMLNS\]](#)

For the purposes of this section, an internal general parsed entity is considered XML namespace-well-formed if a document consisting of an element with no namespace declarations whose contents are the internal general parsed entity would itself be XML namespace-well-formed.

If any of the following error cases are found in the DOM subtree being serialized, then the algorithm must throw an `"InvalidStateError"` `DOMException` instead of returning a string:

- A `Document` node with no child elements.

- A `DocumentType` node that has an external subset system identifier that contains characters that are not matched by the XML `PublChar` production. [\[XML\]](#)

- A node with a local name containing a U+0022 QUOTATION MARK ("") or a U+0027 APOSTROPHE ('') or that contains characters that are not matched by the XML `Char` production. [\[XML\]](#)

- A node with a local name that does not match the XML `Name` production. [\[XML\]](#)

- An `Attr` node with no namespace prefix, where the local name is the lowercase string "`xmlns`". [\[XML\]](#)

- An `Element` node with two or more namespace nodes, with the same local name and namespace URI for each.

- A `Text` node whose data contains two adjacent U+002D HYPHEN-MINUS characters (-) or ends with such a character.

- A `ProcessingInstruction` node whose target name is an ASCII case-insensitive match for the string "`xml`".

- A `ProcessingInstruction` node whose data contains the string "`>`".

These are the only ways to make a DOM unserializable. The DOM enforces all the other XML constraints; for example, trying to append two elements to a `Document` node will throw a `"HierarchyRequestError"` `DOMException`.

13.4 Parsing XML fragments

The *XML fragment parsing algorithm* either returns a `Document`, or throws a `"SyntaxError"` `DOMException`. Given a string `input` and a context element `context`, the algorithm is as follows:

1. Create a new `XML parser`.

2. Feed the `parser` just created the string corresponding to the start tag of the `context` element, declaring all the namespace prefixes that are in scope on that element in the DOM, as well as declaring the default namespace (if any) that is in scope on that element in the DOM.

A namespace prefix is in scope if the DOM `lookupNamespaceURI()` method on the element would return a non-null value for that prefix.

The default namespace is the namespace for which the DOM `isDefaultNamespace()` method on the element would return true.

THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Note
[No DOCTYPE] is passed to the parser, and therefore no external subset is referenced, and therefore no entities will be recognized.

3. **Feed the parser** just created the string **input**.
4. **Feed the parser** just created the string corresponding to the end tag of the **context** element.
5. If there is an XML well-formedness or XML namespace well-formedness error, then throw a **"syntaxError"** **DOMEexception**.
6. If the **document element** of the resulting **Document** has any sibling nodes, then throw a **"syntaxError"** **DOMEexception**.
7. Return the child nodes of the **document element** of the resulting **Document**, in **tree order**.

14 Rendering

User agents are not required to present HTML documents in any particular way. However, this section provides a set of suggestions for rendering HTML documents that, if followed, are likely to lead to a user experience that closely resembles the experience intended by the documents' authors. So as to avoid confusion regarding the normativity of this section, "must" has not been used. Instead, the term "expected" is used to indicate behavior that will lead to this experience. For the purposes of conformance for user agents designated as **supporting the suggested default rendering**, the term "expected" in this section has the same conformance implications as "must".

14.1 Introduction

In general, user agents are expected to support CSS, and many of the suggestions in this section are expressed in CSS terms. User agents that use other presentation mechanisms can derive their expected behavior by translating from the CSS rules given in this section.

In the absence of style-layer rules to the contrary (e.g. author style sheets), user agents are expected to render an element so that it conveys to the user the meaning that the element **represents**, as described by this specification.

The suggestions in this section generally assume a visual output medium with a resolution of 96dpi or greater, but HTML is intended to apply to multiple media (it is a *media-independent* language). User agent implementers are encouraged to adapt the suggestions in this section to their target media.

An element is *being rendered* if it has any associated CSS layout boxes, SVG layout boxes, or some equivalent in other styling languages.

Note
[Not being off-screen does not mean the element is not being rendered.] The presence of the **hidden** attribute normally means the element is not *being rendered*, though this might be overridden by the style sheets.

User agents that do not honor author-level CSS style sheets are nonetheless expected to act as if they applied the CSS rules given in these sections in a manner consistent with this specification and the relevant CSS and Unicode specifications: [\[CSS\]](#) [\[UNICODE\]](#) [\[BIDI\]](#)

Note
This is especially important for issues relating to the **'Display'**, **'unicode-bidi'**, and **'direction'** properties.

14.2 The CSS user agent style sheet and presentational hints

The CSS rules given in these subsections are, except where otherwise specified, expected to be used as part of the user-agent level style sheet defaults for all documents that contain [HTML elements](#).

Some rules are intended for the author-level zero-specificity presentational hints part of the CSS cascade; these are explicitly called out as *presentational hints*.

When the text below says that an attribute *maps to the pixel length property* (or properties) *properties*, it means that if *element* has an attribute *attribute set*, and parsing that attribute's value using the [rules for parsing non-negative integers](#) doesn't generate an error, then the user agent is expected to use the parsed value as a pixel length for a *presentational hint* for *properties*.

When the text below says that an attribute *maps to the dimension property* (or properties) *properties*, it means that if *element* has an attribute *attribute set*, and parsing that attribute's value using the [rules for parsing dimension values](#) doesn't generate an error, then the user agent is expected to use the parsed dimension as the value for a *presentational hint* for *properties*, with the value given as a pixel length if the dimension was a length, and with the value given as a percentage if the dimension was a percentage.

When the text below says that an attribute *maps to the dimension property (ignoring zero)* (or properties) *properties*, it means that if *element* has an attribute *attribute set*, and parsing that attribute's value using the [rules for parsing nonzero dimension values](#) doesn't generate an error, then the user agent is expected to use the parsed dimension as the value for a *presentational hint* for *properties*, with the value given as a pixel length if the dimension was a length, and with the value given as a percentage if the dimension was a percentage.

When a user agent is expected to align *descendants* of a node, the user agent is expected to align only those descendants that have both their **margin-inline-start** and **margin-inline-end** properties computing to a value other than **'auto'**, that are over-constrained and that have one of those margins with a **used value** forced to a greater value, and that do not themselves have an applicable **align** attribute. When multiple elements are to **align** a particular descendant, the most deeply nested such element is expected to override the others. Aligned elements are expected to be aligned by having the **used values** of their margins on the **line-left** and **line-right** sides be set accordingly. [\[CSSLOGICAL\]](#) [\[CSSWML\]](#)

html, body { display: block; }
```

For each property in the table below, given a **body** element, the first attribute that exists *maps to the pixel length property* on the **body** element. If none of the attributes for a property are found, or if the value of the attribute that was found cannot be parsed successfully, then a default value of 8px is expected to be used for that property instead.

Property	Source
margin-top	The body element's marginheight attribute
	The body element's topmargin attribute
	The body element's container frame element's marginheight attribute
	The body element's topmargin attribute
margin-right	The body element's rightmargin attribute
	The body element's container frame element's marginwidth attribute
	The body element's marginright attribute
margin-bottom	The body element's bottommargin attribute
	The body element's container frame element's marginheight attribute
	The body element's bottommargin attribute
margin-left	The body element's leftmargin attribute
	The body element's container frame element's marginwidth attribute

If the **body** element's **node document's browsing context** is a *child browsing context*, and the **container** of that **browsing context** is a **frame** or **iframe** element, then the **container frame** element of the **body** element is that **frame** or **iframe** element. Otherwise, there is no **container frame element**.

⚠Warning!
The above requirements imply that a page can change the margins of another page (including one from another **origin**) using, for example, an **iframe**. This is potentially a security risk, as it might in some cases allow an attack to contrive a situation in which a page is rendered not as the author intended, possibly for the purposes of phishing or otherwise misleading the user.

If a **document's browsing context** is a *child browsing context*, then it is expected to be positioned and sized to fit inside the **content box** of the **container** of that **browsing context**. If the **container** is not *being rendered*, the **browsing context** is expected to have a **viewport** with zero width and zero height.

If a **parent's browsing context** is a *child browsing context*, the **container** of that **browsing context** is a **frame** or **iframe** element, that element has a **scrolling** attribute, and that attribute's value is an **ASCII case-insensitive** match for the string "**off**", "**noscroll**", or "**no**", then the user agent is expected to prevent any scrollbars from being shown for the **viewport** of the **parent's browsing context**, regardless of the **viewport** property that applies to that **viewport**.

When a **body** element has a **background** attribute set to a non-empty value, the new value is expected to be **parsed** relative to the element's **node document**, and if this is successful, the user agent is expected to treat the attribute as a *presentational hint* setting the element's **background-image** property to the **resulting URL string**.

When a **body** element has a **background** attribute set, the new value is expected to be parsed using the [rules for parsing a legacy color value](#), and if that does not return an error, the user agent is expected to treat the attribute as a *presentational hint* setting the element's **background-color** property to the resulting color.

When a **body** element has a **text** attribute, its value is expected to be parsed using the [rules for parsing a legacy color value](#), and if that does not return an error, the user agent is expected to treat the attribute as a *presentational hint* setting the element's **color** property to the resulting color.

When a **body** element has a **link** attribute, its value is expected to be parsed using the [rules for parsing a legacy color value](#), and if that does not return an error, the user agent is expected to treat the attribute as a *presentational hint* setting the **color** property of any element in the **document** matching the **:link pseudo-class** to the resulting color.

When a **body** element has a **link** attribute, its value is expected to be parsed using the [rules for parsing a legacy color value](#), and if that does not return an error, the user agent is expected to treat the attribute as a *presentational hint* setting the **color** property of any element in the **document** matching the **:visited pseudo-class** to the resulting color.

When a **body** element has an **a link** attribute, its value is expected to be parsed using the [rules for parsing a legacy color value](#), and if that does not return an error, the user agent is expected to treat the attribute as a *presentational hint* setting the **color** property of any element in the **document** matching the **:active pseudo-class** and either the **:link pseudo-class** or the **:visited pseudo-class** to the resulting color.

14.3.3 Flow content

```
CSSNamespace url("http://www.w3.org/1999/xhtml");
address, blockquote, center, dialog, div, figure, figcaption, footer, form,
header, hr, legend, listing, main, p, plaintext, pre, xmp {
    display: block;
}

blockquote, figure, listing, p, plaintext, pre, xmp {
    margin-block-start: 1em; margin-block-end: 1em;
}

blockquote, figure { margin-inline-start: 40px; margin-inline-end: 40px; }

address, blockquote, center, dialog, div, figure, figcaption, footer, form,
header, hr, legend, listing, main, p, plaintext, pre, xmp {
    font-style: italic;
    white-space: nowrap;
    font-family: monospace;
    white-space: pre;
}

dialog:not([open]) { display: none; }

/* position: absolute; */
/* offset-inline-start: 0; offset-inline-end: 0; */
/* vertical-align: top; */
/* height: fit-content; */
/* margin: auto; */
/* border-radius: 1em; */
/* padding: 1em; */
/* background: white; */
/* color: black; */

dialog:backdrop {
    background: rgba(0, 0, 0, 0.1);
}
```

site

▶ THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

The following rules are also expected to apply, as [presentational hints](#):

```
CSS8@namespace url(http://www.w3.org/1999/xhtml);
pre[wrap] { white-space: pre-wrap;
}

In quirks mode, the following rules are also expected to apply:
CSS8@namespace url(http://www.w3.org/1999/xhtml);
form { margin-block-end: 1em; }

The center element, and the div element when it has an align attribute whose value is an ASCII case-insensitive match for either the string "center" or the string "middle", are expected to center text within themselves, as if they had their text-align property set to 'center' in a presentational hint, and to align descendants to the center.

The div element, when it has an align attribute whose value is an ASCII case-insensitive match for the string "left", is expected to left-align text within itself, as if it had its text-align property set to 'left' in a presentational hint, and to align descendants to the left.

The div element, when it has an align attribute whose value is an ASCII case-insensitive match for the string "right", is expected to right-align text within itself, as if it had its text-align property set to 'right' in a presentational hint, and to align descendants to the right.

The div element, when it has an align attribute whose value is an ASCII case-insensitive match for the string "justify", is expected to full-justify text within itself, as if it had its text-align property set to 'justify' in a presentational hint, and to align descendants to the left.
```

14.3.4 Phrasing content

```
CSS8@namespace url(http://www.w3.org/1999/xhtml);
cite, dfn, em, i, var { font-style: italic; }
b, bdi, bdo, big, small { font-weight: bolder; }
code, kbd, samp, tt { font-family: monospace; }
big { font-size: larger; }
small { font-size: smaller; }

sub { vertical-align: sub; }
sup { vertical-align: super; }
sub, sup { line-height: normal; font-size: smaller; }

ruby { display: ruby; }
rt { display: ruby-text; }

link { color: #0000EE; }
visited { color: #551A8B; }
link:visited, link:active { color: #FF0000; }
link, visited { text-decoration: underline; cursor: pointer; }

:focus { outline: auto; }

marquee { background-color: yellow; color: black; } /* this color is just a suggestion and can be changed based on implementation feedback */

abbr[title], acronym[title] { text-decoration: dotted underline; }
ins, u { text-decoration: underline; }
del, s { text-decoration: line-through; }

q::before { content: open-quote; }
q::after { content: close-quote; }

hr { display: outside; margin-top: 1em; } /* this also has bidi implications */
nobr { white-space: nowrap; }
wbr { display: outside; break-opportunity: 1; } /* this also has bidi implications */
node_wbr { white-space: normal; }

The following rules are also expected to apply, as presentational hints:
```

```
CSS8@namespace url(http://www.w3.org/1999/xhtml);
br[clear-left] { clear: left; }
br[clear-right] { clear: right; }
br[clear-all] { br[clear-left], br[clear-right] { clear: both; } }
```

For the purposes of the CSS ruby model, runs of children of `ruby` elements that are not `rt` or `rt` elements are expected to be wrapped in anonymous boxes whose `display` property has the value `ruby-base`. ([CSSRUBY](#))

When a particular part of a ruby has more than one annotation, the annotations should be distributed on both sides of the base text so as to minimize the stacking of ruby annotations on one side.

Note	When it becomes possible to do so, the preceding requirement will be updated to be expressed in terms of CSS ruby. (Currently, CSS ruby does not handle nested <code>ruby</code> elements or multiple sequential <code>rt</code> elements, which is how this semantic is expressed.)
-------------	--

User agents that do not support correct ruby rendering are expected to render parentheses around the text of `rt` elements in the absence of `rt` elements.

User agents are expected to support the `clear` property on inline elements (in order to render `br` elements with `clear` attributes) in the manner described in the non-normative note to this effect in CSS.

The initial value for the `color` property is expected to be black. The initial value for the `background-color` property is expected to be 'transparent'. The canvas's background is expected to be white.

When a `font` element has a `color` attribute, its value is expected to be parsed using the [rules for parsing a legacy color value](#), and if that does not return an error, the user agent is expected to treat the attribute as a [presentational hint](#) setting the element's `color` property to the resulting color.

The `font` element is expected to override the color of any text decoration that spans the text of the element to the [used value](#) of the element's `color` property.

When a `font` element has a `face` attribute, the user agent is expected to treat the attribute as a [presentational hint](#) setting the element's `font-family` property to the attribute's value.

When a `font` element has a `size` attribute, the user agent is expected to use the following steps, known as the [rules for parsing a legacy font size](#), to treat the attribute as a [presentational hint](#) setting the element's `font-size` property:

1. Let `input` be the attribute's value.
2. Let `position` be a pointer into `input`, initially pointing at the start of the string.
3. [Skin ASCII whitespace](#) within `input` given position.
4. If `position` is past the end of `input`, there is no [presentational hint](#). Return.
5. If the character at U+002B PLUS SIGN character (+), then let `mode` be `relative-plus`, and advance `position` to the next character. Otherwise, if the character at `position` is a U+002D HYPHEN-MINUS character (-), then let `mode` be `relative-minus`, and advance `position` to the next character. Otherwise, let `mode` be `absolute`.
6. [Collect a sequence of code points](#) that are [ASCII digits](#) from `input` given position, and let the resulting sequence be `digits`.
7. If `digits` is the empty string, there is no [presentational hint](#). Return.
8. Interpret `digits` as a base-ten integer. Let `value` be the resulting number.
9. If `mode` is `relative-plus`, then increment `value` by 3. If `mode` is `relative-minus`, then let `value` be the result of subtracting `value` from 3.
10. If `value` is greater than 7, let it be 7.
11. If `value` is less than 1, let it be 1.
12. Set `font-size` to the keyword corresponding to the value of `value` according to the following table:

<code>value</code> <code>font-size</code> keyword
1 'x-small'
2 'small'
3 'medium'
4 'large'
5 'x-large'
6 'xx-large'
7 'xxx-large'

14.3.5 Bidirectional text

```
CSS8@namespace url(http://www.w3.org/1999/xhtml);
dir[dir=rtl], bdi[dir=rtl], input[type=tel i], dir[ltr] { direction: rtl; }
dir[dir=rtl], bdi[dir=rtl] { direction: rtl; }

address, blockquote, center, div, figure, figcaption, footer, form, header, hr,
legend, listgroup, main, p, plaintext, pre, summary, xmp, article, aside, h1, h2,
h3, h4, h5, h6, hgroup, nav, section, table, caption, colgroup, col, thead,
tbody,tfoot, tr, td, th, dir, dd, dl, dt, menu, ol, ul, li, bdi, output,
dir[rtl i], dir[rtl i], [dir=auto i], [dir=auto i] { unicode-bidi: isolate; }

bdo, bdo[dir] { unicode-bidi: isolate-override; }

input[dir=auto i], matches([type=search i], [type=tel i], [type=url i],
  [type=email i]), textarea[dir=auto i], pre[dir=auto i] { unicode-bidi: plaintext; }

/* see prose for input elements whose type attribute is in the Text state */
/* the rules setting the 'content' property on br and wbr elements also has bidi implications */

When an input element's dir attribute is in the auto state and its type attribute is in the Text state, then the user agent is expected to act as if it had a user-agent-level style sheet rule setting the unicode-bidi property to 'plaintext'.
```

Input fields (i.e. `textarea` elements and `input` elements when their `type` attribute is in the `Text`, `Search`, `Telephone`, `URL`, or `E-mail` state) are expected to present an editing user interface with a directionality that matches the element's `direction` property.

When the document's character encoding is [ISO-8859-8](#), the following rules are additionally expected to apply, following those above: ([ENCODING](#))

```
CSS8@namespace url(http://www.w3.org/1999/xhtml);
address, blockquote, center, div, figure, figcaption, footer, form, header, hr,
legend, listgroup, main, p, plaintext, pre, summary, xmp, article, aside, h1, h2,
h3, h4, h5, h6, hgroup, nav, section, table, caption, colgroup, col, thead,
tbody,tfoot, tr, td, th, dir, dd, dl, dt, menu, ol, ul, li, bdi, output,
dir[rtl i], dir[rtl i], [dir=auto i], [dir=auto i] { unicode-bidi: isolate-override; }

input:not([type=submit i]):not([type=reset i]):not([type=button i]),
  textarea { unicode-bidi: normal; }
```

14.3.6 Quotes

This block is automatically generated from the Unicode Common Locale Data Repository. ([CLDR](#))

User agents are expected to use either the block below (which will be regularly updated) or to automatically generate their own copy directly from the source material. The language codes are derived from the CLDR file names. The quotes are derived from the `delimiter` blocks, with fallback handled as specified in the CLDR documentation.

```
CSS8@namespace url(http://www.w3.org/1999/xhtml);
root { quotes: "\201c" "\201d" "\2018" "\2019"; }
root:lang(ar), :not(:lang(ar)) > :lang(ar) { quotes: "\201c" "\201d" "\2018" "\2019"; }
root:lang(ar), :not(:lang(ar)) > :lang(arq) { quotes: "\201c" "\201d" "\2018" "\2019"; }
root:lang(ar), :not(:lang(ar)) > :lang(am) { quotes: "\201c" "\201d" "\2018" "\2019"; }
root:lang(ar), :not(:lang(ar)) > :lang(an) { quotes: "\201c" "\201d" "\2018" "\2019"; }
root:lang(ar), :not(:lang(ar)) > :lang(as) { quotes: "\201c" "\201d" "\2018" "\2019"; }
root:lang(ar), :not(:lang(ar)) > :lang(asz) { quotes: "\201c" "\201d" "\2018" "\2019"; }
root:lang(ar), :not(:lang(ar)) > :lang(as-Cyrillic) { quotes: "\201c" "\201d" "\2018" "\2019"; }
root:lang(as), :not(:lang(as)) > :lang(as) { quotes: "\201c" "\201d" "\2018" "\2019"; }
root:lang(as), :not(:lang(as)) > :lang(as-Cyrillic) { quotes: "\201c" "\201d" "\2018" "\2019"; }
root:lang(be), :not(:lang(be)) > :lang(be) { quotes: "\201c" "\201d" "\2018" "\2019"; }
```

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

```

border-inline-start-width: 1px;
border-inline-start-style: solid;
border-inline-end-width: 1px;
border-inline-end-style: solid;
}

table[rules=groups 1] > thead,
table[rules=groups 1] > tbody > tr,
table[rules=groups 1] > tfoot {
  border-block-start-width: 1px;
  border-block-start-style: solid;
  border-block-end-width: 1px;
  border-block-end-style: solid;
}

table[rules=rows 1] > tr, table[rules=rows 1] > thead > tr,
table[rules=rows 1] > tbody > tr, table[rules=rows 1] > tfoot > tr {
  border-block-start-width: 1px;
  border-block-start-style: solid;
  border-block-end-width: 1px;
  border-block-end-style: solid;
}
}

In quirks mode, the following rules are also expected to apply:

```

```

CSS@namespace url("http://www.w3.org/1999/xhtml");
table {
  font-weight: initial;
  font-style: initial;
  font-variant: initial;
  font-size: initial;
  line-height: initial;
  white-space: initial;
  text-align: initial;
}

```

For the purposes of the CSS table model, the `col` element is expected to be treated as if it was present as many times as its `span` attribute specifies.

For the purposes of the CSS table model, the `colgroup` element, if it contains no `col` element, is expected to be treated as if it had as many such children as its `span` attribute specifies.

For the purposes of the CSS table model, the `colspan` and `rowspan` attributes on `td` and `th` elements are expected to provide the special knowledge regarding cells spanning rows and columns.

In **HTML documents**, the following rules are also expected to apply:

```

CSS@namespace url("http://www.w3.org/1999/xhtml");
:matches(table, thead, tbody, tfoot, tr) > form { display: none !important; }

```

The `table` element's `cellspacing` attribute maps to the pixel length property `'border-spacing'` on the element.

The `table` element's `cellpadding` attribute maps to the pixel length properties `'padding-top'`, `'padding-right'`, `'padding-bottom'`, and `'padding-left'` of any `td` and `th` elements that have corresponding `cells` in the `table` corresponding to the `table` element.

The `table` element's `height` attribute maps to the dimension property (ignoring zero) `'height'` on the `table` element.

The `table` element's `width` attribute maps to the dimension property (ignoring zero) `'width'` on the `table` element.

The `col` element's `width` attribute maps to the dimension property `'width'` on the `col` element.

The `tr` element's `height` attribute maps to the dimension property `'height'` on the `tr` element.

The `td` and `th` elements' `height` attributes map to the dimension property (ignoring zero) `'height'` on the element.

The `td` and `th` elements' `width` attributes map to the dimension property (ignoring zero) `'width'` on the element.

The `thead`, `tbody`, `tfoot`, `tr`, `td`, and `th` elements, when they have an `align` attribute whose value is an **ASCII case-insensitive** match for either the string `"center"` or the string `"middle"`, are expected to center text within themselves, as if they had their `text-align` property set to `'center'` in a **presentational hint**, and to `align descendants` to the center.

The `thead`, `tbody`, `tfoot`, `tr`, `td`, and `th` elements, when they have an `align` attribute whose value is an **ASCII case-insensitive** match for the string `"left"`, are expected to left-align text within themselves, as if they had their `text-align` property set to `'left'` in a **presentational hint**, and to `align descendants` to the left.

The `thead`, `tbody`, `tfoot`, `tr`, `td`, and `th` elements, when they have an `align` attribute whose value is an **ASCII case-insensitive** match for the string `"right"`, are expected to right-align text within themselves, as if they had their `text-align` property set to `'right'` in a **presentational hint**, and to `align descendants` to the right.

The `thead`, `tbody`, `tfoot`, `tr`, `td`, and `th` elements, when they have an `align` attribute whose value is an **ASCII case-insensitive** match for the string `"justify"`, are expected to full-justify text within themselves, as if they had their `text-align` property set to `'justify'` in a **presentational hint**, and to `align descendants` to the left.

User agents are expected to have a rule in their user agent style sheet that matches `td` elements that have a parent node whose `computed value` for the `text-align` property is its initial value, whose declaration block consists of just a single declaration that sets the `text-align` property to the value `'center'`.

When a `table`, `thead`, `tbody`, `tfoot`, `tr`, `td` or `th` element has a `background` attribute set to a non-empty value, the new value is expected to be `parsed` relative to the element's `node document`, and if this is successful, the user agent is expected to treat the attribute as a **presentational hint** setting the element's `'background-image'` property to the resulting [URL](#).

When a `table`, `thead`, `tbody`, `tfoot`, `tr`, `td` or `th` element has a `bgcolor` attribute set, the new value is expected to be parsed using the [rules for parsing a legacy color value](#), and if that does not return an error, the user agent is expected to treat the attribute as a **presentational hint** setting the element's `'background-color'` property to the resulting color.

When a `table` element has a `bordercolor` attribute, its value is expected to be parsed using the [rules for parsing a legacy color value](#), and if that does not return an error, the user agent is expected to treat the attribute as a **presentational hint** setting the element's `'border-top-color'`, `'border-right-color'`, `'border-bottom-color'`, and `'border-left-color'` properties to the resulting color.

The `table` element's `border` attribute maps to the pixel length properties `'border-top-width'`, `'border-right-width'`, `'border-bottom-width'`, and `'border-left-width'` on the element. If the attribute is present but parsing the attribute's value using the [rules for parsing non-negative integers](#) generates an error, a default value of 1px is expected to be used for that property instead.

Rules marked `"only if border is not equivalent to zero"` in the CSS block above is expected to only be applied if the `border` attribute mentioned in the selectors for the rule is not only present but, when parsed using the [rules for parsing non-negative integers](#), is also found to have a value other than zero or to generate an error.

In **quirks mode**, a `td` element or a `th` element that has a `nowrap` attribute but also has a `width` attribute whose value, when parsed using the [rules for parsing nonzero dimension values](#), is found to be a length (not an error or a number classified as a percentage), is expected to have a **presentational hint** setting the element's `'white-space'` property to `'normal'`, overriding the rule in the CSS block above that sets it to `'nowrap'`.

14.3.10 Margin collapsing quirks

A node is **substantial** if it is a text node that is not `inter-element whitespace`, or if it is an element node.

A node is **blank** if it is an element that contains no **substantial** nodes.

The elements with default margins are the following elements: `blockquote`, `div`, `dl`, `h1`, `h2`, `h3`, `h4`, `h5`, `h6`, `hr`, `img`, `ol`, `ul`, `p`, `pre`, `ul`, `li`.

In **quirks mode**, any element with **default margin** that is the child of a `body`, `td`, or `th` element and has no **substantial** previous siblings is expected to have a user-agent level style sheet rule that sets its `'margin-block-start'` property to zero.

In **quirks mode**, any element with **default margin** that is the child of a `body`, `td`, or `th` element, has no **substantial** previous siblings, and is **blank**, is expected to have a user-agent level style sheet rule that sets its `'margin-block-end'` property to zero also.

In **quirks mode**, any element with **default margin** that is the child of a `td` or `th` element, has no **substantial** following siblings, and is **blank**, is expected to have a user-agent level style sheet rule that sets its `'margin-block-start'` property to zero.

In **quirks mode**, any `g` element that is the child of a `td` or `th` element and has no **substantial** following siblings, is expected to have a user-agent level style sheet rule that sets its `'margin-block-end'` property to zero.

14.3.11 Form controls

```
CSS@namespace url("http://www.w3.org/1999/xhtml");
```

```
input, select, button, textarea {
  letter-spacing: initial;
  word-spacing: initial;
  line-height: initial;
  line-height: normal;
  text-transform: initial;
  vertical-align: baseline;
  text-shadow: initial;
}

input, select, textarea {
  text-align: initial;
}

input.matches([type=reset i], [type=button i], [type=submit i]), button {
  text-align: center;
}

input.matches([type=reset i], [type=button i], [type=submit i], [type=checkbox i]), button {
  display: inline-block;
}

input.matches([type=radio i], [type=checkbox i], [type=reset i], [type=button i],
  [type=submit i], [type=button i], [type=search i]), select, button {
  box-sizing: border-box;
}

textarea { white-space: pre-wrap; }
```

In **quirks mode**, the following rules are also expected to apply:

```
CSS@namespace url("http://www.w3.org/1999/xhtml");
input:not([type=image i]), textarea { box-sizing: border-box; }
```

Each kind of form control is also described in the [Widgets](#) section, which describes the look and feel of the control.

14.3.12 The `hr` element

```
CSS@namespace url("http://www.w3.org/1999/xhtml");
```

```
hr {
  color: gray;
  border: 1px solid black;
  border-width: 1px;
  margin-block-start: 0.5em;
  margin-block-end: 0.5em;
  margin-inline-start: auto;
  margin-inline-end: auto;
  overflow: hidden;
}
```

The following rules are also expected to apply, as **presentational hints**:

```
CSS@namespace url("http://www.w3.org/1999/xhtml");
hr[align=left i] { margin-left: 0; margin-right: auto; }
hr[align=right i] { margin-left: auto; margin-right: 0; }
hr[align=justify i] { margin-left: auto; margin-right: auto; }
hr[align=baseline i], hr[noshade] { border-style: solid; }
```

If an `hr` element has either a `value` attribute or a `maxsize` attribute, and furthermore also has a `size` attribute, and parsing that attribute's value using the [rules for parsing non-negative integers](#) doesn't generate an error, then the user agent is expected to use the parsed value divided by two as a pixel length for **presentational hints** for the properties `'border-top-width'`, `'border-right-width'`, `'border-bottom-width'`, and `'border-left-width'` on the element.

Otherwise, if the `hr` element neither a `value` attribute nor a `maxsize` attribute, but does have a `size` attribute, and parsing that attribute's value using the [rules for parsing non-negative integers](#) doesn't generate an error, then: if the parsed value is one, then the user agent is expected to use the attribute as a **presentational hint** setting the element's `'border-bottom-width'` to zero, otherwise, if the parsed value is greater than one, then the user agent is expected to use the parsed value minus two as a pixel length for **presentational hints** for the `'height'` property on the element.

The `width` attribute on an `hr` element maps to the dimension property `'width'` on the element.

When an `hr` element has a `color` attribute, its value is expected to be parsed using the [rules for parsing a legacy color value](#), and if that does not return an error, the user agent is expected to treat the attribute as a **presentational hint** setting the element's `'color'` property to the resulting color.

14.3.13 The `fieldset` and `legend` elements

```

fieldset {
  display: block;
  margin-block-start: 2px;
  margin-block-end: 2px;
  border: groove 2px ThreeDFace;
  padding-block-start: 0.15em;
  padding-block-end: 0.15em;
  padding-block-end: 0.625em;
  padding-block-start: 0.75em;
  min-inline-size: auto-context;
}

legend {
  padding-block-start: 2px; padding-block-end: 2px;
}

legend[align=left] {
  justify-self: left;
}

legend[align=center] {
  justify-self: center;
}

legend[align=right] {
  justify-self: right;
}

```

The `fieldset` element, when it generates a [CSS box](#), is expected to act as follows:

- The element is expected to establish a new [block formatting context](#).
- The `display` property is expected to act as follows:
 - If the computed value of `display` is a value such that the [outer display type](#) is 'inline', then behave as 'inline-block'.
 - Otherwise, behave as 'flow-root'.

Note
This does not change the computed value.

- If the element's box has a child box that matches the conditions in the list below, then the first such child box is the 'fieldset' element's *rendered legend*:

- The child is a `legend` element.
 - The child's used value of `float` is 'none'.
 - The child's used value of `position` is not 'absolute' or 'fixed'.
- If the element has a `rendered legend`, then the border is expected to not be painted behind the rectangle defined as follows, using the writing mode of the fieldset:
 1. The block-start edge of the rectangle is the smaller of the block-start edge of the `rendered legend`'s margin rectangle at its static position (ignoring transforms), and the block-start outer edge of the `fieldset`'s border.
 2. The block-end edge of the rectangle is the larger of the block-end edge of the `rendered legend`'s margin rectangle at its static position (ignoring transforms), and the block-end outer edge of the `fieldset`'s border.
 3. The inline-start edge of the rectangle is the smaller of the inline-start edge of the `rendered legend`'s border rectangle at its static position (ignoring transforms), and the inline-start outer edge of the `fieldset`'s border.
 4. The inline-end edge of the rectangle is the larger of the inline-end edge of the `rendered legend`'s border rectangle at its static position (ignoring transforms), and the inline-end outer edge of the `fieldset`'s border.

- The space allocated for the element's border on the block-start side is expected to be the element's `border-block-start-width` or the `rendered legend`'s margin box size in the `fieldset`'s block-flow direction, whichever is greater.
- For the purpose of calculating the used `block-size`, if the computed `block-size` is not 'auto', the space allocated for the `rendered legend` and expected to contain the content (including the ':before' and ':after' pseudo-elements) of the `fieldset` element except for the `rendered legend`, if there is one.
- If the element has a `rendered legend`, then that element is expected to be the first child box.
- The [anonymous fieldset content box](#) is expected to appear after the `rendered legend` and is expected to contain the content (including the ':before' and ':after' pseudo-elements) of the `fieldset` element except for the `rendered legend`, if there is one.
- The used value of the `padding-top`, `padding-right`, `padding-bottom`, and `padding-left` properties are expected to be zero.
- For the purpose of calculating the min-content inline size, use the greater of the min-content inline size of the `rendered legend` and the min-content inline size of the [anonymous fieldset content box](#).
- For the purpose of calculating the max-content inline size, use the greater of the max-content inline size of the `rendered legend` and the max-content inline size of the [anonymous fieldset content box](#).

A `fieldset` element's *rendered legend*, if any, is expected to act as follows:

- The element is expected to establish a new [formatting context](#) for its contents. The type of this [formatting context](#) is determined by its `display` value, as usual.
- The `display` property is expected to behave as if its computed value was block/fixed.

Note
This does not change the computed value.

- If the computed value of `min-size` is 'auto', then the used value is the [fit-content inline size](#).

- The element is expected to be positioned in the inline direction as is normal for blocks (e.g., taking into account margins and the `justify-self` property).
- The element's box is expected to be constrained in the inline direction by the inline content size of the `fieldset` as if it had used its computed inline padding.

Example

For example, if the `fieldset` has a specified padding of 50px, then the `rendered legend` will be positioned 50px in from the `fieldset`'s border. The padding will further apply to the [anonymous fieldset content box](#) instead of the `fieldset` element itself.

- The element is expected to be positioned in the block-flow direction such that its border box is centered over the border on the block-start side of the `fieldset` element.

A `fieldset` element's [anonymous fieldset content box](#) is expected to act as follows:

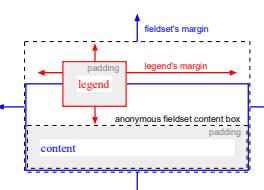

- The `display` property is expected to act as follows:
 - If the computed value of `display` on the `fieldset` element is 'grid' or 'inline-grid', then set the used value to 'grid'.
 - If the computed value of `display` on the `fieldset` element is 'flex' or 'inline-flex', then set the used value to 'flex'.
 - Otherwise, set the used value to 'flow-root'.

- The following properties are expected to inherit from the `fieldset` element:
 - `align-content`
 - `align-items`
 - `border-radius`
 - `columns-count`
 - `columns-fill`
 - `column-gap`
 - `column-span`
 - `column-width`
 - `flex-direction`
 - `flex-wrap`
 - `grid-auto-columns`
 - `grid-auto-flow`
 - `grid-column`
 - `grid-column-end`
 - `grid-column-start`
 - `grid-row`
 - `grid-template-areas`
 - `grid-template-columns`
 - `grid-template-rows`
 - `justify-content`
 - `justify-items`
 - `overflow`
 - `padding-bottom`
 - `padding-left`
 - `padding-right`
 - `padding-top`
 - `text-overflow`
 - `unicode-bidi`

- The `block-size` property is expected to be set to '100%'.

- For the purpose of calculating percentage padding, act as if the padding was calculated for the `fieldset` element.

Note

The legend is rendered over the top border, and the top border area reserves vertical space for the legend. The fieldset's top margin starts at the top margin edge of the legend. The legend's horizontal margins, or the `justify-self` property, gives its horizontal position. The [anonymous fieldset content box](#) appears below the legend.

14.4 Replaced elements

Note
The following elements can be replaced elements: `audio`, `canvas`, `embed`, `iframe`, `img`, `input`, `object`, and `video`.

14.4.1 Embedded content

The `embed`, `iframe`, and `video` elements are expected to be treated as [replaced elements](#).

A `canvas` element that [represents embedded content](#) is expected to be treated as a [replaced element](#); the contents of such elements are the element's bitmap, if any, or else a `transparent black` bitmap with the same [intrinsic dimensions](#) as the element. Other `image` elements are expected to be treated as ordinary elements in the rendering model.

An `object` element that [represents an image, plugin, or its nested browsing context](#) is expected to be treated as a [replaced element](#). Other `object` elements are expected to be treated as ordinary elements in the rendering model.

The `audio` element, when it is [exposing a user interface](#), is expected to be treated as a [replaced element](#) about one line high, as wide as is necessary to expose the user agent's user interface features. When an `audio` element is not [exposing a user interface](#), the user agent is expected to force its `display` property to compute to 'none', irrespective of CSS rules.

Whether a `video` element is [exposing a user interface](#) is not expected to affect the size of the rendering; controls are expected to be overlaid above the page content without causing any layout changes, and are expected to disappear when the user does not need them.

Any subtitles or captions are expected to be overlaid directly on top of their `video` element, as defined by the relevant rendering rules; for WebVTT, those are the [rules for updating the display of WebVTT text tracks \(WEBVTT\)](#)

When the user agent starts [exposing a user interface for a `video` element](#), the user agent should run the [rules for updating the text track rendering](#) of each of the `text tracks` in the `video` element's [list of text tracks](#) that are [showing](#) and whose `text track kind` is one of [subtitles](#) or [captions](#) (e.g., for `text tracks` based on WebVTT, the [rules for updating the display of WebVTT text tracks \(WEBVTT\)](#))

Note
Resizing `video` and `canvas` elements does not interrupt video playback or clear the canvas.

The following CSS rules are expected to apply:

```
CSS@namesapace url(<http://www.w3.org/1999/xhtml>)
iframe { border: 2px inset; }
video { object-fit: contain; }
```

14.4.2 Images

User agents are expected to render `img` elements and `image` elements whose `type` attributes are in the [Image Button](#) state, according to the first applicable rules from the following list:

If the element [represents](#) an image

The user agent is expected to treat the element as a [replaced element](#) and render the image according to the rules for doing so defined in CSS.

If the element does not represent an image and either:

- the element has no `alt` attribute, or
- the `document` is in [quirk mode](#), and the element already has [intrinsic dimensions](#) (e.g., from the [dimension attributes](#) or CSS rules)

The user agent is expected to treat the element as a [replaced element](#) whose content is the text that the element represents, if any, optionally alongside an icon indicating that the image is being obtained (if applicable). For `input` elements, the element is expected to appear button-like to indicate that the element is a [button](#).

If the element is in [img](#) or [image](#) state and the user agent does not expect this to change

The user agent is expected to treat the element as a [replaced element](#) whose content is the text, optionally with an icon indicating that an image is missing, so that the user can request the image be displayed or investigate why it is not rendering. In non-graphical contexts, such an icon should be omitted.

If the element is an `a` element that represents nothing and the user agent does not expect this to change

The user agent is expected to treat the element as an empty inline element. (In the absence of further styles, this will cause the element to essentially not be rendered.)

If the element is a `img` element that does [represent](#) an image and the user agent does not expect this to change

The user agent is expected to treat the element as a [replaced element](#) consisting of a button whose content is the element's alternative text. The [intrinsic dimensions](#) of the button are expected to be about one line in height and whatever width is necessary to render the text on one line.

The icons mentioned above are expected to be relatively small so as not to disrupt most text but be easily clickable. In a visual environment, for instance, icons could be 16 pixels by 16 pixels square, or 1em by 1em if the images are scalable. In an audio environment, the icon could be a short beep. The icons are intended to indicate to the user that they can be used to get to whatever options the UA provides for images, and, where appropriate, are expected to provide access to the context menu that would have come up if the user interacted with the actual image.

All animated images with the same [absolute URL](#), and the same image data are expected to be rendered synchronized to the same timeline as a group, with the timeline starting at the time of the least recent addition to the group.

Note
In other words, when a second image with the same [absolute URL](#), and animated image data is inserted into a document, it jumps to the point in the animation cycle that is currently being displayed by the first image.

When a user agent is to [restart the animation](#) for an `img` element showing an animated image, all animated images with the same [absolute URL](#), and the same image data in that `img` element's `node document` are expected to restart their animation from the beginning.

The following CSS rules are expected to apply when the `document` is in [quirks mode](#):

```
CSS@namesapace url(<http://www.w3.org/1999/xhtml>)
img[align=left i] { margin-right: 3px; }
img[align=right i] { margin-left: 3px; }
```

14.4.3 Attributes for embedded content and images

The following CSS rules are expected to apply as [presentational hints](#):

```
CSS@namesapace url(<http://www.w3.org/1999/xhtml>)
frame[frameborder=0], iframe[frameborder=0] { border: none; }
embed[align=left i], iframe[align=left i], img[align=left i],
input[type=image i][align=left i], object[align=left i] {
  float: left;
}

embed[align=right i], iframe[align=right i], img[align=right i],
input[type=image i][align=right i], object[align=right i] {
  float: right;
}

embed[align=top i], iframe[align=top i], img[align=top i],
input[type=image i][align=top i], object[align=top i] {
  vertical-align: top;
}

embed[align=baseline i], iframe[align=baseline i], img[align=baseline i],
input[type=image i][align=baseline i], object[align=baseline i] {
  vertical-align: baseline;
}

embed[align=texttop i], iframe[align=texttop i], img[align=texttop i],
input[type=image i][align=texttop i], object[align=texttop i] {
  vertical-align: text-top;
}

embed[align=absmiddle i], iframe[align=absmiddle i], img[align=absmiddle i],
input[type=image i][align=absmiddle i], object[align=absmiddle i],
embed[align=abscenter i], iframe[align=abscenter i], img[align=abscenter i],
input[type=image i][align=abscenter i], object[align=abscenter i] {
  vertical-align: middle;
}

embed[align=bottom i], iframe[align=bottom i], img[align=bottom i],
input[type=image i][align=bottom i], object[align=bottom i] {
  vertical-align: bottom;
}
```

When an `embed`, `iframe`, `img`, or `object` element, or an `input` element whose `type` attribute is in the [Image Button](#) state, has an `align` attribute whose value is an [ASCII case-insensitive](#) match for the string "`center`" or the string "`middle`", the user agent is expected to act as if the element's `vertical-align` property was set to a value that aligns the vertical middle of the element with the parent element's baseline.

The `shape` attribute of `embed`, `iframe`, `img`, or `object` elements, and `img` elements with a `type` attribute in the [Image Button](#) state [maps to the dimension properties](#) `'margin-left'` and `'margin-right'` on the element.

The `vspace` attribute of `embed`, `iframe`, `img`, or `object` elements, and `img` elements with a `type` attribute in the [Image Button](#) state, [maps to the dimension properties](#) `'margin-top'` and `'margin-bottom'` on the element.

When an `img` element, `object` element, or `input` element with a `type` attribute in the [Image Button](#) state has a `border` attribute whose value, when parsed using the [rules for parsing non-negative integers](#), is found to be a number greater than zero, the user agent is expected to use the parsed value for eight [presentational hints](#): four setting the parsed value as a pixel length for the element's `'border-top-width'`, `'border-right-width'`, `'border-bottom-width'`, and `'border-left-width'` properties, and four setting the element's `'border-top-style'`, `'border-right-style'`, `'border-bottom-style'`, and `'border-left-style'` properties to the value `'solid'`.

The `width` and `height` attributes on `embed`, `iframe`, `img`, `object`, or `video` elements, and `input` elements with a `type` attribute in the [Image Button](#) state and that either represents an image or that the user expects will eventually represent an image, [map to the dimension properties](#) `'width'` and `'height'` on the element respectively.

The [intrinsic aspect ratio](#) for an `img` element's `img` is computed as follows:

1. If `img`'s [current request](#) is [available](#) and has an [intrinsic aspect ratio](#), then use that [intrinsic aspect ratio](#).
2. If `img`'s `width` and `height` attributes, when parsed using the [rules for parsing dimension values](#), are both not an error, not a percentage, and non-zero, then use the ratio resulting from dividing the `width` attribute value by the `height` attribute value.
3. Otherwise, `img` has no [intrinsic aspect ratio](#).

14.4.4 Image maps

Shapes on an `image map` are expected to act, for the purpose of the CSS cascade, as elements independent of the original `area` element that happen to match the same style rules but inherit from the `img` or `object` element.

For the purposes of the rendering, only the `'cursor'` property is expected to have any effect on the shape.

Example

Thus, for example, if an `area` element has a `style` attribute that sets the `'cursor'` property to `'help'`, then when the user designates that shape, the cursor would change to a Help cursor.

Example

Similarly, if an `area` element had a CSS rule that sets its `'cursor'` property to `'inherit'` (or if no rule setting the `'cursor'` property matched the element at all), the shape's cursor would be inherited from the `img` or `object` element of the `image map`, not from the parent of the `area` element.

14.5 Widgets

14.5.1 Introduction

The elements defined in this section can be rendered in a variety of manners, within the guidelines provided below. User agents are encouraged to set the `'appearance'` CSS property appropriately to achieve platform-native appearances for widgets, and are expected to implement any relevant animations, etc, that are appropriate for the platform.

14.5.2 Button layout

`Button layout` is as follows:

- The `'display'` property is expected to act as follows:
 - If the computed value of `'display'` is `'inline-grid'`, `'grid'`, `'inline-flex'`, or `'flex'`, then behave as the computed value.
 - Otherwise, if the computed value of `'display'` is a value such that the `'outer display type'` is `'inline'`, then behave as `'inline-block'`.
 - Otherwise, behave as `'flow-root'`.
- The element is expected to establish a new [formatting context](#) for its contents. The type of this formatting context is determined by its `'display'` value, as usual.
- If the element is [absolutely positioned](#), then for the purpose of the [CSS visual formatting model](#), act as if the element is a [replaced element](#) [CSS].
- If the `computed value` of `'intrinsic-size'` is `'auto'`, then the `used value` is `'fit-content inline-size'`.
- For the purpose of the `'normal'` keyword of the `'align-self'` property, act as if the element is a replaced element.
- If the element is an `input` element, or if it is a `button` element and its computed value for `'display'` is not `'inline-grid'`, `'grid'`, `'inline-flex'`, or `'flex'`, then the element's box has a child `anonymous button content box` with the following behaviors:
 - The box is a `block-level block container` that establishes a new `block formatting context` (i.e., `display` is `'flow-root'`).
 - If the box does not overflow in the horizontal axis, then it is centered horizontally.
 - If the box does not overflow in the vertical axis, then it is centered vertically.
- Otherwise, there is no `anonymous button content box`.

14.5.3 The `button` element

The `button` element, when it generates a [CSS box](#), is expected to depict a button and to use [button layout](#) whose `anonymous button content box`'s contents (if there is an `anonymous button content box`) are the child boxes the element's box would otherwise have.

14.5.4 The `details` and `summary` elements

```
CSS@namesapace url(<http://www.w3.org/1999/xhtml>)
summary {
  display: list-item;
  counter-increment: list-item 0;
  list-style-type: disclosure-closed inside;
}
```

The `details` element is expected to render as a `block_box`. The element is also expected to have an internal `shadow_tree` with two `slots`, both rendered as a `block_box`. The first `slot` is expected to take the `details` element's first `summary` element child, if any. The second `slot` is expected to take the `details` element's remaining descendants, if any. The first `slot` is expected to allow the user to request the details be shown or hidden.

The second `slot` is expected to be removed from the rendering when the `details` element does not have an `open` attribute.

14.5.5 The `input` element as a text entry widget

An `input` element whose `type` attribute is in the `Text`, `Search`, `Telephone`, `URL`, or `E-mail` state, is expected to render as an `inline-block` box depicting a text control. Additionally, the `line-height` property, if it has a `computed value` equivalent to a value that is less than 1.0, must have a `used value` of 1.0.

An `input` element whose `type` attribute is in the `Password` state is expected to render as an `inline-block` box depicting a text control that obscures data entry.

If these text controls provide a text selection, then, when the user changes the current selection, the user agent is expected to `queue a task`, using the `user interaction task source`, to `fire an event named select` at the element, with the `bubbles` attribute initialized to true.

If an `input` element whose `type` attribute is in one of the above states has a `size` attribute, and parsing that attribute's value using the `rules for parsing non-negative integers` doesn't generate an error, then the user agent is expected to use the attribute as a `presentational hint` for the `width` property on the element, with the value obtained from applying the `converting a character width to pixels` algorithm to the value of the attribute.

If an `input` element whose `type` attribute is in one of the above states does not have a `size` attribute, then the user agent is expected to act as if it had a user-agent-level style sheet rule setting the `width` property on the element to the value obtained from applying the `converting a character width to pixels` algorithm to the number 20.

Converting a `character width to pixels` algorithm returns $(size - 1) \cdot avg + max$, where `size` is the character width to convert, `avg` is the average character width of the primary font for the element for which the algorithm is being run, in pixels, and `max` is the maximum character width of that same font, also in pixels. (The element's `letter-spacing` property does not affect the result.)

14.5.6 The `input` element as domain-specific widgets

An `input` element whose `type` attribute is in the `Date` state is expected to render as an `inline-block` box depicting a date control.

An `input` element whose `type` attribute is in the `Month` state is expected to render as an `inline-block` box depicting a month control.

An `input` element whose `type` attribute is in the `Week` state is expected to render as an `inline-block` box depicting a week control.

An `input` element whose `type` attribute is in the `Time` state is expected to render as an `inline-block` box depicting a time control.

An `input` element whose `type` attribute is in the `Local Date and Time` state is expected to render as an `inline-block` box depicting a local date and time control.

An `input` element whose `type` attribute is in the `Number` state is expected to render as an `inline-block` box depicting a number control.

These controls are all expected to be about one line high, and about as wide as necessary to show the widest possible value.

14.5.7 The `input` element as a range control

An `input` element whose `type` attribute is in the `Range` state is expected to render as an `inline-block` box depicting a slider control.

When the control is wider than it is tall (or square), the control is expected to be a horizontal slider, with the lowest value on the right if the `direction` property on this element has a `computed value` of 'rl', and on the left otherwise. When the control is taller than it is wide, it is expected to be a vertical slider, with the lowest value on the bottom.

Predefined suggested values (provided by the `list` attribute) are expected to be shown as tick marks on the slider, which the slider can snap to.

User agents are expected to use the `used value` of the `direction` property on the element to determine the direction in which the slider operates. Typically, a left-to-right ('lr') horizontal control would have the lowest value on the left and the highest value on the right, and vice versa.

14.5.8 The `input` element as a color well

An `input` element whose `type` attribute is in the `Color` state is expected to depict a color well, which, when activated, provides the user with a color picker (e.g. a color wheel or color palette) from which the color can be changed. The element, when it generates a `CSS box`, is expected to use `button layout`, that has no child boxes of the `anonymous button content box`. The `anonymous button content box` is expected to have a `presentational hint` setting the `background-color` property on the element's `value`.

Predefined suggested values (provided by the `list` attribute) are expected to be shown in the color picker interface, not on the color well itself.

14.5.9 The `input` element as a checkbox and radio button widgets

An `input` element whose `type` attribute is in the `Checkbox` state is expected to render as an `inline-block` box containing a single checkbox control, with no label.

An `input` element whose `type` attribute is in the `Radio Button` state is expected to render as an `inline-block` box containing a single radio button control, with no label.

14.5.10 The `input` element as a file upload control

An `input` element whose `type` attribute is in the `File Upload` state, when it generates a `CSS box`, is expected to render as an `inline-block` box containing a span of text giving the file name(s) of the `selected files`, if any, followed by a button that, when activated, provides the user with a file picker from which the selection can be changed. The button is expected to use `button layout` and the contents of the `anonymous button content box` are expected to be user-agent-defined (and possibly locale-specific) text, for example "Choose file".

14.5.11 The `input` element as a button

An `input` element whose `type` attribute is in the `Submit Button`, `Reset Button`, or `Button` state, when it generates a `CSS box`, is expected to depict a button and use `button layout` and the contents of the `anonymous button content box` are expected to be the text of the element's `value` attribute, if any, or text derived from the element's `type` attribute in a user-agent-defined (and probably locale-specific) fashion, if not.

14.5.12 The `marquee` element

```
CSS@namespace url("http://www.w3.org/1999/xhtml");
marquee {
    text-align: initial;
}
```

The `marquee` element, while `turned on`, is expected to render in an animated fashion according to its attributes as follows:

If the element's `behavior` attribute is in the `scroll` state

Slide the contents of the element in the direction described by the `direction` attribute as defined below, such that it begins off the start side of the `marquee`, and ends flush with the inner end side.

Example
For example, if the `direction` attribute is `left` (the default), then the contents would start such that their left edge are off the side of the right edge of the `marquee`'s `content area`, and the contents would then slide up to the point where the left edge of the contents are flush with the left inner edge of the `marquee`'s `content area`.

Once the animation has ended, the user agent is expected to `increment the marquee current loop index`. If the element is still `turned on` after this, then the user agent is expected to restart the animation.

If the element's `behavior` attribute is in the `slide` state

Slide the contents of the element in the direction described by the `direction` attribute as defined below, such that it begins off the start side of the `marquee`, and ends off the end side of the `marquee`.

Example
For example, if the `direction` attribute is `left` (the default), then the contents would start such that their left edge are off the side of the right edge of the `marquee`'s `content area`, and the contents would then slide up to the point where the `right` edge of the contents are flush with the left inner edge of the `marquee`'s `content area`.

Once the animation has ended, the user agent is expected to `increment the marquee current loop index`. If the element is still `turned on` after this, the user agent is expected to restart the animation.

If the element's `behavior` attribute is in the `alternate` state

When the `marquee current loop index` is even (or zero), slide the contents of the element in the direction described by the `direction` attribute as defined below, such that it begins flush with the start side of the `marquee`, and ends flush with the end side of the `marquee`.

When the `marquee current loop index` is odd, slide the contents of the element in the opposite direction than that described by the `direction` attribute as defined below, such that it begins flush with the end side of the `marquee`, and ends flush with the start side of the `marquee`.

Example
For example, if the `direction` attribute is `left` (the default), then the contents would with their `right` edge flush with the `right` inner edge of the `marquee`'s `content area`, and the contents would then slide up to the point where the `left` edge of the contents are flush with the left inner edge of the `marquee`'s `content area`.

Once the animation has ended, the user agent is expected to `increment the marquee current loop index`. If the element is still `turned on` after this, then the user agent is expected to continue the animation.

The `direction` attribute has the meanings described in the following table:

<code>direction</code> attribute state	<code>Direction of animation</code>	<code>Start edge</code>	<code>End edge</code>	<code>Opposite direction</code>
<code>left</code>	→ Right to left	Right	Left	→ Left to Right
<code>right</code>	→ Left to Right	Left	Right	→ Right to Left
<code>up</code>	↑ Up (Bottom to Top)	Bottom	Top	↓ Down (Top to Bottom)
<code>down</code>	↓ Down (Top to Bottom)	Top	Bottom	↑ Up (Bottom to Top)

In any case, the animation should proceed such that there is a delay given by the `marquee scroll interval` between each frame, and such that the content moves at most the distance given by the `marquee scroll distance` with each frame.

When a `marquee` element has a `bgcolor` attribute set, the value is expected to be parsed using the `rules for parsing a legacy color value`, and if that does not return an error, the user agent is expected to treat the attribute as a `presentational hint` setting the element's `background-color` property to the resulting color.

The `width` and `height` attributes on a `marquee` element set the `dimension properties` `width` and `height` on the element respectively.

The `intrinsic height` of a `marquee` element with its `direction` attribute in the `up` or `down` states is 200 `CSS pixels`.

The `vertical-align` attribute of a `marquee` element maps to the dimension properties `margin-top` and `margin-bottom` on the element. The `haspace` attribute of a `marquee` element maps to the dimension properties `margin-left` and `margin-right` on the element.

The `overflow` property on the `marquee` element is expected to be ignored; overflow is expected to always be hidden.

14.5.13 The `meter` element

The `meter` element is expected to render as an `inline-block` box with a `height` of '1em' and a `width` of '5em', a `vertical-align` of '-0.2em', and with its contents depicting a gauge.

When the element is wider than it is tall (or square), the depiction is expected to be of a horizontal gauge, with the minimum value on the right if the `direction` property on this element has a `computed value` of 'rl', and on the left otherwise. When the element is taller than it is wide, it is expected to depict a vertical gauge, with the minimum value on the bottom.

User agents are expected to use a presentation consistent with platform conventions for gauges, if any.

Note

Requirements for what must be depicted in the gauge are included in the definition of the `meter` element.

14.5.14 The `progress` element

The `progress` element is expected to render as an `inline-block` box with a `height` of '1em' and a `width` of '10em', and a `vertical-align` of '-0.2em'.

When the element is wider than it is tall, the element is expected to be depicted as a horizontal progress bar, with the start on the right and the end on the left if the `direction` property on this element has a `computed value` of 'rl', and with the start on the left and the end on the right otherwise. When the element is taller than it is wide, it is expected to be depicted as a vertical progress bar, with the lowest value on the bottom. When the element is square, it is expected to be depicted as a direction-independent progress widget (e.g. a circular progress ring).

User agents are expected to use a presentation consistent with platform conventions for progress bars. In particular, user agents are expected to use different presentations for determinate and indeterminate progress bars. User agents are also expected to vary the presentation based on the dimensions of the element.

Example

For example, on some platforms for showing indeterminate progress there is a "spinner" progress indicator with square dimensions, which could be used when the element is square, and an indeterminate progress bar, which could be used when the element is wide.

Note

Requirements for how to determine if the progress bar is determinate or indeterminate, and what progress a determinate progress bar is to show, are included in the definition of the `progress` element.

14.5.15 The `select` element

A `select` element is either a `list box` or a `drop-down box`, depending on its attributes.

A `select` element whose `multiple` attribute is absent, and whose `display-size` is greater than 1, is expected to render as a single-select `list box`.

When the element renders as a `list box`, it is expected to render as an `inline-block` box whose `height` is the height necessary to contain as many rows for items as given by the element's `display-size`, or four rows if the attribute is absent, and whose `width` is the `width` of the `select`'s labels plus the width of a scrollbar.

A `select` element whose `multiple` attribute is absent, and whose `display-size` is 1, is expected to render as a one-line `drop-down box` whose width is the `width` of the `select`'s labels.

In either case (`list box` or `drop-down box`), the element's items are expected to be the element's `list of options`, with the element's `optgroup` element `children` providing headers for groups of options where applicable.

An `optgroup` element is expected to be rendered by displaying the element's `label` attribute.

An `option` element is expected to be rendered by displaying the element's `label`, indented under its `optgroup` element if it has one.

The `width` of the `select`'s labels is the wider of the width necessary to render the widest `option`, and the width necessary to render the widest `option` element in the element's `list of options` (including its indent, if any).

If a `select` element contains a `placeholder label option`, the user agent is expected to render that `option` in a manner that conveys that it is a label, rather than a valid option of the control. This can include preventing the `placeholder label option` from being explicitly selected by the user. When the `placeholder label option's selectedness` is true, the control is expected to be displayed in a fashion that indicates that no valid option is currently selected.

User agents are expected to render the labels in a `select` in such a manner that any alignment remains consistent whether the label is being displayed as part of the page or in a menu control.

14.5.16 The `textarea` element

The `textarea` element is expected to render as an `inline-block` box depicting a multiline text control. If this multiline text control provides a selection, then, when the user changes the current selection, the user agent is expected to queue a task, using the user interaction task source, to fire an event named `select` at the element, with the `bubbles` attribute initialized to true.

If the element has a `size` attribute, and parsing that attribute's value using the `rules for parsing non-negative integers` doesn't generate an error, then the user agent is expected to use the attribute as a `presentational hint` for the `width` property on the element, with the value being the `textarea effective width` (as defined below). Otherwise, the user agent is expected to act as if it had a user-agent-level style sheet rule setting the `width` property on the element to the `textarea effective width`.

The `textarea effective width` of a `textarea` element is $size \times \text{avg } \text{char width}$, where $size$ is the element's `character width`, avg is the average character width of the primary font of the element, in `CSS pixels`, and shw is the width of a scrollbar, in `CSS pixels`. (The element's `letter-spacing` property does not affect the result.)

If the element has a `rows` attribute, and parsing that attribute's value using the `rules for parsing non-negative integers` doesn't generate an error, then the user agent is expected to use the attribute as a `presentational hint` for the `height` property on the element, with the value being the `textarea effective height` (as defined below). Otherwise, the user agent is expected to act as if it had a user-agent-level style sheet rule setting the `height` property on the element to the `textarea effective height`.

The `textarea effective height` of a `textarea` element is the height in `CSS pixels` of the number of lines specified the element's `character height`, plus the height of a scrollbar in `CSS pixels`.

User agents are expected to apply the `white-space` CSS property to `textarea` elements. For historical reasons, if the element has a `wrap` attribute whose value is an `ASCII case-insensitive` match for the string `"tt"`, then the user agent is expected to treat the attribute as a `presentational hint` setting the element's `white-space` property to `'pre'`.

14.6 Frames and framesets

User agent are expected to render `frameset` elements as a box with the height and width of the `viewport`, with a surface rendered according to the following layout algorithm:

1. Let `cols` and `rows` variables are lists of zero or more pairs consisting of a number and a unit, the unit being one of `percentage`, `relative`, and `absolute`.

Use the `rules for parsing a list of dimensions` to parse the value of the element's `cols` attribute, if there is one. Let `cols` be the result, or an empty list if there is no such attribute.

Use the `rules for parsing a list of dimensions` to parse the value of the element's `rows` attribute, if there is one. Let `rows` be the result, or an empty list if there is no such attribute.

2. For any of the entries in `cols` or `rows` that have the number zero and the unit `relative`, change the entry's number to one.

3. If `cols` has no entries, then add a single entry consisting of the value 1 and the unit `relative` to `cols`.

If `rows` has no entries, then add a single entry consisting of the value 1 and the unit `relative` to `rows`.

4. Invoke the algorithm defined below to `convert a list of dimensions to a list of pixel values` using `cols` as the input list, and the width of the surface that the `frameset` is being rendered into, in `CSS pixels`, as the input dimension. Let `sized cols` be the resulting list.

Invoke the algorithm defined below to `convert a list of dimensions to a list of pixel values` using `rows` as the input list, and the height of the surface that the `frameset` is being rendered into, in `CSS pixels`, as the input dimension. Let `sized rows` be the resulting list.

5. Split the surface into a grid of $w \times h$ rectangles, where w is the number of entries in `sized cols` and h is the number of entries in `sized rows`.

Size the columns so that each column in the grid is as many `CSS pixels` wide as the corresponding entry in the `sized cols` list.

Size the rows so that each row in the grid is as many `CSS pixels` high as the corresponding entry in the `sized rows` list.

6. Let `children` be the list of `frame` and `frameset` elements that are `children` of the `frameset` element for which the algorithm was invoked.

7. For each row of the grid of rectangles created in the previous step, from top to bottom, run these substeps:

1. For each rectangle in the row, from left to right, run these substeps:

1. If there are any elements left in `children`, take the first element in the list, and assign it to the rectangle.

If this is a `frameset` element, then recurse the entire `frameset` layout algorithm for that `frameset` element, with the rectangle as the surface.

Otherwise, it is a `frame` element; render its `nested browsing context`, positioned and sized to fit the rectangle.

2. If there are any elements left in `children`, remove the first element from `children`.

8. If the `frameset` element `has a border`, draw an outer set of borders around the rectangles, using the element's `frame border color`.

For each rectangle, if there is an element assigned to that rectangle, and that element `has a border`, draw an inner set of borders around that rectangle, using the element's `frame border color`.

For each (visible) border that does not abut a rectangle that is assigned a `frame` element with a `resizable` attribute (including rectangles in further nested `frameset` elements), the user agent is expected to allow the user to move the border, resizing the rectangles within, keeping the proportions of any nested `frameset` grids.

`A frameset or frame element has a border` if the following algorithm returns true:

1. If the element has a `frameborder` attribute whose value is not the empty string and whose first character is either a U+0031 DIGIT ONE (1) character, a U+0079 LATIN SMALL LETTER Y character (y), or a U+0059 LATIN CAPITAL LETTER Y character (Y), then return true.

2. Otherwise, if the element has a `frameborder` attribute, return false.

3. Otherwise, if the element has a parent element that is a `frameset` element, then return true if that element `has a border`, and false if it does not.

4. Otherwise, return true.

The `frame border color` of a `frameset` or `frame` element is the color obtained from the following algorithm:

1. If the element has a `bordercolor` attribute, and applying the `rules for parsing a legacy color value` to that attribute's value does not result in an error, then return the color so obtained.

2. Otherwise, if the element has a parent element that is a `frameset` element, then return the `frame border color` of that element.

3. Otherwise, return gray.

The algorithm to `convert a list of dimensions to a list of pixel values` consists of the following steps:

1. Let `input list` be the list of numbers and units passed to the algorithm.

Let `output list` be a list of numbers the same length as `input list`, all zero.

Entries in `output list` correspond to the entries in `input list` that have the same position.

2. Let `input dimension` be the size passed to the algorithm.

3. Let `count percentage` be the number of entries in `input list` whose unit is `percentage`.

Let `total percentage` be the sum of all the numbers in `input list` whose unit is `percentage`.

Let `count relative` be the number of entries in `input list` whose unit is `relative`.

Let `total relative` be the sum of all the numbers in `input list` whose unit is `relative`.

Let `count absolute` be the number of entries in `input list` whose unit is `absolute`.

Let `total absolute` be the sum of all the numbers in `input list` whose unit is `absolute`.

Let `remaining space` be the value of `input dimension`.

4. If `total absolute` is greater than `remaining space`, then for each entry in `input list` whose unit is `absolute`, set the corresponding value in `output list` to the number of the entry in `input list` multiplied by `remaining space` and divided by `total absolute`. Then, set `remaining space` to zero.

Otherwise, for each entry in `input list` whose unit is `absolute`, set the corresponding value in `output list` to the number of the entry in `input list`. Then, decrement `remaining space` by `total absolute`.

5. If `total percentage` multiplied by `input dimension` and divided by 100 is greater than `remaining space`, then for each entry in `input list` whose unit is `percentage`, set the corresponding value in `output list` to the number of the entry in `input list` multiplied by `remaining space` and divided by `total percentage`. Then, set `remaining space` to zero.

Otherwise, for each entry in `input list` whose unit is `percentage`, set the corresponding value in `output list` to the number of the entry in `input list` multiplied by the `input dimension` and divided by 100. Then, decrement `remaining space` by `total percentage` multiplied by the `input dimension` and divided by 100.

6. For each entry in `input list` whose unit is `relative`, set the corresponding value in `output list` to the number of the entry in `input list` multiplied by `remaining space` and divided by `total relative`.

7. Return `output list`.

User agents working with integer values for frame widths (as opposed to user agents that can lay frames out with subpixel accuracy) are expected to distribute the remainder first to the last entry whose unit is `relative`, then equally (not proportionally) to each entry whose unit is `percentage`, then equally (not proportionally) to each entry whose unit is `absolute`, and finally, failing all else, to the last entry.

The contents of a `frame` element that does not have a `frameset` parent are expected to be rendered as `transparent black`; the user agent is expected to not render its `nested browsing context` in this case, and its `nested browsing context` is expected to have a `viewport` with zero width and zero height.

14.7 Interactive media

14.7.1 Links, forms, and navigation

User agents are expected to allow the user to control aspects of `hyperlink` activation and `form submission`, such as which `browsing context` is to be used for the subsequent `navigation`.

User agents are expected to allow users to discover the destination of `hyperlinks` and of `forms` before triggering their `navigation`.

User agents are expected to inform the user of whether a `hyperlink` includes `hyperlink auditing`, and to let them know at a minimum which domains will be contacted as part of such auditing.

User agents may allow users to `navigate browsing contexts` to the URLs indicated by the `cite` attributes on `a`, `blockquote`, `ins`, and `del` elements.

User agents may surface `hyperlinks` created by `link` elements in their user interface.

Note

While `link` elements that create `hyperlinks` will match the `:link` or `:visited` pseudo-classes, will react to clicks if visible, and so forth, this does not extend to any browser interface constructs that expose those same links. Activating a link through the browser's interface, rather than in the page itself, does not trigger `click` events and the like.

14.7.2 The `title` attribute

User agents are expected to expose the `advisory information` of elements upon user request, and to make the user aware of the presence of such information.

On interactive graphical systems where the user can use a pointing device, this could take the form of a tooltip. When the user is unable to use a pointing device, then the user agent is expected to make the content available in some other fashion, e.g. by making the element a `focalable area` and always displaying the `advisory information` of the currently `focused` element, or by showing the `advisory information` of the elements under the user's finger on a touch device as the user pans around the screen.

U+000A LINE FEED (LF) characters are expected to cause line breaks in the tooltip; U+0009 CHARACTER TABULATION (tab) characters are expected to render as a nonzero horizontal shift that lines up the next glyph with the next tab stop, with tab stops occurring at points that are multiples of 8 times the width of a U+0020 SPACE character.

Example

For example, a visual user agent could make elements with a `title` attribute `focalable`, and could make any `focused` element with a `title` attribute show its tooltip under the element while the element has focus. This would allow a user to tab around the document to find all the advisory text.

Example

As another example, a screen reader could provide an audio cue when reading an element with a tooltip, with an associated key to read the last tooltip for which a cue was played.

14.7.3 Editing hosts

The current text editing caret (i.e. the `active_range`, if it is empty and in an `editing_host`), if any, is expected to act like an inline `replaced_element` with the vertical dimensions of the caret and with zero width for the purposes of the CSS rendering model.

Note

This means that even an empty block can have the caret inside it, and that when the caret is in such an element, it prevents `margin-top` from collapsing through the element.

14.7.4 Text rendered in native user interfaces

User agents are expected to honor the Unicode semantics of text that is exposed in user interfaces, for example supporting the bidirectional algorithm in text shown in dialogs, title bars, pop-up menus, and tooltips. Text from the contents of elements is expected to be rendered in a manner that honors the `directionality` of the element from which the text was obtained. Text from attributes is expected to be rendered in a manner that honours the `directionality` of the attribute.

Example

Consider the following markup, which has Hebrew text asking for a programming language, the languages being text for which a left-to-right direction is important given the punctuation in some of their names:

```
<form>
<label> שפה מומלצת <span>NS</span>
<select dir="rtl" lang="he">
<option value="C++" dir="ltr">C++</option>
<option value="C" dir="ltr">C</option>
<option value="C#" dir="ltr">C#</option>
<option value="Pascal" dir="rtl">Pascal</option>
<option value="P#" dir="ltr">P#</option>
</select>
</label>
</form>
```

If the `select` element was rendered as a drop down box, a correct rendering would ensure that the punctuation was the same both in the drop down, and in the box showing the current selection.

**Example**

The directionality of attributes depends on the attribute and on the element's `dir` attribute, as the following example demonstrates. Consider this markup:

```
<table>
<tr>
<td abbr="(*" dir="ltr">A
<td abbr="(*" dir="rtl">B
<td abbr="(*" dir="auto">A
</table>
```

If the `abbr` attributes are rendered, e.g. in a tooltip or other user interface, the first will have a left parenthesis (because the direction is 'ltr'), the second will have a right parenthesis (because the direction is 'rtl'), and the third will have a right parenthesis (because the direction is determined from the attribute value to be 'rtl').

However, if instead the attribute was not a `directionality-capable attribute`, the results would be different:

```
<table>
<tr>
<td data-abbr="(*" dir="ltr">A
<td data-abbr="(*" dir="rtl">B
<td data-abbr="(*" dir="auto">A
</table>
```

In this case, if the user agent were to expose the `data-abbr` attribute in the user interface (e.g. in a debugging environment), the last case would be rendered with a *left* parenthesis, because the direction would be determined from the element's contents.

A string provided by a script (e.g. the argument to `window.alert()`) is expected to be treated as an independent set of one or more bidirectional algorithm paragraphs when displayed, as defined by the bidirectional algorithm, including, for instance, supporting the paragraph-breaking behavior of U+00A LINE FEED (LF) characters. For the purposes of determining the paragraph level of such text in the bidirectional algorithm, this specification does *not* provide a higher-level override of rules P2 and P3. [BIDI]

When necessary, authors can enforce a particular direction for a given paragraph by starting it with the Unicode U+200E LEFT-TO-RIGHT MARK or U+200F RIGHT-TO-LEFT MARK characters.

Example

Thus, the following script:

```
alert("שלום HTML \u200f")
```

...would always result in a message reading "שלום HTML \u200f" (not "\u200f HTML \u200f"), regardless of the language of the user agent interface or the direction of the page or any of its elements.

Example

For a more complex example, consider the following script:

```
/* Warning: this script does not handle right-to-left scripts correctly */
if (s = prompt("What is your name?")) {
  alert('! Ok, Fred, ' + s + ', and Wilma will get the car.');
}
```

When the user enters "kitty", the user agent would alert "kitty! Ok, Fred, Kitty, and Wilma will get the car.". However, if the user enters "נמי", then the bidirectional algorithm will determine that the direction of the paragraph is right-to-left, and so the output will be the following unintended mess:

```
"נמי! Ok, Fred, !נמי וילם יקבלו מכונית."
```

To force an alert that starts with user-provided text (or other text of unknown directionality) to render left-to-right, the string can be prefixed with a U+200E LEFT-TO-RIGHT MARK character:

```
var s;
if (s = prompt("What is your name?")) {
  alert("\u200e" + s + '! Ok, Fred, ' + s + ', and Wilma will get the car.');
}
```

14.8 Print media

User agents are expected to allow the user to request the opportunity to obtain a physical form (or a representation of a physical form) of a `Document`. For example, selecting the option to print a page or convert it to PDF format. [PDF]

When the user actually obtains a physical form (or a representation of a physical form) of a `Document`, the user agent is expected to create a new rendering of the `Document` for the print media.

14.9 Unstyled XML documents

HTML user agents may, in certain circumstances, find themselves rendering non-HTML documents that use vocabularies for which they lack any built-in knowledge. This section provides for a way for user agents to handle such documents in a somewhat useful manner.

While a `Document` is an `unstyled document`, the user agent is expected to render an `unstyled document view`.

A `Document` is an *unstyled document* while it matches the following conditions:

- The `Document` has no author style sheets (whether referenced by HTTP headers, processing instructions, elements like `link`, inline elements like `style`, or any other mechanism).
- None of the elements in the `Document` have any `styling_hints`.
- None of the elements in the `Document` have any `styling_descriptions`.
- None of the elements in the `Document` are in any of the following namespaces: `HTML namespace`, `SVG namespace`, `MathML namespace`.
- The `Document` has no `font_weight` (e.g. from XLink) other than the `document`.
- The `Document` has no `hyperlinks` (e.g. from XLink).
- There exists no `script` whose `settings_object` specifies this `Document` as the `responsive_document`.
- None of the elements in the `Document` have any registered event listeners.

An `unstyled document view` is one where the DOM is not rendered according to CSS (which would, since there are no applicable styles in this context, just result in a wall of text), but is instead rendered in a manner that is useful for a developer. This could consist of just showing the `Document` object's source, maybe with syntax highlighting, or it could consist of displaying just the DOM tree, or simply a message saying that the page is not a styled document.

Note
If a `Document` stops being an `unstyled document`, then the conditions above stop applying, and thus a user agent following these requirements will switch to using the regular CSS rendering.

15 Obsolete features**15.1 Obsolete but conforming features**

Features listed in this section will trigger warnings in conformance checkers.

Authors should not specify a `border` attribute on an `img` element. If the attribute is present, its value must be the string "0". CSS should be used instead.

Authors should not specify a `charset` attribute on a `script` element. If the attribute is present, its value must be an `ASCII case-insensitive` match for "`text/html`". (This has no effect in a document that conforms to the requirements elsewhere in this standard of being encoded as `UTF-8`.)

Authors should not specify a `language` attribute on a `script` element. If the attribute is present, its value must be an `ASCII case-insensitive` match for the string "`JavaScript`" and either the `type` attribute must be omitted or its value must be an `ASCII case-insensitive` match for the string "`text/javascript`". The attribute should be entirely omitted instead (with the value "`JavaScript`", if it has no effect), or replaced with use of the `type` attribute.

Authors should not specify a `value` attribute on `script` elements. If the attribute is present, its value must be the empty string or a `JavaScript MIME type essence match`. Instead, they should omit the attribute, which has the same effect.

Authors should not specify a `type` attribute on a `style` element. If the attribute is present, its value must be an `ASCII case-insensitive` match for "`text/css`".

Authors should not specify the `name` attribute on `elements`. If the attribute is present, its value must not be the empty string and must neither be equal to the value of any of the `ID`s in the element's `trees` other than the element's own `ID`, if any, nor be equal to the value of any of the other `name` attributes on `elements` in the element's `trees`. If this attribute is present and the element has an `ID`, then the attribute's value must be equal to the element's `ID`. In earlier versions of the language, this attribute was intended as a way to specify possible targets for `fragments` in `URLs`. The `id` attribute should be used instead.

Authors should not, but may despite requirements to the contrary elsewhere in this specification, specify the `maxlength` and `size` attributes on `input` elements whose `type` attributes are in the `Number` state. One valid reason for using these attributes regardless is to help legacy user agents that do not support `input` elements with `type="number"` to still render the text control with a useful width.

15.1.1 Warnings for obsolete but conforming features

To ease the transition from HTML4 Transitional documents to the language defined in this specification, and to discourage certain features that are only allowed in very few circumstances, conformance checkers must warn the user when the following features are used in a document. These are generally old obsolete features that have no effect, and are allowed only to distinguish between likely mistakes (regular conformance errors) and mere vestigial markup or unusual and discouraged practices (these warnings).

The following features must be categorized as described above:

- The presence of a `border` attribute on an `img` element if its value is the string "0".
- The presence of a `charset` attribute on a `script` element if its value is an `ASCII case-insensitive` match for "`utf-8`".
- The presence of a `language` attribute on a `script` element if its value is an `ASCII case-insensitive` match for the string "`JavaScript`" and if there is no `type` attribute or there is and its value is an `ASCII case-insensitive` match for the string "`text/javascript`".
- The presence of a `type` attribute on a `script` element if its value is a `JavaScript MIME type essence match`.
- The presence of a `type` attribute on a `style` element if its value is an `ASCII case-insensitive` match for "`text/css`".
- The presence of a `name` attribute on a `element`, if its value is not the empty string.
- The presence of a `maxlength` attribute on an `input` element whose `type` attribute is in the `Number` state.
- The presence of a `size` attribute on an `input` element whose `type` attribute is in the `Number` state.

Conformance checkers must distinguish between pages that have no conformance errors and have none of these obsolete features, and pages that have no conformance errors but do have some of these obsolete features.

► THIS IS A REVIEW DRAFT OF THE STANDARD AND A W3C CANDIDATE RECOMMENDATION.

EXPAND

Example
For example, a validator could report some pages as "Valid HTML" and others as "Valid HTML with warnings".

15.2 Non-conforming features

Elements in the following list are entirely obsolete, and must not be used by authors:

`applet`

Use `embed` or `object` instead.

`acronym`

Use `abbr` instead.

`bgsound`

Use `audio` instead.

`dir`

Use `ul` instead.

`frame`

`frameset`

`noframes`

Either use `iframe` and CSS instead, or use server-side includes to generate complete pages with the various invariant parts merged in.

`isindex`

Use an explicit `form` and `textcontrol` combination instead.

`keygen`

For enterprise device management use cases, use native on-device management capabilities.

For certificate enrollment use cases, use the Web Cryptography API to generate a keypair for the certificate, and then export the certificate and key to allow the user to install them manually. ([WEBCRYPTO](#))

`listing`

Use `pre` and `code` instead.

`menuitem`

To implement a custom context menu, use script to handle the `contextmenu` event.

`naked`

Use GUIDs instead.

`noembed`

Use `object` instead of `embed` when fallback is necessary.

`plaintext`

Use the "`text/plain`" MIME type instead.

`rb`

`rtc`

Providing the ruby base directly inside the `ruby` element or using nested `ruby` elements is sufficient.

`strike`

Use `del` instead if the element is marking an edit, otherwise use `u` instead.

`xmp`

Use `pre` and `code` instead, and escape "<" and ">" characters as "<" and ">" respectively.

`basefont`

`big`

`blink`

`center`

`font`

`hangul`

`multitool`

`nobr`

`spacer`

`tt`

Use appropriate elements or CSS instead.

Where the `uu` element would have been used for marking up keyboard input, consider the `input` element; for variables, consider the `var` element; for computer code, consider the `code` element; and for computer output, consider the `pre` element.

Similarly, if the `uu` element is being used to denote a heading, consider using the `h1` element; if it is being used for marking up important passages, consider the `strong` element; and if it is being used for highlighting text for reference purposes, consider the `mark` element.

See also the [text-level semantics usage summary](#) for more suggestions with examples.

The following attributes are obsolete (though the elements are still part of the language), and must not be used by authors:

`charset` on `a` elements

`charset` on `link` elements

Use an HTTP "`Content-Type`" header on the linked resource instead.

`charset` on `script` elements (except as noted in the previous section)

Omit the attribute. Both documents and scripts are required to use [UUE](#), so it is redundant to specify it on the `script` element since it inherits from the document.

`coords` on `a` elements

`shape` on `a` elements

Use `area` instead of `a` for image maps.

`method` on `a` elements

`method` on `link` elements

Use the HTTP OPTIONS feature instead.

`name` on `a` elements (except as noted in the previous section)

`name` on `area` elements

`name` on `img` elements

MDN

[HTMLImageElement/name](#)

Support in all current engines.

[FirefoxYesSafariYesChrome1+](#)

[OperaYesEdge79+](#)

[Edge \(Legacy\)12+Internet Explorer?](#)

[FirefoxAndroidYesSafari iOSYesChrome AndroidYesWebView AndroidYesSamsung InternetYesOpera Android?](#)

`name` on `action` elements

Use the `id` attribute instead.

`rev` on `a` elements

`rev` on `link` elements

Use the `rel` attribute instead, with an opposite term. (For example, instead of `rev="made"`, use `rel="author"`.)

`urn` on `a` elements

`urn` on `link` elements

Specify the preferred persistent identifier using the `base` attribute instead.

`accept` on `form` elements

Use the `accept` attribute directly on the `input` elements instead.

`autocomplete` on `form` elements

These attributes do not do anything useful, and for historical reasons there are no corresponding IDL attributes on `area` elements. Omit them altogether.

`nohref` on `area` elements

Omitting the `target` attribute is sufficient; the `nohref` attribute is unnecessary. Omit it altogether.

`profile` on `head` elements

Unnecessary. Omit it altogether.

`version` on `head` elements

Unnecessary. Omit it altogether.

`ismap` on `input` elements

Unnecessary. Omit it altogether. All `input` elements with a `usemap` attribute in the `Image Button` state are processed as server-side image maps.

`usemap` on `input` elements

Use `img` instead of `input` for image maps.

`longdesc` on `iframe` elements

`longdesc` on `img` elements

lowercase on `img` elements
Use a progressive JPEG image (given in the `src` attribute), instead of using two separate images.

`target` on `link` elements
Unnecessary. Omit it altogether.

`type` on `menu` elements
To implement a custom context menu, use script to handle the `contextmenu` event. For toolbar menus, omit the attribute.

`label` on `menu` elements
`contextmenu` on all elements
`onshow` on all elements
To implement a custom context menu, use script to handle the `contextmenu` event.

`scheme` on `area` elements
Use only one scheme per field, or make the scheme declaration part of the value.

`declare` on `object` elements
Repeat the `object` element completely each time the resource is to be reused.

`standby` on `select` elements
Optimize the linked resource so that it loads quickly or, at least, incrementally.

`typecastmatch` on `object` elements
Avoid using `object` elements with untrusted resources.

`type` on `param` elements
`value` on `param` elements
Use the `name` and `value` attributes without declaring value types.

`language` on `script` elements (except as noted in the previous section)
Omit the attribute for JavaScript; for `data-blocks`, use the `type` attribute instead.

`event` on `script` elements
`for` on `script` elements
Use DOM events mechanisms to register event listeners. [DOM]

`type` on `style` elements (except as noted in the previous section)
Omit the attribute for CSS; for `data-blocks`, use `script` as the container instead of `style`.

`datapaginate` on `table` elements
Unnecessary. Omit it altogether.

`summary` on `table` elements
Use one of the [techniques for describing tables](#) given in the `table` section instead.

`abbr` on `td` elements
Use text that begins in an unambiguous and terse manner, and include any more elaborate text after that. The `title` attribute can also be useful in including more detailed text, so that the cell's contents can be made terse. If it's a heading, use `th` (which has an `abbr` attribute).

`axis` on `td` and `th` elements
Use the `scope` attribute on the relevant `th`.

`scope` on `td` elements
Use `th` elements for heading cells.

`datastore` on `button`, `div`, `frame`, `iframe`, `img`, `input`, `label`, `legend`, `marquee`, `object`, `option`, `select`, `span`, `table`, and `textarea` elements
`datastoreid` on `button`, `div`, `fieldset`, `frame`, `iframe`, `img`, `input`, `label`, `legend`, `marquee`, `object`, `param`, `select`, `span`, and `textarea` elements
`datastoreid` on `button`, `div`, `input`, `label`, `legend`, `marquee`, `object`, `param`, `select`, `span`, and `table` elements

Use script and a mechanism such as `XMLHttpRequest` to populate the page dynamically. [XHR]

`dragzone` on all elements
Use script to handle the `dragenter` and `dragover` events instead.

`alink` on `body` elements
`bgcolor` on `body` elements
`bottommargin` on `body` elements
`leftmargin` on `body` elements
`link` on `body` elements
`marginheight` on `body` elements
`marginwidth` on `body` elements
`rightmargin` on `body` elements
`text` on `body` elements
`topmargin` on `body` elements
`vlink` on `body` elements
`clear` on `hr` elements
`align` on `hr` elements
`align` on `img` elements
`char` on `img` elements
`charoff` on `img` elements
`valign` on `img` elements
`width` on `img` elements
`align` on `input` elements
`compact` on `input` elements
`align` on `embed` elements
`hspace` on `embed` elements
`vspace` on `embed` elements
`align` on `input` elements
`cols` on `input` elements
`noisindex` on `input` elements
`size` on `input` elements
`width` on `input` elements
`align` on `input` elements
`compact` on `input` elements
`align` on `input` elements
`allowtransparency` on `frame` elements
`frameborder` on `frame` elements
`framespacing` on `frame` elements
`hspace` on `frame` elements
`noisindex` on `frame` elements
`noisindex` on `frame` elements
`scrolling` on `frame` elements
`vspace` on `frame` elements
`align` on `input` elements
`border` on `input` elements

```

Use CSS instead.

15.3 Requirements for implementations

15.3.1 The marquee element

The marquee element is a presentational element that animates content. CSS transitions and animations are a more appropriate mechanism. [CSSANIMATIONS] [CSSTRANSITIONS]

The task source for tasks mentioned in this section is the DOM manipulation task source.

```

IDL[Exposed=Window]
interface HTMLOutlineElement : HTMLElement {
  [HTMLElement] constructor();
  [CEReactions] attribute DOMString behavior;
  [CEReactions] attribute DOMString bgcolor;
  [CEReactions] attribute DOMString dir;
  [CEReactions] attribute DOMString height;
  [CEReactions] attribute unsigned long hspace;
  [CEReactions] attribute unsigned long scrollAmount;
  [CEReactions] attribute unsigned long scrollDelay;
  [CEReactions] attribute unsigned long vpace;
  [CEReactions] attribute DOMString width;
  attribute EventHandler onbounce;
  attribute EventHandler onfinish;
  attribute EventHandler onstart;
  void start();
  void stop();
}

```

A marquee element can be turned on or turned off. When it is created, it is turned on.

When the start() method is called, the marquee element must be turned on.

When the stop() method is called, the marquee element must be turned off.

When a marquee element is created, the user agent must queue a task to fire an event named start at the element.

The behavior content attribute on marquee elements is an enumerated attribute with the following keywords (all non-conforming):

Keyword State
scroll scroll
slide slide
alternate alternate

The missing value default and invalid value default are the scroll state.

The direction content attribute on marquee elements is an enumerated attribute with the following keywords (all non-conforming):

Keyword State
left left
right right
up up
down down

The missing value default and invalid value default are the left state.

The trueSpeed content attribute on marquee elements is a boolean attribute.

A marquee element has a marquee scroll interval, which is obtained as follows:

- If the element has a scrollDelay attribute, and parsing its value using the rules for parsing non-negative integers does not return an error, then let delay be the parsed value. Otherwise, let delay be 85.
- If the element does not have a trueSpeed attribute, and the delay value is less than 60, then let delay be 60 instead.
- The marquee scroll interval is delay, interpreted in milliseconds.

A marquee element has a marquee scroll distance, which, if the element has a scrollAmount attribute, and parsing its value using the rules for parsing non-negative integers does not return an error, is the parsed value interpreted in CSS pixels, and otherwise is 6 CSS pixels.

A marquee element has a marquee loop count, which, if the element has a loop attribute, and parsing its value using the rules for parsing integers does not return an error or a number less than 1, is the parsed value, and otherwise is -1. The loop IDL attribute, on getting, must return the element's marquee loop count; and on setting, if the new value is different than the element's marquee loop count and either greater than zero or equal to -1, must set the element's loop content attribute (adding it if necessary) to the valid integer that represents the new value. (Other values are ignored.)

A marquee element also has a marquee current loop index, which is zero when the element is created.

The rendering layer will occasionally increment the marquee current loop index, which must cause the following steps to be run:

- If the marquee loop count is -1, then return.
- Increment the marquee current loop index by one.
- If the marquee current loop index is now equal to or greater than the element's marquee loop count, turn off the marquee element and queue a task to fire an event named finish at the marquee element.
- Otherwise, if the behavior attribute is in the alternate state, then queue a task to fire an event named bounce at the marquee element.
- Otherwise, queue a task to fire an event named start at the marquee element.

The following are the event handlers (and their corresponding event handler event types) that must be supported, as event handler content attributes and event handler IDL attributes, by marquee elements:

Event handler Event handler event type

onbounce bounce
onfinish finish
onstart start

The behavior, direction, height, hspace, vspace, and width IDL attributes must reflect the respective content attributes of the same name.

The bgColor IDL attribute must reflect the bgcolor content attribute.

The scrollAmount IDL attribute must reflect the scrollAmount content attribute. The default value is 6.

The scrollDelay IDL attribute must reflect the scrollDelay content attribute. The default value is 85.

The trueSpeed IDL attribute must reflect the trueSpeed content attribute.

15.3.2 Frames

The frameset element acts as the body element in documents that use frames.

The frameset element must implement the HTMLFrameSetElement interface.

[**JSON**]

HTMLFrameSetElement

Support in all current engines.

Firefox 1+ Safari Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes

IDL[Exposed=Window]
interface HTMLFrameSetElement : HTMLElement {
 [HTMLElement] constructor();
 [CEReactions] attribute DOMString cols;

`IDLExposedWindow` includes `WindowEventHandlers`.
The `cols` and `rows` IDL attributes of the `frame` element must `reflect` the respective content attributes of the same name.
The `frameset` element exposes as `event handler attributes` a number of the `event handlers` of the `window` object. It also mirrors their `event handler IDL attributes`.

The `event handlers` of the `window` object named by the `frame`-reflecting `body` element `event handler set`, exposed on the `frameset` element, replace the generic `event handlers` with the same names normally supported by `HTML elements`.

The `frame` element has a `nested browsing context` similar to the `iframe` element, but rendered within a `frameset` element.

A `frame` element is said to be an `active frame element` when it is `in a document`.

When a `frame` element `element` is created as an `active frame element`, or becomes an `active frame element` after not having been one, the user agent must run these steps:

1. Create a new nested browsing context for element.
2. Process the `frame` attributes for the first time.

When a `frame` element stops being an `active frame element`, the user agent must `discard` the element's `nested browsing context`, and then set the element's `nested browsing context` to null.

Whenever a `frame` element with a non-null `nested browsing context` has its `src` attribute set, changed, or removed, the user agent must `process the frame attributes`.

When the user agent is to `process the frame attributes`, it must run the first appropriate steps from the following list:

If the element has no `src` attribute specified, and the user agent is processing the `frame`'s attributes for the first time:

 Queue a task to fire an event named `load` at the `frame` element using the `DOM manipulation task source`.

Otherwise:

 Run the otherwise steps for `iframe` or `frame` elements.

Any `navigation` required of the user agent in the `process the frame attributes` algorithm must use the `frame` element's `node document's browsing context` as the `source browsing context`.

Furthermore, if the `active document` of the element's `nested browsing context` before such a `navigation` was not `completely loaded` at the time of the new `navigation`, then the `navigation` must be completed with `replacement enabled`.

Similarly, if the element's `nested browsing context's session history` contained only one `document`, when the `process the frame attributes` algorithm was invoked, and that was the `about:blank document` created when its `nested browsing context` was created, then any `navigation` required of the user agent in that algorithm must be completed with `replacement enabled`.

When a `document` in a `frame` is marked as `completely loaded`, the user agent must `fire an event` named `load` at the `frame` element.

The `frame` element `potentially delays the load event`.

The `frame` element must implement the `HTMLFrameElement` interface.

```
IDLExposedWindow
interface HTMLFrameElement : HTMLElement {
    [HTMLConstructor] constructor();
    [CRActions] attribute DOMString name;
    [CRActions] attribute DOMString scrolling;
    [CRActions] attribute DOMString longdesc;
    [CRActions] attribute DOMString border;
    [CRActions] attribute DOMString marginheight;
    [CRActions] attribute DOMString marginwidth;
    [CRActions] attribute boolean noresize;
    [CRActions] attribute Document? parentDocument;
    [CRActions] attribute WindowProxy? contentWindow;
    [CRActions] attribute [TreatNullAs=EmptyString] DOMString marginheight;
    [CRActions] attribute [TreatNullAs=EmptyString] DOMString marginwidth;
};
```

The `name`, `scrolling`, and `src` IDL attributes of the `frame` element must `reflect` the respective content attributes of the same name. For the purposes of reflection, the `frame` element's `src` content attribute is defined as containing a `URL`.

The `frameborder` IDL attribute of the `frame` element must `reflect` the element's `frameborder` content attribute.

The `longdesc` IDL attribute of the `frame` element must `reflect` the element's `longdesc` content attribute, which for the purposes of reflection is defined as containing a `URL`.

The `noresize` IDL attribute of the `frame` element must `reflect` the element's `noresize` content attribute.

The `contentDocument` IDL attribute, on getting, must return the `frame` element's `content document`.

The `contentWindow` IDL attribute must return the `WindowProxy` object of the `frame` element's `nested browsing context`, if the element's `nested browsing context` is non-null, or return null otherwise.

The `marginheight` IDL attribute of the `frame` element must `reflect` the element's `marginheight` content attribute.

The `marginwidth` IDL attribute of the `frame` element must `reflect` the element's `marginwidth` content attribute.

15.3.3 Other elements, attributes and APIs

User agents must treat `area` elements in a manner equivalent to `a` elements in terms of semantics and for purposes of rendering.

```
IDLpartial interface HTMLAreaElement {
    [CRActions] attribute DOMString coords;
    [CRActions] attribute DOMString href;
    [CRActions] attribute DOMString hreflang;
    [CRActions] attribute DOMString name;
    [CRActions] attribute DOMString type;
    [CRActions] attribute DOMString alt;
};
```

The `coords`, `charset`, `name`, `rev`, and `shape` IDL attributes of the `a` element must `reflect` the respective content attributes of the same name.

```
IDLpartial interface HTMLAreaElement {
    [CRActions] attribute boolean noRef;
};
```

The `noRef` IDL attribute of the `area` element must `reflect` the element's `noRef` content attribute.

```
IDLpartial interface HTMLBodyElement {
    [CRActions] attribute [TreatNullAs=EmptyString] DOMString text;
    [CRActions] attribute [TreatNullAs=EmptyString] DOMString link;
    [CRActions] attribute [TreatNullAs=EmptyString] DOMString vlink;
    [CRActions] attribute [TreatNullAs=EmptyString] DOMString alink;
    [CRActions] attribute [TreatNullAs=EmptyString] DOMString bgcolor;
    [CRActions] attribute DOMString background;
};
```

The `text` IDL attribute of the `body` element must `reflect` the element's `text` content attribute.

The `link` IDL attribute of the `body` element must `reflect` the element's `link` content attribute.

The `alink` IDL attribute of the `body` element must `reflect` the element's `alink` content attribute.

The `vlink` IDL attribute of the `body` element must `reflect` the element's `vlink` content attribute.

The `bgcolor` IDL attribute of the `body` element must `reflect` the element's `bgcolor` content attribute.

The `background` IDL attribute of the `body` element must `reflect` the element's `background` content attribute. (The `background` content is *not* defined to contain a `URL`, despite rules regarding its handling in the rendering section above.)

```
IDLpartial interface HTMLBRElement {
    [CRActions] attribute DOMString clear;
};
```

The `clear` IDL attribute of the `br` element must `reflect` the content attribute of the same name.

```
IDLpartial interface HTMLECaptionElement {
    [CRActions] attribute DOMString align;
};
```

The `align` IDL attribute of the `caption` element must `reflect` the content attribute of the same name.

```
IDLpartial interface HTMLETableCaptionElement {
    [CRActions] attribute DOMString align;
    [CRActions] attribute DOMString border;
    [CRActions] attribute DOMString chOff;
    [CRActions] attribute DOMString valign;
    [CRActions] attribute DOMString width;
};
```

The `align` and `width` IDL attributes of the `caption` element must `reflect` the respective content attributes of the same name.

The `chOff` IDL attribute of the `caption` element must `reflect` the element's `chOff` content attribute.

The `valign` IDL attribute of the `caption` element must `reflect` the element's `valign` content attribute.

User agents must treat `div` elements in a manner equivalent to `p` elements in terms of semantics and for purposes of rendering.

```
The div element must implement the HTMLDirectoryElement interface.
IDLExposedWindow
interface HTMLDirectoryElement : HTMLElement {
    [HTMLConstructor] constructor();
    [CRActions] attribute boolean compact;
};
```

The `compact` IDL attribute of the `div` element must `reflect` the content attribute of the same name.

```
IDLpartial interface HTMLDivElement {
    [CRActions] attribute DOMString align;
};
```

The `align` IDL attribute of the `div` element must `reflect` the content attribute of the same name.

```
IDLpartial interface HTMLFormElement {
    [CRActions] attribute boolean compact;
};
```

The `compact` IDL attribute of the `div` element must `reflect` the content attribute of the same name.

```
IDLpartial interface HTMLImageElement {
    [CRActions] attribute DOMString align;
    [CRActions] attribute DOMString name;
};
```

The `name` and `align` IDL attributes of the `img` element must `reflect` the respective content attributes of the same name.

The `font` element must implement the `HTMLFontElement` interface.

```
IDL [Exposed=Window]
interface HTMLFontElement : HTMLElement
  [NOFORWARD] attribute [TreatNullAs=EmptyString] DOMString color;
  [NOFORWARD] attribute DOMString face;
  [NOFORWARD] attribute DOMString size;
};

The color, face, and size IDL attributes of the font element must reflect the respective content attributes of the same name.
```

```
IDLpartial interface HTMLHeadingElement {
  [NOFORWARD] attribute DOMString align;
};

The align IDL attribute of the h1-h6 elements must reflect the content attribute of the same name.
```

Note
The `profile` IDL attribute on `head` elements (with the `HTMLHeadElement` interface) is intentionally omitted. Unless so required by another applicable specification, implementations would therefore not support this attribute. (It is mentioned here as it was defined in a previous version of DOM.)

```
IDLpartial interface HTMLImageElement {
  [NOFORWARD] attribute DOMString align;
  [NOFORWARD] attribute boolean noShade;
  [NOFORWARD] attribute DOMString alt;
  [NOFORWARD] attribute DOMString width;
};

The align, color, size, and width IDL attributes of the img element must reflect the respective content attributes of the same name.
```

The `noShade` IDL attribute of the `img` element must `reflect` the element's `noShade` content attribute.

```
IDLpartial interface HTMLTableElement {
  [NOFORWARD] attribute DOMString align;
  [NOFORWARD] attribute DOMString border;
  [NOFORWARD] attribute DOMString cellPadding;
  [NOFORWARD] attribute DOMString cellSpacing;
  [NOFORWARD] attribute [TreatNullAs=EmptyString] DOMString marginHeight;
  [NOFORWARD] attribute [TreatNullAs=EmptyString] DOMString marginWidth;
};

The align and scrolling IDL attributes of the frame element must reflect the respective content attributes of the same name.
```

The `frameBorder` IDL attribute of the `frame` element must `reflect` the element's `frameborder` content attribute.

The `longDesc` IDL attribute of the `frame` element must `reflect` the element's `longdesc` content attribute, which for the purposes of reflection is defined as containing a [URL](#).

The `marginHeight` IDL attribute of the `frame` element must `reflect` the element's `marginheight` content attribute.

The `marginWidth` IDL attribute of the `frame` element must `reflect` the element's `marginwidth` content attribute.

```
IDLpartial interface HTMLFrameElement {
  [NOFORWARD] attribute DOMString name;
  [NOFORWARD] attribute DOMString longDesc;
  [NOFORWARD] attribute unsigned long marginHeight;
  [NOFORWARD] attribute unsigned long marginWidth;
  [NOFORWARD] attribute DOMString border;
};

ZMDN
```

HTMLImageElement/border

HTMLImageElement/vspace

Support in all current engines.

FirefoxYesSafariYesChrome1+

OperaYesEdge79+

Edge (Legacy)12+Internet Explorer?

Firefox AndroidYes Safari iOSYes Chrome AndroidYes WebView AndroidYes Samsung InternetYes Opera AndroidYes

The `name`, `align`, `border`, `height`, and `vspace` IDL attributes of the `img` element must `reflect` the respective content attributes of the same name.

The `longDesc` IDL attribute of the `img` element must `reflect` the element's `longdesc` content attribute, which for the purposes of reflection is defined as containing a [URL](#).

The `lowsrc` IDL attribute of the `img` element must `reflect` the element's `lowsrc` content attribute, which for the purposes of reflection is defined as containing a [URL](#).

```
IDLpartial interface HTMLImageElement {
  [NOFORWARD] attribute DOMString align;
  [NOFORWARD] attribute DOMString lowsrc;
};

The align IDL attribute of the input element must reflect the content attribute of the same name.
```

The `useMap` IDL attribute of the `input` element must `reflect` the element's `usemap` content attribute.

```
IDLpartial interface HTMLLegendElement {
  [NOFORWARD] attribute DOMString align;
};

The align IDL attribute of the legend element must reflect the content attribute of the same name.
```

```
IDLpartial interface HTMLUListElement {
  [NOFORWARD] attribute DOMString type;
};

The type IDL attribute of the ul element must reflect the content attribute of the same name.
```

The `charset`, `rev`, and `target` IDL attributes of the `link` element must `reflect` the respective content attributes of the same name.

Use agents must treat `listing` elements in a manner equivalent to `pre` elements in terms of semantics and for purposes of rendering.

```
IDLpartial interface HTMLMenuItemElement {
  [NOFORWARD] attribute boolean compact;
};

The compact IDL attribute of the menu element must reflect the content attribute of the same name.
```

```
IDLpartial interface HTMLFormElement {
  [NOFORWARD] attribute DOMString scheme;
};

The suggested processing of this markup, however, would be equivalent to the following:
```

```
<meta name="edMS:subject:keyword" schema="LOGL" content="Abandoned vehicles">
<meta name="edMS:subject:keyword" schema="ORLY" content="Mah car: kthxbye">
```

User agents may treat the `schema` content attribute on the `meta` element as an extension of the element's `name` content attribute when processing a `meta` element with a `name` attribute whose value is one that the user agent recognizes as supporting the `schema` attribute.

User agents encouraged to ignore the `schema` attribute and instead process the value given to the metadata name as if it had been specified for each expected value of the `schema` attribute.

Example

For example, if the user agent acts on `meta` elements with `name` attribute having the value "eGMS:subject:keyword", and knows that the `schema` attribute is used with this metadata name, then it could take the `schema` attribute into account, acting as if it was an extension of the `name` attribute. Thus the following two `meta` elements could be treated as two elements giving value for two different metadata names, one consisting of a combination of "eGMS:subject:keyword" and "LOCL", and the other consisting of a combination of "eGMS:subject:keyword" and "ORLY":

```
<!-- this markup is invalid -->
<meta name="eGMS:subject:keyword" schema="LOCL" content="Abandoned vehicles">
<meta name="eGMS:subject:keyword" schema="ORLY" content="Mah car: kthxbye">
```

The suggested processing of this markup, however, would be equivalent to the following:

```
<meta name="eGMS:subject:keyword" content="Abandoned vehicles">
<meta name="eGMS:subject:keyword" content="Mah car: kthxbye">
```

The `schema` IDL attribute of the `meta` element must `reflect` the content attribute of the same name.

```
IDLpartial interface HTMLObjectElement {
  [NOFORWARD] attribute DOMString align;
  [NOFORWARD] attribute DOMString code;
  [NOFORWARD] attribute unsigned long height;
  [NOFORWARD] attribute DOMString name;
  [NOFORWARD] attribute DOMString codeBase;
  [NOFORWARD] attribute DOMString codeType;
  [NOFORWARD] attribute [TreatNullAs=EmptyString] DOMString border;
};

The align, code, height, name, codeBase, codeType, and border IDL attributes of the object element must reflect the respective content attributes of the same name.
```

The `codeBase` IDL attribute of the `object` element must [reflect](#) the element's `codebase` content attribute, which for the purposes of reflection is defined as containing a [URL](#).

The `codeType` IDL attribute of the `object` element must [reflect](#) the element's `codetype` content attribute.

`IDPartial interface HTMLListElement {
 [CRActions] attribute boolean compact;
};`

The `compact` IDL attribute of the `ul` element must [reflect](#) the content attribute of the same name.

`IDPartial interface HTMLParagraphElement {
 [CRActions] attribute DOMString align;
};`

The `align` IDL attribute of the `p` element must [reflect](#) the content attribute of the same name.

`IDPartial interface HTMLTextElement {
 [CRActions] attribute DOMString type;
 [CRActions] attribute DOMString valueType;
};`

The `type` IDL attribute of the `input` element must [reflect](#) the content attribute of the same name.

The `valueType` IDL attribute of the `param` element must [reflect](#) the element's `valueType` content attribute.

User agents must treat `plaintext` elements in a manner equivalent to `pre` elements in terms of semantics and for purposes of rendering. (The parser has special behavior for this element, though.)

`IDPartial interface HTMLPreElement {
 [CRActions] attribute long width;
};`

The `width` IDL attribute of the `pre` element must [reflect](#) the content attribute of the same name.

`IDPartial interface HTMLStyleElement {
 [CRActions] attribute DOMString type;
};`

The `type` IDL attribute of the `style` element must [reflect](#) the element's `type` content attribute.

`IDPartial interface HTMLScriptElement {
 [CRActions] attribute DOMString charset;
 [CRActions] attribute DOMString event;
 [CRActions] attribute DOMString htmlFor;
};`

The `charset` and `event` IDL attributes of the `script` element must [reflect](#) the respective content attributes of the same name.

The `htmlFor` IDL attribute of the `script` element must [reflect](#) the element's `for` content attribute.

`IDPartial interface HTMLTableElement {
 [CRActions] attribute DOMString align;
 [CRActions] attribute DOMString border;
 [CRActions] attribute DOMString frame;
 [CRActions] attribute DOMString rules;
 [CRActions] attribute DOMString summary;
 [CRActions] attribute DOMString width;
 [CRActions] attribute [TreatNullAs=EmptyString] DOMString bgColor;
 [CRActions] attribute [TreatNullAs=EmptyString] DOMString cellPadding;
 [CRActions] attribute [TreatNullAs=EmptyString] DOMString cellSpacing;
};`

The `align`, `border`, `frame`, `summary`, and `width` IDL attributes of the `table` element must [reflect](#) the respective content attributes of the same name.

The `bgColor` IDL attribute of the `table` element must [reflect](#) the element's `bgColor` content attribute.

The `cellPadding` IDL attribute of the `table` element must [reflect](#) the element's `cellpadding` content attribute.

The `cellspacing` IDL attribute of the `table` element must [reflect](#) the element's `cellspacing` content attribute.

`IDPartial interface HTMLTableSectionElement {
 [CRActions] attribute DOMString align;
 [CRActions] attribute DOMString border;
 [CRActions] attribute DOMString cellOfff;
 [CRActions] attribute DOMString valign;
};`

The `align` IDL attribute of the `tbody`, `thead`, and `tfoot` elements must [reflect](#) the content attribute of the same name.

The `ch` IDL attribute of the `tbody`, `thead`, and `tfoot` elements must [reflect](#) the elements' `char` content attributes.

The `charoff` IDL attribute of the `tbody`, `thead`, and `tfoot` elements must [reflect](#) the elements' `charoff` content attributes.

The `vAlign` IDL attribute of the `tbody`, `thead`, and `tfoot` element must [reflect](#) the elements' `vAlign` content attributes.

`IDPartial interface HTMLTableCaptionElement {
 [CRActions] attribute DOMString align;
 [CRActions] attribute DOMString axis;
 [CRActions] attribute DOMString ch;
 [CRActions] attribute DOMString chOfff;
 [CRActions] attribute DOMString width;
 [CRActions] attribute DOMString ch;
 [CRActions] attribute DOMString chOfff;
 [CRActions] attribute boolean nowrap;
 [CRActions] attribute DOMString valign;
 [CRActions] attribute [TreatNullAs=EmptyString] DOMString bgColor;
};`

The `align`, `axis`, `height`, and `width` IDL attributes of the `td` and `th` elements must [reflect](#) the respective content attributes of the same name.

The `ch` IDL attribute of the `td` and `th` elements must [reflect](#) the elements' `char` content attributes.

The `charoff` IDL attribute of the `td` and `th` elements must [reflect](#) the elements' `charoff` content attributes.

The `nowrap` IDL attribute of the `td` and `th` elements must [reflect](#) the elements' `nowrap` content attributes.

The `vAlign` IDL attribute of the `td` and `th` elements must [reflect](#) the elements' `vAlign` content attributes.

The `bgColor` IDL attribute of the `td` and `th` elements must [reflect](#) the elements' `bgColor` content attributes.

`IDPartial interface HTMLTableDataCellElement {
 [CRActions] attribute DOMString align;
 [CRActions] attribute DOMString ch;
 [CRActions] attribute DOMString chOfff;
 [CRActions] attribute DOMString height;
 [CRActions] attribute DOMString width;
 [CRActions] attribute [TreatNullAs=EmptyString] DOMString bgColor;
};`

The `align` IDL attribute of the `td` element must [reflect](#) the content attribute of the same name.

The `ch` IDL attribute of the `td` element must [reflect](#) the element's `char` content attribute.

The `charoff` IDL attribute of the `td` element must [reflect](#) the element's `charoff` content attribute.

The `height` IDL attribute of the `td` element must [reflect](#) the element's `height` content attribute.

The `width` IDL attribute of the `td` element must [reflect](#) the element's `width` content attribute.

The `bgColor` IDL attribute of the `td` element must [reflect](#) the element's `bgColor` content attribute.

`IDPartial interface HTMLTableCaptionElement {
 [CRActions] attribute boolean compact;
 [CRActions] attribute DOMString type;
};`

The `compact` and `type` IDL attributes of the `caption` element must [reflect](#) the respective content attributes of the same name.

User agents must treat `www` elements in a manner equivalent to `pre` elements in terms of semantics and for purposes of rendering. (The parser has special behavior for this element though.)

`IDPartial interface Document {
 [CRActions] attribute [TreatNullAs=EmptyString] DOMString fgColor;
 [CRActions] attribute [TreatNullAs=EmptyString] DOMString linkColor;
 [CRActions] attribute [TreatNullAs=EmptyString] DOMString vlinkColor;
 [CRActions] attribute [TreatNullAs=EmptyString] DOMString alinkColor;
 [CRActions] attribute [TreatNullAs=EmptyString] DOMString bgColor;
 [SameObject] readonly attribute HTMLCollection anchors;
 [SameObject] readonly attribute HTMLCollection pings;
 void clear();
 void captureEvents();
 void releaseEvents();
 [SameObject] readonly attribute HTMLAllCollection all;
};`

The attributes of the `Document` object listed in the first column of the following table must [reflect](#) the content attribute on the `body` element with the name given in the corresponding cell on the same row, if the `body` element is a `body` element (as opposed to a `frameset` element). When there is no `body` element or if it is a `frameset` element, the attributes must instead return the empty string on getting and do nothing on setting.

IDL attribute Content attribute

<code>fgColor</code>	<code>text</code>
<code>linkColor</code>	<code>link</code>
<code>vlinkColor</code>	<code>vlink</code>
<code>alinkColor</code>	<code>alink</code>
<code>bgColor</code>	<code>bgcolor</code>

The `anchors` attribute must return an `HTMLCollection` rooted at the `Document` node, whose filter matches only `a` elements with `name` attributes.

The `applies` attribute must return an `HTMLCollection` rooted at the `Document` node, whose filter matches nothing. (It exists for historical reasons.)

The `clear()`, `captureEvents()`, and `releaseEvents()` methods must do nothing.

The `all` attribute must return an `HTMLAllCollection` rooted at the `Document` node, whose filter matches all elements.

```
void releaseEvents();
  ↪ [Replaceable, SameObject] readonly attribute External external;
}

The captureEvents() and releaseEvents() methods must do nothing.

The external attribute of the window interface must return an instance of the External interface.

IDI[EventSearchProvider]
interface EventSearch {
  void AddSearchProvider();
  void IsSearchProviderInstalled();
}

The AddSearchProvider() and IsSearchProviderInstalled() methods must do nothing.
```

16 IANA considerations

16.1 text/html

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:
text
Subtype name:
html
Required parameters:
No required parameters
Optional parameters:
charset

The charset parameter may be provided to specify the document's character encoding, overriding any character encoding declarations in the document other than a Byte Order Mark (BOM). The parameter's value must be an ASCII case-insensitive match for the string "utf-8" [ENCODING].

Encoding considerations:
SRI (see the section on character encoding declarations)
Security considerations:

Entire novels have been written about the security considerations that apply to HTML documents. Many are listed in this document, to which the reader is referred for more details. Some general concerns bear mentioning here, however:

HTML is scripted language, and has a large number of APIs (some of which are described in this document). Script can expose the user to potential risks of information leakage, credential leakage, cross-site scripting attacks, cross-site request forgeries, and a host of other problems. While the designs in this specification are intended to be safe if implemented correctly, a full implementation is a massive undertaking and, as with any software, user agents are likely to have security bugs.

Even without scripting, there are specific features in HTML which, for historical reasons, are required for broad compatibility with legacy content but that expose the user to unfortunate security problems. In particular, the img element can be used in conjunction with some other features as a way to effect a port scan from the user's location on the Internet. This can expose local network topologies that the attacker would otherwise not be able to determine.

HTML relies on a compartmentalization scheme sometimes known as the same-origin policy. An origin in most cases consists of all the pages served from the same host, on the same port, using the same protocol.

It is critical, therefore, to ensure that any untrusted content that forms part of a site be hosted on a different origin than any sensitive content on that site. Untrusted content can easily spoof any other page on the same origin, read data from that origin, cause scripts in that origin to execute, submit forms to and from that origin even if they are protected from cross-site request forgeries by unique tokens, and make use of any third-party resources exposed to or rights granted to that origin.

Interoperability considerations:

Rules for processing both conforming and non-conforming content are defined in this specification.

Published specification:
This document is the relevant specification. Labeling a resource with the text/html type asserts that the resource is an HTML document using the HTML syntax.

Applications that use this media type:
Web browsers, tools for processing Web content, HTML authoring tools, search engines, validators.

Additional information:

Magic number(s):
The sequence of bytes can uniquely identify an HTML document. More information on detecting HTML documents is available in MIME Sniffing [MIMESNIFF].

File extension(s):
".htm" and ".html" are commonly, but certainly not exclusively, used as the extension for HTML documents.

Macintosh file type codes(s):
WZC

Person & email address to contact for further information:
Ian Hickson <ian@hixie.ch>

Intended usage:

Common

Restrictions on usage:

No restrictions apply.

Author:
Ian Hickson <ian@hixie.ch>

Change controller:
W3C

Fragments used with text/html resources either refer to the indicated part of the document or provide state information for in-page scripts.

16.2 multipart/x-mixed-replace

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:
multipart

Subtype name:
x-mixed-replace

Required parameters:
None

Optional parameters:
Content-type (defined in RFC2046) [RFC2046]

File extension(s):

No specific file extensions are recommended for this type.

Macintosh file type codes(s):

No specific Macintosh file type codes are recommended for this type.

Person & email address to contact for further information:
Ian Hickson <ian@hixie.ch>

Intended usage:

Common

Restrictions on usage:

No restrictions apply.

Author:
Ian Hickson <ian@hixie.ch>

Change controller:
W3C

Fragments used with multipart/x-mixed-replace resources apply to each body part as defined by the type used by that body part.

16.3 application/xhtml+xml

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:
application

Subtype name:
xhtml+xml

Required parameters:
Same as for application/xml [RFC7303]

Optional parameters:
Same as for application/xml [RFC7303]

Encoded considerations:
Same as for application/xml [RFC7303]

Security considerations:
Same as for application/xml [RFC7303]

Intercerfacing considerations:
Same as for application/xml [RFC7303]

Published specification:
Labeling a resource with the application/xhtml+xml type asserts that the resource is an XML document that likely has a document element from the HTML namespace. Thus, the relevant specifications are XML, Namespaces in XML, and this specification. [XML] [XMLNS]

Applications that use this media type:
Same as for application/xml [RFC7303]

Additional information:
Magic number(s):
Same as for application/xml [RFC7303]

File extension(s):

".xhtml" and ".xml" are sometimes used as extensions for XML resources that have a document element from the HTML namespace.

Macintosh file type codes(s):

Person & email address to contact for further information:
Ian Hickson <ian@hixie.ch>

Intended usage:

Common

Restrictions on usage:

No restrictions apply.

Author:
Ian Hickson <ian@hixie.ch>

Change controller:
W3C

Fragments used with application/xhtml+xml resources have the same semantics as with any XML MIME type [RFC7303].

16.4 text/cache-manifest

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:
text

Subtype name:
cache-manifest

Required parameters:
No parameters
Optional parameters:
`charset`

The `charset` parameter may be provided. The parameter's value must be "`utf-8`". This parameter serves no purpose; it is only allowed for compatibility with legacy servers.

Encoding considerations:
Shift (always UTF-8)
Security considerations:

Cache manifests themselves pose no immediate risk unless sensitive information is included within the manifest. Implementations, however, are required to follow specific rules when populating a cache based on a cache manifest, to ensure that certain origin-based restrictions are honored. Failure to correctly implement these rules can result in information leakage, cross-site scripting attacks, and the like.

Interoperability considerations:
Rules for processing both conforming and non-conforming content are defined in this specification.

Published specification:
This document is the relevant specification.

Applications that use this media type:
Web browsers.

Additional information:
Magic number(s):

Cache manifests begin with the string "`CACHE MANIFEST`", followed by either a U+0020 SPACE character, a U+0009 CHARACTER TABULATION (tab) character, a U+00A LINE FEED (LF) character, or a U+00D CARRIAGE RETURN (CR) character.

File extension(s):

"`appcache`"

Macintosh file type codes:

No specific Macintosh file type codes are recommended for this type.

Person & email address to contact for further information:
Ian Hickson <ian@hixie.ch>

Intended usage:
Common

Restrictions on usage:
No restrictions apply.

Author:
Ian Hickson <ian@hixie.ch>

Change controller:
W3C

Fragments have no meaning with `text/cache-manifest` resources.

16.5 `text/ping`

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:
`text`
Subtype name:
`ping`
Required parameters:
No parameters
Optional parameters:
`charset`

The `charset` parameter may be provided. The parameter's value must be "`utf-8`". This parameter serves no purpose; it is only allowed for compatibility with legacy servers.

Encoding considerations:
Not applicable.
Security considerations:

If used exclusively in the fashion described in the context of [hyperlink auditing](#), this type introduces no new security concerns.

Interoperability considerations:
Rules applicable to this type are defined in this specification.

Published specification:
This document is the relevant specification.

Applications that use this media type:
Web browsers.

Additional information:
Magic number(s):

`text/ping` resources always consist of the four bytes 0x50 0x49 0x4E 0x47 ('PING').

File extension(s):

No specific file extension is recommended for this type.

Macintosh file type codes:

No specific Macintosh file type codes are recommended for this type.

Person & email address to contact for further information:
Ian Hickson <ian@hixie.ch>

Intended usage:
Common

Restrictions on usage:
Only intended for use with HTTP POST requests generated as part of a Web browser's processing of the `ping` attribute.

Author:
Ian Hickson <ian@hixie.ch>

Change controller:
W3C

Fragments have no meaning with `text/ping` resources.

16.6 `application/microdata+json`

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:
`application`
Subtype name:
`microdata+json`
Required parameters:
Same as for [application/json](#) [JSON]

Optional parameters:
Same as for [application/json](#) [JSON]

Encoding considerations:

Shift (always UTF-8)

Security considerations:
Same as for [application/json](#) [JSON]

Interoperability considerations:
Same as for [application/json](#) [JSON]

Published specification:

Labels a resource with the `application/microdata+json` type asserts that the resource is a JSON text that consists of an object with a single entry called "`items`" consisting of an array of entries, each of which consists of an object with an entry called "`id`" whose value is a string, an entry called "`type`" whose value is another string, and an entry called "`properties`" whose value is an object whose entries each have a value consisting of an array of either objects or strings, the objects being of the same form as the objects in the aforementioned "`items`" entry. Thus, the relevant specifications are [JSON](#) and this specification. [\[JSON\]](#)

Applications that use this media type:

Applications that transfer data intended for use with HTML's microdata feature, especially in the context of drag-and-drop, are the primary application class for this type.

Additional information:

Magic number(s):

Same as for [application/json](#) [JSON]

File extension(s):

Same as for [application/json](#) [JSON]

Macintosh file type codes:

Same as for [application/json](#) [JSON]

Person & email address to contact for further information:
Ian Hickson <ian@hixie.ch>

Intended usage:
Common

Restrictions on usage:
No restrictions apply.

Author:
Ian Hickson <ian@hixie.ch>

Change controller:
W3C

Fragments used with `application/microdata+json` resources have the same semantics as when used with `application/json` (namely, at the time of writing, no semantics at all). [\[JSON\]](#)

16.7 `text/event-stream`

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:
`text`
Subtype name:
`event-stream`
Required parameters:
No parameters
Optional parameters:
`charset`

The `charset` parameter may be provided. The parameter's value must be "`utf-8`". This parameter serves no purpose; it is only allowed for compatibility with legacy servers.

Encoding considerations:
Shift (always UTF-8)
Security considerations:

An event stream from an origin distinct from the origin of the content consuming the event stream can result in information leakage. To avoid this, user agents are required to apply CORS semantics. [\[FETCH\]](#)

Event streams can overwhelm a user agent; a user agent is expected to apply suitable restrictions to avoid depleting local resources because of an overabundance of information from an event stream.

Servers can be overwhelmed if a situation develops in which the server is causing clients to reconnect rapidly. Servers should use a 5xx status code to indicate capacity problems, as this will prevent conforming clients from reconnecting automatically.

Interoperability considerations:

Rules for processing both conforming and non-conforming content are defined in this specification.

Published specification:
This document is the relevant specification.

Applications that use this media type:
Web browsers and tools using Web services.

Additional information:
Magic number(s):

No sequence of bytes can uniquely identify an event stream.

File extension(s):

No specific Macintosh file type codes are recommended for this type.

Person & email address to contact for further information:

Ian Hickson <ian@hixie.ch>

Intended usage:

Comment

Restrictions on usage:

This format is only expected to be used by dynamic open-ended streams served using HTTP or a similar protocol. Finite resources are not expected to be labeled with this type.

Author:

Ian Hickson <ian@hixie.ch>

Change controller:

W3C

Fragments have no meaning with [text/event-stream](#) resources.

16.8 'Ping-From'

This section describes a header for registration in the Permanent Message Header Field Registry: [\[RFC3864\]](#)

Header field name:

Ping-From

Applicable protocol:

http

Status:

standard

Author/Change controller:

W3C

Specification document(s):

This document is the relevant specification.

Related information:

None.

16.9 'Ping-To'

This section describes a header for registration in the Permanent Message Header Field Registry: [\[RFC3864\]](#)

Header field name:

Ping-To

Applicable protocol:

http

Status:

standard

Author/Change controller:

W3C

Specification document(s):

This document is the relevant specification.

Related information:

None.

16.10 'Refresh'

This section describes a header for registration in the Permanent Message Header Field Registry: [\[RFC3864\]](#)

Header field name:

Refresh

Applicable protocol:

http

Status:

standard

Author/Change controller:

WHATWG

Specification document(s):

This document is the relevant specification.

Related information:

None.

16.11 'Last-Event-ID'

This section describes a header for registration in the Permanent Message Header Field Registry: [\[RFC3864\]](#)

Header field name:

Last-Event-ID

Applicable protocol:

http

Status:

standard

Author/Change controller:

W3C

Specification document(s):

This document is the relevant specification.

Related information:

None.

16.12 web+ scheme prefix

This section describes a convention for use with the IANA URI scheme registry. It does not itself register a specific scheme: [\[RFC795\]](#)

Scheme name:

Schemes starting with the four characters "web+" followed by one or more letters in the range a-z.

Status:

Final

Scheme syntax:

Scheme-specific

Scheme semantics:

Scheme-specific

Encoding considerations:

All "web+" schemes should use UTF-8 encodings where relevant.

Applications protocols that use this scheme name:

Scheme-specific

Interoperability considerations:

The scheme is expected to be used in the context of Web applications.

Security considerations:

Any Web page is able to register a handler for all "web+" schemes. As such, these schemes must not be used for features intended to be core platform features (e.g. network transfer protocols like HTTP or FTP). Similarly, such schemes must not store confidential information in their URLs, such as usernames, passwords, personal information, or confidential project names.

Contacts:

Ian Hickson <ian@hixie.ch>

Change controller:

Ian Hickson <ian@hixie.ch>

References:

[Custom scheme handlers](#), HTML Living Standard: <https://html.spec.whatwg.org/#custom-handlers>

Index

The following sections only cover conforming elements and features.

Elements

This section is non-normative.

Element	Description	Categories	Parents*	Children	List of elements	Attributes	Interface
a	Hyperlink	flow; phrasing*, interactive; palpable	phrasing	transparent*	globals: href; target; download; ping; rel; referrerpolicy		HTMLAnchorElement
abbr	Abbreviation	flow; phrasing; palpable	phrasing	phrasing	globals		HTMLElement
address	Contact information for a page or article element	flow; palpable	flow	flow*	globals		HTMLElement

<code>fieldset</code>	Group of form controls	<code>flow; positioning; root; listed; form-associated; palpable</code>	<code>flow</code>	<code>legend*; flow</code>	<code>globals; disabled; form; name</code>	<code>HTMLFieldSetElement</code>
<code>figcaption</code>	Caption for <code>figure</code>	<code>flow</code>	<code>flow</code>	<code>flow</code>	<code>globals</code>	<code>HTMLElement</code>
<code>figure</code>	Figure with optional caption	<code>flow; sectioning root; palpable</code>	<code>flow</code>	<code>figcaption*; flow</code>	<code>globals</code>	<code>HTMLFigureElement</code>
<code>footer</code>	Footer for a page or section	<code>flow; palpable</code>	<code>flow</code>	<code>flow*</code>	<code>globals</code>	<code>HTMLElement</code>
<code>form</code>	User-submittable form	<code>flow; palpable</code>	<code>flow</code>	<code>flow*</code>	<code>globals; accept-charset; action; autocomplete; enctype; method; name; novalidate; target</code>	<code>HTMLFormElement</code>
<code>h1</code> <code>h2</code> <code>h3</code> <code>h4</code> <code>h5</code> <code>h6</code>	Section heading	<code>flow; heading; palpable</code>	<code>hgroup; flow</code>	<code>phrasing</code>	<code>globals</code>	<code>HTMLHeadingElement</code>
<code>head</code>	Container for document metadata	none	<code>html</code>	<code>meta-data; content*</code>	<code>globals</code>	<code>HTMLHeadElement</code>
<code>header</code>	Introductory or navigational aids for a page or section	<code>flow; palpable</code>	<code>flow</code>	<code>flow*</code>	<code>globals</code>	<code>HTMLElement</code>
<code>hgroup</code>	heading group	<code>flow; heading; palpable</code>	<code>flow</code>	<code>h1; h2; h3; h4; h5; h6; script-supporting elements</code>	<code>globals</code>	<code>HTMLElement</code>
<code>hr</code>	Thematic break	<code>flow</code>	<code>flow</code>	<code>empty</code>	<code>globals</code>	<code>HTMLHRElement</code>
<code>html</code>	Root element	none	<code>none*</code>	<code>head*; body*</code>	<code>globals; manifest</code>	<code>HTMLHtmlElement</code>
<code>i</code>	Alternate voice	<code>flow; phrasing; palpable</code>	<code>phrasing</code>	<code>phrasing</code>	<code>globals</code>	<code>HTMLTextElement</code>
<code>iframe</code>	Nested browsing context	<code>flow; phrasing; embedded; interactive; palpable</code>	<code>phrasing</code>	empty	<code>globals; src; srcdoc; name; sandbox; allow; fullscreen; allowpaymentrequest; width; height; referrerpolicy</code>	<code>HTMLIFrameElement</code>
<code>img</code>	Image	<code>flow; phrasing; embedded; interactive*; form-associated; palpable</code>	<code>phrasing; picture</code>	<code>empty</code>	<code>globals; alt; alt-set; crossorigin; usemap; img-x; width; height; decoding; referrerpolicy</code>	<code>HTMLImageElement</code>
<code>input</code>	Form control	<code>flow; phrasing; interactive*; listed; labelable; submitable; resettable; form-associated; palpable</code>	<code>phrasing</code>	<code>empty</code>	<code>globals; accept; alt; autocomplete; checked; dirname; disabled; form; formation; formenctype; formmethod; formnovalidate; step; value; required; size; step-size; step-step; step-type; step-value; width</code>	<code>HTMLInputElement</code>
<code>ins</code>	An addition to the document	<code>flow; phrasing*; palpable</code>	<code>phrasing</code>	<code>transparent</code>	<code>globals</code>	<code>HTMLModElement</code>
<code>kbd</code>	User input	<code>flow; phrasing; palpable</code>	<code>phrasing</code>	<code>phrasing</code>	<code>globals</code>	<code>HTMLKeyElement</code>
<code>label</code>	Caption for a form control	<code>flow; phrasing; interactive; palpable</code>	<code>phrasing</code>	<code>phrasing*</code>	<code>globals</code>	<code>HTMLLabelElement</code>
<code>legend</code>	Caption for <code>fieldset</code>	none	<code>fieldset</code>	<code>phrasing</code>	<code>globals</code>	<code>HTMLLegendElement</code>
<code>li</code>	List item	none	<code>ol; ul; menu*</code>	<code>flow</code>	<code>globals; value*</code>	<code>HTMLListElement</code>
<code>link</code>	Link metadata	<code>metadata; flow*; phrasing*</code>	<code>head; pointer*</code>	<code>phrasing*</code>	<code>globals; href; crossorigin; rel; as; media; hreflang; type; sizes; imagesrcset; imagesizes; referrerpolicy; integrity</code>	<code>HTMLLinkElement</code>
<code>main</code>	Container for the dominant contents of the document	<code>flow; palpable</code>	<code>flow*</code>	<code>flow</code>	<code>globals</code>	<code>HTMLElement</code>
<code>map</code>	Image map	<code>flow; phrasing*; palpable</code>	<code>phrasing</code>	<code>transparent; area*</code>	<code>globals</code>	<code>HTMLMapElement</code>
<code>mark</code>	Highlight	<code>flow; phrasing; palpable</code>	<code>phrasing</code>	<code>phrasing</code>	<code>globals</code>	<code>HTMLElement</code>
<code>math</code>	MathML root	<code>flow; palpable*</code>	<code>flow</code>	<code>1; script-supporting elements</code>	<code>globals</code>	<code>per [MATHML]</code>
<code>menu</code>	Menu of commands	<code>text metadata</code>	<code>head; noscript*</code>	<code>empty</code>	<code>globals</code>	<code>HTMLMenuElement</code>
<code>meta</code>	Text metadata	<code>flow; phrasing*; palpable</code>	<code>phrasing</code>	<code>name; http-equiv; content; charset</code>	<code>globals</code>	<code>HTMLMetaElement</code>
<code>meter</code>	Gauge	<code>flow; phrasing; labelable; palpable</code>	<code>phrasing</code>	<code>value; min; max; low; high; optimum</code>	<code>globals</code>	<code>HTMLMeterElement</code>
<code>nav</code>	Section with navigational links	<code>flow; sectioning; palpable</code>	<code>flow; sectioning; palpable</code>	<code>flow</code>	<code>globals</code>	<code>HTMLElement</code>
<code>noscript</code>	Fallback content for script	<code>flow; phrasing; interactive*; listed; labelable; palpable</code>	<code>phrasing</code>	<code>script; transparent</code>	<code>globals</code>	<code>HTMLNoScriptElement</code>
<code>object</code>	Image, nested browsing context, or plugin	<code>flow; phrasing; embedded; interactive*; listed; labelable; palpable</code>	<code>phrasing</code>	<code>param*, transparent</code>	<code>globals; data-type; name; usemap; form; width; height</code>	<code>HTMLObjectElement</code>
<code>ol</code>	Ordered list	none	<code>list-item*</code>	<code>list-item*</code>	<code>globals; reversed; start; type</code>	<code>HTMLOLListElement</code>
<code>optgroup</code>	Group of options in a list box	<code>option</code>	<code>select</code>	<code>optgroup*</code>	<code>globals; disabled; label; selected; value</code>	<code>HTMLOptGroupElement</code>
<code>option</code>	Option in a list box or combo box	none	<code>select</code>	<code>text</code>	<code>globals; for; form-name</code>	<code>HTMLOptionElement</code>
<code>output</code>	Calculated output value	<code>flow; phrasing; listed; labelable; resettable; form-associated; palpable</code>	<code>phrasing</code>	<code>phrasing</code>	<code>globals</code>	<code>HTMLOutputElement</code>
<code>p</code>	Paragraph	<code>flow; palpable</code>	<code>flow</code>	<code>phrasing</code>	<code>globals; name; value</code>	<code>HTMLParagraphElement</code>
<code>param</code>	Parameter for <code>object</code>	none	<code>object</code>	<code>empty</code>	<code>globals</code>	<code>HTMLParamElement</code>
<code>picture</code>	Image	<code>flow; phrasing; embedded</code>	<code>phrasing</code>	<code>src*; one; lang; script-supporting elements</code>	<code>globals</code>	<code>HTMLPictureElement</code>
<code>pre</code>	Block of preformatted text	<code>flow; palpable</code>	<code>flow</code>	<code>phrasing</code>	<code>globals</code>	<code>HTMLPreElement</code>
<code>progress</code>	Progress bar	<code>flow; phrasing; labelable; palpable</code>	<code>phrasing</code>	<code>phrasing*</code>	<code>globals; value; max</code>	<code>HTMLProgressElement</code>
<code>s</code>	Quotation	<code>flow; phrasing; palpable</code>	<code>phrasing</code>	<code>phrasing</code>	<code>globals; cite</code>	<code>HTMLQuotationElement</code>
<code>rt</code>	Ruby annotation text	none	<code>ruby</code>	<code>phrasing</code>	<code>globals</code>	<code>HTMLTextElement</code>
<code>rb</code>	Ruby annotation(s)	<code>flow; phrasing; palpable</code>	<code>phrasing</code>	<code>phrasing; rt; rt*</code>	<code>globals</code>	<code>HTMLTextElement</code>
<code>s</code>	Inaccurate text	<code>flow; phrasing; palpable</code>	<code>phrasing</code>	<code>phrasing</code>	<code>globals</code>	<code>HTMLTextElement</code>
<code>small</code>	Computer output	<code>flow; phrasing; palpable</code>	<code>phrasing</code>	<code>phrasing</code>	<code>globals</code>	<code>HTMLTextElement</code>
<code>script</code>	Embedded script	<code>metadata; flow; phrasing; script-supporting supporting</code>	<code>head; phrasing; script-supporting</code>	<code>script, data, or script documentation*</code>	<code>globals; src-type; async; defer; crossorigin; integrity; referrerpolicy</code>	<code>HTMLScriptElement</code>
<code>section</code>	Generic document or application section	<code>flow; sectioning; palpable</code>	<code>flow</code>	<code>flow</code>	<code>globals</code>	<code>HTMLSectionElement</code>
<code>select</code>	List box control	<code>flow; phrasing; interactive; listed; labelable; resettable; form-associated; palpable</code>	<code>phrasing</code>	<code>option;optgroup; script-supporting elements</code>	<code>globals; autocomplete; disabled; form; multiple; name; required; size</code>	<code>HTMLSelectElement</code>
<code>slot</code>	Shadow tree slot	none	<code>shadow-root*</code>	<code>transparent</code>	<code>globals; name</code>	<code>HTMLSlotElement</code>
<code>small</code>	Side comment	<code>flow; phrasing; palpable</code>	<code>phrasing</code>	<code>phrasing</code>	<code>globals</code>	<code>HTMLTextElement</code>
<code>source</code>	Image source for <code>img</code> or media source for <code>video</code> or <code>audio</code>	none	<code>picture; video; audio</code>	<code>empty</code>	<code>globals; src-type; srcset; sizes; media</code>	<code>HTMLSourceElement</code>
<code>span</code>	Generic phrasing container	<code>flow; phrasing; palpable</code>	<code>phrasing</code>	<code>phrasing</code>	<code>globals</code>	<code>HTMLSpanElement</code>
<code>strong</code>	Emboldened styling information	<code>flow; phrasing; palpable</code>	<code>phrasing</code>	<code>phrasing</code>	<code>globals</code>	<code>HTMLTextElement</code>
<code>sub</code>	Subscript	<code>metadata</code>	<code>head; noscript*</code>	<code>text</code>	<code>globals; media</code>	<code>HTMLTextElement</code>
<code>summary</code>	Caption for <code>details</code>	none	<code>details</code>	<code>phrasing</code>	<code>globals</code>	<code>HTMLTextElement</code>
<code>sup</code>	Superscript	<code>flow; phrasing; palpable</code>	<code>phrasing</code>	<code>phrasing</code>	<code>globals</code>	<code>HTMLTextElement</code>
<code>SVG</code>	SVG root	<code>flow; phrasing; embedded; palpable</code>	<code>phrasing</code>	<code>per [SVG]</code>	<code>per [SVG]</code>	<code>SVGSVGElement</code>
<code>table</code>	Table	<code>flow; palpable</code>	<code>flow</code>	<code>caption; colgroup*; thead; tbody*; tfoot*; t; script-supporting elements</code>	<code>globals</code>	<code>HTMLTableElement</code>
<code>tbody</code>	Group of rows in a table	none	<code>table</code>	<code>script-supporting elements</code>	<code>globals</code>	<code>HTMLTableSectionElement</code>
<code>td</code>	Table cell	<code>scripting; root</code>	<code>t</code>	<code>script</code>	<code>globals; colspan; rowspan; headers</code>	<code>HTMLTableCellElement</code>
<code>template</code>	Template	<code>metadata; flow; phrasing; script-supporting supporting</code>	<code>colspan*</code>	<code>empty</code>	<code>globals</code>	<code>HTMLTemplateElement</code>
<code>textarea</code>	Multiline text controls	<code>flow; phrasing; interactive; listed; labelable; resettable; form-associated; palpable</code>	<code>phrasing</code>	<code>text</code>	<code>globals; cols; dirlang; disabled; form; maxlen; minlength; name; placeholder; readonly; rows; wrap</code>	<code>HTMLTextAreaElement</code>
<code>tfoot</code>	Group of footer rows in a table	none	<code>table</code>	<code>script-supporting elements</code>	<code>globals</code>	<code>HTMLTableSectionElement</code>
<code>th</code>	Table header cell	<code>interactive*</code>	<code>th</code>	<code>flow*</code>	<code>globals; colspan; rowspan; headers; scope; abbr</code>	<code>HTMLTableHeaderCellElement</code>
<code>thead</code>	Group of heading rows in a table	none	<code>table</code>	<code>script-supporting elements</code>	<code>globals</code>	<code>HTMLTableSectionElement</code>
<code>time</code>	Machine-readable equivalent of date- or time-related data	<code>flow; phrasing; palpable</code>	<code>phrasing</code>	<code>phrasing</code>	<code>globals; datetime</code>	<code>HTMLTimeElement</code>
<code>title</code>	Document title	<code>metadata</code>	<code>head; text</code>	<code>text</code>	<code>globals</code>	<code>HTMLTitleElement</code>
<code>u</code>	Table row	none	<code>table; head; tbody; tfoot</code>	<code>*, sc; script-supporting elements</code>	<code>globals</code>	<code>HTMLTableRowElement</code>
<code>track</code>	Timed text track	none	<code>audio; video</code>	<code>empty</code>	<code>globals; default; kind; label; src; srclang</code>	<code>HTMLTrackElement</code>
<code>u</code>	Unarticulated annotation	<code>flow; phrasing; palpable</code>	<code>phrasing</code>	<code>phrasing</code>	<code>globals</code>	<code>HTMLTextElement</code>
<code>ul</code>	List	<code>flow; palpable*</code>	<code>flow</code>	<code>1; script-supporting elements</code>	<code>globals</code>	<code>HTMLULListElement</code>
<code>var</code>	Variable	<code>flow; phrasing; palpable</code>	<code>phrasing</code>	<code>phrasing</code>	<code>globals</code>	<code>HTMLTextElement</code>
<code>video</code>	Video player	<code>flow; phrasing; embedded; interactive; palpable</code>	<code>phrasing</code>	<code>source*; track*; transparent*</code>	<code>globals; src; crossorigin; poster; preload; autoplay; playsinline; loop; muted; controls; width; height</code>	<code>HTMLVideoElement</code>
<code>wbr</code>	Line breaking opportunity	<code>flow; phrasing</code>	<code>phrasing</code>	<code>empty</code>	<code>globals</code>	<code>HTMLTextElement</code>
<code>custom elements</code>	Author-defined elements	<code>flow; phrasing; palpable</code>	<code>flow; phrasing</code>	<code>transparent</code>	<code>globals; any, as decided by the element's author</code>	Supplied by the element's author (inherits from <code>HTMLElement</code>)

Categories in the "Parents" column refer to parents that list the given categories in their content model, not a parent to an α element.

Element content categories
This section lists the element categories.

This section is non-normative.

Category

Category	Elements	Elements with exceptions
Autocapitalize input elements	<code>button</code> : <code>fieldset</code> : <code>input</code> : <code>output</code> : <code>select</code> : <code>textarea</code>	
Labelable elements	<code>button</code> : <code>input</code> : <code>meter</code> : <code>output</code> : <code>progress</code> : <code>select</code> : <code>textarea</code> : <code>form-associated custom elements</code>	
Palpable content	<code>a</code> : <code>area</code> : <code>address</code> : <code>article</code> : <code>aside</code> : <code>button</code> : <code>checkbox</code> : <code>button</code> : <code>canvas</code> : <code>code</code> : <code>data</code> : <code>details</code> : <code>dfn</code> : <code>div</code> : <code>em</code> : <code>embed</code> : <code>fieldset</code> : <code>figure</code> : <code>footer</code> : <code>form</code> : <code>hi</code> : <code>h3</code> : <code>h4</code> : <code>h5</code> : <code>h6</code> : <code>header</code> : <code>img</code> : <code>input</code> : <code>map</code> : <code>img</code> : <code>label</code> : <code>main</code> : <code>mark</code> : <code>Math</code> : <code>math</code> : <code>meter</code> : <code>nav</code> : <code>object</code> : <code>output</code> : <code>p</code> : <code>pre</code> : <code>progress</code> : <code>q</code> : <code>span</code> : <code>section</code> : <code>select</code> : <code>small</code> : <code>span</code> : <code>strong</code> : <code>sub</code> : <code>sup</code> : <code>SVG</code> : <code>table</code> : <code>tbody</code> : <code>tfoot</code> : <code>tr</code> : <code>td</code> : <code>th</code> : <code>u</code> : <code>video</code> : <code>input</code> : <code>autonomous custom elements</code>	
Script-supporting elements	<code>script</code> : <code>template</code>	
* The <code>tabindex</code> attribute can also make any element into interactive content .		
Attributes		
This section is non-normative.		
Attribute	Element(s)	List of attributes (excluding event handler content attributes)
<code>abbr</code>	<code>abbr</code>	Alternative label to use for the header cell when referencing the cell in other contexts
<code>accept</code>	<code>input</code>	Hint for expected file type in file upload controls
<code>accept-charset</code>	<code>form</code>	Character encodings to use for form submission
<code>accesskey</code>	<code>HTML elements</code>	Keyboard shortcut to activate or focus element
<code>action</code>	<code>form</code>	URL to use for form submission
<code>allow</code>	<code>iframe</code>	
<code>allowFullScreen</code>	<code>iframe</code>	Whether to allow the <code>iframe</code> 's contents to use the <code>requestFullScreen()</code> interface to make payment requests
<code>allowPaymentRequest</code>	<code>iframe</code>	Whether the <code>iframe</code> 's contents are allowed to use the <code>PaymentRequest</code> interface to make payment requests
<code>alt</code>	<code>area</code> : <code>img</code> : <code>input</code>	Replacement text for use when images are not available
<code>as</code>	<code>link</code>	Potential destination for a preload request (for <code>rel="preload"</code> and <code>rel="modulepreload"</code>)
<code>async</code>	<code>script</code>	Execute script when available, without blocking while fetching
<code>autocomplete</code>	<code>HTML elements</code>	Recommended autocompletion behavior (for supported input methods)
<code>autocomplete</code>	<code>input</code> : <code>select</code> : <code>textarea</code>	Default setting for autofill feature for controls in the form
<code>autofocus</code>	<code>HTML elements</code>	Hint for form autofill feature
<code>autoplay</code>	<code>audio</code> : <code>video</code>	Automatically focus the element when the page is loaded
<code>charset</code>	<code>meta</code>	Hint that the character set can be started automatically when the page is loaded
<code>checked</code>	<code>input</code>	Character setting declaration
<code>date</code>	<code>input</code> : <code>button</code> : <code>del</code> : <code>ins</code> : <code>q</code>	Whether the control is checked
<code>class</code>	<code>HTML elements</code>	Link to the source of the quotation or more information about the edit
<code>color</code>	<code>input</code>	Classes to which the element belongs
<code>cols</code>	<code>textarea</code>	Color to use when customizing a site's icon (for <code>rel="mask-icon"</code>)
<code>colspan</code>	<code>td</code> : <code>th</code>	Maximum number of characters per line
<code>content</code>	<code>meta</code>	Number of columns that the cell is to span
<code>contenteditable</code>	<code>HTML elements</code>	Value of the element
<code>controls</code>	<code>audio</code> : <code>video</code>	Whether the element is editable
<code>coords</code>	<code>area</code>	Show user agent controls
<code>crossorigin</code>	<code>audio</code> : <code>img</code> : <code>link</code> : <code>script</code> : <code>video</code>	Coordinates for the shape to be created in an image map
<code>data</code>	<code>object</code>	How the element handles crossorigin requests
<code>datetime</code>	<code>datETIME</code>	Address of the resource
		Date and (optionally) time of the change
		Machine-readable value
<code>decoding</code>	<code>img</code>	Decoding hint to use when processing this image for presentation
<code>default</code>	<code>track</code>	Enable the track if no other <code>text track</code> is more suitable
<code>defers</code>	<code>script</code>	Defer script execution
<code>dir</code>	<code>HTML elements</code>	The text directionality of the element
<code>dir</code>	<code>body</code>	The text directionality of the element
<code>dirname</code>	<code>input</code> : <code>textarea</code>	Name of form control to use for sending the element's directionality in form submission
<code>disabled</code>	<code>form-associated custom elements</code>	Whether the form control is disabled
<code>disabled</code>	<code>fieldset</code>	Whether the descendant form controls, except any inside <code>legend</code> , are disabled
<code>download</code>	<code>a</code> : <code>area</code>	Whether to download the resource instead of navigating to it, and its file name if so
<code>draggable</code>	<code>HTML elements</code>	Whether the element is draggable
<code>enterkeyhint</code>	<code>HTML elements</code>	Entry list encoding type to use for form submission
<code>for</code>	<code>label</code>	Hint for selecting an enter key action
<code>for</code>	<code>output</code>	Associate the label with form control
<code>form</code>	<code>form</code>	Specifiers controls from which the output was calculated
<code>formaction</code>	<code>button</code> : <code>fieldset</code> : <code>input</code> : <code>object</code> : <code>output</code> : <code>select</code> : <code>textarea</code>	Associates the element with a <code>form</code> element
<code>formenctype</code>	<code>button</code> : <code>input</code>	URL to use for form submission
<code>formmethod</code>	<code>button</code> : <code>input</code>	Entry list encoding type to use for form submission
<code>formnovalidate</code>	<code>button</code> : <code>input</code>	Variant to use for form submission
<code>formtarget</code>	<code>button</code> : <code>input</code>	Bypass form control validation for form submission
<code>headers</code>	<code>link</code> : <code>th</code>	Browsing context for form submission
<code>height</code>	<code>canvas</code> : <code>embed</code> : <code>iframe</code> : <code>img</code> : <code>input</code> : <code>object</code>	The header cells for this cell
<code>hidden</code>	<code>HTML elements</code>	Vertical dimension
<code>high</code>	<code>meter</code>	Whether the element is relevant
<code>href</code>	<code>a</code> : <code>area</code>	Low limit of high range
<code>href</code>	<code>link</code>	Address of the hyperlink
<code>href</code>	<code>base</code>	Address of the hyperlink
<code>hreflang</code>	<code>a</code> : <code>link</code>	Document base URL
<code>http-equiv</code>	<code>meta</code>	Language of the linked resource
<code>id</code>	<code>HTML elements</code>	Pragma directive
<code>imagesizes</code>	<code>img</code>	The element's <code>ID</code>
<code>imageorient</code>	<code>img</code>	Image size for different page layouts
<code>inputmode</code>	<code>HTML elements</code>	Images to use in different situations (e.g., high-resolution displays, small monitors, etc.)
<code>integrity</code>	<code>img</code> : <code>script</code>	Hint for selecting an input modality
<code>is</code>	<code>HTML elements</code>	Integrity metadata used in Resource Integrity checks (SRI)
<code>ismap</code>	<code>img</code>	Creates a customized built-in element
<code>itemmid</code>	<code>HTML elements</code>	Whether the image is a server-side image map
<code>itemprop</code>	<code>HTML elements</code>	Global identifier for a microdata item
<code>itemref</code>	<code>HTML elements</code>	Property name of a microdata item
<code>itemscope</code>	<code>HTML elements</code>	Referenced elements
<code>itemtype</code>	<code>HTML elements</code>	Introduces a microdata item
<code>kind</code>	<code>track</code>	<code>itemType</code> of a microdata item
<code>label</code>	<code>optgroup</code> : <code>option</code> : <code>track</code>	Type of text track
<code>lang</code>	<code>HTML elements</code>	User-visible label
<code>list</code>	<code>input</code>	Language of the element
<code>loop</code>	<code>audio</code> : <code>video</code>	List of autocomplete options
<code>low</code>	<code>meter</code>	Whether to loop the media resource
<code>manifest</code>	<code>html</code>	High limit of low range
<code>max</code>	<code>input</code>	Application cache manifest
<code>maxlength</code>	<code>input</code> : <code>textarea</code>	Maximum value
<code>media</code>	<code>input</code> : <code>source</code> : <code>style</code>	Upper bound of range
<code>method</code>	<code>form</code>	Maximum length of value
<code>min</code>	<code>input</code>	Applicable media
<code>minlength</code>	<code>input</code>	Variants to use for form submission
<code>multiple</code>	<code>input</code> : <code>select</code>	Minimum value
<code> muted</code>	<code>audio</code> : <code>video</code>	Lower bound of range
<code>name</code>	<code>button</code> : <code>fieldset</code> : <code>input</code> : <code>output</code> : <code>select</code> : <code>textarea</code>	Minimum length of value
<code>name</code>	<code>form</code>	Whether to allow multiple values
<code>noModule</code>	<code>script</code>	Whether to mute the media resource by default
<code>nonce</code>	<code>HTML elements</code>	Name of the element to use for form submission and in the form-elements API
<code>noValidate</code>	<code>form</code>	Name of form to use in the document.form API
<code>open</code>	<code>details</code>	Name of nested browsing context
<code>open</code>	<code>dialog</code>	Name of image map to reference from the <code>usemap</code> attribute
<code>optimum</code>	<code>meter</code>	Metadata name
<code>pattern</code>	<code>input</code>	Name of parameter
<code>ping</code>	<code>a</code> : <code>area</code>	Name of shadow tree slot
<code>placeholder</code>	<code>input</code> : <code>textarea</code>	Prevents executors in user agents that support module scripts
<code>playinline</code>	<code>video</code>	Cryptographic nonce used in Content Security Policy checks (CSP)
<code>poster</code>	<code>video</code>	Bypass form control validation for form submission
<code>preload</code>	<code>audio</code> : <code>video</code>	Whether the details are visible
<code>readonly</code>	<code>input</code> : <code>textarea</code>	Whether the dialog box is showing
<code>readonly</code>	<code>form-associated custom elements</code>	Optimum value in gauge
<code>referrerpolicy</code>	<code>a</code> : <code>area</code> : <code>img</code> : <code>link</code> : <code>script</code>	Pattern to be matched by the form control's value
<code>rel</code>	<code>a</code> : <code>area</code>	<code>URL</code> to ping
<code>rel</code>	<code>link</code>	User-visible label to be placed within the form control
<code>rel</code>	<code>video</code>	Encourage the user agent to display video content within the element's playback area
<code>rel</code>	<code>video</code>	Poster frame to show prior to video playback
<code>rel</code>	<code>video</code>	Hints how much buffering the media resource will likely need
<code>rel</code>	<code>video</code>	Whether to allow the value to be edited by the user
<code>rel</code>	<code>form-associated custom elements</code>	Affects <code>willValidate</code> , plus any behavior added by the custom element author
<code>rel</code>	<code>link</code>	Referer policy for <code>fetches</code> initiated by the element
<code>rel</code>	<code>a</code> : <code>area</code> : <code>img</code> : <code>link</code> : <code>script</code>	Relationship between the location in the document containing the hyperlink and the destination resource
<code>rel</code>	<code>link</code>	Relationship between the document containing the hyperlink and the destination resource

Attribute	Element(s)	Description	Value
onabort	HTML elements	abort event handler	Event handler content attribute
oncancelclick	HTML elements	cancelclick event handler	Event handler content attribute
oncancelscript	body	cancelscript event handler for <code>Window</code> object	Event handler content attribute
onbeforeprint	body	beforeprint event handler for <code>Window</code> object	Event handler content attribute
onbeforewrite	body	beforewrite event handler for <code>Window</code> object	Event handler content attribute
onbeforewindowload	body	beforewindowload event handler for <code>Window</code> object	Event handler content attribute
onblur	HTML elements	blur event handler	Event handler content attribute
oncancel	HTML elements	cancel event handler	Event handler content attribute
oncancelplay	HTML elements	cancelplay event handler	Event handler content attribute
oncancelplaythrough	HTML elements	cancelplaythrough event handler	Event handler content attribute
onchange	HTML elements	change event handler	Event handler content attribute
onclick	HTML elements	click event handler	Event handler content attribute
onclose	HTML elements	close event handler	Event handler content attribute
oncontextmenu	HTML elements	contextmenu event handler	Event handler content attribute
oncopy	HTML elements	copy event handler	Event handler content attribute
onchangechange	HTML elements	changechange event handler	Event handler content attribute
oncut	HTML elements	cut event handler	Event handler content attribute
ondblclick	HTML elements	dblclick event handler	Event handler content attribute
ondrag	HTML elements	drag event handler	Event handler content attribute
ondragend	HTML elements	dragend event handler	Event handler content attribute
ondragenter	HTML elements	dragenter event handler	Event handler content attribute
ondragexit	HTML elements	dragexit event handler	Event handler content attribute
ondragleave	HTML elements	dragleave event handler	Event handler content attribute
ondragover	HTML elements	dragover event handler	Event handler content attribute
ondragstart	HTML elements	dragstart event handler	Event handler content attribute
ondrop	HTML elements	drop event handler	Event handler content attribute
ondurationchange	HTML elements	durationchange event handler	Event handler content attribute
onemptied	HTML elements	emptied event handler	Event handler content attribute
onended	HTML elements	ended event handler	Event handler content attribute
onerror	HTML elements	error event handler	Event handler content attribute
onfocus	HTML elements	focus event handler	Event handler content attribute
onformdata	HTML elements	formdata event handler	Event handler content attribute
onhashchange	body	hashchange event handler for <code>Window</code> object	Event handler content attribute
oninput	HTML elements	input event handler	Event handler content attribute
oninvalid	HTML elements	invalid event handler	Event handler content attribute
onkeydown	HTML elements	keydown event handler	Event handler content attribute
onkeypress	HTML elements	keypress event handler	Event handler content attribute
onkeyup	HTML elements	keyup event handler	Event handler content attribute
onlanguagechange	body	languagechange event handler for <code>Window</code> object	Event handler content attribute
onload	HTML elements	load event handler	Event handler content attribute
onloadeddata	HTML elements	loadeddata event handler	Event handler content attribute
onloadedmetadata	HTML elements	loadedmetadata event handler	Event handler content attribute
onloadstart	HTML elements	loadstart event handler	Event handler content attribute
onmessage	body	message event handler for <code>Window</code> object	Event handler content attribute
onmessagerecv	body	messagerecv event handler for <code>Window</code> object	Event handler content attribute
onmousedown	HTML elements	mousedown event handler	Event handler content attribute
onmouseenter	HTML elements	mouseenter event handler	Event handler content attribute
onmouseleave	HTML elements	mouseleave event handler	Event handler content attribute
onmousemove	HTML elements	mousemove event handler	Event handler content attribute
onmouseout	HTML elements	mouseout event handler	Event handler content attribute
onmouseover	HTML elements	mouseover event handler	Event handler content attribute
onmouseup	HTML elements	mouseup event handler	Event handler content attribute
onoffline	body	offline event handler for <code>Window</code> object	Event handler content attribute
online	body	online event handler for <code>Window</code> object	Event handler content attribute
onpagehide	body	pagehide event handler for <code>Window</code> object	Event handler content attribute
onpageshow	body	pageshow event handler for <code>Window</code> object	Event handler content attribute
onpaste	HTML elements	paste event handler	Event handler content attribute
onpause	HTML elements	pause event handler	Event handler content attribute
onplay	HTML elements	play event handler	Event handler content attribute
onplaying	HTML elements	playing event handler	Event handler content attribute
onpopstate	body	popstate event handler for <code>Window</code> object	Event handler content attribute
onprogress	HTML elements	progress event handler	Event handler content attribute
onratechange	HTML elements	ratechange event handler	Event handler content attribute
onreset	HTML elements	reset event handler	Event handler content attribute
onresize	HTML elements	resize event handler	Event handler content attribute
onselectionchanged	body	selectionchanged event handler for <code>Window</code> object	Event handler content attribute
onscroll	HTML elements	scroll event handler	Event handler content attribute
onsecuritypolicyviolation	HTML elements	securitypolicyviolation event handler	Event handler content attribute
onsecedit	HTML elements	secedit event handler	Event handler content attribute
onseeking	HTML elements	seeking event handler	Event handler content attribute
onselect	HTML elements	select event handler	Event handler content attribute
onslotchange	HTML elements	slotchange event handler	Event handler content attribute
onstalled	HTML elements	stalled event handler	Event handler content attribute
onstorage	body	storage event handler for <code>Window</code> object	Event handler content attribute
onsubmit	HTML elements	submit event handler	Event handler content attribute
onsuspend	HTML elements	suspend event handler	Event handler content attribute
ontimeupdate	HTML elements	timeupdate event handler	Event handler content attribute
ontoggle	HTML elements	toggle event handler	Event handler content attribute
onunhandledrejection	body	unhandledrejection event handler for <code>Window</code> object	Event handler content attribute
onunload	body	unload event handler for <code>Window</code> object	Event handler content attribute
onvolumechange	HTML elements	volumechange event handler	Event handler content attribute
onwaiting	HTML elements	waiting event handler	Event handler content attribute
onwheel	HTML elements	wheel event handler	Event handler content attribute

Element Interfaces

Event	Interface	Interesting targets	Description
paste	Event	Elements	Fired at elements when the user will insert the clipboard data in the most suitable format (if any) supported for the given context
popstate	Event	Window	Fired at the Window when the user navigates the session history
YON			
Window.popstate_event			
Support in all current engines.			
Firefox4+ Safari6+ Chrome5+	PopStateEvent	Window	
Opera11.5+ Edge79+			
Edge (Legacy)12+ Internet Explorer10+			
Firefox Android4+ Safari iOS5.1+ Chrome Android18+ WebView Android37+ Samsung Internet1.0+ Opera Android11.5+			
readystatechange	Event	Document	Fired at the Document when it finishes parsing and again when all its subresources have finished loading
YON			
Document.onreadystatechange_event			
Support in all current engines.			
Firefox Yes Safari Yes Chrome Yes	Event	Document	
Opera Yes Edge Yes			
Edge (Legacy)12+ Internet Explorer Yes			
Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes			
rejectionhandled	PromiseRejectionEvent	Global scope objects	Fired at global scope objects when a previously-unhandled promise rejection becomes handled
reset			
YON			
HTMLFormElement.reset_event			
Support in all current engines.			
Firefox Yes Safari Yes Chrome Yes	Event	Form elements	Fired at a form element when it is reset
Opera Yes Edge Yes			
Edge (Legacy)12+ Internet Explorer Yes			
Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes			
securitypolicyviolation	Event	Elements	Fired at elements when a Content Security Policy violation is generated [CSP]
select	Event	Form controls	Fired at form controls when their text selection is adjusted (whether by an API or by the user)
selectionchange	Event	Global elements	Fired at global elements when their assigned nodes change
storage			
MDN			
Window.storage_event			
Firefox45+Safari? Chrome1+	StorageEvent	Window	Fired at Window event when the corresponding localStorage or sessionStorage storage areas change
Opera15+ Edge79+			
Edge (Legacy)18+ Internet Explorer?			
Firefox Android45+Safari iOS? Chrome Android18+ WebView Android37+ Samsung Internet1.0+ Opera Android14+			
submit			
YON			
HTMLFormElement.submit_event			
Support in all current engines.			
Firefox1+ Safari3+ Chrome1+	Event	Form elements	Fired at a form element when it is submitted
Opera8+ Edge79+			
Edge (Legacy)12+ Internet Explorer9+			
Firefox Android4+ Safari iOS1+ Chrome Android18+ WebView Android1+ Samsung Internet1.0+ Opera Android10.1+			
topsite			
YON			
HTMLDetailsElement.toggle_event			
Support in all current engines.			
Firefox Yes Safari Yes Chrome Yes	Event	details element	Fired at details elements when they open or close
Opera Yes Edge Yes			
Edge (Legacy) No Internet Explorer?			
Firefox Android Yes Safari iOS Yes Chrome Android Yes WebView Android Yes Samsung Internet Yes Opera Android Yes			
unhandledrejection	PromiseRejectionEvent	Global scope objects	Fired at global scope objects when a promise rejection goes unhandled
unload			Fired at the Window object when the page is going away
Note			
See also media element events , application cache events , and drag-and-drop events .			

MIME Types

This section is non-normative.

The following MIME types are mentioned in this specification:

```
application/atom+xml
Atom [ATOM]
application/atom+xml
  Atom [ATOM]
application/ecmascript
  JavaScript (legacy type) [JAVASCRIPT]

[INDEXEDDB] [Indexed Database API](#), A. Alabas, J. Bell. W3C.

[INBAND]
[INBAND] [Recording In-band Media Resource Tracks from Media Containers into HTML](#), S. Pfeiffer, B. Lund. W3C.

[INFRA]
[INFRA] [\[infra\] A. van Kesteren, D. Denicola. WHATWG.](#)

[INTERSECTIONOBSEVER]
[INTERSECTIONOBSEVER] [Intersection Observer](#), S. Zager. W3C.

[ISO3166]
[ISO3166] [ISO 3166: Codes for the representation of names of countries and their subdivisions](#), ISO.

[ISO4217]
[ISO4217] [ISO 4217: Codes for the representation of currencies and funds](#), ISO.

[ISO8601]
[ISO8601] (Non-normative) [ISO8601: Data elements and interchange formats — Information interchange — Representation of dates and times](#), ISO.

[JAVASCRIPT]
[JAVASCRIPT] [ECMAScript Language Specification](#), Ecma International.

[JLREQ]
[JLREQ] [Requirements for Japanese Text Layout](#), W3C.

[JPEG]
[JPEG] [JPEG File Interchange Format](#), E. Hamilton.

[JSERBETRACKS]
[JSERBETRACKS] (Non-normative) [Error Stacks](#), Ecma International.

[JSIMPORTMETA]
[JSIMPORTMETA] [import.meta](#), Ecma International.

[JSINTL]
[JSINTL] [ECMAScript Internationalization API Specification](#), Ecma International.

[JSON]
[JSON] [The JavaScript Object Notation \(JSON\) Data Interchange Format](#), T. Bray. IETF.

[LONGTASKS]
[LONGTASKS] [Long Tasks](#), D. Denicola, I. Grigorik, S. Panicker. W3C.

[MAILTO]
[MAILTO] (Non-normative) [The 'mailto' URI scheme](#), M. Duerst, L. Masinter, J. Zawinski. IETF.

[MATHML]
[MATHML] [Mathematical Markup Language \(MathML\)](#), D. Carlisle, P. Ion, R. Miner. W3C.

[MEDIAFRAG]
[MEDIAFRAG] [Media Fragments URI](#), R. Troncy, E. Mannens, S. Pfeiffer, D. Van Deursen. W3C.

[MEDIASOURCE]
[MEDIASOURCE] [Source Extensions](#), A. Colwell, A. Bateman, M. Watson. W3C.

[MEDIASTREAM]
[MEDIASTREAM] [Media Capture and Streams](#), D. Burnett, A. Bergkvist, C. Jennings, A. Narayanan. W3C.

[MFREL]
[MFREL] [Microformats Wiki: existing rel values](#), Microformats.

[MIMESNFF]
[MIMESNFF] [MIME Sniffing](#), G. Hemsley. WHATWG.

[MX]
[MX] [Mixed Content](#), M. West. W3C.

[MNG]
[MNG] [MNG \(Multiple-image Network Graphics\) Format](#), G. Randers-Pehrson.

[MPERF]
[MPERF] [ISO/IEC 13818-1: Information technology — Generic coding of moving pictures and associated audio information: Systems](#), ISO/IEC.

[MPGE4]
[MPGE4] [ISO/IEC 14496-12: ISO base media file format](#), ISO/IEC.

[MQ]
[MQ] [Media Queries](#), H. Liu, T. Çelik, D. Glazman, A. van Kesteren. W3C.

[MULTIPLEBUFFERING]
[MULTIPLEBUFFERING] (Non-normative) [Multiple buffering](#), Wikipedia.

[NAVMODEL]
[NAVMODEL] [A Model of Navigation History](#), C. Brewster, A. Jeffrey.

[NPAPI]
[NPAPI] (Non-normative) [Gecko Plugin API Reference](#), Mozilla.

[OGGSKELTONHEADERS]
[OGGSKELTONHEADERS] [SkeletonHeaders](#), Xiph.Org.

[OPENSEARCH]
[OPENSEARCH] [Autodiscovery in HTML/XHTML](#), In OpenSearch 1.1 Draft 4, Section 4.6.2. OpenSearch.org.

[ORIGIN]
[ORIGIN] (Non-normative) [The Web Origin Concept](#), A. Barth. IETF.

[PAINTTIMING]
[PAINTTIMING] [Paint Timing](#), S. Panicker. W3C.

[PAGEVIS]
[PAGEVIS] (Non-normative) [Page Visibility Level 2](#), I. Grigorik, A. Jain, J. Mann. W3C.

[PAYMENTREQUEST]
[PAYMENTREQUEST] [Payment Request API](#), A. Bateman, Z. Koch, R. McElmurry. W3C.

[PDF]
[PDF] (Non-normative) [Document management — Portable document format — Part 1](#), PDF, ISO.

[PINGBACK]
[PINGBACK] [Pingback 1.0](#), S. Langridge, I. Hickson.

[PNG]
[PNG] [Portable Network Graphics \(PNG\) Specification](#), D. Duec. W3C.

[POINTEREVENTS]
[POINTEREVENTS] [Pointer Events](#), J. Rossi, M. Brueck, R. Byers, P. H. Lauke. W3C.

[POINTERLOCK]
[POINTERLOCK] [Pointer Lock](#), V. Scheibl. W3C.

[PUTTFS]
[PUTTFS] (Non-normative) [The Properties and Promises of UTF-8](#), M. Dürst. University of Zürich. In *Proceedings of the 11th International Unicode Conference*.

[RELOAD]
[RELOAD] [Reload](#), I. Grigorik. W3C.

[PRESENTATION]
[PRESENTATION] [Presentation API](#), M. Foltz, D. Röttches. W3C.

[REFERERPOLICY]
[REFERERPOLICY] [Referer Policy](#), J. Eisinger, E. Stark. W3C.

[REQUESTABLECALLBACK]
[REQUESTABLECALLBACK] [Cooperative Scheduling of Background Tasks](#), R. McElroy, I. Grigorik. W3C.

[RESOURCESHINTS]
[RESOURCESHINTS] [Resource Hints](#), I. Grigorik. W3C.

[RFC1034]
[RFC1034] [Domain Names - Concepts and Facilities](#), P. Mockapetris. IETF, November 1987.

[RFC1123]
[RFC1123] [Requirements for Internet Hosts – Application and Support](#), R. Braden. IETF, October 1989.

[RFC2045]
[RFC2045] [Multipurpose Internet Mail Extensions \(MIME\) Part Two: Media Types](#), N. Freed, N. Borenstein. IETF.

[RFC2397]
[RFC2397] [The "data" URL scheme](#), I. Masinter. IETF.

[RFC2545]
[RFC2545] [Internet Calendar and Scheduling Core Object Specification \(iCalendar\)](#), B. Desruisseaux. IETF.

[RFC2483]
[RFC2483] [URI Resolution Services Necessary for URN Resolution](#), M. Mealling, R. Daniel. IETF.

[RFC3676]
[RFC3676] [The Text/Plain Format and DelSp Parameters](#), R. Gellens. IETF.

[RFC3864]
[RFC3864] [Registration Procedures for Message Header Fields](#), G. Klyne, M. Nottingham, J. Mogul. IETF.

[RFC4329]
[RFC4329] (Non-normative) [Scripting Media Types](#), B. Höhmann. IETF.

[RFC4337]
[RFC4337] (Non-normative) [MIME Type Registration for MP4Box](#), Y. Lim, D. Singer. IETF.

[RFC3595]
[RFC3595] [Content-Disposition and Registration Procedures for URI Schemes](#), D. Thaler, T. Hansen, T. Hardie. IETF.

[RFC3222]
[RFC3222] [Internet Message Format](#), P. Resnick. IETF.

[RFC6381]
[RFC6381] [The 'Codes' and 'Profiles' Parameters for "Bucket" Media Types](#), R. Gellens, D. Singer, P. Frojdh. IETF.

[RFC46350]
[RFC46350] [Use of the Content-Disposition Header Field in the Hypertext Transfer Protocol \(HTTP\)](#), J. Reschke. IETF.

[RFC6350]
[RFC6350] [Card Format Specification](#), S. Perreau. IETF.

[RFC6596]
[RFC6596] [The Canonical Link Relation](#), M. Ohye, J. Kupke. IETF.

[RFC7074]
[RFC7074] [XML Media Types](#), H. Thompson, C. Lilley. IETF.

[RFC7578]
[RFC7578] [Returning Values from Forms: multipart/form-data](#), L. Masinter. IETF.

[SCRENORIENTATION]
[SCRENORIENTATION] [Screen Orientation API](#), M. Lamouri, M. Cáceres. W3C.

[SCS1]
[SCS1] (Non-normative) [IUT #6: A Standard Compression Scheme For Unicode](#), M. Wolf, K. Whistler, C. Wicksteed, M. Davis, A. Freytag, M. Scherer. Unicode Consortium.

[SECURECONTEXTS]
[SECURECONTEXTS] [Secure Contexts](#), M. West. W3C.

[SELECTION]
[SELECTION] [Selection API](#), R. Niwa. W3C.

[SELECTORS]
[SELECTORS] [Selectors](#), E. Elenad, T. Çelik, D. Glazman, I. Hickson, P. Linss, J. Williams. W3C.

[SMS]
[SMS] (Non-normative) [URL Scheme for Global System for Mobile Communications \(GSM\) Short Message Service \(SMS\)](#), E. Wilde, A. Vaha-Sipila. IETF.

[SRGB]
[SRGB] [ICC 61966-2-1: Multimedia systems and equipment — Colour measurement and management — Part 2-1: Colour management — Default RGB colour space — sRGB](#), IEC.

[SR]
[SR] [Subresource Integrity](#), D. Akhawe, F. Braun, F. Marier, J. Weinberger. W3C.

[SVG]
[SVG] [Scalable Vector Graphics \(SVG\) 2](#), N. Andronikos, R. Atanassov, T. Bah, B. Birtles, B. Brinza, C. Concolato, E. Dahlström, C. Lilley, C. McCormack, D. Schepers, R. Schwerdtfeger, D. Storey, S. Takagi, J. Watt. W3C.

[SW]
[SW] [Service Workers](#), A. Russell, I. Song, J. Archibald. W3C.

[TOR]
[TOR] (Non-normative) [Tor](#).

[TOUCH]
[TOUCH] [Touch Events](#), D. Schepers, S. Moon, M. Brueck, A. Barstow, R. Byers. W3C.

[TZDATABASE]
[TZDATABASE] (Non-normative) [Time Zone Database](#), IANA.

Status of This Document

This section describes the status of this document at the time of its publication. Other documents may supersede this document. A list of current W3C publications and the latest revision of this technical report can be found in the W3C technical reports index at <https://www.w3.org/TR/>.

The following features are **at-risk** for the purpose of the W3C Candidate Recommendation:

- `OffscreenCanvas`
- `scrollIntoView()` method of `CanvasRenderingContext2D`
- `srcObject` setter for `HTMLMediaElement`, with media provider other than `MediaStream` (that is, a `MediaSource` or `Blob`)
- `close()` method of `SharedWorkerGlobalScope`
- `fontFace` sheets
- `autoColorization`
- `theme-color`
- `accessKeyLabel` property of `HTMLElement`
- `dir pseudo-class`
- `prefers-reduced运动`
- `prefers-reduced运动` link type
- `prefers-reduced运动` link type
- `dragexit` event
- `cancel` event
- `cancel` event handler

The W3C HTML Working Group co-produced this document under the [W3C Patent Policy](#) and the [01 March 2019 W3C Process Document](#). W3C maintains a [public list of any patent disclosures](#) made in connection with the deliverables of the group; that page also includes instructions for disclosing a patent. An individual who has actual knowledge of a patent which the individual believes contains [Essential Claim\(s\)](#) must disclose the information in accordance with [section 6 of the W3C Patent Policy](#).

This Candidate Recommendation is expected to advance to Proposed Recommendation no earlier than 16 July 2020.
